Notice the tool now has the erroneous path definition stored internally. From here, you might want to check for any additional details about this particular definition:

```
report_false_paths -debug_error -from B_input -to_clock all_outputs

// False Path -from B_input -to_clock all_outputs did not find any
//      gate for "B_input all_outputs"
```

Example 5

The following example deletes the erroneous path definition, enters a corrected version of the definition, then confirms there are no remaining errors in any of the false or multicycle path definitions:

```
delete_false_paths -from B_input -to_clock all_outputs
// Deleted 1 false path

report_false_paths

// False Path -from_clock clk1 -to_clock clk2
// False Path -from clk2 reset scan_in1 -to y[2] y[1] y[0]
// Total reported false paths = 2

add_false_paths -from B -to y[2] y[1] y[0]
report_false_paths

// False Path -from_clock clk1 -to_clock clk2
// False Path -from clk2 reset scan_in1 -to y[2] y[1] y[0]
// False Path -from B -to y[2] y[1] y[0]
// Total reported false paths = 3

report_false_paths -error

// Total reported false paths = 0
```

Example 6

The following example reads the SDC file *my_block_sdc* and applies the information it contains to instance U1 of the design module *my_block*:

```
read_sdc my_block_sdc -instance U1
// Reading SDC file my_block_sdc ...
// Finished reading SDC file my_block_sdc.
// read_sdc summary: 2 false paths, 0 multicycle paths, 0 erroneous paths
//      0 disable timings, 0 case analyses, 0 clock groups
```

Example 7

The following example reads the file of the preceding example and applies the SDC information to instances U2 and U3 of the same design module:

```
read_sdc my_block_sdc -instance U2 -instance U3
// Reading SDC file my_block_sdc ...
// Finished reading SDC file my_block_sdc.
// read_sdc summary: 4 false paths, 0 multicycle paths, 0 erroneous paths
//      0 disable timings, 0 case analyses, 0 clock groups
```

Example 8

The following example reads the SDC file *my_block_sdc* and applies the information to every instance of the design module *my_block*:

```
delete_false_paths -all
read_sdc my_block_sdc -module my_block

// Reading SDC file my_block_level_sdc ...
// Finished reading SDC file my_block_level_sdc.
// read_sdc summary: 6 false paths, 0 multicycle paths, 0 erroneous paths
//      0 disable timings, 0 case analyses, 0 clock groups
```

Example 9

This example shows that we can read an SDC file in setup mode, transition to analysis mode, and perform X-bounding based on the paths in the SDC file:

```
read_sdc my_design.sdc
set_system_mode analysis
analyze_xbounding
```

read_sdf

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Loads timing data from a Standard Delay Format (IEEE SDF 1497) file.

Usage

```
read_sdf sdf_filename...
  [-MInimum_delay | -TTypical_delay | -MAximum_delay]
  [-Replace | -Append | -INCremental]
  [-INstance hierarchical_instance_name]
```

Description

Loads timing data from a Standard Delay Format (IEEE SDF 1497) file.

The SDF file is generated by your static timing analysis tool. For complete information, refer to “[Timing-Aware ATPG](#)”, in the *Tessent Scan and ATPG User’s Manual*.

For descriptions of any errors and warnings reported by read_sdf, see “[Errors and Warnings While Reading SDF Files](#)” in the *Tessent Scan and ATPG User’s Manual*.

The following limitations apply to the SDF file:

- For SDF conditional delays, the tool will load them into an internal database. However, only the maximum delay will be used for calculating actual delay. For example:
 - (COND b (IOPATH a y (0.21) (0.54)))
(COND ~b (IOPATH a y (0.27) (0.34)))
 - Timing-aware ATPG uses (0.27) (0.54) regardless of the value of b.
 - Only the first two delay value tokens are used.
- PATHPULSE, PATHPULSEPERCEN, DEVICE, and RETAIN statements are ignored.
- Delays on Memory and Latch are ignored.
- Hold time information is ignored.
- Delays in clock lines are ignored.
- Latch is assumed to be either a launch or capture point, not as a combinational logic in-between.

Arguments

- *sdf_filename*

A required string that specifies the name of the SDF file to read.

- **-MInimum_delay**
An optional switch that loads only the SDF minimum delay data into the tool.
- **-Typical_delay**
An optional switch that loads only the SDF typical delay data into the tool. This is the default.
- **-MAximum_delay**
An optional switch that loads only the SDF maximum delay data into the tool.
- **-REplace**
An optional switch that removes any previously loaded SDF file information before loading the new SDF file information.
- **-APpend**
An optional switch that loads the new SDF file information in addition to the existing information. This is the default. This switch allows you to load multiple SDF files for different modules.

The tool will issue an error message if the new SDF file contains delay data for a flattened pin that was already defined by a previously loaded SDF file. Use the **-INCremental** switch if you want to merge all delay data for a flattened pin.

Note

 When using this switch, if the selected delay type (minimum, typical or maximum delay) is different from the previous `read_sdf` command, all previously loaded SDF timing information will be discarded.

- **-INCremental**
An optional switch that loads the new SDF file information in addition to the existing information. If the new SDF file contains delay data for a flattened pin that was already defined by a previously loaded SDF file, the new delay data will be cumulated with the previous delay data for that pin. Use the **-APpend** switch if you do not want to merge any delay data for a flattened pin.
- **-INstance *hierarchical_instance_name***
An optional switch and string pair that specifies the hierarchical instance name to which the SDF file is associated. This option is useful when the SDF file is at the module level.

Examples

The following example reads the typical delay data from the `top_worst.sdf` file:

```
read_sdf top_worst.sdf
```

The following example reads the delay data for multiple modules:

```
read_sdf file1.sdf -maximum_delay -instance /top/module1  
read_sdf file2.sdf -maximum_delay -append -instance /top/module2  
read_sdf file3.sdf -maximum_delay -append -instance /top/module3
```

[report_statistics](#)

[set_atpg_timing](#)

read_upf

Context: all contexts

Mode: setup

Loads a UPF (Unified Power Format) file and removes any previously loaded power data.

Usage

`read_upf filename`

Description

Loads a UPF (Unified Power Format) file and removes any previously loaded power data.

You can load multiple UPF files using the native UPF “load_upf” command.

When you use the `read_upf` command, power data is loaded into the tool and the [report_gates](#) command enables power data reporting and shows the power on (PON) or power off (POFF) as well as the power domain of the gate.

The tools support UPF version 2.0.

For information about what happens when you load power data, refer to “[Power-Aware DRC and ATPG](#)” in the *Tessent Scan and ATPG User’s Manual*.

Note

 As described in the [create_dft_specification](#) command description, the DftSpecification is affected by the power domain information to make sure that groups of DesignInstances associated to different power domains are isolated by a SIB. This is done to avoid daisy chaining them with elements from a different power domain and running into issues when accessing the elements in a given power domain while the other power domains are off.

Arguments

- *filename*

A required string that specifies the name of the UPF file.

Examples

Example 1

The following example loads a UPF file:

`read_upf upf_file`

Example 2

In this example, `read_upf` loads power data into the tool and the `report_gates` command reports the power on (PON) status as well as the power domain of the gate.

read_upf *upf_file*

report_gates /lp_case_si_RST_SMS/ati_RST_SYNC/sync_r/U3/Udff

```
//  /lp_case_si_RST_SMS/ati_RST_SYNC/sync_r  sync3msfqxsslul
//  SDI    I(PON)  /vl_sms_lp_case_si_SMS_Proc_SMS_1_stp/U_lp_case_si_SMS_Proc_BIST/uu5/Z
//  D      I(PON)  /lp_case_si_RST_SMS/ati_RST_SYNC/sync_buf/Z
//  SEN    I(PON)  /se
//  CLK    I(PON)  /lp_case_si_RST_SMS/ati_RST_SYNC/uu1/Z
//  Q      O(PON)  /lp_case_si_RST_SMS/ati_RST_SYNC/uu2/A  /lp_case_si_RST_SMS/and_r/B
//  in power domain PD_P2
```

read_verilog

Context: all contexts

Mode: setup

Reads one or more Verilog files into the specified or default logical library.

Usage

dft -no_rtl and patterns -no_rtl Contexts

```
read_verilog [design_path ...] [-verbose] [-force | -no_overwrite_modules]
[-interface_only] [-exclude_from_file_dictionary]
[-no_lib_rescan] [-format {1995 | 2001 | sv31a | sv2005 | sv2009}]
[-pragma_list pragma_list] [-ignore_synthesis_off_sections {On | Off}]
[-ffiles] [-no_duplicate_modules_warnings] [-no_limited_rtl [-report_all_errors]]
```

dft -rtl and patterns -rtl Contexts

```
read_verilog [design_path ...] [-verbose] [-force | -no_overwrite_modules]
[-interface_only] [-exclude_from_file_dictionary]
[-in_library logical_lib_name] [-no_lib_rescan] [-no_mfcu]
[-format {1995 | 2001 | sv31a | sv2005 | sv2009}]
[-pragma_list pragma_list] [-ignore_synthesis_off_sections {On | Off}]
[-vcs_compatibility] [-ffiles] [-no_duplicate_modules_warnings]
```

Description

Reads one or more Verilog files into the specified or default logical library.

You define the list of available libraries with the [set_logical_design_libraries](#) command which you only use in rtl context; only one library exists in no_rtl context and it is named “work”.

Note that the MGC_TESSENT and SYNTHESIS design macros are defined by default. For more information, refer to the [set_design_macros](#) command description.

When in -no_rtl context ([set_context context -no_rtl](#)), the tool issues a warning when parsing RTL constructs. See the -no_limited_rtl switch for additional guidance.

Arguments

- *design_path*

One or more optional files containing Verilog elements to load. A well formatted Tcl list of filenames can also be supplied, such as the list returned by the Tcl glob command. The names of the files can contain wildcards. The *design_path* is optional if you use the -f switch to specify a file that contains at least one *design_path*.

If you have used the [set_design_sources](#) command, child modules found instantiated into the currently read modules are searched for in the specified -y directories and the -v files.

- **-verbose**

An optional switch that reports each file read. For every file read, including the ‘include’ files, the following messages are returned:

```
// Reading Verilog file filename  
// Finished reading file filename
```

- **-force**

An optional switch that suppresses the error message that normally prevents the accidental deletion of previously defined setup information. After you read in a design using this command, you can incrementally issue the command again to read more files. However, once the tool builds the design using `set_current_design` and you add any configuration information to it (for example, `add_clocks` or `add_scan_chains`), executing the `read_verilog` command causes the setup information to be discarded. In this case, to prevent configuration information from being discarded unintentionally, the tool requires that you execute the command with the `-force` switch to indicate that it is acceptable to delete the setup data.

- **-no_overwrite_modules**

An optional switch that instructs the tool not to replace existing modules. If a module is read that has been read before, the tool reports an error. You can use this switch to avoid overwriting modules or accidentally deleting the design.

- **-interface_only**

An optional switch that instructs the tool to ignore the internals of all of the modules specified in the filename argument and extract only the module port definitions and parameters.

- **-exclude_from_file_dictionary**

An optional switch used when you input a Verilog simulation model into Tessent Shell, and the model does not have a `celldefine; issuing this switch ensures that the read is excluded in the file dictionary and, consequently, excluded in the DC shell load script.

- **-in_library *logical_lib_name*** (“`set_context context -rtl`” only)

An optional switch that specifies which logical library the modules are to be read into. The list of possible logical libraries, including the default library, is defined by the `set_logical_design_libraries` command. If this option is not specified, the modules are read into the default library.

- **-no_lib_rescan**

An optional switch that specifies to not rescan the `-y` directories and the `-v` files from the beginning each time, but to search for the module beginning with the directory or file in which the previous module was found.

- **-no_mfcu** (“`set_context context -rtl`” only)

An optional switch that applies to SystemVerilog formats which specifies to compile each file into a separate compile unit. By default, the tool compiles into a multiple-file unit.

- **-format {1995 | 2001 | sv31a | sv2005 | sv2009}**

An optional switch that specifies the format of the input Verilog files. The default is 2001. In a mixed-format situation, you should be sure to re-define your -y and -v library search path when loading modules in a new format because you cannot mix formats within a single `read_verilog` command invocation.

In the `-no_rtl` context, you must use this switch together with the `-interface_only` switch to read modules that have interfaces without special System Verilog ports.

In the `-rtl` context, you can use the `-format` switch with or without the `-interface_only` switch.

The `sv31a` is not a standard format but it is the default inside Design Compiler when `hdlin_sv_packages` is not defined.

- **-pragma_list *pragma_list***

An optional switch and string pair that defines the pragmas for the input files. The `pragma_list` is a Tcl list containing one or more objects. When this option is not specified, the following list of strings is used as default pragmas: {`pragma synthesis mgc_tessent synopsys LV_pragma mentor`}. You can override the default pragmas by specifying a new pragma list as shown here:

```
read_verilog 1.v -pragma_list {my_pragma1 mgc_tessent}
```

You can create an empty list of pragmas by specifying an empty Tcl list as shown here:

```
read_verilog 1.v -pragma_list {}
```

Pragmas are special comments in the source. They control how the tool interprets the source. This example of source code uses a pragma pair to turn translation on or off:

```
module ram1 ( ...
  ...
  // synopsys translate_off
  myram u_atpg ( ... );
  // synopsys translate_on
```

By default, `synopsys` is a pragma. The tool will ignore all input from when it reads the `pragma` directive “`// synopsys translate_off`” until the “`// synopsys translate_on`” `pragma` directive. The tool does not include the `myram` instance.

If you use the command, “`read_verilog` with `-pragma_list {}`”, you unset the default pragmas and the tool includes the `myram` instance.

- **-ignore_synthesis_off_sections {On|Off}**

An optional switch and literal pair that specifies whether to ignore the `synthesis_off` sections in the input files. The default is On.

On — A literal that specifies to ignore `synthesis_off` sections and to NOT compile the code found within the `synthesis_off/on` block.

Off — A literal that specifies to not ignore the `synthesis_off` sections and to compile the code found within the `synthesis_off/on` block.

- **-vcs_compatibility** (“*set_context context -rtl*” only)

An optional switch that specifies to ignore a series of syntax errors allowed by the Synopsys compilers. By default, the tool reports these non-compliant usages as errors.

When specified, this setting is in effect until you execute the *delete_design*. You only specify this switch in the first execution of the *read_verilog* command after tool invocation, or after the *delete_design* command is executed.

- **-f files**

An optional switch and Tcl list that specifies the name(s) of one or more ASCII files that contains pointers to design files. The referenced file is usually generated by another tool, so the *-f* option allows you to conveniently use the file rather than to reformat the contents of the file into a *read_verilog* command line. The file can contain only the following elements, one per line:

- *design_path* — A string that specifies the name of a Verilog file to load.
- *-v design_path* — A string that specifies the name of a Verilog file to load.
- *-y dir_path* — A string that specifies a path to a directory that contains Verilog files to load.
- *+libext+file_extension* — A string that specifies which files in the “*-y dir_path*” to load. For example: “*+libext+.v*” loads all *.v* files.
- *+define+XXX[=YYY]* — A string that defines a macro called “*XXX*” with an optional value of “*YYY*”. The defined macro is used when compiling any files listed in the *-f* file.
- *+incdir+dir_path1+dir_path2+...* — A string that defines one or more directory paths to directories that contain files that use the ‘*include*’ directive.

- **-no_duplicate_modules_warnings**

An optional switch that suppresses overwrite warnings when loading a netlist.

- **-no_limited_rtl [-report_all_errors]** (“*set_context context -no_rtl*” only)

An optional switch to flag an error when parsing RTL when the tool is in *-no_rtl* context. When not specified, RTL Verilog constructs are flagged with a warning.

The environment variable TESSENT_NO_LIMITED_RTL can be used instead of the *-no_limited_rtl* switch. Verilog attributes are ignored with a warning by default and with the switch. The optional *-report_all_errors* switch reports all of the RTL construction errors found by the tool in all modules. Usage is as follows:

- *-no_limited_rtl* — When the tool encounters the RTL construct, the tool reports one error per module for all files.
- *-no_limited_rtl -report_all_error* — The tool reports all the RTL construct errors that are encountered in all the modules in all files.

- TESSENT_NO_LIMITED_RTL = 1 (it can be any value except "report_all_errors")
 - When the tool encounters the RTL construct, the tool reports one error per module for all modules in all files.
- TESSENT_NO_LIMITED_RTL = report_all_errors (it can be upper case or lower case) — The tool reports all the RTL construct errors which are encountered in all the modules in all files.

Examples

Example 1

The following example loads all Verilog files matching *.v inside the directory src:

```
read_verilog src/*.v
```

Example 2

The following example loads a mixed-language design in the dft context in RTL mode. The results files are written into the edited_design directory.

```
SETUP> set_context dft -rtl
# Specify LIBRARY1 to be mapped into <workdir>/lib1
# work will be mapped to a scratch dir

SETUP> set_logical_design_libraries -logical_library_list { library1 work}
# Define macro1 for Verilog compilation

SETUP> set_design_macros macro1=5
# Search for Verilog modules in /design/abc/*.v

SETUP> set_design_sources -y /design/abc -extension v
# Read Verilog files

SETUP> read_verilog top.v core.v -in_library work -format 2001
# Read VHDL files

SETUP> read_vhdl core1.vhdl -in_library work -format 1993
SETUP> read_vhdl {core2.vhdl core3.vhdl} -in_library library1 -format 1993
# Set the top

SETUP> set_current_design top
# Enter insertion mode

SETUP> set_system_mode insertion
# Perform design query and manipulation commands

INSERTION> ...
# Write the design
```

INSERTION> write_design -output_directory edited_design -modified

INSERTION> exit

Example 3

The following example uses the *-f files* switch to load in the design file(s) specified within an ASCII file that contains spaces in the filename:

SETUP> read_verilog -f [list “updated cores.f”]

Example 4

The following example uses the *-f files* switch to load in the design files specified within two different ASCII files:

SETUP> read_verilog -f {block_a_cores.f block_b_cores.f}

Context: all contexts

Mode: setup

Reads one or more VHDL files into the specified or default logical library.

Usage

dft -no_rtl and patterns -no_rtl Contexts

```
read_vhdl [design_path] [-interface_only] [-exclude_from_file_dictionary]  
[-force | -no_overwrite_modules] [-format {1987 | 1993 | 2002 | 2008}]  
[-pragma_list pragma_list] [-ignore_synthesis_off_sections {on | off}]  
[-ffiles] [-no_duplicate_modules_warnings]
```

dft -rtl and patterns -rtl Contexts

```
read_vhdl [design_path] [-interface_only] [-exclude_from_file_dictionary]  
[-force | -no_overwrite_modules] [-in_library logical_lib_name]  
[-format {1987 | 1993 | 2002 | 2008}] [-pragma_list pragma_list]  
[-ignore_synthesis_off_sections {on | off}] [-ffiles]  
[-no_duplicate_modules_warnings]
```

Description

Reads one or more VHDL files into the specified or default logical library. The list of possible logical libraries, including the default library, is defined by the [set_logical_design_libraries](#) command.

You can execute this command with the -force switch but without a *design_path* argument to clear design setup data only and not read any new files.

Arguments

- *design_path*

An optional Tcl list that specifies the name(s) of one or more VHDL files to load. The names of the files can contain wildcards. The *design_path* option is optional if you use the -f switch to specify a file that contains at least one *design_path*.

This command includes an example that shows a suggested way of loading different VHDL files into different libraries.

- -interface_only

An optional switch that instructs the tool to ignore the internals of all of the modules specified in the filename argument and extract only the module port definitions and parameters.

- **-exclude_file_dictionary**

An optional switch that is used when you input a VHDL simulation model into Tessent Shell, and the model does not have a `celldefine; issuing this switch ensures that the read is excluded from the file dictionary and, consequently, excluded in the DC shell load script.

- **-force**

An optional switch that suppresses the error message that normally prevents the accidental deletion of previously defined setup information. After you read in a design using this command, you can incrementally issue the command again to read more files. However, once the tool builds the design using set_current_design and you add any configuration information to it (for example, add_clocks or add_scan_chains), executing the read_vhdl command causes the setup information to be discarded. In this case, to prevent configuration information from being discarded unintentionally, the tool requires that you execute the command with the -force switch to indicate that it is acceptable to delete the setup data.

- **-no_overwrite_modules**

An optional switch that instructs the tool not to replace existing modules. If a module is read that has been read before, the tool reports an error. You can use this switch to avoid overwriting modules or accidentally deleting the design.

- **-in_library *logical_lib_name*** (“set_context context -rtl” only)

An optional switch that specifies which logical library the modules are to be read into. The list of possible logical libraries, including the default library, is defined by the set_logical_design_libraries command. If this option is not specified, the modules are read into the default library. This switch is only available in -rtl context.

- **-format {1987 | 1993 | 2002 | 2008}**

An optional switch that specifies the expected format of the input files and which VHDL language constructs can be understood during parsing. The default is 1993.

- **-pragma_list *pragma_list***

An optional switch and string pair that defines the pragmas for the input files. The pragma_list is a Tcl list containing one or more objects. When this option is not specified, the following list of strings is used as default pragmas: {pragma synthesis mgc_tessent synopsys LV_pragma mentor}. You can overwrite the default pragmas by specifying a new pragma list as shown here:

```
read_vhdl 1.v -pragma_list {my_pragma1 mgc_tessent}
```

You can create an empty list of pragmas by specifying an empty Tcl list as shown here:

```
read_vhdl 1.v -pragma_list {}
```

Pragmas are special comments in the source. They are used to control how the tool interprets the source. This example of source code uses a pragma pair to turn translation on and off:

```
begin
  -- synthesis translate_off
  myram: work.comp_decls.topmem port map(...);
  -- synthesis translate_on
```

If synthesis is specified as a pragma, either by using the `-pragma_list {synthesis}` switch pair for `read_vhdl` or because it is a default pragma, the tool will recognize the “`-- synthesis translate_off`” directive and will ignore all input from the source until it encounters the “`-- pragma translate_on`” directive. The result will be, in this case, that `myram` will not be included.

If you issue a `read_vhdl` with `-pragma_list {}`, the default pragmas will be unset and the instance `myram` will be included by the tool.

- `-ignore_synthesis_off_sections {On | Off}`

An optional switch and literal pair that specifies whether to ignore the `synthesis_off` sections in the input files. The default is On.

On — A literal that specifies to ignore `synthesis_off` sections and to NOT compile the code found within the `synthesis_off/on` block.

Off — A literal that specifies to not ignore the `synthesis_off` sections and to compile the code found within the `synthesis_off/on` block.

- `-f files`

An optional switch and Tcl list that specifies the name(s) of one or more ASCII files that contains pointers to design files to load. The names of the files can contain wildcards. The referenced file is usually generated by another tool, so the `-f` option allows you to conveniently use the file rather than to reformat the contents of the file into a `read_vhdl` command line. The file can contain only the following elements, one per line:

- `design_path` — A string that specifies the name of a VHDL file to load.
- `-no_duplicate_modules_warnings`

An optional switch that suppresses overwrite warnings when loading a netlist.

Examples

Example 1

The following example instructs the tool to read only the interface of the modules/entities and ignore the contents:

```
set_context dft -no_rtl
read_verilog data/pll.v -interface_only
read_vhdl {data/ram_bist.vhd data/edt_ip*.vhf} -interface_only
```

Example 2

The following example loads a mixed-language design in the dft context in RTL mode. The results files are written into the *edited_design* directory.

```
SETUP> set_context dft -rtl
# Specify LIBRARY1 to be mapped into <workdir>/lib1
# work will be mapped to a scratch dir

SETUP> set_logical_design_libraries -logical_library_list { library1 work}

# Define macro1 for Verilog compilation

SETUP> set_design_macros macro1=5

# Search for Verilog modules in /design/abc/*.v

SETUP> set_design_sources -y /design/abc -extension v

# Read Verilog files

SETUP> read_verilog top.v core.v -in_library work -format 2001

# Read VHDL files

SETUP> read_vhdl core1.vhdl -in_library work -format 1993
SETUP> read_vhdl {core2.vhdl core3.vhdl} -in_library library1 -format 93

# Set the top

SETUP> set_current_design top

# Enter insertion mode

SETUP> set_system_mode insertion

# Perform design query and manipulation commands

INSERTION> ...
# Write the design

INSERTION> write_design -output_directory edited_design -modified

INSERTION> exit
```

Example 3

The following example uses the *-f files* switch to load in the design file(s) specified within an ASCII file that contains spaces in the filename:

```
SETUP> read_vhdl -f {updated cores.f}
```

Example 4

The following example uses the *-f files* switch to load in the design files specified within two different ASCII files:

```
SETUP> read_vhdl -f {block_a_cores.f block_b_cores.f}
```

[set_current_design](#)

read_visualizer_preferences

Context: unspecified, all contexts

Mode: setup, analysis

Reads a DFTVisualizer preferences file and sets current preferences as described in the file.

Usage

`read_visualizer_preferences filename`

Description

Reads a DFTVisualizer preferences file and sets current preferences as described in the file.

The `read_visualizer_preferences` command reads a DFTVisualizer preference file previously saved with the [write_visualizer_preferences](#) command and updates the current DFTVisualizer session to use the preferences in the specified file.

Tip

 When DFTVisualizer first opens in a tool session, it reads the `$HOME/.DftVisualizerrc` preference file if it is present and sets the preferences accordingly; otherwise, it uses hard-coded defaults. Current preference settings are written to this file when you click the Write Prefs button at the bottom of the DFTVisualizer Preferences window.) DFTVisualizer uses the preferences in the default file until overridden by a `read_visualizer_preferences` command. The last such command entered establishes the preferences DFTVisualizer uses.

Arguments

- *filename*

A required string that specifies the name of the preference file to read.

Examples

The following example reads the DFTVisualizer preference file, `my_prefs.dftvis`, and updates the current tool session to use the preferences specified in the file:

```
set_system_mode analysis  
read_visualizer_preferences my_prefs.dftvis
```

[write_visualizer_preferences](#)

read_window_contents

Context: all contexts

Mode: setup, analysis

Reads the contents of the specified file into a DFTVisualizer window.

Usage

```
read_window_contents file.pathname -display window_name [-format format]
```

Description

Reads the contents of the specified file into a DFTVisualizer window. The file specified by the *file.pathname* argument must be in a supported format as described in the *-format* argument description.

The **-display** argument specifies which DFTVisualizer window is opened (if needed) and into which the *file.pathname* content is to be read.

Arguments

- ***file.pathname***

A required string that specifies the pathname of the file that is to be read into a DFTVisualizer window. If the file is to be read into a Flat Schematic or Hierarchical Schematic window, the file must be in the Mentor Graphics Tessent schematic format as generated by the [write_window_contents](#) command.

- **-display *window_name***

A required switch and literal pair that specifies the DFTVisualizer window into which the *file.pathname* content is to be read. Select the window name from the following list:

FLAt_schematic — A literal that specifies the Flat Schematic window. This is the default.

HIErarchical_schematic — A literal that specifies the Hierarchical Schematic window.

Text_editor — A literal that specifies the Text Editor window.

- **-format *format***

An optional switch and literal pair that specify the format of the file to be read. The file displays in the Text Editor window with appropriate highlighting and formatting. This option is not valid with **-display FLAt_schematic** or **HIErarchical_schematic** arguments which require Mentor Graphics Tessent schematic file format. Switch options for *-format* include:

TEXt — A literal that specifies an ASCII text format. This is the default.

Verilog — A literal that specifies the Verilog format.

VHdl — A literal that specifies the VHDL format.

TESt_procedure — A literal that specifies the Test Procedure format.

Dofile — A literal that specifies the Dofile format.

register_attribute

Context: unspecified, all contexts

Mode: all modes

Registers a new user-defined attribute.

Usage

```
register_attribute -name attribute_name -value_type data_type -default default_value
    [-min min_value] [-max max_value] [-enum enum_values] -object_types type_list
    [-dense] [-description description_text] [-show_default] [-hidden]
```

Description

Registers a new user-defined attribute.

This command allows you to define new attributes for object types available in Tesson Shell. After registration, the value of the new attribute can be set and retrieved on objects such as a module or an instance.

If an attribute with the same name already exists for the specified object type, or if an object type in *type_list* does not exist, or if a data type is invalid for one of the options, an error message displays.

If you want an attribute set on a module to be visible (inherited) on the instances of the module, register the attribute only on the *module* object type and not on the instance object type. The same is true for inheritance between ports and pins and between nets and pins. The following exceptions to this inheritance rule exist for Boolean attributes:

- For Boolean attributes registered on module and instance object types — When the value is queried on an instance and it is the default value (usually false), the value from the corresponding module is returned.
- For Boolean attributes registered on port and pin object types — When the value is queried on a pin and it is the default value (usually false), the value from the corresponding port is returned.

Arguments

- **-name *attribute_name***

A required switch and value pair that specifies the name of the attribute to register. An attribute name must begin with an alpha character and must only contain alpha-numeric characters and the underscore (_).

- **-value_type *data_type***

A required switch and value pair that specifies the attribute's data type. The -value_type argument is an enumerated list with the following possible values: Boolean, integer, double, and string.

- **-default *default_value***

A required switch and value pair that specifies the default value for the attribute when the attribute is not explicitly set. This pair is required for attributes with non-Boolean data types only; it cannot be set for attributes whose data type is Boolean. Attributes with a data type of Boolean automatically default to false.

- **-min *min_value***

An optional switch and value pair that specifies the minimum value for the attribute. When this argument is specified, the value of the attribute is only accepted if it is greater than or equal to *min_value*. This argument is only valid for attributes whose data type is integer or double. For more information on these data types, see “[Attribute Value Types](#).”

- **-max *max_value***

An optional switch and value pair that specifies the maximum value for the attribute. When this argument is specified, the value of the attribute is only accepted if it is less than or equal to *max_value*. This argument is only valid for attributes whose data type is integer or double. For more information on these data types, see “[Attribute Value Types](#).”

- **-enum *enum_values***

An optional switch and value pair that specifies a Tcl list of possible values for the attribute. The *enum_values* value can only be set to one value in the list. This argument is only valid for attributes whose data type is string.

- **-object_types *type_list***

A required switch and value pair that specifies the object type to which the new attribute can be assigned. The *type_list* string is a Tcl list that contains one or more of the following object types: module, instance, port, pin, net, or icl_module. If an object type is not included in the *type_list*, the new attribute cannot be assigned to that object_type.

Extra data types will be available in subsequent releases and the *type_list* will be augmented as they become available.

- **-dense**

An optional Boolean switch that specifies the storage type for the attribute.

When not specified — Specifies *sparse* storage which only stores values for objects that have an attribute value set to something different than the default value. This option is a good choice when many of the attributes on an object are set to their default value because it saves memory. However, indexing and searching can be slower and end up consuming more memory if the number of objects having the attribute specified is more than 10% of the object count.

When specified — Specifies *dense* storage which creates an entry for each object and its attribute value. This option is a good choice when many objects with the same attribute have a distributed set of attribute values because it enables faster indexing and searching. However, it has a higher memory usage when less than 10% of the objects have the attribute specified.

- **-description** *description_text*

An optional switch and value pair that specifies to store a string describing the attribute. The description is displayed when the [report_attributes](#) command is executed for the attribute.

The *description_text* argument is a quoted string that can be formatted as a Tcl string which includes support for escaped characters such as “\n” and “\t”.

- **-show_default**

An optional Boolean switch that specifies how the registered attribute is handled by the [get_attribute_list](#) and [report_attributes](#) commands.

false — If set to false during registration, the “[get_attribute_list](#) *obj_spec*” and “[report_attribute](#) *obj_spec*” command executions list or report attributes found on any object within *obj_spec* only if the attribute is set to a non default value.

true — If set to true, the attribute is always listed or reported if *obj_spec* contains at least one object of the type for which the attribute is registered for.

- **-hidden**

An optional switch that specifies the attribute should not be listed or reported by the [get_attribute_list](#) and [report_attributes](#) commands. The attribute can be set and queried using the [set_attribute_value](#) and [get_attribute_value_list](#) commands. You use this switch when you want to keep an attribute hidden. For example, while you develop a new feature and want to only make the attribute visible when you are ready to release the new feature.

Examples

Example 1

The following example registers the attribute named speed with a range of possible values equal to or greater than 100 and less than or equal to 500; assigns a default value of 200 to it; sets it as an attribute for the pin design object type only. Notice how the Tcl append command is used to allow typing the string on multiple lines without inserting extra white spaces into the string.

```
set desc "This attribute is used to hold the target frequency the pin is \n"
append desc "allowed to have.\n"
append desc "The allowed frequency range of 100 to 500 was chosen to match\n"
append desc "the technology spec."
register_attribute -name speed \
    -value_type integer \
    -default 200 \
    -min 100 \
    -max 500 \
    -object_types pin \
    -description$desc
```

Example 2

The following example defines the attribute named added_by as a string with a value of either “John”, “Patrick”, or “Susan” with a default of John, and a design object type of module:

```
register_attribute -name added_by \
    -value_type string \
    -default John \
    -enum {John Patrick Susan} \
    -object_types net
```

register_callback

Context: unspecified, all contexts

Mode: all modes

Register a Tcl proc which is to automatically run before or after a built-in feature of Tesson Shell.

Usage

```
register_callback feature_identifier proc_name
    [-order integer] [-static_arguments list_of_argument_values]
```

Description

The register_callback command registers a Tcl proc to automatically run before or after a Tesson Shell builtin feature runs. You use this command in a Tcl file located at *tcl_modules/your_company_name/any_name.tcl* file in one of your [plugin directory](#).

Once you have created and registered a callback procedure to run before or after a specific feature, the proc behaves as if it is part of the builtin behavior of the tool.

You can display the run time for the callbacks you have registered by setting the following environment variable prior to invoking the tool:

```
TESSENT_DISPLAY_CALLBACKS_RUN_TIME 1
```

When set to '1', the tool displays the execution time of those callbacks registered by you.

Arguments

- ***feature_identifier***

A special string that identifies the Tesson Shell builtin feature before or after which you want your proc to run. The following lists all supported feature names and the arguments your proc must have:

- `create_dft_specification.post`

Registers a Tcl proc that automatically runs after the DftSpecification wrapper has been created within the [create_dft_specification](#) command.

If a proc called “`create_dft_specification.post`” is declared in the global namespace, the proc is automatically run after all other procs registered for that feature. If you explicitly register the proc called “`create_dft_specification.post`” in the global namespace, the proc runs at the specified order value instead of at the end.

The proc must be declared with these arguments: `{root_wrapper args}`.

The `root_wrapper` argument holds the value of the DftSpecification wrapper that was created. The wrapper can then be modified using the configuration editing commands listed in [Table 10-1](#) on page 3175.

This callback is useful to automatically apply custom edits to the created DftSpecification wrapper.

- `create_flat_model.post`

Registers a Tcl proc that automatically runs after the flat model is created. The proc must be declared with this argument: `{args}`.

This callback is useful to attach attributes on the newly generated gate_pin objects.

The “`get_system_mode -is_in_transition`” command will return a “1” when used in the registered callback associated with this feature and the feature is used in a system mode transition. For more information on `-is_in_transition`, see the [get_system_mode](#) command description.

- `create_flat_model.pre`

Registers a Tcl proc that automatically runs before the flat model is created. The proc must be declared with this argument: `{args}`.

This callback is useful to insert checks that you want to enforce prior to generating the flat model. You can also use it to set the `preserve_boundary` attribute (see “[Built-In Attributes](#)” on page 3058) on hierarchical pins you want preserved in the flat_model. To block the creation of the flat model, issue the error condition with the `display_message` command and terminate the proc with the “`return -code error`” command.

The “`get_system_mode -is_in_transition`” command will return a “1” when used in the registered callback associated with this feature and the feature is used in a system mode transition. For more information on `-is_in_transition`, see the [get_system_mode](#) command description.

- `create_patterns_specification.post`

Registers a Tcl proc that automatically runs after the [PatternsSpecification](#) wrapper has been created within the `create_patterns_specification` command.

If a proc called “`create_patterns_dft_specification.post`” is declared in the global namespace, it is automatically run after all other procs registered for that feature. If you explicitly register the proc called “`create_patterns_specification.post`” in the global namespace, it will run at the specified order value instead of at the end.

The proc must be declared with these arguments: `{root_wrapper args}`.

The `root_wrapper` argument holds the value of the [PatternsSpecification](#) wrapper that was created. The wrapper can then be modified using the configuration editing commands listed in [Table 10-1](#) on page 3175.

This callback is useful to automatically apply custom edits to the created [PatternsSpecification](#) wrapper.

- `delete_design.pre`

Registers a Tcl proc that automatically runs before the design is deleted. The proc must be declared with these arguments: {args}.

This callback is useful to insert checks that you want to enforce prior to deleting the design data. To block the deletion of the design, issue the error condition with the `display_message` command and terminate the proc with the “`return -code error`” command.

- `elaboration_creation.post`

Registers a Tcl proc that automatically runs after the design is elaborated. The proc must be declared with this argument: {args}.

This callback is useful to automatically perform actions on the newly-elaborated design such as setting attributes on the design objects. The `get_current_design` command can be used within this proc to get the module that was elaborated.

The “`get_system_mode -is_in_transition`” command will return a “1” when used in the registered callback associated with this feature and the feature is used in a system mode transition. For more information on `-is_in_transition`, see the [get_system_mode](#) command description.

- `elaboration_creation.pre`

Registers a Tcl proc that automatically runs before the design is elaborated. The proc must be declared with this argument: {args}.

The args consist of a dictionary containing two keys: `design_name` and `library_name`. The `design_name` key holds the name of the design that is going to be elaborated. The `library_name` contains the name of the logical library in which the design being elaborated exists.

This callback is useful to automatically perform actions before the design is elaborated such as reading some extra design files.

The “`get_system_mode -is_in_transition`” command will return a “1” when used in the registered callback associated with this feature and the feature is used in a system mode transition. For more information on `-is_in_transition`, see the [get_system_mode](#) command description.

- `exit.pre`

Registers a Tcl proc that automatically runs before the tool exits.

The proc must be declared with this argument: {args}.

Use “`array set ARGS $args`” to set the arguments into an array and “`$ARGS(force)`” to know if the `-force` Boolean option was specified or not. The `ARGS(force)` value is 1 when the `-force` Boolean switch of the `exit` command was specified and 0 when it was not.

This callback is useful to automatically perform checks that you want to enforce prior to exiting the tool. To block the exit of the tool, issue the error condition with the [display_message](#) command and terminate the proc with the “return -code error” command.

- **extract_icl.post**

Registers a Tcl proc that automatically runs after ICL extraction has completed. This includes the writing of the ICL to file.

The proc does not need any argument but it is recommended to use the {args} argument to ensure forward compatibility.

This callback allows you to post process any files written out during ICL extraction. If you need to add attributes to ICL objects before the ICL is written out to file, use the extract_icl.pre_write callback.

- **extract_icl.pre**

Registers a Tcl proc that automatically runs before any check and setup of the design to ensure proper ICL extraction.

The proc does not need any argument but it is recommended to use the {args} argument to ensure forward compatibility.

This callback allows you to perform your own check and setup of the design to ensure successful ICL extraction and assuming that you have added some DFT circuitry yourself.

- **extract_icl.pre_write**

Registers a Tcl proc that automatically runs after ICL extraction has completed but before the writing of the ICL to a file. The callback is called even if [extract_icl -write_in_tsdb](#) is set to off.

The proc does not need any argument but it is recommended to use the {args} argument to ensure forward compatibility.

This callback is useful to add attributes to ICL objects before the ICL is written out to file. To perform actions on the written out file, use the extract_icl.post callback that is called at the very end of the ICL extraction feature.

- **insert_test_logic.post**

Registers a Tcl proc that automatically runs after the [insert_test_logic](#) has done all its actions including saving the design.

The proc must be declared with this argument: {args}.

This callback is useful to do design introspection and generate custom reports.

- **insert_test_logic.post_insertion**

Registers a Tcl proc that automatically runs after the [insert_test_logic](#) has done all its insertion actions but before it saves the design.

The proc must be declared with this argument: {args}.

This callback is useful to do custom editing to the netlist which you want to be part of the saved netlist.

- o [insert_test_logic.pre](#)

Registers a Tcl proc that automatically runs after the [insert_test_logic](#) has done all its insertion actions but before it saves the design.

The proc must be declared with this argument: {args}.

This callback is useful to do custom checks prior to letting the [insert_test_logic](#) do its job. If your check fails, then you issue error messages with the “[display_message -error](#)” command and return with -code error to cause the [insert_test_logic](#) operations to be interrupted. The user will be left in analysis mode, able to fix the issues reported by your custom checks.

- o [module_matching.post](#)

Registers a Tcl proc that automatically runs after the module matching feature was performed. See the [set_module_matching_options](#) and the [set_design_sources](#) command description for more information about this feature.

The proc must be declared with this argument: {args}.

This callback is useful to set attribute on the design objects from the matched ICL or TCD views—see “[Tessent Core Description](#)” on page 3755. For example, you can use the `get_ijtag_instances` or “`get_modules -filter instrument_name`” commands to get the list of design instances or modules for which there is a matched ICL module then use the ICL introspection commands to transfer information from ICL to the associated design objects.

The “`get_system_mode -is_in_transition`” command will return a “1” when used in the registered callback associated with this feature and the feature is used in a system mode transition. For more information on `-is_in_transition`, see the [get_system_mode](#) command description.

- o [module_matching.pre](#)

Registers a Tcl proc that automatically runs before the module matching feature is performed. See the [set_module_matching_options](#) and the [set_design_sources](#) command description for more information about this feature.

The proc must be declared with this argument: {args}.

This callback is useful to adjust the `set_design_sources` and/or the `set_module_matching_option` settings prior to doing the module matching.

The “get_system_mode -is_in_transition” command will return a “1” when used in the registered callback associated with this feature and the feature is used in a system mode transition. For more information on -is_in_transition, see the [get_system_mode](#) command description.

- [process_dft_specification.post_insertion](#)

Registers a Tcl proc that automatically runs after the insertion of the instruments was performed within the [process_dft_specification](#) command.

If a proc called “process_dft_specification.post_insertion” is declared in the global namespace, it is automatically run after all other procs registered for that feature. If you explicitly register the proc called “process_dft_specification.post_insertion” in the global namespace, it runs at the specified order value instead of at the end.

The proc must be declared with those arguments: {root_wrapper args}.

The root_wrapper argument holds the value of the DftSpecification wrapper that was processed.

This callback is useful to automatically apply custom edits to the design after all instruments were inserted but prior to when the modified design is written out into the dft_inserted_design directory.

- [process_patterns_specification.post_open](#)

Registers a Tcl proc that automatically runs immediately after the [open_pattern_set](#) command associated to every TestStep or ProcedureStep wrapper found in the processed PatternsSpecification.

The proc must be declared with those arguments: {config_path args}. The config_path argument holds the path to the TestStep or ProcedureStep wrapper being processed.

This callback is useful to add debug code that introspects the initial state of the network prior to running the iCalls associated to the given TestStep or ProcedureStep wrapper. Commands such as [get_iclock_list](#), [get_iclock_option](#), and [get_pattern_set_option](#) are used to introspect the relevant information to echo to the screen.

- [process_patterns_specification.pre_close](#)

Registers a Tcl proc that automatically runs immediately before the [close_pattern_set](#) command associated to every [TestStep](#) or [ProcedureStep](#) wrapper found in the processed [PatternsSpecification](#).

The proc must be declared with these arguments: {config_path args}. The config_path argument holds the path to the TestStep or ProcedureStep wrapper being processed.

This callback is useful to add debug code that introspects the end state of the network after having run the iCalls associated to the given TestStep or ProcedureStep wrapper. Commands such as [get_iclock_list](#), [get_iclock_option](#), and [get_pattern_set_option](#) are used to introspect the relevant information to echo to the screen.

- [set_context.post](#)

Registers a Tcl proc that automatically runs after the context was changed.

The proc must be declared with these arguments: {context args}. The context argument hold the name of the context that was just entered.

This callback is useful to automatically set the context upon entering that context.

- [set_context.pre](#)

Registers a Tcl proc that automatically runs before the context is changed.

The proc must be declared with these arguments: {context args}. The context argument holds the name of the context that is to be entered.

This callback is useful to automatically perform checks that you want to enforce prior to changing context. To block the context change, issue the error condition with the `display_message` command and terminate the proc with the “return -code error” command.

- [set_current_mode.post](#)

Registers a Tcl proc that automatically runs after the current mode was changed.

The proc must be declared with these arguments: {mode_name args}. The mode_name argument hold the name of the mode that was just set.

This callback is useful to automatically perform automatic setting when the current mode was changed. See the [set_current_mode](#) command for more information about the current mode setting.

- [set_current_mode.pre](#)

Registers a Tcl proc that automatically runs before the current mode is changed.

The proc must be declared with these arguments: {mode_name args}. The mode_name argument hold the name of the mode that is to be set.

This callback is useful to automatically perform checks that you want to enforce prior to changing the current the mode name. To block the mode name change, issue the error condition with the `display_message` command and terminate the proc with the “return -code error” command.

- [system_mode_transition.post](#)

Registers a Tcl proc that automatically runs after the system mode was changed.

The proc must be declared with these arguments: {from to args}. The “from” argument hold the name of the system mode prior to the system mode transition while the “to” argument holds the name of the system mode after the system mode transition.

This callback is useful to automatically perform automatic setting automatically after the system mode was changed. Use the get_context command to configure your actions to specific contexts.

- system_mode_transition.pre

Registers a Tcl proc that automatically runs before the system mode is changed.

The proc must be declared with these arguments: {from to args}. The “from” argument hold the name of the system mode prior to the system mode transition while the “to” argument holds the name of the system mode after the system mode transition.

This callback is useful to automatically perform checks that you want to enforce prior to changing the system mode. To block the system mode transition, issue the error condition with the display_message command and terminate the proc with the “return -code error” command. Use the get_context command to configure your actions to specific contexts.

- write_edt_files.post_insertion

Registers a Tcl proc that automatically runs after the insertion of the EDT instruments was performed within the [write_edt_files](#) command.

The proc does not take any arguments.

This callback is useful to automatically apply custom edits to the design after EDT instruments were inserted but prior to when the modified design is written out into the [dft_inserted_designs](#) directory.

- **proc_name**

Specifies the name of the proc to call when the specified feature is happening. The proc name can be with a fully specified namespace prefix or not. When the proc name does not start with ::, it is search relative to the current namespace. Using “[namespace current]::proc_name” is equivalent to specifying proc_name.

- **-order integer**

Specifies the execution order relative to the other callbacks registered for the same feature. When unspecified, the order defaults to 5. You can specify any integer between 1 and 10. A callback with an order value of N is guaranteed to run prior to the callbacks having an order value greater than N . For callbacks having the same order value, they are run in the order they were registered. It is not possible to control the registration order for two callbacks declared into two separate plugin directories so when the order is important, specify appropriate order values.

- -static_arguments *list_of_argument_values*

Specifies a list of argument values to pass to the proc in front of the normal arguments being passed.

This feature is useful to reuse a common proc for two different callback features. You use the values specified in this list to specialize your proc. In the feature_identifier section above, the list of arguments the proc must have for each feature name is documented.

For example, the argument list of the proc associated to the process_dft_specification.post_insertion feature is {root_wrapper args}. If you specified an static argument list with two values, you would need to declare two new variable in front of the root_wrapper argument as follow {static_arg1 static_arg2 root_wrapper args}. The actual name of the argument is not important but their position and count must match the specified list_of_argument_values.

Examples

This example below registers a proc to run before the system mode transition. When it detects that the context is dft and the transition is from setup to analysis, it deletes the existing Design(*design_name,design_id*) wrapper if it already exists and creates a new empty one. With this callbacks, the wrapper is guaranteed to exist and be empty when entering the analysis system mode in dft context. For this code to be available whenever Tessent Shell runs, it is included in the file *tcl_modules/your_company_name/any_name.tcl* file in one of your [plugin directory](#).

```
proc reset_design_wrapper { from_mode to_mode args } {
    if {[get_context] eq "dft" && $from_mode eq "setup" && $to_mode eq "analysis"} {
        set cur_design [get_single_name [get_current_design]]
        set design_id [get_context -design_id]
        if {[get_config_value Design("$cur_design","$design_id") -exists]} {
            delete_config_element Design("$cur_design","$design_id")
        }
        add_config_element Design("$cur_design","$design_id")
    }
}
register_callback system_mode_transition.pre reset_design_wrapper
```

register_drc

Context: dft, patterns, unspecified

Mode: setup

A command used to register a custom DRC rule, and make it look and behave as a built-in DRC rule fully supported by the [analyze_drcViolation](#) command and the Tesson DFTVisualizer GUI.

Usage

```
register_drc name -class class_name -short_help short_help
  -drc_proc drc_proc -context_list context_list
  [-summary_text summary_text]
  [-severity {error | warning | note | ignore}]
  [-lowest_downgradable_severity {error | warning | note | ignore}]
  [-verbose {auto | on | off}] [-rtl_synthesis_proc rtl_synthesis_proc]
  [-runs_after drc_name] [-allow_auto_fix]
```

Description

A command used to register a custom DRC rule, and make it look and behave as a built-in DRC rule fully supported by the [analyze_drcViolation](#) command and the Tesson DFTVisualizer GUI. Tesson Shell includes several high-level commands such as [trace_flat_model](#) and [set_attribute_value](#) giving you the ability to code in a few lines of Tcl code very complex DRC rules that run quickly and perform arbitrary complex custom checks. A comprehensive set of examples is provided below. The examples describe the complete implementation of four different DRC rules and provide the complete source code to serve as the basis for your own custom rules.

Arguments

- ***name***

A required string that will be appended to the DRC class name to make up a unique name for the DRC. Each registered DRC must have a unique <class_name><name> value. You typically use an integer as the name, and a string that identifies your company name and DRC type in the class name.

For example, the DRC rules presented in the examples below have a class name of “XYZ_S” and a name from 1 to 4. The complete DRC names are therefore “XYZ_S1”, “XYZ_S2”, “XYZ_S3”, and “XYZ_S4”. It is important to use a suffix like “XYZ_” in your class names to make sure you do not collide with built-in DRC names which do not have such prefixes. For example, even if DRC C27 does not yet exist as a built-in DRC name, it is likely it will exist in the future and your plugin would start failing when you load it into the newer version of Tesson Shell.

By default, the order of execution of the user-defined DRC rules is extracted by doing a numerical sort on the DRC name. To precisely control the order of execution, use the *-runs_after* switch described below.

- **-class *class_name***

A required switch-string pair that identifies the class name in which the DRC belongs. You must pre-register the *class_name* using the [register_drc_class](#) command.

- **-short_help *short_help***

A required switch-string pair that provides a one line description of the DRC rule. This string is used to identify the DRCs in the [DRC Violation Browser](#) of the GUI and when the [report_drc_rules](#) command is called. See the examples below for an illustration of the wording you would typically use.

- **-drc_proc *drc_proc***

A required switch-string pair defining the name of a proc that is to be called to perform the DRC. As is described in [Example 1](#) of the [plugin directory](#) section, you use the following:

```
-drc_proc [create_wrapper_proc my_tcl_proc]
```

when you are packaging your custom DRC in a plugin. The created wrapper proc adds lots of functionality to your proc such as proper Ctrl-C handling, showing the Tcl-Stack if you have a bug in your code, and most importantly loading the body of your rule the first time it is used instead of when Tesson Shell starts. The examples below illustrates the use of this switch with the use of the `create_wrapper_proc` command.

The supplied proc must accept two arguments: mode and *drc_name*. The proc will be called with the *drc_name* argument specifying the name of the DRC that called the proc. This argument is useful when you want to share a common proc for more than one DRC name. The *drc_name* value allows you to customize it for each DRC while keeping the common part common. The mode argument will have two values: enabled and run. When it has the value “enabled”, the proc must return 1 if the DRC is enable and you want it to run. Otherwise you return 0. If and only if you returned 1 will it then be called with mode equal to “run”. See the examples below for a suggested way to establish if a DRC is enabled or not.

Another way to control when the DRC runs is to specify a default severity of ignore using the -severity switch described below. You then use `set_drc_handling drc_name {error | warning | note}` when you want it to run.

- **-context_list *context_list***

A required switch-string pair that is used to define in which context the registered DRC is to be run. You typically will use “dft -no_sub_context” which means the DRC will only be requested to run in the DFT context when no sub-context (for example, -scan or -test_points) was specified. If you choose to enable the DRC in some other contexts, you may not have the information needed for it. The XYZ_S3 DRC shown in [Example 3](#) below depends on the attributes populated by running the [DFT_C6](#) DRC. DFT_C6 is only allowed in dft context with no sub context specified. It would therefore not be possible to activate XYZ_S3 in any other sub-context as the information computed by DFT_C6 would not be available.

- **-summary_text *summary_text***

An optional switch-string pair that specifies a string that is used when a DRC summary line is echoed to reflect the presence of violations for the given DRC. By default, DRC rules with severity warning or below only echo to the summary line if there was at least one violation. If you do not specify this switch, then the **short_help** string will also be used as the summary text, which is what is done in the examples shown below and in most built-in DRCs.

- **-severity error | warning | note | ignore**

An optional switch-value pair specifying the default severity the DRC is to have when enabled. If the **-lowest_downgradable_severity** is specified with a lower value, then the severity can be downgraded in your dofile using the **set_drc_handling** command. It is always possible to increase the severity of a DRC. When unspecified, the severity defaults to “error”.

A way to create a DRC that never runs by default but can be activated with the **set_drc_handling** command is to register the DRC with a default severity of “ignore”. When you want to activate the DRC, you use the “**set_drc_handling *drc_name severity***” command to bring it up to the required severity.

- **-lowest_downgradable_severity error | warning | note | ignore**

An optional switch-value pair specifying the lowest severity the DRC can be downgraded to. When unspecified, the lowest downgrade value is the default severity specified with the **-severity** switch. The lowest downgrade value cannot be higher than the default severity value specified by the **-severity** switch.

Note that the severity of a DRC can always be upgraded. For example, even if the default severity is “warning”, you can increase the severity to “error” using the **set_drc_handling** command.

- **-verbose auto | on | off**

An optional switch that controls the verbosity of the DRC. When set to “auto”, the DRC will generate one Error message per violation if the severity is “error”. Only a summary line showing the number of violations for the given DRC will be issued for severity warning or below. Setting **-verbose** to “on” will cause a note or warning to be issued for each violation even if the severity is below “error”. Setting **-verbose** to “off” will suppress the individual error message for each violation and only a summary line with the violation count will be issued, even if the severity is “error”. To view the individual violations, use the “**report_drc_rules *drc_name***” to obtain the list of violations for the given DRC name.

- **-rtl_synthesis_proc *rtl_synthesis_proc***

An optional switch-value pair that specifies the name of a proc that will be called to determine if the DRC requires anything to be synthesized in order for the DRC to check the logic. As with the DRC proc, the RTL synthesis proc has two arguments: mode and **drc_name**. Just like with the DRC proc, the RTL synthesis proc will be called with the **drc_name** argument specifying the name of the DRC that called the proc. This argument is useful when you want to share a common proc for more than one DRC name. In [Example 1](#)

below, you can see that this technique was used and a common proc called “xyz_synth.tcl” was used for all four XYZ_S DRC rules.

As with the DRC proc, it is best to use the create_wrapper_proc to encapsulate your proc as follows:

```
-rtl_synthesis_proc [create_wrapper_proc my_tcl_proc2]
```

The mode argument has multiple values. The values and their meaning are described in [Table 5-5](#).

Table 5-5. Mode values for the RTL Synthesis Proc

Mode Value	Meaning
enabled	In this mode, the proc returns 1 or 0 to indicate if it requires anything to be synthesized or not.
complete_start_module	In this mode, the proc returns a collection of modules that needs to be synthesized downward. All modules below the returned modules will also be synthesized unless the lower module is returned in the specified “complete_stop_module” collection. It must return a null string when nothing needs to be synthesized completely. You typically return the current_design when doing DRC that deals with flip-flops because until a module is synthesized, it is not possible to know if it has flip-flops or not. The DRC XYZ_S3 in Example 3 below is an example of a DRC that requires full synthesis. When you are checking connections between top-level port or pins of instances, you do not need to synthesize everything; instead, you use the selective modes described below to request synthesizing logic in the fanin or fanout of specific nodes.
complete_stop_module	In this mode, the proc returns a collection of modules that stop the downward synthesis from the specified “complete_start_module” collection. For example, if you only want to see flip-flops in the top module, you would specify the current design as the “complete_start_module” and the modules of the instances found in the current_design as the “complete_stop_module”. The code to create the “complete_stop_module” collection would be “get_modules -of_instances [get_instances * -of_type design]”.

Table 5-5. Mode values for the RTL Synthesis Proc (cont.)

Mode Value	Meaning
selective_fanin	In this mode, the proc returns a collection of pins or ports for which the fanin must be synthesized. For each node in the collection, the fanin is traced until either a net with no source, a top-level PI, or a sequential element is reached. If a net that is part of an RTL expression is reached, its associated module will be synthesized, and the above tracing process will be recursively repeated. The selective_fanin_stop_equation described next is another condition that stops the tracing.
selective_fanin_stop_equation	In this mode, the proc returns a string that represent a filtering equation based on port and pin attributes. When the equation evaluation is true, the fanin traversal is stopped at this point. The usage of such equation is illustrated in the RTL synthesis proc shown in Example 1 .
selective_fanout	In this mode, the proc returns a collection of pins or ports for which their fanout must be synthesized. For each node in the collection, the fanout is traced until either a net with no destination, a top-level PO, or a sequential element is reached. If a net that is part of an RTL expression is reached, its associated module will be synthesized, and the above tracing process recursively repeated. The selective_fanout_stop_equation describe next is another condition that stops the tracing.
selective_fanout_stop_equation	In this mode, the proc returns a string that represent a filtering equation based on port and pin attributes. When the equation evaluation is true, the fanout traversal is stopped.

- `-runs_after drc_name`

An optional switch-value pair that specifies the order a given DRC runs relative to the other DRC rules. You use this to create a sequential order of execution of the DRCs. When unspecified, the DRC will run after the DRC it follows when doing a numerical sort. Remember that each DRC has an independent way of specifying that it is enabled or not. Even if you specify `-runs_after DRCX`, the DRC will run after DRCX whether DRCX is enabled or not.

- `-allow_auto_fix`

An optional Boolean switch used that enables auto fix support within this DRC. When the switch is used, the command “`set_drc_handling drc_name`” supports the `-auto_fix` on | off switch. The default value is on. Use “`get_drc_handling drc_name -auto_fix`” to determine if auto fix is enabled or disabled for a specific DRC. The rest of the work is in the coding of the DRC. Under certain conditions, when auto fix is on, you can choose to implement an auto fix instead for given a violation. See [DFT_C9](#) for an example of a DRC rule that

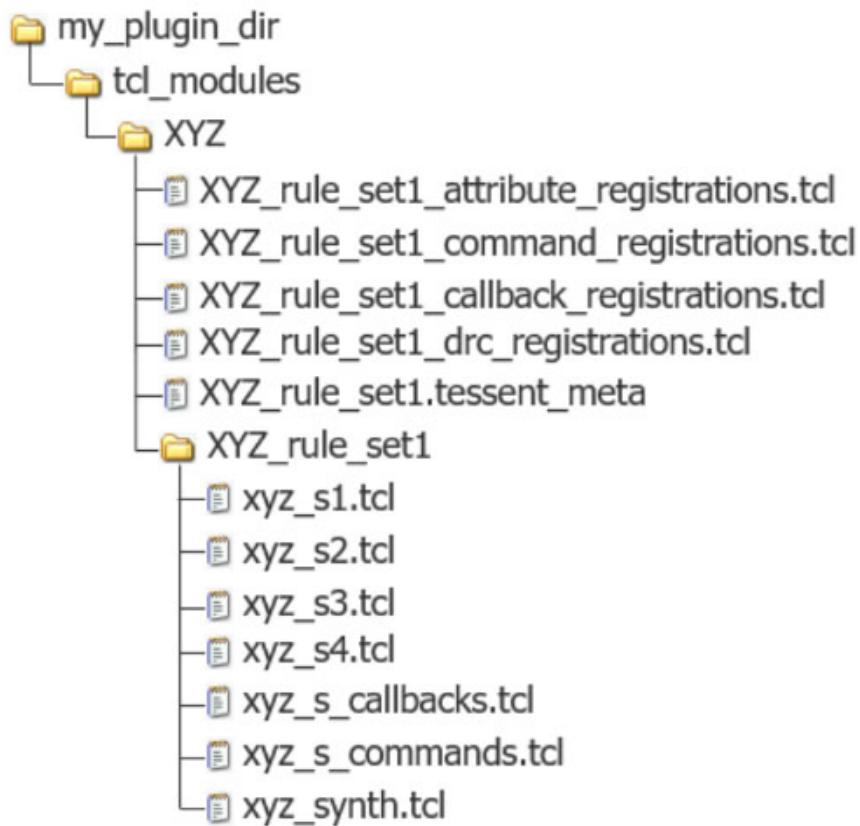

supports auto fix. Instead of giving a violation, the tool infers a DFT control point to make the set or reset sources controllable during shift.

Examples

The following examples are a set of four custom DRC rules used to provide you with guidance for coding your own rules. The four examples were chosen to cover a wide spectrum of the available infrastructure. Some of the commands and procedures described in [Example 1](#) are re-used in the other three examples.

The four DRCs rules are packaged in a *tcl_modules* plugin directory following the same organization described in the [plugin directory](#) section. The directory and files described in the examples below follow the organization presented in [Figure 5-4](#). The files located in the *XYZ* directory are loaded when Tesson Shell starts (assuming the `TESSENT_PLUGIN_PATH` environment variable points to the *my_plugin_dir* directory). The files inside the *XYZ_rule_set1* sub-directory are loaded the first time the DRC rules run. As described in the [plugin directory](#) section, you must perform the registrations and the metadata declarations in the files that are loaded into Tesson Shell at start time. The body of the procs that implement the commands, the callbacks, and the DRC rules are loaded on demand the first time the command, callback, or DRC, respectively, is run. The four example DRC rules are as follows:

- [Example 1](#) — *XYZ_S1*: All ports must go through a buffer before any other logic
- [Example 2](#) — *XYZ_S2*: No combinational path except pure feed-through paths
- [Example 3](#) — *XYZ_S3*: No inter-domain path not going through sync cells
- [Example 4](#) — *XYZ_S4*: Input pins must be sourced by output pins with consistent *xyz_function*

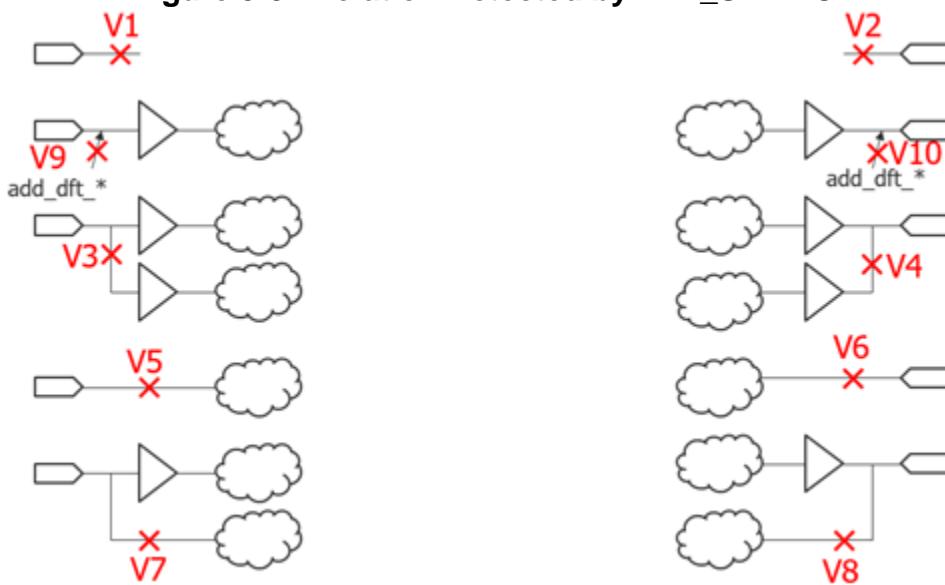

Figure 5-4. Plugin Directory Contains XYZ Custom DRC Rules

Example 1

This example implements a DRC rule that verifies that each port of the current design connects to one and only one buffer cell. Some design groups have the practice of having a single buffer connected to each port of a physical layout region such that it can be placed near the physical port of the layout region ensuring that there is no long unbuffered net inside the layout region. Some ports like a clock port are excluded automatically from this check because their buffering is handled during Clock Tree Synthesis, which happens later in the flow during layout.

The types of violation that must be detected by the DRC rule are illustrated in [Figure 5-5](#). The V1 and V2 violations detect unconnected ports. The V3 and V4 violations detect ports connected to more than one buffer cells. The V5 and V6 violations detect ports connected to logic without going through a buffer cell. The V7 and V8 violations detect ports connected to a single buffer cell but also to other logic. The V9 and V10 detects ports properly connected to a single buffer but which were the target of a [add_dft_control_points](#) or [add_dft_clock_mux](#) command. The logic is not yet inserted but after the [process_dft_specification](#) command is run, logic will be inserted, and the port will no longer be directly connected to a buffer cell.

Figure 5-5. Violation Detected by XYZ_S1 DRC

The following is the content of the *XYZ_rule_set1_command_registrations.tcl* file. It contains the registration of commands used to configure or report the settings of the XYZ_S DRC rules. The file also contains a namespace import of the `::mentor::DrcUtilities::*` procedure that will be used to facilitate the coding of the custom DRC rules. The imported commands will be described later when they are used in the DRC body description. Finally, the file declares a namespace variable that is used to store a Tcl dictionary holding the enable status as well as other options for the DRC rules.

```
#### XYZ_rule_set1_command_registrations.tcl ####
namespace eval XYZ_rule_set1 {

    ##### Command imports

    # ITCL classes
    # DrcViolation
    #
    # Procs
    # get_add_dft_node_filter
    #     returns a string used to filter gate_pin collection to know
    #     if they were the target of an add_dft_* command
    # get_add_dft_node_message
    #     returns a string explaining which add_dft_* command was
    #     issued on the node
    # get_synchronous_clock_label_groups

    namespace import ::mentor::DrcUtilities::*;

    ##### Command registration

    register_tcl_command report_xyz_s_drc_options \
        -context_list {unspecified dft patterns} \
        -system_mode_list {setup analysis insertion} \
        -syntax_bnf {} \
        -transcript tool_command \
        -tcl_proc "[create_wrapper_proc report_xyz_s_drc_options]"
}
```

```
# Variable definitions
variable xyz_s_drc_dict {
    drc_indexes {
        1 {
            enable 0
            excluded_ports {}
        }
        2 {
            enable 0
        }
        3 {
            enable 0
            excluded_clocks {}
        }
        4 {
            enable 0
        }
    }
    synchronizer_cells {}
}
```

The next section of code includes the content of the file *xyz_s_commands.tcl*. The file contains the body of the procs used to implement the registered commands. There is nothing specific to DRC rules in this file, and this is simply provided for completeness. You can use this example to see a use of the Tcl “dict” commands and how Tcl dictionaries are perfect to store structured data.

```
##### xyz_s_commands.tcl #####

The next code block shows the content of the file *XYZ_rule_set1_drc_registrations.tcl*. This file includes the registration of the four XYZ_S DRC rules. The first line registers the XYZ_S DRC class using the `register_drc_class` command. Below are the four DRC rule registrations using the `register_drc` command. Notice how the `create_wrapper_proc` command is used around the referenced proc names. The wrapper proc provides a lot of built-in functionality to your proc such as proper Ctrl-C handling, dumping the stack if you have a Tcl bug in your code, and most importantly, loading the body of the procs the first time the DRC runs. Because the `create_wrapper_proc` is called inside namespace “XYZ_rule_set1”, the “*.tcl” files found inside the subdirectory by the name of the namespace will be loaded the first time the wrapper proc is called.

```
##### XYZ_rule_set1_drc_registrations.tcl #####
namespace eval XYZ_rule_set1 {
    # DRC registrations

    register_drc_class XYZ_S
    register_drc 1 \
        -class XYZ_S \
        -short_help "All ports must go through a buffer before any other
logic" \
        -context_list "dft -no_sub_context" \
        -drc_proc [create_wrapper_proc XYZ_S1_drc] \
        -rtl_synthesis_proc [create_wrapper_proc XYZ_S_synth]

    register_drc 2 \
        -class XYZ_S \
        -short_help "No combinational path except pure feed-through paths" \
        -context_list "dft -no_sub_context" \
        -drc_proc [create_wrapper_proc XYZ_S2_drc] \
        -rtl_synthesis_proc [create_wrapper_proc XYZ_S_synth]

    register_drc 3 \
        -class XYZ_S \
        -short_help "No inter-domain path not going through sync cells" \
        -context_list "dft -no_sub_context" \
        -drc_proc [create_wrapper_proc XYZ_S3_drc] \
        -rtl_synthesis_proc [create_wrapper_proc XYZ_S_synth]

    register_drc 4 \
        -class XYZ_S \
        -short_help "Input pins must be sourced by output pins with
consistent xyz_function" \
        -context_list "dft -no_sub_context" \
        -drc_proc [create_wrapper_proc XYZ_S4_drc] \
        -rtl_synthesis_proc [create_wrapper_proc XYZ_S_synth]
}
```

The next code block section shows the content of the *xyz_s1.tcl* file which contains the body definition of the XYZ_S1 DRC rule. The first proc is the main proc that has the mode and drc_name arguments. When called with mode equal to “enabled”, the proc returns the enable flag of the XYZ_S1 DRC found in the *xyz_s_drc_dict*. The command used to populate the

dictionary was presented above in the second code block of [Example 1](#) and is found in file *xyz_s_commands.tcl*. The proc that actually checks if any of the situations described in [Figure 5-5](#) are present is the second proc named “XYZ_S1_check_port”. When this proc detects an error condition, it returns a Tcl dictionary with the following keys: “path_list0”, “path_list1”, and “msg_list”. The returned value is then used to add the DRC violation with the [add_drcViolation](#) command. As stated in the [add_drcViolation](#) command section, it requires one argument, which is an object of an ITCL class having a prescribed set of methods. A complete ITCL class definition is already provided in the tool, and you typically will never need to define your own as the definition is very flexible and should be enough to cover most of your needs. See the [add_drcViolation](#) command section for a detailed description of this ITCL class and the method it provides to configure it and to service the DRC commands.

You create a new object of the `DrcViolation` class using the following command:

```
set violation [DrcViolation #auto]
```

You use the “dict_set” method of the object stored in the “violation” variable to configure the object. Once configured, you add the object as a violation using the following command:

```
add_drcViolation [namespace current] ::$violation
```

This DRC is not doing complex tracing, and the tracing does not need to traverse cells, nor does the tracing need to consider simulation values. This is why the “XYZ_S1_check_port” proc makes use of the [get_fanins](#) and [get_fanouts](#) commands instead of the [trace_flat_model](#) command. In such simple situation, using the [get_fanins](#)/[get_fanouts](#) is better because the commands operate on the hierarchical data model. If you have a port that goes down through several levels of hierarchy but ends up having no fanout to a cell, then the port will be seen as having no destination in the flat model; however, because this DRC is using [get_fanouts](#), the violation will highlight the path to the internal pin, which has no further connection. In more complex DRC like the other three examples, using the [trace_flat_model](#) command is needed because the DRCs involve tracing through multiple levels of logic and must consider a simulation context.

```

Below is the source code used to request various parts of the design to be synthesized based on which DRC was enabled. The “drc_name” argument is used to decide what needs to be synthesized or not. The XYZ_S1, XYZ_S2, and XYZ_S4 DRC rules use the selective approach because they check the fanin and fanout of ports and pins. The XYZ_S3 DRC uses the complete synthesis methods because the DRC checks for inter-domain paths between sequential elements, and the sequential elements can only be identified after complete synthesis. Refer to the *-rtl_synthesis_proc rtl_synthesis_proc* argument section above for more details about the various argument values for this proc.

```
##### xyz_synth.tcl #####

```

Example 2

This example implements a DRC rule that verifies that the design does not have combinational path between input and output ports unless they are pure feed-through paths containing only single-input cells such as inverters and buffers. [Figure 5-6](#) shows the kind of paths that need to be allowed or rejected. The example DRC rule only detects that a path has no multi-input gate along the way. If you also run XYZ_S1 presented in [Example 1](#), you would reject the path from I1 to O1 because it has no buffer. You could also chose to write another DRC to make sure there is no inversion in the feed-through paths if this is one of your requirements. You would do this after you have found the path meeting XYZ_S2. You would use [trace_flat_model](#) with the “-controllability controlling” switch and use the “-store_polarity_to_tagged_objects” switch to store the polarity of the paths.

In the XYZ_S2 DRC, the [trace_flat_model](#) command is used to trace the connected fanin of every output ports and tag any path that reaches an input port of the current design. A simple [filter_collection](#) command using the “gate_input_count” [Gate_pin](#) attribute is used to detect if any multi-input gate exists along the path between the PO and the PI. As you can see below, the code to implement this DRC is very simple and fits in a page of code.

Figure 5-6. Combinational Paths Allowed and Rejects by XYZ_S2

```

Example 3

This example implements a DRC rule that verifies there is no path from a sequential cell on a given synchronous clock group that reaches a sequential cell on another synchronous clock group unless the destination sequential cell is a synchronizer cell. The types of violations that are to be found are illustrated in [Figure 5-7](#). The implementation of this DRC is very simple once DFT_C6 has run and properly set the `clock_domain_label` attribute on each flip-flops. The implementation is shown in the example. You can see that it creates a collection of all DFF Q gate_pins. It then filters them per synchronous clock groups and issue one `trace_flat_model` command per groups. The hit equation is any DFF or DLAT gate_pin on a different synchronous clock group. The “xyz_exclude” attribute is used to tag the inputs of the synchronizer cells and any gate_pin of a sequential cell belonging to an excluded clock domain. If you go back to the example code block describing the content of the file `XYZ_rule_set1_command_registrations.tcl` in [Example 1](#), you will see that the “`set_xyz_s_drc_options`” command was equipped with an `-excluded_clocks_from_xyz_s3` switch to allow excluding some clock domains from the check. For example, it is common to allow interactions between the IJTAG static signal (TCK domain) and the functional logic without going through a synchronizer cell. The “xyz_exclude” attribute was registered in the file `XYZ_rule_set1_attribute_registrations.tcl` file, and its content is shown below.

Finally, notice that the `trace_flat_model` command is used to do a forward walk. [Figure 5-8](#) on page 1342 and [Figure 5-9](#) on page 1342 illustrate the difference between using a forward versus a backward walk. The `trace_flat_model` command is very efficient and never traverses the same gate twice in a given trace. You would be visiting each gate potentially thousands of times if you traced through a gate as part of all possible paths it belongs to. When you use a backward trace, you are guaranteed to find all hits in the fanin, but not all the sources that may reach the hits. The same is true in the other direction. In this example DRC, we are interested in finding all the destination gates sourced by at least one sequential cell on a different domain. We do not need to find all the source elements, just the failing destinations which is why a forward tracing is used. If you wanted to find all elements sourcing a different domain and all elements receiving from a different domain, you would need to use two traces, one forward and one backward. The backward trace would identify the TX flops and the forward trace would identify the RX flop.

This DRC example also makes use of the `register_callback` command to implement a check when `check_design_rules` is called to make sure the synchronizer cell was defined using the `set_xyz_s_drc_options` command and that the DFT_C6 rule was turned on. The files to register the callback and the one containing the body definition are listed at the end of this example. Notice that DFT_C6 is enabled by using the “`set_dft_specification_requirements -logic_test on`” command. That also enables DFT_C9. If you don’t want to have to worry about the asynchronous Set and Reset issues to run this DRC, you can simply disable DFT_C9 using “`set_drc_handling dft_c9 ignore`”.

```

Example 4

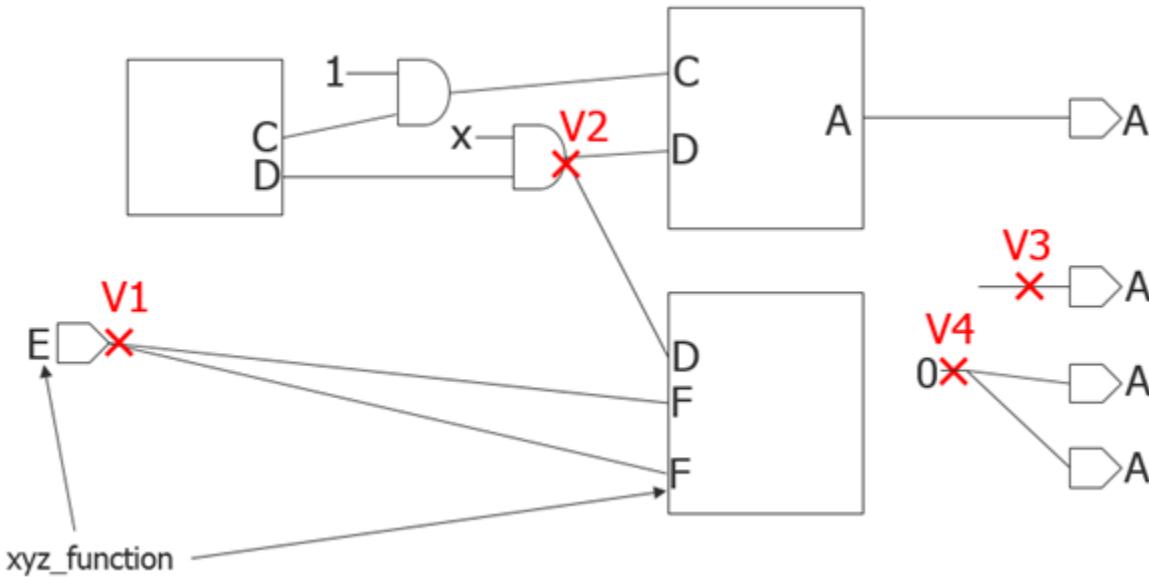

This example implements a DRC rule that verifies that output ports or input pins with a given xyz_function attribute value are controlled by input ports or output pins with the same xyz_function attribute value. This DRC could be used to verify that, for example, special pins of pad buffers are connected to the right programming logic. The kind of violation detected by this DRC is illustrated in [Figure 5-10](#). The names shown on the pins or ports are not their names but the value of the xyz_function attribute. The V1 violation detects an input port with xyz_function

equal to E driving two pins with xyz_function equal to F. The V2 violation detects two pins with xyz_function equal to D driven by a gate that blocks the controlling path from the valid source. The V3 violation is an output port with no source. Finally, the V4 violation is two output ports driven by a common source which is a constant value. The DRC is implemented such that it only issues one violation per invalid source and not one violation per incorrect destinations. You will see this is achieved by tracing backward from the output port and the input pins with an xyz_function value. When the controlling walk stops, a forward walk is used to collect all output ports and input pins with the same xyz_function value in the controlling fanout of the stop point. This avoids tracing backward from all incorrectly connected destination sharing a common source. This make sure that V1 and V2 in [Figure 5-10](#) are issued once instead of twice. For the V4 violation, because the first port to trace evaluate to a constant, a constant source tracing is done to find the source of the constant, the constant source is then forced to X and a forward controlling walk is performed to collect all destinations sharing the same invalid constant source.

Note

This DRC relies on having the user-defined attribute called xyz_function set on pins of instances and ports of the current design. Refer to Example 5 below for a description on how you can use configuration files to automate the process of setting the attribute.

Figure 5-10. Violations Detected by XYZ_S4_DRC

The xyz_attribute is registered in the file *XYZ_rule_set1_attribute_registrations.tcl* and its content was shown in [Example 3](#). Again the `trace_flat_model` command is used. This time the controllability switch is set to controlling and to constant when tracing a pin that has a constant value.

}
}

```

Example 5

This example does not show a new DRC example, but instead a method to populate the xyz_function attribute needed for the XYZ_S4 DRC rule shown in the previous example. Configuration data is a very convenient way of defining attributes on ports of a module. With a simple callback shown below, you can easily transfer the attribute values from the configuration file to the ports of the current design and the pins of the instances of the modules.

Below is an example configuration file describing attributes on ports of modules. Even though the example has multiple Core wrappers in the same file, you can choose to use one file per Core wrapper or merge them in a single file.

```

##### modules.tcd_xyz #####
Core(epoch_counter) {
    Xyz {
        Port(tic_enable) {
            function : tic_enable;
        }
    }
}
Core(code_gen) {
    Xyz {
        Port(tic_enable) {
            function : tic_enable;
        }
    }
}
Core(time_base) {
    Xyz {
        Port(tic_enable) {
            function : tic_enable;
        }
        Port(rstn) {
            function : reset;
        }
    }
}

```

```
Core(gps_baseband) {
    Xyz {
        Port(hw_rstn) {
            function : reset;
        }
    }
}
```

Below is the metadata used to define the legal syntax of the XYZ wrapper. See the “[Metadata Configuration Syntax](#)” chapter for more information about the metadata syntax. The location of the metadata file within the plugin was shown in [Figure 5-4](#) on page 1321.

```
##### XYZ_rule_set1.tessent_meta #####
Partitions: default, tcd;
Wrapper(/Core) {
    Wrapper(Xyz) {
        Repeatable: off;
        Property(version) {
            Value(version) {
                Type: int;
                DefaultValue : 1;
            }
        }
        Wrapper(Port) {
            Id(port_name) {
                Type: string;
            }
            Property(function) {
                Value(enum) {
                    LegalString : "",tic_enable, pre_tic_enable, reset;
                    DefaultValue : "";
                }
            }
        }
    }
}
```

You use the [read_core_descriptions](#) command to load the *.tcd_xyz* files. Below is a callback procedure that you can use in your plugin to automatically transfer the *xyz_function* value to the ports of the current design and pins of instances of the sub modules. Notice the use of the *-use_module_matching_options* switch in the [get_modules](#) command usage. This ensures that if your module names were unqualified during synthesis that the modules will still be matched to the RTL module names found in the Core wrapper. See the [set_module_matching_options](#) command for more information about module matching.

```
# Callback registration
namespace eval XYZ_rule_set1 {
    module_matching.post [create_wrapper_proc apply_xyz_function]
}
```

```

# Body of callback

proc apply_xyz_function {args} {
    reset_attribute_value -object_types {port pin} -name xyz_function
    foreach_in_collection tcd_xyz_wrapper [get_config_elements core/xyz \
                                              -partition tcd -silent] {
        set core_wrapper [get_config_value $tcd_xyz_wrapper -parent_object]
        set core_name [get_config_value $core_wrapper -id <0>]
        set matched_modules [get_module [list $core_name] \
                                     -use_module_matching_options -silent]
        if {[sizeof_collection $matched_modules] > 0} {
            if {[compare_collections $matched_modules \
                                         [get_current_design]] == 0} {
                set is_current_design 1
            } else {
                set is_current_design 0
                set matched_instances [get_instances \
                                         -of_modules $matched_modules -silent]
            }
            if {$is_current_design || \
                 [sizeof_collection $matched_instances] > 0} {
                foreach_in_collection port_wrapper [get_config_elements Port \
                                              -below_wrappers $tcd_xyz_wrapper -silent] {
                    set port_name [get_config_value $port_wrapper -id <0>]
                    set function_name [get_config_value function \
                                      -in_wrapper $port_wrapper]
                    if {$is_current_design} {
                        set objects [get_ports [list $port_name]]
                    } else {
                        set objects [get_pins [list $port_name] \
                                         -of_instances $matched_instances]
                    }
                    set_attribute_value $objects -name xyz_function \
                                       -value $function_name
                }
            }
        }
    }
}

```

register_drc_class

Context: dft. patterns, unspecified

Mode:setup

Registers a new class of DRC rules such that a DRC of that class can be registered

Usage

```
register_drc_class class_name [-runs_after class_name]
```

Description

A command used to register a new class of DRCs. Once you register a class, you use the “[register_drc](#) *drc_name -class class*” command to register DRC rules of that class. If you are registering your own DRC rules, it is best to use your own class name containing something specific to your company in the name such that you will never collide with future built-in DRC rules. In the example shown in the [register_drc](#) command section, the class name “XYZ_S” was used. The “XYZ” part is meant to represent your company and the “S” represent the further classification you may want to use.

Arguments

- ***class_name***

A required string that must start with a capital letter and is followed by only capital letters, numbers, and underscores.

- **-runs_after *class_name***

An optional switch-value pair that specifies the order in which the current DRC class is to run relative to the other custom-registered DRC classes. When unspecified, the class will run after the class that it follows in a numerical sorted list of the custom-registered class names.

When you register a DRC using the [register_drc](#) command, you can control precisely in which order the DRC runs. It is not a requirement that all DRC rules of a class run before the DRC rules of another class. You can intermix them as you needed. The class run order only affects registered DRC rules that do not use the -runs_after switch.

Examples

The following example registers a new DRC class called XYZ_T and specifies that it runs before the DRC class XYZ_D. If the -runs_after switch was not specified, the order would be reversed because XYZ_T is after the XYZ_D in a numerical sort.

```
register_drc_class XYZ_T -runs_after XYZ_D
```

register_static_dft_signal_names

Context: unspecified, all contexts

Mode: all modes

Registers new static DFT signal names and their attributes.

Usage

```
register_static_dft_signal_names {name ...}
    [-usage {global_dft_control | logic_test_control | scan_mode}]
    [-scan_mode_type {unwrapped | internal | external | retargeting}]
    [-default_value_in_all_test {auto | 0 | 1}]
    [-reset_value {0 | 1}]
    [-value_in_pre_scan_drc {x | 0 | 1}]
```

Description

Registers new static DFT signal names and their attributes. The tool has built-in pre-registered DFT signal names that you can view using the [report_dft_signal_names](#) command.

You use the register_static_dft_signal_names command to create a new dft_signal and specify its behavior (for example, reset_value, default_value_in_all_test).

You only use this command if the pre-defined dft_signals do not fit your needs. For example, if you have logic you want controlled in different test modes and none of the pre-defined dft_signals will work for your logic, then you can register a new dft_signal.

After you have registered your dft_signal, you use the [add_dft_signals](#) command to create the hardware needed to implement your new dft_signal. You are now able to use your new dft_signal to control logic by referencing your new dft_signal with the “dft_signal_source_name” option of the [add_dft_control_points](#) or [add_dft_clock_mux](#) commands.

You can also register new scan_mode signals using this command if you find that you do not have the one you need in the pre-registered list. It is important that you set the proper -scan_mode_type value when registering a DFT signal of usage scan_mode. See the description of the [set_static_dft_signal_values](#) command to understand how the scan_mode_type affects the implied value of the int_ltest_en and ext_ltest_en signals.

Arguments

- ***name***

A required repeatable string that specifies the name of the DFT signals to register. The string is also allowed to be a well formatted Tcl list of names. The names must start with a letter and be followed by only letters, numbers, and/or underscores.

- **-usage {global_dft_control | logic_test_control | scan_mode}**

An optional switch and literal pair that specifies the usage of the newly-registered DFT signal names. When the -usage switch is not specified, the default is global_dft_control.

Choose one from the following:

global_dft_control — This usage is for signals controlling global resources like clocking and power management signals. Those signals are automatically set to their specified “default_value_in_all_test” values unless the value is explicitly requested to be differently set using either the DftControlSetting wrapper of the [Patterns](#) wrapper or using the [set_static_dft_signal_values](#) command. See [Table 3-10](#) on page 190 in the [add_dft_signals](#) command description of the pre-registered global DFT controls.

logic_test_control — This usage is for signals used to control aspects of the logic test modes. Unlike the signal with usage scan_mode, the signals are not mutually exclusive to each other and can be set high or low when using the same scan configuration. See [Table 3-10](#) on page 190 in the [add_dft_signals](#) command description of the pre-registered logic test controls.

scan_mode — This usage is for signals used to control the scan chain configurations within a module. All scan_mode signals are mutually exclusive and only one of them per instance can be set to 1.

- **-scan_mode_type {unwrapped | internal | external | retargeting}**

An optional switch and literal pair that specifies the type of the scan_mode signal. You must ensure you set the proper -scan_mode_type value when registering a DFT signal of usage scan_mode. See the description of the [set_static_dft_signal_values](#) command to understand how the scan_mode_type affects the implied value of the int_ltest_en and ext_ltest_en signals.

When the -scan_mode_type switch is not specified, the default is unwrapped.

Choose one from the following:

unwrapped — Used for scan_mode signal enabling scan configuration having no wrapper isolation. When a scan_mode signal having the type unwrapped is set to 1 using the [set_static_dft_signal_values](#) command, the int_ltest_en and ext_ltest_en signal that may exist in the same instance are automatically set to 0.

internal — Used for scan_mode signal enabling scan configuration using the inward isolation of the wrapper chains. When a scan_mode signal having the type internal is set to 1 using the [set_static_dft_signal_values](#) command, the int_ltest_en and ext_ltest_en signal that typically exist in the same instance are automatically set to 1 and 0, respectively.

external — Used for scan_mode signal enabling scan configuration using the outward isolation of the wrapper chains. When a scan_mode signal having the type external is set to 1 using the [set_static_dft_signal_values](#) command, the int_ltest_en and ext_ltest_en signal that typically exist in the same instance are automatically set to 0 and 1, respectively.

retargeting — Used for scan_mode signal enabling of channel access to combinations of lower-level blocks. The lower-level blocks typically have one of their internal scan_mode signals activated.

- **-default_value_in_all_test {reset_value | 0 | 1}**

An optional switch and literal pair that specifies the default value the signals with usage global_dft_control should have in all tests. The default value of reset_value means that the value specified for the -reset_value switch is also used as the default value in all tests.

- **-reset_value {0 | 1}**

An optional switch and literal pair that specifies the reset value for the corresponding global_dft_control signal. This value corresponds to the value you want this signal to have in functional mode. It is illegal to specify -reset_value 1 when the -usage switch is not global_dft_control. If you want to register a DFT signal with a reset value of 1, then you must register the signal as global_dft_control.

- **-value_in_pre_scan_drc {x | 0 | 1}**

An optional switch and literal pair that specifies the value the logic_test_signal should be set to when running the Pre-DFT DRC rules. This value, with the Xs converted to 0s, also serves as the default value the given logic test control is set to when using the [set_static_dft_signal_values](#) command. See the [set_static_dft_signal_values](#) section for a description of where this value is used.

Examples

Example 1

The following example registers a new global DFT control signal to control the select of a clock multiplexer. By default, the select is driven high in all DFT test modes but the select can be set to 0 using the DftControlSettings wrapper in the [Patterns](#) wrapper or using the [set_static_dft_signal_values](#) command to configure the test_setup of a logic test mode.

```
register_static_dft_signal_name clockb_select -reset_value 0 -default_value_in_all_test 1
add_dft_control_points clock_mux/s -dft_signal_source_name clockb_select
```

Example 2

The following example illustrates how you can create a plugin to augment the *.tcd_scan* syntax with a new logic_test_control DFT signal. The DFT signal will automatically be registered. If included inside a *.tcd_scan* file, the DFT signal will automatically be understood during sub-chain tracing in context dft -scan (see [set_context](#)). Also, if the port is seen to be tied off on the instance, the scan insertion tool will automatically attach the port to the source of the DFT signal as returned by the [get_dft_signal](#) command.

Below is the content of file *path/my_plugin/metadata/tcd_scan.tessent_meta*. As you can see, it defines a new logic_test_control called my_sig1. The tracing_condition property defines the value that must be forced on the signal when tracing the sub-chain. This value becomes the “value_in_pre_scan_drc” value of the registered DFT signal. You must use a different usr[#]

index for each signal you registered. In the following example, you can only modify the items in bold. The rest of the entries must appear exactly as shown.

```
Partitions: default,tcd;

Wrapper (/Core/Scan) {
    Wrapper (MySig1) {
        Options(PreDftDrcs) {
            dft_control_type : scan_control;
            dft_scan_signal : usr[0]:0;
            dft_scan_function : my_sig1; //Any name
            tracing_condition : active; //active or inactive
            reset_state : inactive;//active or inactive
        }
        Id(port_name*) {
            type : string;
        }
        // use active_polarity_default_all_zeros when the default
        // active polarity of the signal is 0.
        reference =
    /tcd_scan/active_polarity_default_all_ones/active_polarity;
    }
}
```

To have the metadata automatically loaded by the tool when you invoke Tesson Shell, set the TESSENT_PLUGIN_PATH environment variable to *path/my_plugin*. For more information about using plugins, refer to “[Adding Custom Plugin Functionality](#)” on page 3921.

register_tcl_command

Context: unspecified, all contexts

Mode: all modes

Registers a Tcl command and makes it available in the global name space.

Usage

```
register_tcl_command command_name
  {-syntax_bnf syntax_bnf}
  {-tcl_proc tcl_proc}
  {-context_list context_list}
  {-system_mode_list system_mode_list}
  [-resource_list resource_list]
  [-extra_help extra_help]
  [-integer_list_option integer_list_option]
  [-string_list_option string_list_option]
  [-real_list_option real_list_option]
  [-integer_list_value integer_list_value]
  [-string_list_value string_list_value]
  [-real_list_value real_list_value]
  [-boolean_option boolean_option]
  [-integer_option integer_option]
  [-string_option string_option]
  [-real_option real_option]
  [-integer_value integer_value]
  [-string_value string_value]
  [-real_value real_value]
  [-transcript_style {tool_command | normal}]
```

Description

Registers a Tcl command and makes it available in the global name space.

The registered command appears as a normal tool command with proper option parsing and online help messages. The body of the registered command is implemented in a Tcl proc referenced by the -tcl_proc option. After the options are validated, they are packaged into a Tcl list of option-value pairs that are packed into a Tcl array for easy random access as shown in [Example 1](#).

You control the availability of the newly registered command using the -context_list and -system_mode_list options.

Note

 Commands in Tesson Shell are not case-sensitive. Therefore, if you register a Tcl command that contains upper-case letters, the tool will not preserve the case of that command, and they will be displayed as lower case in the online help.

When registering a Tcl command with embedded commands, you use a double hyphen (--) to specify the end of the command options passed to the embedded command. Passing an argument value to the registered Tcl command that starts with a hyphen (-) can result in an error when the value is ultimately used as an argument to an embedded command in the proc that is registered.

The following Tesson Shell transcript shows the behavior of the [is_collection](#) command in various situations that require the usage of double hyphens:

```
SETUP> set v -a
-a
# Here, 'is_collection' wrongly tries to interpret '-a' as one of its
# arguments
SETUP> is_collection $v
// Error: Unrecognized argument '-a'. ( help is_collection )

# With the double hyphen, the value is recognized as NOT being a
# collection.
SETUP> is_collection -- $v
0
# Other arguments recognized by the command can be passed BEFORE the
# double hyphen
SETUP> is_collection -single_type_object -- $v
0
SETUP>
```

The above usage of the double hyphen (--) is demonstrated in the [Example 1](#).

Arguments

- ***command_name***

A required string that specifies the name of the command to register. Because the command will exist in the global name space, its name must be unique so that it does not collide with other already registered commands. You can unregister any registered Tcl command using [unregister_tcl_command](#) until you execute the [lock_current_registration](#) command. After you issue [lock_current_registration](#), all registered commands and attributes are locked and can no longer be modified.

All commands loaded with an automated plugin mechanism are locked before the interactive shell is released to the user. “[Example 2](#)” on page 1367 explains how to initially debug your commands interactively when it is still possible to unregister them, and then shows you how to package them into a plugin directory which is automatically loaded at tool invocation. For more information about plugins, see the [lock_current_registration](#) command.

- **-syntax_bnf syntax_bnf**

A required switch and string value pair that specifies the grammar rules of your command using simple Backus-Naur Form (BNF). You should place the syntax_bnf string in braces to avoid needing to escape square brackets which are used to express that an option or value is optional. You should use parentheses to group options that are exclusive to others. You can use the | symbol to denote exclusivity of options. BNF uses the symbols you defined when declaring the *option and *value arguments; the symbols must always be enclosed in <> characters.

The following example defines five arguments; the first two are required and the last three are optional. The fifth argument is mutually exclusive of the third and fourth arguments. An argument is repeatable if its tag is declared with an * as its last character.

```
{ <arg1> <arg2> ([arg3] [arg4]) | [arg5] }
```

- **-tcl_proc tcl_proc**

A required switch and string pair that specifies the name, including its namespace, of the Tcl proc this command will call. To facilitate packaging the new command as a plugin that is automatically loaded into local namespaces, you should specify tcl_proc using the following format: [namespace current]::proc_name. This format ensures that the registered Tcl command always knows where to look for the Tcl proc regardless of which namespace the command is evaluated in.

For easy interactive debugging that can be easily deployed as a plugin, you should package both your Tcl proc and the register_tcl_command into a single file and surround it with a namespace eval name_space {} wrapper. Do not put :: in front of the specified name_space string so that this namespace string will be automatically appended to the one automatically created for all plugins. See the examples for more information on how to do this.

- **-context_list context_list**

A required switch and string pair that specifies a Tcl list of contexts the command is enabled in. Each element of the Tcl list is a context with an optional sub-context option, as shown here:

```
-context_list {{dft} {patterns -ijtag}}
```

The available literals are: all, dft, patterns. The available sub-contexts are listed under “[Contexts](#)” in the *Tessent Shell User’s Manual*.

- **-system_mode_list system_mode_list**

A required switch and string pair that specifies a Tcl list of system modes in which you want to enable the command. The available literals are: all, setup, analysis, and insertion.

- **-resource_list resource_list**

An optional switch and string pair that specifies the list of resources required for the command to be available; if any of the specified resources is not available, the command is

not available. The resource_list argument is a Tcl list of strings that identify the resources required. Possible values are:

`design_is_elaborated` — Used to check that the hierarchical data model has been created using the `set_current_design` command.

`design_modules_exist` — Used to check that at least one Verilog or VHDL module exists in memory and can be accessed using the `get_modules` command.

`flat_model_exists` — Used to check that the flat data model is available. The flat data model was created by either the `create_flat_model` command or by the “`set_system_mode analysis`” command.

`ic1_is_elaborated` — Used to check that the ICL hierarchical data model exists. It exists after the `set_current_design` command if an ICL module corresponding to the current design existed prior to issuing the command. It also exists in the analysis mode if the top-level ICL module was successfully extracted with ICL extract.

`ic1_modules_exist` — Used to check that at least one ICL module exists in memory and can be accessed using the `get_icl_modules` command.

`rtl_mode_enabled` — Used to check that the `-rtl` option switch was used when specifying the context and that read-in Verilog and VHDL files can contain RTL constructs.

- **-extra_help extra_help**

An optional switch and string pair that enables you to define a multi-line help paragraph that is displayed at the bottom of the online help. You can use `\n` to break your strings into multiple lines. The easiest way to create a multi-line help string is to construct it line by line as shown here:

```
set extra_help "This is line1\n"
append extra_help "and this is line 2\n"
append extra_help "and this the last line."
register_tcl_command -extra_help "$extra_help" ...
```

- **-integer_list_option integer_list_option**

An optional switch and string pair that defines an argument that is an option-value pair where the allowed value is a Tcl list of integers. The `integer_list_option_list` string is a Tcl list with three required elements and five optional elements as shown here:

```
{ {<symbol>} {-option_name} {tag} [{description_string}] [{range}]
[ {enum_list} ] [{<help_symbol>}] [{<visibility>}]}]
```

`<symbol>` — The first element of the list is required. It defines a unique symbol for the argument that you use in the `-syntax_bnf` `syntax_bnf` string to refer to it and it also displays in the online help description. The symbol string must always begin with a `<` character and end with a `>` character.

`-option_name` — The second element of the list is required. It defines a unique option name. The option name must start with a `-` character. The online help displays this option as shown here: “`-option_name <symbol>`”.

`tag` — The third element of the list is required. It defines a unique tag that is used to identify the argument value when invoking the associated Tcl proc. You can use an `*`

character as the last character of the tag string to denote that it is repeatable. If the argument is not repeatable (specifically tag does not end with an *), the Tcl list passed to the Tcl proc will include the tag string followed by the value specified for it. If the argument is repeatable, the tag will be appended with “,#” where # is an integer incremented from 0 to uniquely identify each instance of the argument. For example, if the tag is specified as range* and the argument is specified three times, the Tcl list passed to the Tcl proc will include those six elements as shown here:

```
{ {range,0}{value1}{range,1}{value2}{range,2}{value3} }
```

description_string — The forth element is optional. It can be used to define a one-line description for the argument that displays in the online help. If you need to specify the range or enum_list element but do not want to specify a description string, specify this fourth element as empty by using an empty brace pair.

range — The fifth element is optional. It consists of one or two integers specifying the minimum and maximum value for the argument. When the range is not specified or is specified as empty, the smallest allowed value is a MIN_INT. When the second integer is not specified, the largest allowed value is MAX_INT. If you need to specify the enum_list element but do not want to limit the range, specify this fifth element as empty using an empty brace pair.

enum_list — The sixth element is optional. It allows you to specify strings as allowed values. For example, you may want to define an option that allows a positive integer or the literal “last”. This is achieved by using a minimum value of 0 and an enum string called “last”.

<help_symbol> — The seventh element is optional. It allows you to specify a different symbol for the option to display in the help message. By default the <symbol> specified as the first element of the list is used in the help message. However, the <symbol> must be unique across all options as it is referenced in the syntax_bnf string. For example, the help message of the get_instances command shows “[-parent_of_instances <instance_objects> | -below_instances <instance_objects>]”. The symbol for each option has to be different such as <inst_for_parent_of> and <inst_for_below> but the display symbol in the help message can be made to be <instance_objects> for both by specifying the eighth element.

visibility — The eighth element is optional. It allows you to specify if you want the option to be hidden from the help message. You use a null string if you want the option to show up in the help message and you use the string “hidden” if you want the option to be hidden.

- **-string_list_option** *string_list_option*

An optional switch and string pair that defines an argument that is an option-value pair where the allowed value is a Tcl list of strings. The string_list_option is a Tcl list with three mandatory elements and four optional elements as shown here:

```
{ {<symbol>} {-option_name} {tag} [{description_string}]  
[ {enum_list} ] [ {<help_symbol>} ] [ {<visibility>} ] }
```

<symbol> — The first element of the list is required. It defines a unique symbol for the argument that you use in the -syntax_bnf syntax_bnf string to refer to it and it also

displays in the online help description. The symbol string must always begin with a < character and end with a > character.

-option_name — The second element of the list is required. It defines a unique option name. The option name must start with a - character. The online help displays this option as shown here: “-option_name <symbol>”.

tag — The third element of the list is required. It defines a unique tag that is used to identify the argument value when invoking the associated Tcl proc. You can use an * character as the last character of the tag string to denote that it is repeatable. If the argument is not repeatable (specifically tag does not end with an *), the Tcl list passed to the Tcl proc will include the tag string followed by the value specified for it. If the argument is repeatable, the tag will be appended with “,#” where # is an integer incremented from 0 to uniquely identify each instance of the argument. For example, if the tag is specified as range* and the argument is specified three times, the Tcl list passed to the Tcl proc will include those six elements as shown here:

```
{ {name, 0} {value1} {name, 1} {value2} {name, 2} {value3} }
```

description_string — The forth element is optional. It can be used to define a one-line description for the argument that displays in the online help. If you need to specify the range or enum_list element but do not want to specify a description string, specify this fourth element as empty by using an empty brace pair.

enum_list — The fifth element is optional. It allows you to specify strings as allowed values. When omitted or specified as an null string, the string_list_option allows any string values.

<help_symbol> — The sixth element is optional. It allows you to specify a different symbol for the option to display in the help message. By default the <symbol> specified as the first element of the list is used in the help message. However, the <symbol> must be unique across all options as it is referenced in the syntax_bnf string. For example, the help message of the get_instances command shows “[parent_of_instances <instance_objects> | -below_instances <instance_objects>]”. The symbol for each option has to be different such as <inst_for_parent_of> and <inst_for_below> but the display symbol in the help message can be made to be <instance_objects> for both by specifying the eight element.

visibility — The seventh element is optional. It allows you to specify if you want the option to be hidden from the help message. You use a null string if you want the option to show up in the help message and you use the string “hidden” if you want the option to be hidden.

- -real_list_option *real_list_option*

An optional switch and string pair that defines an argument that is an option-value pair where the allowed value is a Tcl list of real numbers. The real_list_option is a Tcl list with three required elements and five optional elements as shown here:

```
{ {<symbol>} {-option_name} {tag} [{description_string}] [{range}]  
[{enum_list}] [{<help_symbol>}] [{<visibility>}]}
```

<symbol> — The first element of the list is required. It defines a unique symbol for the argument that you use in the -syntax_bnf syntax_bnf string to refer to it and it also

displays in the online help description. The symbol string must always begin with a < character and end with a > character.

-option_name — The second element of the list is required. It defines a unique option name. The option name must start with a - character. The online help displays this option as shown here: “-option_name <symbol>”.

tag — The third element of the list is required. It defines a unique tag that is used to identify the argument value when invoking the associated Tcl proc. You can use an * character as the last character of the tag string to denote that it is repeatable. If the argument is not repeatable (specifically tag does not end with an *), the Tcl list passed to the Tcl proc will include the tag string followed by the value specified for it. If the argument is repeatable, the tag will be appended with “,#” where # is an integer incremented from 0 to uniquely identify each instance of the argument. For example, if the tag is specified as range* and the argument is specified three times, the Tcl list passed to the Tcl proc will include those six elements as shown here:

```
{ {range,0}{value1}{range,1}{value2}{range,2}{value3} }
```

description_string — The forth element is optional. It can be used to define a one-line description for the argument that displays in the online help. If you need to specify the range or enum_list element but do not want to specify a description string, specify this fourth element as empty by using an empty brace pair.

range — The fifth element is optional. It consists of one or two integers specifying the minimum and maximum value for the argument. When the range is not specified or is specified as empty, the smallest allowed value is a MIN_DOUBLE. When the second integer is not specified, the largest allowed value is MAX_DOUBLE. If you need to specify the enum_list element but do not want to limit the range, specify this fifth element as empty using an empty brace pair.

enum_list — The sixth element is optional. It allows you to specify strings as allowed values. For example, you may want to define an option that allows a positive integer or the literal “last”. This is achieved by using a minimum value of 0 and an enum string called “last”.

<help_symbol> — The seventh element is optional. It allows you to specify a different symbol for the option to display in the help message. By default the <symbol> specified as the first element of the list is used in the help message. However, the <symbol> must be unique across all options as it is referenced in the syntax_bnf string. For example, the help message of the get_instances command shows “[<parent_of_instances> | <instance_objects> | <below_instances> | <instance_objects>]”. The symbol for each option has to be different such as <inst_for_parent_of> and <inst_for_below> but the display symbol in the help message can be made to be <instance_objects> for both by specifying the eighth element.

visibility — The eighth element is optional. It allows you to specify if you want the option to be hidden from the help message. You use a null string if you want the option to show up in the help message and you use the string “hidden” if you want the option to be hidden.

- **-boolean_option boolean_option**

An optional switch and string pair that defines an argument that is an option without a value. The boolean_option string is a Tcl list with three required elements and two optional elements as shown here:

```
{ {<symbol>} {-option_name} {tag} [{description_string}]  
[ {<visibility>} ] }
```

<symbol> — The first element of the list is required and defines a unique symbol for the argument. You use this element in the -syntax_bnf syntax_bnf string to refer to it. The symbol string must always begin with a < character and end with a > character.

-option_name — The second element of the list is required and defines a unique option name. The option name must start with a - character. The online help displays this option as shown here: “-option_name”.

tag — The third element of the list is required and defines a unique tag that is used to identify the argument value when invoking the associated Tcl proc.

description_string — The forth element is optional and can be used to define a one-line description for the argument that displays in the online help.

visibility — The fifth element is optional and can be used to specify whether the option is included in the help message. You specify a null string “” if you want the option to show up in the help message and you specify the string “hidden” if you want the option to be hidden.

- **-integer_list_value integer_list_value**

An optional switch and string pair that is identical to the -integer_list_option switch and string pair except that it defines a value as opposed to an option-value pair.

The integer_list_value string is a Tcl list with two required elements and five optional elements. This string has exactly the same definition as the integer_list_option string except that the second element does not exist because there is no option name to define. The tag is not allowed to end with an * character because only options can be defined as repeatable.

```
{ {<symbol>} {tag} [{description_string}] [{range}] [{enum_list}] [{<help_symbol>}]  
[ {<visibility>} ] }
```

- **-string_list_value string_list_value**

An optional switch and string pair that is identical to the -string_list_option switch and string pair except that it defines a value as opposed to an option-value pair.

The string_list_value string is a Tcl list with two required elements and four optional elements. This string has exactly the same meaning as the string_list_option string except that the second element does not exist because there is no option name to define. The tag is not allowed to end with an * character as only options can be defined as repeatable.

```
{ {<symbol>} {tag} [{description_string}] [{enum_list}] [{<help_symbol>}]  
[ {<visibility>} ] }
```

- **-real_list_value *real_list_value***

An optional switch and string pair that is identical to the -real_list_option switch and string pair except that it defines a value as opposed to an option-value pair.

The *real_list_value* string is a Tcl list with two required elements and five optional elements. This string has exactly the same meaning as the *real_list_option* string except that the second element does not exist because there is no option name to define. The tag is not allowed to end with a * as only options can be defined as repeatable.

```
{ {<symbol>} {tag} [{description_string}] [{range}] [{enum_list}] [{<help_symbol>}]  
[ {<visibility>} ] }
```

- **-integer_option *integer_option***

An optional switch and string pair that is identical to the -integer_list_option switch and string pair except that only a single integer is allowed as the value as opposed to a Tcl list of integers.

- **-string_option *string_option***

An optional switch and string pair that is identical to the -string_list_option switch and string pair except that only a single string is allowed as the value as opposed to a Tcl list of strings.

- **-real_option *real_option***

An optional switch and string pair that is identical to the -real_list_option switch and string pair except that only a single real is allowed as the value as opposed to a Tcl list of real numbers.

- **-integer_value *integer_value***

An optional switch and string pair that is identical to the -integer_list_value switch and string pair except that only a single integer is allowed as the value as opposed to a Tcl list of integers.

- **-string_value *string_value***

An optional switch and string pair that is identical to the -string_list_value switch and string pair except that only a single string is allowed as the value as opposed to a Tcl list of strings.

- **-real_value *real_value***

An optional switch and string pair that is identical to the -real_list_value switch and string pair except that only a single real number is allowed as the value as opposed to a Tcl list of real numbers.

- **-transcript_style {tool_command | normal}**

An optional switch and literal that specifies whether the command transcripts like a normal command or like a tool command. The default is *tool_command*.

tool_command —Transcripts tool commands, including all arguments, as the commands execute. The command string is transcribed after being evaluated by Tcl so all

variable and command references are resolved. For more information on how a tool command transcripts, see the “[set_transcript_style full](#)” command and option.
normal — Transcripts the command before any Tcl evaluation is done. This includes all Tcl commands and constructs. For more information on how a tool command transcripts, see the “[set_transcript_style tool_commands_only](#)” command and option.

Examples

Example 1

The following example defines a simple proc called “example” that displays the arguments it receives. The register_tcl_command defines a command called “example” that accepts a repeatable integer list option, a non-repeatable string list option, and a string value. Notice that the registered command will be located in the global namespace and the Tcl proc that it calls is located in the ::ExampleCommands namespace so that the two identical proc names do not collide.

```
namespace eval ExampleCommands {
    proc example {args} {
        # Initialize default values
        array set all_args {object ""}
        # convert args list into an array for easy random access
        array set all_args $args
        puts "chain = $all_args(chain)"
        # Without '--', 'is_collection' would fail if 'all_args(object)'
        # is a string that starts with a '-' since it would try to interpret
        # this value as an option to the command.
        if { [is_collection -single_type_objects -- $all_args(object)] && \
            [sizeof_collection $all_args(object)] > 0 } {
            puts "Object name(s) { [lget_name_list -silent $all_args(object)] }"
            puts -none newline " of type "
            set obj [index_collection $all_args(object) 0]
            puts "'[get_attribute_value_list -name object_type $obj -silent]'"
        } elseif { [is_collection -- $all_args(object)] && \
            [sizeof_collection $all_args(object)] > 0 } {
            foreach_in_collection obj $all_args(object) {
                puts -none newline "Object name '[get_single_name $obj -silent]' \
                    of type "
                puts "'[get_attribute_value_list -name object_type $obj -silent]'"
            }
        } else {
            puts "Object name(s) verbatim '$all_args(object)'"
        }
        # Range is repeatable, so its tags are indexed
        for {set i 0} {1} {incr i} {
            if {[info exists all_args(range,$i)]} {
                puts "range $i = $all_args(range,$i)"
            } else {
                break
            }
        }
    }
}
```

```
register_tcl_command example \
-string_value {{<chain_name>} {chain}} \
-string_list_option { {<object>} {-object} {object} } \
-integer_list_option { {<range>} {-range} {range*} } \
-syntax_bnf {<chain_name> [<object>] [<range>]} \
-context_list {dft patterns} \
-system_mode_list {setup insertion} \
-tcl_proc "[namespace current]::example"
}
```

Here is a transcript of a Tessent Shell session that uses that register command, assuming that the above content has been sourced beforehand:

```
SETUP> set_context dft -rtl
# show the help
SETUP> example
// Error: Missing options ( <chain_name> [ -object <object> ]

```

INSERTION>

Example 2

The following example defines a wrapper Tcl proc that is used to call the intercept_with_cell procedure described in [Example 5](#) of the get_dft_cell command. The code is surrounded in a namespace eval block which puts the intercept_with_cell_wrapper proc in that name space and avoids polluting the global namespace with the Tcl procs when sourcing it. The [namespace current] command, used with the register_tcl_command -tcl_proc option, ensures the tool knows to search in the correct name space. It also ensures that the registered Tcl command in the global namespace does not collide with the Tcl proc of the same name.

After you verify that your registered commands and/or attributes work correctly, you can make them into a *plugin* directory that Tessent Shell automatically loads during initialization. To create the plugin directory, simply place your files in a directory called <plugin>/tcl_modules/<MySpace> where <plugin> and <MySpace> are arbitrary directory names. Set a TESSENT_PLUGIN_PATH environment variable to point to the <plugin> directory and any files with a .tcl extension found inside <plugin>/tcl_modules/<MySpace> will be evaluated into the Tcl namespace ::tcl_modules::<MySpace>. Just like the PATH environment variable, you can specify more than one search location by separating multiple directory names with a colon. A utility command initialize_module is used to load all files ending with .tcl found inside a local directory having the exact same name as the name space.

In the example below, the namespace is called InterceptWithCell which means that initialize_module will source all files matching *./InterceptWithCell/*.tcl*. The advantage of using the initialize_command is that the Tcl proc is only loaded the first time it is needed.

If you name your <plugin> directory name “tessent_plugin” and place it one level above the bin directory of Tessent Shell, the directory will be automatically loaded unless the environment variable TESSENT_PLUGIN_IGNORE_DEFAULT_PATH is defined. Once the plugins are loaded, the [lock_current_registration](#) command is issued so that they cannot be unregistered accidentally.

```
namespace eval InterceptWithCell {  
    proc intercept_with_cell_wrapper {args} {  
        initialize_module  
        intercept_with_cell_body {*}$args  
    }  
    set extra_help "Command accepts a pin, port, or net object as first"  
    append extra_help "argument. It is intercepted with cell returned by \n"  
    append extra_help "get_dft_cell <cell_function_name>."  
  
    set cell_list "One of mux, clock_mux, and, clock_and, clock_or,"  
    append cell_list "buffer, clock_buffer, or inverter."  
  
    set bnf {<node> <function_name> [<input2_source>] [<select_source>] }  
    append bnf {[<level>] [<reset_intercept_list>]}  
}
```

```
register_tcl_command intercept_with_cell \
    -context_list {dft} \
    -system_mode_list {insertion} \
    -resource_list {design_is_elaborated} \
    -extra_help $extra_help \
    -string_value {"<node>" {node} {} } \
    -string_option [list "<function_name>" "-cell_function_name" \
        {cell_sel} $cell_list {mux clock_mux and clock_and or \
        clock_or buffer clock_buffer inverter}] \
    -string_option {"<input2_source>" "-input2" {input2} {} } \
    -string_option {"<select_source>" "-select" {select} {} } \
    -integer_option {"<level>" "-cascading_level" {level} {} {1 9}} \
    -boolean_option {"<reset_intercept_list>" "-reset_intercept_list" \
        {clear}} \
    -syntax_bnf "$bnf" \
    -transcript tool_command \
    -tcl_proc "[namespace current]::intercept_with_cell_wrapper"
}
```

The online help for the registered command is shown here:

```
INSERTION> help intercept_with_cell
intercept_with_cell <node> -cell_function_name <function_name>
    [-input2 <input2_source>] [-select <select_source>]
    [-cascading_level <level>] [-reset_intercept_list]
```

DESCRIPTION

-cell_function_name: One of mux, clock_mux, and, clock_and, or,
clock_or, buffer, clock_buffer

Command accepts a pin, port, or net object as first argument. It is
intercepted with cell returned by get_dft_cell <cell_function_name>.

[unregister_tcl_command](#)

[remove_from_collection](#)

Context: unspecified, all contexts

Mode: all modes

Removes objects found in obj_spec from a collection, resulting in a new collection.

Usage

`remove_from_collection base_collection obj_spec`

Description

Removes objects found in obj_spec from a collection, resulting in a new collection.

The base_collection remains unchanged.

If obj_spec is a null collection, the resulting collection is a copy of the base collection. If everything in base_collection is included in obj_spec, the result is an empty collection.

Arguments

- ***base_collection***

A required value that specifies the base collection from which objects within obj_spec are to be removed.

- ***obj_spec***

A required value that specifies a Tcl list of one or more object names, or a collection of one or more objects.

Examples

The following example creates a collection of all input and inout ports minus the port called CLK.

```
set data_in [remove_from_collection [get_ports -direction input inout] CLK]
{"in1", "in2"}
```

rename_instance

Context: all contexts

Mode: insertion

Renames the leaf name of an instance.

Usage

```
rename_instance obj_spec -new_leaf_name leaf_inst_name [-silent]
```

Description

Renames the leaf name of an instance.

This command returns a collection containing the renamed instance.

If the instance within *obj_spec* does not exist or if an object already exists with the same *leaf_inst_name* within the *parent_instance*, the tool generates an error. You can use the *-silent* switch to specify to not generate an error message and ignore the renaming request in which case the command returns a null collection.

Arguments

- *obj_spec*

A required value that specifies a single instance name or a collection of a single instance object as returned by the [get_instances](#) command.

- **-new_leaf_name *leaf_inst_name***

A required switch and value pair that specifies the new leaf name to assign to the instance object referenced in *obj_spec*.

- *-silent*

An optional argument that specifies to ignore any of the two following error conditions: the instance within *obj_spec* does not exist or if an object already exists with the same *leaf_inst_name* within the *parent_instance*.

Examples

Example 1

The following example renames the leaf name and3 to my_and3.

```
rename_instance /modB/and3 -new_leaf_name my_and3
```

Example 2

The following example identifies all instances having the user-defined attribute *is_my_type* set to true and adds a special prefix called “myPrefix_” to their leaf instance name such that it will be easier to find them in the downstream steps of the flow using the SDC command “*get_cells myPrefix_* -hierarchical*”.

```
foreach_in_collection inst [ get_instance -filter "is_my_type"] {  
    set leaf_name [get_attribute_value_list $inst -name leaf_name]  
    rename_instance $inst -new_leaf_name myPrefix_${leaf_name}  
}
```

rename_net

Context: dft

Mode: insertion

Renames the leaf name of a net.

Usage

```
rename_net obj_spec -new_leaf_name leaf_net_name [-silent]
```

Description

Renames the leaf name of a net.

If a net already exists with the same *leaf_net_name*, the tool chooses an unused net name by adding the net unqualification suffix.

Arguments

- ***obj_spec***
A required value that specifies a single net name or a collection of a single net objects as returned by the [get_nets](#) command.
- **-new_leaf_name *leaf_net_name***
A required switch and value pair that specifies the new leaf name to assign to the net object referenced in *obj_spec*.
- **-silent**
An optional argument that specifies to ignore the following error condition: the net within *obj_spec* does not exist.

Examples

Example 1

The following example demonstrates the use of this command:

```
INSERTION> get_nets
{joe[1] joe[0]}

INSERTION> rename_net [get_nets joe] -new_leaf_name jack
{jack[1] jack[0]}

INSERTION> get_nets
{jack[1] jack[0]}
```

Example 2

The following example illustrates the uniquification suffix if a net already exists with the same *leaf_net_name*:

```
INSERTION> get_nets
{w1 w2}

INSERTION> rename_net [get_net w1] -new_leaf_name w2
{w2_ts1}
```

replace_instances

Context: dft

Mode: insertion

Replaces the module definition of an instance with a new module definition.

Usage

```
replace_instances obj_spec1 -with_module obj_spec2 [-silent]
```

Description

Replaces the module definition of an instance with a new module definition. The module definition assigned to the instance during instantiation is replaced with the module specified by the module within *obj_spec2*. If the new module has new ports that have the [function](#) attribute set to “tie0” or “tie1”, then these are automatically tied on the new instance pins.

Connections to pins that exist on both the original and new module remain unchanged. New pins that did not exist on the original module are left open after the replacement. Pins that existed on the original module but do not exist on the new module are silently disconnected.

This command returns a collection containing the new instance.

If *obj_spec1* does not exist, the tool generates an error. You can use the -silent switch to specify to not generate an error message when the object within *obj_spec1* does not exist. If *obj_spec2* is the same module as the original module, no change is made.

Arguments

- ***obj_spec1***

A required value that is Tcl list of one or more instance names, or a collection of one or more instances as generated by the [get_instances](#) command.

- **-with_module *obj_spec2***

A required switch and value pair that specifies the new module object to assign to the instances within *obj_spec1*. The *obj_spec2* value must be a single module name or a collection of a single module object as created by the [s](#) command.

- **-silent**

An optional argument that specifies to ignore specified objects of *obj_spec1* or *obj_spec2* that do not exist and to not generate error messages.

Examples

Example 1

The following example replaces the module definition of the instance u1/u2 with the module named nor2.

```
replace_instances u1/u2 -with_module nor2
```

Example 2

The following example replaces the module definition for instance u1/u2 to ModB. The original connection to pin u1/u2/a is preserved while the new pin u1/u2/b is left open.

```
get_attribute_value_list u1/u2 -name module_name
```

```
{ModA}
```

```
get_fanin u1/u2/a -stop_on net
```

```
{u1/n45}
```

```
replace_instances u1/u2 -with_module ModB
```

```
{u1/u2}
```

```
get_fanin u1/u2/a -stop_on net
```

```
{u1/n45}
```

```
get_fanin u1/u2/b -stop_on net
```

```
{}
```

rename_module

Context: dft

Mode: insertion

Assigns a new name to an existing module.

Usage

```
rename_module object_spec -new_name module_name [-silent]
```

Description

Assigns a new name to an existing module. If the *object_spec* is a parameterized view of a module, then only the particular view is renamed.

When specified, all instances of *object_spec* in the hierarchy will be bound to the new module. The old module still exists and instances that are not in the current hierarchy are not bound to the new module, but are still bound to the old one.

Arguments

- ***object_spec***

A required string or collection that specifies the module.

The *object_spec* must match exactly one module/parameterized view otherwise an error is given.

- ***-new_name module_name***

A required switch and string that specifies the new module name for *object_spec*.

- ***-silent***

An optional argument that suppresses the error issued if the *object_spec* does not exist or if more than one module is specified.

Related Topics

[rename_instance](#)

report_aborted_faults

Context: dft -edt, patterns -scan

Mode: analysis

Displays information on some potentially testable faults that remain undetected (UD) after the ATPG process.

Usage

`report_aborted_faults [format_type] [>|>>] file_pathname]`

Description

Displays information on testable faults that remain undetected (UD) after the ATPG process.

The report_aborted_faults command can help you determine why the tool aborted faults in the undetected fault list. You can then analyze whether to change the current abort limit to possibly allow ATPG to generate tests for those faults before the tool aborts them. To change the abort limit, use the [set_abort_limit](#) command.

Arguments

- *format_type*

An optional literal that specifies the type of information that you want the tool to display regarding the aborted faults. The literal choices for the *format_type* argument are as follows:

SUMMARY — A literal that displays a summary of the number of aborted faults for each category. This is the default.

All — A literal that displays all the aborted faults that are currently in the undetected fault list.

Backtrack — A literal that displays all the aborted, undetected faults that exceeded the backtrack limit.

CLOCK_control — A literal that displays all the aborted, undetected faults that are due to clock control.

CONtention — A literal that displays all the aborted, undetected faults due to bus contention or ram write contention.

DECisions — A literal that displays all the aborted, undetected faults that exceeded the maximum number of decisions.

DETected — A literal that displays all the faults that the tool aborted and then later detected.

Edt — (**Available only when EDT is on**) A literal that displays EDT aborted faults.

When the tool generates an effective fault test but is unable to compress the pattern, the fault is classified as an EDT aborted fault. Each of the following increases the probability of EDT aborted faults:

- Relatively aggressive compression (large chain-to-channel ratio)

- Large number of ATPG constraints
- Relatively small design

IDdq_restriction — A literal that displays all the undetected faults that the tool aborted while trying to satisfy the IDDQ restrictions.

INterrupt — A literal that displays all the undetected faults that the tool aborted because you interrupted the ATPG process with a Control-C.

MULtiple_clock_restriction — A literal that displays all the aborted, undetected faults due to multiple clock restrictions.

Ram_sequential — A literal that displays all the undetected faults that the tool aborted because of inconsistencies between the ram_sequential patterns.

TRansition — A literal that displays all the undetected faults that the tool aborted because of inconsistencies between the initial and final transition pattern.

WRite_pass_thru — A literal that displays all the undetected faults that the tool aborted because of inconsistencies between write off and write on for RAM pass through patterns.

- >*file_pathname*

An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.

- >>*file_pathname*

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

Example 1

report_aborted_faults

The following example displays the default summary of all the aborted faults for the design.

report_aborted_faults

```
10 backtrack
1  clock_control
2  mult_clock_restriction
```

This is the same as the command report_aborted_faults summary.

Example 2

This example displays all the aborted faults that are currently in the undetected fault list.

report_aborted_faults all

```
1    UO.AAB    /I$1/I$954/I4
0    UO.AAB    /I$1/I$952/OUT
1    UO.AAB    /I$1/I$952/OUT
0    EQ        /I$1/I$952/I3
0    EQ        /I$1/I$952/I2
0    EQ        /I$1/I$952/I1
0    EQ        /I$1/I$952/I0
1    UO.AAB    /I$1/I$952/I3
1    UO.AAB    /I$1/I$952/I2
1    UO.AAB    /I$1/I$952/I1
1    UO.AAB    /I$1/I$952/I0
```

[report_faults](#)
[set_abort_limit](#)
[set_atpg_limits](#)

report_atpg_constraints

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Displays all the current ATPG state restrictions and the pins on which they reside.

Usage

```
report_atpg_constraints [[{> | >>} file_pathname] [-Display {FLAt_schematic}]]
```

Description

Displays all the current ATPG state restrictions and the pins on which they reside.

The report_atpg_constraints command displays the pins and their state restrictions defined using the add_atpg_constraints command. The tool uses the state restrictions (constraints) during the ATPG process.

Arguments

- *>file_pathname*
An optional redirection operator and pathname pair for creating *or* replacing the contents of *file_pathname*.
- *>>file_pathname*
An optional redirection operator and pathname pair for appending to the contents of *file_pathname*.
- *-Display FLAt_schematic*
An optional switch and literal that specify to display the specific ATPG state of the primary input(s) as callouts in the Flat Schematic window.

Examples

The following example creates two ATPG pin constraints and then displays the information on those definitions:

```
add_atpg_functions and_b_in and /i$144/q /i$141/q /i$142/q
add_atpg_constraints 0 /i$135/q
add_atpg_constraints 1 and_b_in
report_atpg_constraints

0 /I$135/Q (23)
1 and_b_in
```

Related Topics

[add_atpg_constraints](#)
[delete_atpg_constraints](#)

report_atpg_functions

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Displays all the current ATPG function definitions.

Usage

```
report_atpg_functions [<> | >>] file_pathname]
```

Description

Displays all the current ATPG function definitions.

The report_atpg_functions command displays the definitions of the ATPG functions created using the add_atpg_functions command. You can use an ATPG function as an argument to the add_atpg_constraints command, which then lets you create state restrictions on pins that the tool uses during the ATPG process.

Arguments

- *>file_pathname*
An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.
- *>>file_pathname*
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

The following example creates two ATPG functions and then displays their definitions:

```
add_atpg_functions and_b_in and /i$143/q /i$141/q /i$142/q
add_atpg_functions select_b_in select /i$144/q /i$142/q
report_atpg_functions

USER_AND and_b_in
  Input 0: /I$143/Q (27)
  Input 1: /I$141/Q (23)
  Input 2: /I$142/Q (25)
SELECT select_b_in
  Input 0: /I$144/Q (29)
  Input 1: /I$142/Q (25)
```

report_atpg_timing

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Reports the current ATPG timing setup.

Usage

```
report_atpg_timing [<> | >>} file_pathname]
```

Description

Reports the current ATPG timing setup. For complete information, see “[Timing-Aware ATPG](#)” in the *Tessent Scan and ATPG User’s Manual*.

The report uses the following format:

```
// ATPG timing = { ON | OFF }
// Timing source = { no timing |
//                   SDF minimum delay |
//                   SDF typical delay |
//                   SDF maximum delay }
// Hold PIs = { ON | OFF }
// Mask POs = { ON | OFF }
// Exclude inter-clock paths = { ON | OFF }
// Timing scale = { N/A | 1 ms | 1 us |
//                   1 ns | 1 ps }
// Slack margin for fault dropping = { OFF | slack_margin |
//                                         slack_margin_percentage% }
// Delay fault distribution function = { UNIFORM | HISTOGRAM
//                                         | EXPONENTIAL | INV_POLY }
// [ f(t)=function(t), (begin time = min and end time = max) ]
// Longest delay (rising, falling) = { max_rising, max_falling }
// Clock waveform = { UNDEFINED | USER_DEFINED }
//
// Clock Name           Test Clock           System Clock
//                     {Period, Offset, Width} {Period, Offset, Width}
// -----
// clock_name          num1,num2,num3        num1,num2,num3
...

```

- **ATPG timing** — The status of timing-aware ATPG.
- **Timing source** — The source of the timing information.
- **Hold PIs** — The state of holding PIs when doing static timing analysis for arrival time, propagation time, path delay, and slack.
- **Mask POs** — The state of masking POs when doing static timing analysis for arrival time, propagation time, path delay, and slack.
- **Exclude inter-clock paths** — The state of excluding inter-clock paths when doing static timing analysis for arrival time, propagation time, path delay, and slack.

- **Timing scale** — The time units used. The timing scale is set by the SDF file and defaults to 1 ns.
- **Slack margin for fault dropping** — The margin specified using the set_atpg_timing command.
- **Longest delay** — From static timing analysis.
- **Clock waveform** — The clock information specified by the set_atpg_timing command and reports the following:
 - **Clock Name**
 - **Test Clock** — The ATE testing clock frequency, which may not be the same as the normal operation frequency (System Clock). Timing-aware ATPG uses the test clock frequency.
 - **System Clock** — Normal operating frequency.

Arguments

- *>file_pathname*
An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.
- *>>file_pathname*
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

The following example shows the timing-aware ATPG settings.

```
read_sdf top_worst.sdf
set_atpg_timing -clock test_clk_dd 16000 8000 8000
set_atpg_timing -clock test_clk_cc 8000 4000 4000
set_atpg_timing -clock test_clk_aa 4000 2000 2000
set_atpg_timing -clock default 36000 18000 18000
set_atpg_timing on
report_atpg_timing
```

```
// ATPG timing = ON
// Timing source = SDF typical delay
// Time scale = 1 ns
// Slack margin for fault dropping = OFF
// Delay fault distribution function = EXPONENTIAL
// f(t) = 0.00158*e^(-0.0021t) + 4.94e-06, (begin time=0, end time=50000)
// Longest delay (rising, falling) = (50547.0000, 50547.0000)
// Clock waveform = USER DEFINED
//
// Clock Name Test Clock System Clock
// {Period, Offset, Width} {Period, Offset, Width}
// -----
// /test_clk_dd (4) 16000, 8000, 8000 16000, 8000, 8000
// /test_clk_cc (3) 8000, 4000, 4000 8000, 4000, 4000
// /test_clk_aa (2) 4000, 2000, 2000 4000, 2000, 2000
// /clk_in (6) 36000, 18000, 18000 36000, 18000, 18000
```

Related Topics

[read_sdf](#)

[set_atpg_timing](#)

report_attributes

Context: unspecified, all contexts

Mode: all modes

Creates a human readable report for the set of attributes based on the usage options.

Usage

Usage 1: Creates a report of attributes defined on a list of objects

```
report_attributes obj_spec [-predefined | -user_defined] [-silent] [-verbose]
```

Usage 2: Creates a report of attributes defined for specific object types

```
report_attributes -object_types type_list [-predefined | -user_defined] [-silent] [-verbose]
```

Usage 3: Creates a report for a specific attribute name

```
report_attributes -name attribute_name [-silent] [-verbose]
```

Usage 4: Creates a report of all registered attributes

```
report_attributes [-predefined | -user_defined] [-silent] [-verbose]
```

Description

Creates a human readable report for the set of attributes based on the usage options. In all usages, specifying the -predefined option restricts the report to only predefined attributes and specifying the -user_defined option restricts the report to only user-defined attributes.

Usage 1: Creates a tabular report for the attributes set on any object found in *obj_spec*. The attributes on an object that are inherited from an associated object are reported. For example, an attribute registered for the module object type and set on a given module object is reported in the list of attributes for the instances of that module. By default, attributes which have not been set on the objects are not listed in the report unless the attribute was registered with the -show_default option. If an object in *obj_spec* does not exist, an error message is displayed unless the -silent switch is specified.

Usage 2: Creates a tabular report for all attributes registered on the specified object types. These do not include the inherited attributes from one object type to another such as the module attributed inherited by the associated instances.

Usage 3: Creates a tabular detailed report for a specific attribute.

Arguments

- *obj_spec*

A required value used in Usage 1 that specifies a Tcl list of one or more object names or a collection of one or more objects.

- **-object_types type_list**

A required value used in Usage 2 to enumerate the object types for which the attribute report is requested. The supported object types are module, port, instance, pin and net.

- **-name attribute_name**

An optional switch and string pair that specify the name of the attribute whose information is to be reported. This argument is mutually exclusive with the *obj_spec* and -object_types *type_list* arguments.

- **-predefined | -user_defined**

An optional switch that constrains the report to only pre-defined attribute names or only user-defined attribute names. If this argument is not specified, by default no constraints are applied and both pre-defined and user-defined attributes are reported.

- **-silent**

An optional switch that specifies to suppress error messages if there are objects in the *obj_spec* that do not exist.

- **-verbose**

An optional switch that specifies to report the full list of possible attribute values. By default, only one line is dedicated to reporting the attribute values; additional values are truncated and replaced with “...”.

Examples

Example 1

The following example reports the attribute definitions using the report_attributes command:

```
report_attributes
Attribute Definition Report

Attributes defined for all objects:

Name      Object     Type      Class      Default    Constraints
-----
name      all        string    Pre-defined   -
speed     pin        integer   User-defined  200       100 to 500
added_by net        string    User-defined  John      John Patrick Susan
```

The same result would be achieved by executing:

```
report_attributes -object_types all
```

Example 2

The following example reports the attribute definitions for the pin object type:

```
report_attributes -object_types pin
```

Attribute Definition Report

Attributes defined for 'pin' objects:

Name	Object	Type	Class	Default	Constraints
<hr/>					
name	all	string	Pre-defined	-	-
speed	pin	integer	User-defined	200	100 to 500

Example 3**Scenario 1**

The following example reports the attribute definitions only for a list of pin objects:

report_attributes {u7/CLK u6/A2}

Attribute Definition Report

Attributes defined for object 'u7/CLK':

Name	Value	Inheritance
<hr/>		
base_name	u7	-
direction	input	-
is_valid	true	-
leaf_name	CLK	-
module_name	dff	-
name	u7/CLK	-
object_type	pin	-
parent_instance	-	-
parent_is_hard_module	true	-

Attributes defined for object 'u6/A2':

Name	Value	Inheritance
<hr/>		
base_name	u6	-
direction	input	-
is_valid	true	-
leaf_name	A2	-
module_name	xor3	-
name	u6/A2	-
object_type	pin	-
parent_instance	-	-
parent_is_hard_module	true	-

Scenario 2

This example reports the attributes for all scan elements of the class wrapper.

report_attributes [get_scan_elements -class wrapper]

Command Dictionary (R)
report_attributes

```

Example 4

The following example reports the attribute definitions for the speed attribute:

report_attributes -name speed

Attribute Definition Report

Name: Speed
Description:

This attribute is used to hold the target frequency that the pin is allowed to have.
The allowed frequency range of 100 to 500 was chosen to match the technology spec.

Global Option Settings:

Setting	Value
Class	User-Defined
Type	int
Default	200
Show_Default	false
Minimum	100
Maximum	500
Object	pin

Specific 'pin' Type settings:

Name	Value
dense	false
export_to_netlist	off
save_in_flat_model	off
preserve_boundary_in_flat_model	off

Example 5

The following example reports the possible cell_type attribute values with the -verbose switch both enabled and disabled.

report_attribute -name cell_type

Attribute Definition Report

Name:

cell_type

Description:

This is a library model attribute

Setting	Value
Class	Pre-Defined
Value_Type	string
Enum	and buffer clock_and clock_buffer ...

GUI.Strings	cell_type = %

report_bisr_repair_register_icl_instances

Context: all contexts

Mode: all modes

Reports a list of BISR repair registers found in the design.

Usage

```
report_bisr_repair_register_icl_instances [-power_domain_group pdg_list]
```

Description

Reports the list of available memory BISR repair registers found in the design, providing the ICL instance name, design instance name and power domain group for each register. You can use the -power_domain_group argument to specify a listing of repair registers within specific power domain groups.

You must have already inserted the ICL modules with the [process_dft_specification](#) command and extracted the top-level ICL description with the [extract_icl](#) command before using report_bisr_repair_register_icl_instances.

Arguments

- **-power_domain_group pdg_list**

An optional argument and value pair that specifies one or more power domain groups from which the report lists available memory BISR repair register instances.

The *pdg_list* value supports [glob](#) expressions to aid in defining the desired list. For example, providing the argument -power_domain_group [list pdg*] will report the BISR register ICL instances for all registers that are on a power domain group that begins with “pdg”.

Examples

The following example reports the list of available memory BISR repair register instances on power domain groups “-” and “pdgA”:

```
report_bisr_repair_register_instances -power_domain_group [list - pdgA]

// BISR Repair Registers
// -----
// ----- Power Domain Group      ICL Instance          Design Instance -----
// ----- -
// -           core_blkA_i1_mem6_bisr_inst    core/blkA_i1/mem6_bisr_inst
// pdgA        core_blkA_i2_mem6_bisr_inst    core/blkA_i2/mem6_bisr_inst
// -           core_blkB_i1_memA_bisr_inst    core/blkB_i1/memA_bisr_inst
//
```

report_bist_capture_ranges

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Displays a list of the currently defined BIST capture ranges.

Usage

```
report_bist_capture_ranges
```

Description

The report_bist_capture_ranges command displays a list of the capture ranges that are currently defined as a result of the [add_bist_capture_range](#) command. A BIST capture range is defined by a named capture procedure that is stored in the test procedure file, and a range of patterns that will use this capture procedure. The complete range of patterns reported by the report_bist_capture_ranges command typically represents a small subset of the entire pseudo-random pattern space, and is applied to the complete pattern space by repeating the sequence until all the pseudo-random patterns have been simulated.

Arguments

None

Examples

The following example shows the output from the report_bist_capture_ranges command.

```
report_bist_capture_ranges

// List of currently defined Logic BIST capture ranges
// Procedure name    from pattern   to pattern
// -----  -----
// cap1              0            14
// cap2              15           15
//
// NOTE: This list defines the active named capture range during pseudo-
// random pattern simulation. The tool automatically restarts at the top
// of the list when the pattern counter matches the final "to pattern"
// value.
```

[add_bist_capture_range](#)

[delete_bist_capture_ranges](#)

report_black_boxes

Context: all contexts

Mode: setup, analysis

Displays information on blackboxes and undefined models.

Usage

```
report_black_boxes
  {{-INStances [ins_pathnames]} | {-Modules [module_names]} | -All | -Undefined}
  [-INClude_pins]
  [>|>>} file.pathname]
```

Description

Displays information on blackboxed modules, instances, and undefined modules.

The report_black_boxes command reports on the status of any instance-based and/or module-based blackboxes, or undefined models that are not yet blackboxed. The tool displays the string MODULE/MODEL/INSTANCE followed by the name in the following format:

```
// Black Boxed Modules and Instances:
// Default tie value = X
// MODULE:
// MODEL:
// INSTANCE:
```

Displaying Pins

When the optional -INClude_pins switch is specified, the tool displays a list of pins as in the following example:

```
// Black Boxed Modules and Instances:
// Default tie value = X
// MODULE: 'foo'
//   USER: Output pin 'b' tied to X
// MODEL: xor02
//   USER: Output pin 'Y' tied to X
// INSTANCE: 'hal'
//   USER: Output pin 's' tied to X
//   USER: Output pin 'c_out' tied to X
```

Arguments

- **-Instances [ins_pathnames]**

A switch and optional string that specify for the tool to display information on instance-based blackboxes. The *ins_pathnames* argument can be a Tcl list of one or more instances, or a collection of one or more instances. If you do not specify an *ins_pathname*, the tool displays information on all instance-based blackboxes. If you specify an *instance pathnames*, it reports on that single, instance-based blackbox.

- **-Modules** [*module_names*]

A switch and optional string that specify for the tool to display information on module-based blackboxes. The *module_names* argument can be a Verilog module or Tessent Cell library model, a Tcl list of modules, or a collection of modules. If you do not supply a *module_name*, the tool displays information on all module-based blackboxes. If you specify a *module_name*, it reports on that single, module-based blackbox.

- **-All**

A switch that specifies for the tool to display information on all defined blackboxes, as well as undefined models. This is the command default.

- **-Undefined**

A switch that specifies for the tool to display information on undefined models that have not yet been blackboxed. Use this switch to determine whether your design is complete, or is missing library models. If you intend to blackbox undefined models, this report allows you to verify that only the intended models are undefined.

- **-INClude_pins**

An optional switch that specifies reporting pins for defined blackboxes. See “[Displaying Pins](#).”

- **>file_pathname**

An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of file_pathname.

- **>>file_pathname**

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of file_pathname.

Examples

The following example defines module- and instance- based blackboxes then reports on them.

```
add_black_box -module halfadder -pin s 1
add_black_box -instance final_carry -pin Y 0
report_black_box -include_pins

// Black Boxed Modules and Instances:
// Default tie value = X
// MODULE: 'halfadder'
//     USER: Output pin 's' tied to 1
//     USER: Output pin 'c_out' tied to x
// INSTANCE: 'final_carry'
//     USER: Output pin 'Y' tied to 0
```

[add_black_boxes](#)

[delete_black_boxes](#)

report_boundary_scan_port_options

Context: dft, patterns

Mode: all modes

Displays a table listing all of the ports with their inferred or specified cell_options.

Usage

```
report_boundary_scan_port_options
```

Description

Displays a table listing all of the ports with their inferred or specified cell_options as specified by the [set_boundary_scan_port_options](#) command.

When the design level is physical_block or sub_block, as specified using the [set_design_level](#) command, all ports not listed in the “[set_boundary_scan_port_options -pad_io_ports](#)” list are inferred as dont_touch. For more information on the dont_touch, see [Table 10-4](#) for a description of these values.

Arguments

None.

Examples

The following example runs the report_boundary_scan_port_options command on a design in which the level was set to physical_block using the set_design_level command.

```
set_design_level sub_block
set_boundary_scan_port_options -pad_io_ports [get_port gpio*]
set_boundary_scan_port_options gpio00 -cell_options clock
report_boundary_scan_port_options

// Pad io pins : gpio00 gpio01 gpio02 gpio03 gpio04 gpio05 gpio06 gpio07
//
// Port name          Options
// -----
// gpio00             clock
// gpio01             normal
// gpio02             normal
// gpio03             normal
// gpio04             normal
// gpio05             normal
// gpio06             normal
// gpio07             normal
// clk                dont_touch
// ina                dont_touch
// outa               dont_touch
```

Related Topics

[set_boundary_scan_port_options](#)

[get_boundary_scan_port_option](#)

report_bus_data

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Displays the bus data information for either an individual bus gate or for the buses of a specific type.

Usage

```
report_bus_data type [{>|>>} file.pathname]
```

Description

Displays the bus data information for either an individual bus gate or for the buses of a specific type.

The report_bus_data command displays the following bus information:

- Instance name
- Gate identification number
- Contention handling (pass, bidi, fail, or abort)
- Type of bus (strong or weak)
- Number of drivers on the bus
- Any learned behavior of the bus.

The design rule that checks for bus contention mutual exclusivity is rule E10. For more information on rule E10, refer to the “[Extra Rules \(E Rules\)](#)” section.

If you enable the learn reporting by using the [set_learn_report](#) command, the tool provides the following two additional lines of information with the report_bus_data command:

- Information on whether or not the bus is capable of being set to an X, set to a Z, or having multiple drivers turned on.
- A list of drivers and their corresponding gate type. Drivers that are equivalent have a gate type of EQ.

The design rule that checks to see if there is any possible input combination that can force a bus into the high-impedance state (Z) is rule E11. For more information on rule E11, refer to the “[Extra Rules \(E Rules\)](#)” section.

Arguments

- **type**

A required literal or integer that specifies the type of bus for which you want the tool to display information. The choices for the **type** argument are as follows:

gate_id# — An integer that specifies the gate identification number whose bus data you want to display.

All — A literal that displays the bus data for all buses.

Weak — A literal that displays the bus data for the weak buses.

Strong — A literal that displays the bus data for the strong buses.

Dominant — A literal that displays the bus data for the final bus of every set of cascaded buses.

NONDominant — A literal that displays the bus data for all but the final bus in every set of cascaded buses.

Pass — A literal that displays the bus data for the buses that passed the contention mutual exclusivity checking.

Bidi — A literal that displays the bus data for the bidirectional buses that have possible contention problems. For the tool to place a bus in this category, the bidirectional pin must have only a single tri-state driver.

Fail — A literal that displays the bus data for the buses that failed the contention mutual exclusivity checking.

Abort — A literal that displays the bus data for the buses that aborted contention mutual exclusivity checking.

Buf — A literal that displays the bus data for all buses that have the buffer learned behavior.

Xor — A literal that displays the bus data for all buses that have the exclusive OR learned behavior.

Mux — A literal that displays the bus data for all buses that have the multiplexer learned behavior.

AND — A literal that displays the bus data for all buses that have the AND learned behavior.

OR — A literal that displays the bus data for all buses that have the OR learned behavior.

POSS_Mult_dr_on — A literal that displays the bus data for all buses that have a possibility of having multiple drivers turned on at the same time.

POSS_X — A literal that displays the bus data for all buses that have a possibility of being at an unknown state.

POSS_Z — A literal that displays the bus data for all buses that have a possibility of being at the high-impedance state.

Histogram — A literal that displays a summary of information identifying the number of buses that are in each of the possible categories.

ZPass — A literal that displays the bus data for the buses that pass the E11 design rule.

ZFail — A literal that displays the bus data for the buses that fail the E11 design rule check.

ZAbort — A literal that displays the bus data for the buses that abort the E11 design rule check.

- *>file.pathname*

An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file.pathname*.

- *>>file.pathname*

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file.pathname*.

Examples

Example 1

The following example displays the information on a specific bus gate—an inverter (INV):

```
report_bus_data 31
/FA1/XOR1/OUT/ (31)Handling=pass type=strong #Drivers=2 (INV)
    Bus Drivers: 30(SW) 28(SW)
```

Example 2

The following example first enables access to the static learning data, then displays both the learned information and the bus data on a specific bus gate, again, an inverter (INV):

```
set_learn_report on
report_bus_data 31
/FA1/XOR1/OUT/ (31)Handling=pass type=strong #Drivers=2 (INV)
    Learn Data : poss_X=no, poss_Z=no, poss_mult_drivers_on=no
    Bus Drivers: 30(SW) 28(SW)
```

Related Topics

[set_learn_report](#)

report_bypass_chains

Context: dft -edt, patterns -scan (EDT On), patterns -scan_diagnosis

Mode: setup, analysis

Displays the defined EDT bypass scan chain connections.

Usage

```
report_bypass_chains [-All_blocks | {-Edt_chain chain_name} |  
{-Bypass_chain chain_number}] [{>|>>} file_pathname]
```

Description

Displays the defined EDT bypass scan chain connections. If issued from Setup mode, the report_bypass_chains command lists scan chain connections for bypass scan chains defined using the [set_bypass_chains](#) command.

If issued from analysis mode, all bypass scan chain connections are reported, whether defined by the tool or with the set_bypass_chains command.

You can display the chain connection information for all bypass chains, or optionally include the -Edt_chain or -Bypass_chain switch to display only the information for a particular bypass chain. The order, left to right, in which the display lists the scan chains in a particular bypass chain is the order in which the chains are series-connected from channel input to channel output.

The -All_blocks switch is only for the top-level Pattern Generation Phase of modular Tessent TestKompress, where the netlist read in includes multiple EDT blocks. In this case, the command by default reports the chain connection information as described above, but only for the EDT block you have specified as the current EDT block. If you include the -All_blocks switch, the command displays information for all the EDT bypass chains in every EDT block. You set the current EDT block using either the add_edt_blocks or set_current_edt_block command. “EDT block” is the term used for a decompressor/compactor pair and the scan chains it controls/observes. For more information, refer to the “[Modular Compressed ATPG](#)” chapter of the *Tessent TestKompress User’s Manual*.

Arguments

- -All_blocks

Note

 This switch is only for the top-level Pattern Generation Phase of modular Tessent TestKompress, where the netlist read in includes multiple EDT blocks. If you are using a standard (non-modular) Tessent TestKompress flow, you do not need this switch.

An optional switch that specifies to display all chain connection information for all EDT blocks. Without this switch, the tool displays information for only the current EDT block, if

it is defined. If a current EDT block is not defined, the tool displays the information for all EDT blocks.

- **-Edt_chain *chain_name***

An optional switch and string pair that specify to display the scan chain connections for only the EDT bypass chain that includes the EDT scan chain, *chain_name*. You can use this switch to see which bypass chain or scan channel is associated with a particular scan chain.

- **-Bypass_chain *chain_number***

An optional switch and positive integer pair that specify to display the scan chain connections for the EDT bypass chain, *chain_number*. Use this switch to list the scan chain connections for a particular EDT bypass chain. The *chain_number* is the same as the number of the scan channel connected to the bypass chain.

- **> *file_pathname***

An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file_pathname*.

- **>> *file_pathname***

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

Example 1

Assume a design has eight scan chains named “chain1” through “chain8” and that the chains have been incorporated into two EDT bypass channels configured from two EDT scan channels. The following example displays the scan chain connection information for the EDT bypass chain containing chain3. You can see from the report that chain3 is part of a bypass chain connected to scan channel 2.

```
report_bypass_chains -edt_chain chain3
//      Reporting user-defined bypass chains:
//
//      Bypass#      EDT chains
//      -----      -----
//          2          chain2, chain3, chain4, chain7, chain8
```

Example 2

The following example displays the connection information for EDT bypass chain 1 (scan channel 1).

```
report_bypass_chains -bypass_chain 1
//      Reporting user-defined bypass chains:
//
//      Bypass#      EDT chains
//      -----      -----
//          1          chain1, chain5, chain6
```

Again, notice that the EDT bypass chain number (Bypass# in the display) is the same as the number of the scan channel to which the bypass chain is connected.

[reset_bypass_chains](#)

[set_bypass_chains](#)

report_capture_handling

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Displays any special data capture handling currently in use.

Usage

```
report_capture_handling [List | Summary | SSources | SInks | Gates]  
[{> | >>} file_pathname]
```

Description

Displays any special data capture handling currently in use. To change how the tool handles data capturing on level-sensitive and trailing-edge state elements, use the add_capture_handling command. If you have not set up any special data capture handling, then the report_capture_handling command does not generate a report.

Arguments

- List
A literal that displays the handling settings (old, new, or X), whether the element is a sink or source, the instance pathname, and the gate identification number. This is the default.
- Summary
A literal that displays the handling settings for both level-sensitive and trailing-edge state elements, the number of sources, the number of primitive gates in the flattened netlist between source and sink points, and the number of sinks.
- Sources
A literal that displays the gates that have source-point, special data capture handling.
- SInks
A literal that displays the gates that have sink-point, special data capture handling.
- Gates
A literal that displays the identification numbers of all the primitive gates between the source and sink points.
- >file_pathname
An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.
- >>file_pathname
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

The following example sets up the data capture handling for one gate, and then issues the set_capture_handling command to identify the associated sinks for that source:

```
add_capture_handling new 1158 -source
set_capture_handling
```

The following set of commands show the different formats for the available reports:

```
report_capture_handling
```

```
NEW Source /I_1_16/DF0/ (1158)
```

```
report_capture_handling list
```

```
NEW Source /I_1_16/DF0/ (1158)
```

```
report_capture_handling summary
```

```
Capture handling summary: LS=OLD, TE=NEW, #sources=1,
#int_gates=14, #sinks=2
```

```
report_capture_handling source
```

```
Source list : 1158-X
```

```
report_capture_handling sink
```

```
Sink list : 1160-X 1165-X
```

```
report_capture_handling gates
```

```
Int_gate list: 13 14 39 40 51 52 53 61 62 63 68 69 79 86
```

Related Topics

[add_capture_handling](#)

[set_capture_handling](#)

report_capture_procedures

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Displays the cyclized information for a specified named capture procedure.

Usage

```
report_capture_procedures [-Clock_sequence] [-Created_capture_procedure |  
-Loaded_capture_procedure | -Enabled | -Disabled | capture_procedure_name...] [  
[-All | -Summary | -Internal | -External] [-Display Wave] [{> | >>} file.pathname]
```

Description

Displays the cyclized information for a specified named capture procedure. Cyclizing is a processing step performed prior to ATPG that merges internal mode cycles when needed to optimize them and/or expand other internal mode cycles to ensure correct simulation results.

For example, when a named capture procedure contains a cycle that pulses multiple clocks at different times, the cycle must be expanded into multiple cycles (one for each clock pulse) in order to simulate it. The cyclized information shows the cycles ATPG will actually use when creating patterns, after any merging or expansion of cycles. The display also includes comments about the timing of the cycles and where the at-speed sequences begin and end to aid your understanding.

The displayed information resembles the original procedure as defined in the test procedure file, but it does not have any timeplates. Therefore, it will not work if copied and pasted as is into a dofile; you must add timeplates. To display the procedure as it actually exists in the test procedure file, use the [report_procedures](#) command.

The number of cycles reported is the sequential depth used during test generation. The display of merged or expanded cycles is illustrated in the examples. See also “[Named Capture Procedures Display](#)” in the *Tessent Scan and ATPG User’s Manual*.

Note

 If the named capture procedure is modified to cyclize it for ATPG, the modifications are internal only; the named capture procedure is not altered in the test procedure file.

Arguments

- **-Clock_sequence**
An optional switch that displays the clock sequence of the named capture procedures. The scan load cycle(s), at-speed cycle(s), and the number of patterns the named capture procedure is associated with are also displayed.
- **-Created_capture_procedure**
An optional switch that displays only the created named capture procedures.

- **-Loaded_capture_procedure**
An optional switch that displays only the named capture procedures loaded from the read_procfile command or from the procedure file associated with the scan group definition.
- **-Enabled**
An optional switch that displays only enabled named capture procedures.
- **-Disabled**
An optional switch that displays only disabled named capture procedures.
- ***capture_procedure_name***
An optional, repeatable string that displays only the specified named capture procedures. By default, information for all named capture procedures is displayed.
- **-All**
An optional switch that displays information for both the internal and external modes of the named capture procedure. This is the default.
- **-Summary**
An optional switch that displays only summary information about the named capture procedure.
- **-Internal**
An optional switch that displays information for only the internal mode of the named capture procedure.
- **-External**
An optional switch that displays information for only the external mode of the named capture procedure.
- **-Display Wave**
An optional switch that displays the specified capture procedure in the Wave window of DFTVisualizer. This is for optimized NCP's. Use the [report_procedures](#) command to display unoptimized NCP's.
- **> *file.pathname***
An optional redirection operator and pathname pair used at the end of the argument list to create or replace the contents of *file.pathname*.
- **>> *file.pathname***
An optional redirection operator and pathname pair used at the end of the argument list to append the contents of *file.pathname*.

Examples

Example 1

The following example displays summary information for the named capture procedures *nam_cap1*, *nam_cap2*, *my_cap1*, and *my_cap2*, including the scan load cycle(s), the at-speed

cycle(s), and the number of patterns with which the named capture procedures are associated. It also indicates *nam_cap1* and *nam_cap2* were loaded from an external file and *my_cap1* and *my_cap2* were internally created.

report_capture_procedures -summary

capture_proc_name	cycles	at_speed_cycle	active	source	# associated patterns	
					internal	external
nam_cap1	1	1	no	loaded	0	-
nam_cap2	1	1	yes	loaded	10	-
my_cap1	2	{1 to 2}	yes	created	5	-
my_cap2	2	{2 to 2}	no	created	0	-

Example 2

The following example displays the clock sequence of the named capture procedures *capture1*, *capture2*, *user_capture_proc*, and *user_capture_proc_1* in addition to the summary information.

report_capture_procedures -clock_sequence

capture_proc_name	cycles	at_speed_cycle	active	source	# associated patterns		capture_clock_sequence
					internal	external	
capture1	1	1	yes	loaded	6	-	S(c4,c3,c2,c1,c0)
capture2	1	1	yes	loaded	8	-	S(c9,c8,c7,c6,c5)
user_capture_proc	3	{1 to 3}	yes	created	0	-	S(c0)(c1,c0)(c3,c2)
user_capture_proc_1	3	{1 to 3}	yes	created	0	-	S(c0),(c1,c0)(c3,c2)

Example 3

The following example displays information for all the named capture procedures (*capture1*, *capture2*, and *my_cap1*). The first line displayed for each named capture procedure indicates if the procedure is currently enabled for test generation (ACTIVE) or disabled (INACTIVE). You can enable or disable capture procedures with the [set_capture_procedures](#) command.

report_capture_procedures

```
procedure capture "capture1" = // (INACTIVE) (loaded capture procedure)
    cycle = // cycle 1 starts at time 0 (Begin_AC_test) (Force PI) (Measure PO)
        condition "/inst_0/clkenhold/reg_sco/" 1 ;
        force "/clock[4]" 0 ;
        force "/clock[3]" 0 ;
        force "/clock[2]" 0 ;
        force "/clock[1]" 0 ;
        force "/clock[0]" 0 ;
        force "/clear" 0 ;
        force "/scan_en" 0 ;
        force "/test_clk" 0 ;
        force_pi ;
        measure_po ;
        pulse "/clock[1]" ;
        pulse "/clock[0]" ;
    end ; // cycle 1 (End_AC_test)
    // mode external is not defined.
end ; // procedure "capture1"
```

Command Dictionary (R)
report_capture_procedures

```
procedure capture "capture2" = // (ACTIVE) (loaded capture procedure)
    cycle = // cycle 1 starts at time 0 (Begin_AC_test) (Force PI) (Measure PO)
        condition "/inst_0/clkenhold/reg_sco/" 0 ;
        force "/clock[4]" 0 ;
        force "/clock[3]" 0 ;
        force "/clock[2]" 0 ;
        force "/clock[1]" 0 ;
        force "/clock[0]" 0 ;
        force "/clear" 0 ;
        force "/scan_en" 0 ;
        force "/test_clk" 0 ;
        force_pi ;
        measure_po ;
        pulse "/clock[4]" ;
        pulse "/clock[3]" ;
    end ; // cycle 1 (End_AC_test)
    // mode external is not defined.
end ; // procedure "capture2"

procedure capture "my_cap1" = // (ACTIVE) (created capture procedure)
    cycle = slow // cycle 1 starts at time 0 (Force PI)
        force "/clock[4]" 0 ;
        force "/clock[3]" 0 ;
        force "/clock[2]" 0 ;
        force "/clock[1]" 0 ;
        force "/clock[0]" 0 ;
        force "/clear" 0 ;
        force "/scan_en" 0 ;
        force "/test_clk" 0 ;
        force_pi ;
        measure_po ;
        pulse "/clock[4]" ;
        pulse "/clock[3]" ;
    end ; // cycle 1
    cycle = // cycle 2 starts at time 50 (Begin_AC_test) (Force PI) (Measure PO)
        condition "/inst_0/clkenhold/reg_sco/" 0 ;
        force "/clock[4]" 0 ;
        force "/clock[3]" 0 ;
        force "/clock[2]" 0 ;
        force "/clock[1]" 0 ;
        force "/clock[0]" 0 ;
        force "/clear" 0 ;
        force "/scan_en" 0 ;
        force "/test_clk" 0 ;
        force_pi ;
        measure_po ;
        pulse "/clock[2]" ;
        pulse "/clock[1]" ;
    end ; // cycle 1 (End_AC_test)
    // mode external is not defined.
end ; // procedure "my_cap1"
```

Example 4

The following example displays how the tool will use the cycle during ATPG (the command's output is excerpted for brevity):

report_capture_procedures -internal

```
...
Mode internal =
    Cycle = // cycle 1 starts at time 0 (Begin_AC_test)
              // (Force PI)
        Force_pi ;
        Pulse /clk1 ;
    End ; // cycle 1 at time 20
    Cycle = // cycle 2 starts at time 20
        Pulse /clk2 ;
    End ; // cycle 2 at time 50
...

```

The display shows that for this particular design and cycle definition, the tool expands the one cycle from the test procedure file into two cycles internally. Notice that the combined time of the two cycles is the same as the period of the original cycle in the test procedure file. The tool will automatically adjust the sequential depth used during ATPG to accord with the resultant change in number of cycles.

Example 5

The next example shows a case where the tool merges two cycles described in the test procedure file into one cycle for ATPG. The relevant excerpts from the test procedure file are shown first; the example then displays the cyclized data for the three cycles.

```
mode_internal =
...
timeplate tp2 =
    force_pi 0;
    pulse clk 10 10;
    period 50;
end;
cycle =
    force_tms 0;
    pulse clk;
end;
cycle =
    force_tms 0;
    pulse clk;
end;
...

```

report_capture_procedures -internal

```
...
Mode internal =
    Cycle = // cycle 1 starts at time 0 (Begin_AC_test)
        // (Force PI)
        Force_pi ;
        Force /tms 0 ;
        Pulse /clk ;
    End ;      // cycle 1 at time 100
    Cycle = // cycle 2 starts at time 100
        Force /tms 0 ;
        Pulse /clk ;
    End ;      // cycle 2 at time 150
```

report_cell_constraints

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Displays a list of the constrained cells.

Usage

```
report_cell_constraints [-Scan_cell | -Non_scan_cell]
[{-Chain chain_name} | {-Clock clock_name}]
[{> | >>} file.pathname]
```

Description

The report_cell_constraints command displays a list of all the scan cells (also non-scan cells for DX and SX constraints) that you previously constrained to a constant value using the [add_cell_constraints](#) command. The display may consist of up to seven columns, as follows (columns that contain no data for all cell constraints are not displayed):

- Constraint value — Specifies the constraint value.
- Chain name — Specifies the scan chain name if the constraint is on a scan cell. If the constraint is on a non-scan cell, then this column is blank.
- Cell position — Specifies the position in the scan chain if the constraint is on a scan cell. If the constraint is on a non-scan cell, then this column is blank.
- Cell instance name — Specifies the cell instance of the constraint. This column is blank unless you originally specified the constraint with a *pin.pathname*.
- Gate instance name — Specifies the gate instance of the constraint. This column is blank unless you originally placed the constraint on a non-scan cell using the -Clock switch.
- Constraint properties — Displays constraint properties, as applicable, from the following list:
 - Internal — Constraint was applied by the tool automatically in response to certain DRC results
 - Whole Chain — Constraint was applied using the -Chain switch
 - Drc C6 — Constraint was applied using the “-Drc C6” argument combination.
 - Clock — Constraint was applied using the -Chain switch
 - Drc D8 Warn — Constraint was applied by the tool automatically to a D8 failing master cell when “set_drc_handling d8 warning” was in effect for DRC. See “[D8](#)” for more information.
 - Dynamic — Constraint was applied in analysis mode
 - Static — Constraint was applied in setup mode

- Pattern scope — Specifies the pattern scope of the constraint: whether the tool uses the constraint only when creating scan patterns, or uses the constraint for both scan and chain pattern creation.

Arguments

- **-Scan_cell**
An optional switch that specifies to report_cell_constraints at scan cells only. This switch is valid in analysis modes only.
- **-Non_scan_cell**
An optional switch that specifies to report_cell_constraints at non-scan cells only. This switch is valid in analysis modes only.
- **-CHain *chain_name***
An optional switch and string pair that specifies to report_cell_constraints added to the scan chain, chain name, by an earlier add_cell_constraints -Chain command. This switch is valid in analysis modes only.
- **-Clock *clock_name***
An optional switch and string pair that specifies to report the cell constraints added by an earlier add_cell_constraints -Clock command to latches and flip-flops controlled by the clock, *clock_name*. This switch is valid in analysis modes only.
- **> *file_pathname***
An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file_pathname*.
- **>> *file_pathname***
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

Example 1

The following example begins in Setup mode and constrains a single scan cell to be at a constant zero for the generation of all patterns. The example then displays current cell constraints, leaves Setup mode, triggering the tool's automatic DRC process and again reports the cell constraints:

```
add_cell_constraints sdff1/q c0 -all_patterns
report_cell_constraints

// constraint cell_instance    constraint      pattern scope
//   value       name        properties
// -----
//   C0          sdff1/q     (Static)    Chain + Scan Patterns

set_system_mode analysis
report_cell_constraints
```

```
// const chain cell      cell_inst constraint      pattern scope
// value   name  pos       name    properties
// ----- -----
// C0      c1     2        sdff1/q  (Static)  Chain + Scan Patterns
```

Notice that once the tool has identified the scan chains during the DRC process, the report identifies the chain and cell position of the constrained scan cell.

Example 2

The next example adds DX constraints on all flip-flops clocked by clk2. You can see from the cell constraint report that these flip-flops are not scan cells (no chain or cell position). Notice also that the gate instances are reported for them since each flip-flop is a standalone gate, not part of a scan cell.

```
add_cell_constraints -clock /clk2 -type flop dx
report_cell_constraints

// const chain cell      cell_inst gate_inst constraint      pattern scope
// value   name  pos       name    name    properties
// ----- -----
//      DX                                /dff6   (Clock)  Scan Patterns only
//      DX                                /dff5   (Clock)  Scan Patterns only
// ----- -----
// C0      c1     2        sdff1/q  (Static)  Chain + Scan Pattern
```

[delete_cell_constraints](#)

report_cell_models

Context: dft -scan, dft -test_points

Mode: setup, analysis

Displays a list of either all cell models or the DFT library models associated with the specified cell type.

Usage

report_cell_models [-All | {-Type *cell_model_type*}]

Description

The report_cell_models command displays the cell models that you either added with the [add_cell_models](#) command, or described in the DFT library with the [cell_type](#) attribute.

Arguments

- -All
An optional switch that specifies to display all cell model definitions that you added with the [add_cell_models](#) command. This is the default.
- -Type *cell_model_type*
An optional switch and literal pair that specifies to display a listing of all the cell models of a particular type. The valid *cell_model_types* are as follows (with the minimum typing characters shown in uppercase):
 - INV** — A literal that specifies a one-input inverter gate.
 - And — A literal that specifies a two-input AND gate.
 - Buf — A literal that specifies a one-input buffer gate.
 - OR — A literal that specifies a two-input OR gate.
 - NAnd — A literal that specifies a two-input NAND gate.
 - NOr — A literal that specifies a two-input NOR gate.
 - Xor — A literal that specifies a two-input exclusive OR gate.
 - Mux — A literal that specifies a 2-1 multiplexer.
 - Scancell — A literal that specifies a cell with four input pins (clock, data, scan in, and scan enable), clocked scan cell with four inputs (clock, data, scan clock, and scan enable), or LSSD scan cell with five inputs (clock, data, scan in, master clock, and slave clock).
 - DFf — A literal that specifies a D flip-flop with two input pins (clock and data).
 - LATCH — A literal that specifies a D latch with two input pins (enable and data).

Examples

The following example displays a list of all added cell models:

```
add_clocks 0 clk
set_test_logic -set on -re on -clock on
set_system_mode analysis
report_scan_elements
add_cell_models and2 -type and
add_cell_models or2 -type or
add_cell_models mux21h -type mux s a b
add_cell_models nor2 -type nor
report_cell_models
insert_test_logic
```

[set_test_logic](#)

report_chain_masks

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Reports the list of masked scan chains and their associated unload value.

Usage

```
report_chain_masks
```

Description

Reports the list of masked scan chains and their associated unload value.

Arguments

None

Examples

The following example adds several chain masks and then reports the added chain masks:

```
add_chain_masks chain2 chain4 chain5
report_chain_masks

// Masked scan chain Unload value Cell constraints
// -----
//      chain2          X          OX
//      chain4          X          OX
//      chain5          X          OX
```

The following example adds several chain masks, specifies load values, and then reports the added chain masks:

```
add_chain_masks chain2 -load_value 0
add_chain_masks chain4 -load_value 0
add_chain_masks chain5 -load_value 1
report_chain_masks

// Masked scan chain Load value Unload value Cell constraints
// -----
//      chain2          0          X          OX
//      chain4          0          X          OX
//      chain5          1          X          OX
```

Related Topics

[delete_chain_masks](#)

report_clock_controller_pins

Context: dft -logic_bist

Mode: setup, analysis

Reports the clock controller pins specified with the set_clock_controller_pins command.

Usage

```
report_clock_controller_pins [> | >>file.pathname]
```

Description

Reports the clock controller pins specified with the set_clock_controller_pins command.

This command is used with the hybrid TK/LBIST flow—refer to the [Hybrid TK/LBIST Flow User's Manual](#) for complete information.

Arguments

- `>file.pathname`
An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of `file.pathname`.
- `>>file.pathname`
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of `file.pathname`.

Examples

This example reports all clock_controller pins specified so far using the set_clock_controller_pins command.

```
report_clock_controller_pins
```

```
//
// PinType           Connection
// -----           -----
// Shift clock      clock_control_i1/SLOW_CLK clock_control_i2/
SLOW_CLK clock_control_i3/SLOW_CLK
// Scan enable     clock_control_i1/SCAN_EN clock_control_i2/
SCAN_EN clock_control_i3/SCAN_EN
// LBIST enable    clock_control_i1/LBIST clock_control_i2/LBIST
clock_control_i3/LBIST
// Capture procedure index NCP_INDEX_1/A NCP_INDEX_0/A
//
```

Related Topics

[set_clock_controller_pins](#)

[set_lbist_power_controller_options](#)

report_clock_controls

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Displays current configuration information for clock control definitions.

Usage

```
report_clock_controls
```

Description

Displays current configuration information for clock control definitions.

For more information, see “[Support for Internal Clock Control](#)” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

None

Examples

The following example illustrates how clock control definitions are reported.

The following clock control is defined in a test procedure file.

```
clock_control clk =
    source_clock pll_clk;
    atpg_cycle 0=
        condition ctl_dff2/Q 1;
    end;
    atpg_cycle 1=
        condition ctl_dff1/Q 1;
    end;
end;
```

The Report Clock Control command reports the definition as follows:

```
report_clock_controls

CLOCK_CONTROL "/clk (6)" =
SOURCE_CLOCK "/pll_clk (4)";
    ATPG_CYCLE 0 =
        CONDITION "/ctl_dff2/ (56)" 1;
    END;
    ATPG_CYCLE 1 =
        CONDITION "/ctl_dff1/ (55)" 1;
    END;
END;
```

Related Topics

[set_clock_controls](#)

report_clock_domains

Context: dft -edt, patterns -scan

Mode: analysis

Displays all clocks and their corresponding clock domain numbers.

Usage

```
report_clock_domains [{-Compatible_clocks [-Details]} | {-Race_points clk1 clk2}]  
[{> | >>} file_pathname]
```

Description

During ATPG, if “set_clock_restriction domain_clock” is set, the tool may simultaneously turn on any subset of compatible clocks. This allows fault effects to be captured by more than one clock in the same cycle without risk of simulation mismatches due to clock skew. As a result, the test pattern count may be reduced and the fault coverage improved for the same clock sequential depth, compared with when only one clock is turned on in each cycle.

The report_clock_domains command lists defined clocks by groups based on their compatibility. Clocks are compatible (occupy the same clock domain) if capturing with them simultaneously can be performed reliably. Use this command to assess the overall clock compatibilities in your design, and to determine if using “set_clock_restriction domain_clock” would be beneficial.

Note

 The basic display enables you to quickly evaluate the overall clock compatibility of your design. It is summary information, however, and does not necessarily show the compatibility relationship between all possible clock pairings. That is, two clocks listed with different clock domains are not necessarily incompatible. Use the -Compatible_clocks switch if you need to check the compatibility information for a specific pair of clocks.

Arguments

- Compatible_clocks

An optional switch that includes in the display the pair-wise clock compatibility information the tool uses during ATPG. Because two clocks with different clock domain numbers are not necessarily incompatible, this switch enables you to determine precisely whether two clocks are compatible or not.

The tool treats two clocks as compatible if the clocks can be in their “on” state at the same time without causing clock skew problems or race conditions. To make this determination, the tool analyzes the clocking relationship between source and sink memory elements where the source is clocked by one clock and the sink is clocked by a different clock.

[Table 5-6](#) summarizes the conditions under which the tool determines the two clocks to be compatible (C) or incompatible (I).

Table 5-6. Clock Compatibility Summary

Source	Sink			
	LE ¹	TE ²	AH ³ (TE)	AL ⁴ (LE)
LE	I	C	C	I
TE	C	I	I	C
AH (LE)	I	C	C	I
AL (TE)	C	I	I	C

1. LE = Captures on PI clock's leading edge
2. TE = Captures on PI clock's trailing edge
3. AH = Active high, level sensitive element
4. AL = Active low, level sensitive element

- Details

An optional switch that displays the same compatibility information provided by the -Compatible_clocks switch, but instead of using an “x” in the display to mark each incompatible clock pair, use as the marker the number of state elements at which the tool determined the pair to be incompatible.

- Race_points *clk1 clk2*

An optional switch and pair of strings that lists the instances that cause the two clocks, *clk1* and *clk2*, to be incompatible. The tool includes the gate ID and type of state element (scan, non-scan or RAM) for each instance listed.

- >*file.pathname*

An optional redirection operator and pathname pair used at the end of the argument list or creating or replacing the contents of *file.pathname*.

- >>*file.pathname*

An optional redirection operator and pathname pair used at the end of the argument list for appending to the contents of *file.pathname*.

Examples

Example 1

The following example displays the defined clocks and their domains of the design. The numbers in parentheses are the unique gate identification numbers assigned to each gate during the model flattening process.

```
set_system_mode analysis
report_clock_domains
```

```
// No. | Clock name      Domain
// ---+-----+
//   1 | '/ck11m' (8)    1
//   2 | '/ck22m' (9)    1
//   3 | '/ck2_75m' (10)  2
//   4 | '/ck5_5m' (11)   2
//   5 | '/nreset' (39)   3
//   6 | '/scan_reset' (63) 4
//
// 6 clocks classified into 4 domains.
// This is only one of the possible clock classifications. To see all
// dependencies of clock pairs, use 'report_clock_domains
// -Compatible_clocks'
```

Example 2

The following example displays the clock domains in example 1 with added information about the possible clock pairs in the design. Notice that although the tool assigned the /scan_reset clock to a domain different from the others, it is actually incompatible only with clocks /ck2_75m, and /nreset. This is indicated by an “x” in the /scan_reset row, above the index number that corresponds to each of those two clocks.

report_clock_domains -compatible_clocks

```
// No. | Clock name      Domain | Clock compatibility
// ---+-----+-----+
//   1 | '/ck11m' (8)    1| .
//   2 | '/ck22m' (9)    1| ..
//   3 | '/ck2_75m' (10)  2| .x.
//   4 | '/ck5_5m' (11)   2| ....
//   5 | '/nreset' (39)   3| .xxx.
//   6 | '/scan_reset' (63) 4| ..x.x.
//
//          No. | 123456
//  . = Compatible (non-interacting) clock pair
//  x = Incompatible (interacting) clock pair
//
// 6 clocks classified into 4 domains.
// This is one of possible clock classifications.
```

Example 3

The following example displays the same information as the preceding example, but directs the tool to substitute for each “x” the number of state elements at which the tool found the pair to be incompatible.

report_clock_domains -compatible_clocks -details

```
// No. | Clock name      Domain | Clock compatibility
// ---+-----+-----+
//   1 | '/ck11m' (8)    1| .
//   2 | '/ck22m' (9)    1| . .
//   3 | '/ck2_75m' (10)  2| . 3 .
//   4 | '/ck5_5m' (11)   2| . . . .
//   5 | '/nreset' 39)    3| . 6 1 6 .
//   6 | '/scan_reset' (63) 4| . . 8 . 4 .
// -----
//           No.| 1 2 3 4 5 6
// . = Compatible (non-interacting) clock pair
// x = Incompatible (interacting) clock pair
//
// 6 clocks classified into 4 domains.
// This is one of possible clock classifications.
```

The report shows there are three state elements that cause clocks /ck2_75m and /ck22m to be incompatible. The next example lists the instance name, gate ID and type of element for each of these elements.

report_clock_domains -race_points /ck2_75m /ck22m

```
//     /ff30/ (57) non-scan
//     /ff31/ (58) non-scan
//     /ff31b/ (58) non-scan
// 3 state elements cause clocks "/ck2_75m" and "/ck22m" to be
// incompatible.
```

Example 4

This is an example of a clock domain report with a norace synchronous clock group:

report_clock_domains -compatible_clocks

```
//  No. | Clock Name  Domain | Clock Compatibility
//  ---+-----+-----+
//   1 | '/c1' (4)    1 | .
//   2 | '/c2' (5)    2 | x.
//   3 | '/c3' (6)    1 | .n.
//  -
//           No. | 123
// . = Compatible (non-interacting) clock pair
// x = Incompatible (interacting) clock pair
// n = Norace (synchronous group) specified between compatible clock pair (1)
// N = Norace (synchronous group) specified between incompatible clock pair (0)
//
// 3 clocks grouped into 2 domains.
// This is one of possible clock grouping that ATPG may use.
// Compatibility analysis is based on same-edge clock interaction.
```

Example 5

This is an example of a clock domain report with a race specified between an incompatible clock pair:

report_clock_domains -compatible_clocks

```
// No. | Clock Name Domain | Clock Compatibility
// -----+-----+-----+
//   1 | '/c1' (4)      1 | .
//   2 | '/c2' (5)      2 | r.
//   3 | '/c3' (6)      1 | ...
// -----+-----+-----+
//           No. | 123
// . = Compatible (non-interacting) clock pair
// x = Incompatible (interacting) clock pair
// R = Race specified between compatible clock pair (0)
// r = Race specified between incompatible clock pair (1)
//
// 3 clocks grouped into 2 domains.
// This is one of possible clock grouping that ATPG may use.
// Compatibility analysis is based on same-edge clock interaction.
```

report_clock_gating

Context: dft -scan, dft -test_points

Mode: analysis

Reports specified clock gating instances or modules in the design.

Usage

`report_clock_gating object_spec`

Description

Reports specified clock gating instances or modules in the design. Only clock gaters with unconnected or tied test enable pins are reported.

The report includes the following information for each clock gater:

- Unconnected Port — Specifies the unconnected test enable port that will be used to control the clock gater.
- Shift Control — Specifies the scan enable signal (or signals) that will be used to enable the clock gater during shift. The value is only available after issuing `analyze_scan_chains` or if there is an enable signal defined for the clock gater with the `set_clock_gating_enable` command.
- Capture Control — If the clock gater drives input or output wrapper cells, the column will display the appropriate mode enable signal name that will be ORed together with scan enable to guarantee correct wrapper chain operation. If the clock gater does not drive any input or output wrapper cells the column shows “Functional”, which means that the clock gater is not enabled during capture neither in internal nor external mode. The value is available only after issuing the `analyze_wrapper_cells` and `analyze_scan_chains` commands.
- Origin — Specifies how the tool first learned about the clock gater. The possible values are: User-specified, Cell library, Auto-identified.
- Status — Specifies the status of each clock gater. The possible values are:
 - Unconnected — Will get connected during scan insertion.
 - Hard module — The clock gater is inside a hard module and cannot be connected.
 - Excluded — Explicitly excluded by you with the “`set_clock_gating off`” command.
 - Non-scan — The clock gater does not drive any scannable cells.

Arguments

- *object_spec*

A Tcl list of one or more instances or modules or a collection of instances or modules.

Examples

The following example demonstrates the use of the report_clock_gating command:

report_clock_gating

```
report_clock_gating
-----
Clock Gating      Unconnected     Shift      Capture      Origin      Status

[set_clock_gating](#)

report_clocks

Context: all contexts

Mode: setup, analysis

Displays a list of all user-defined clocks and SDC-defined clocks.

Usage

```
report_clocks [-All | -User | -Sdc] [-Display | [FLAt_schematic] | [HIEarchical_schematic] |  
[DAta] | [Wave] | ALl [APpend]] [{> | >>} file_pathname]
```

Description

Displays a list of all user-defined clocks and SDC-defined clocks. The report_clocks command lists all user-defined clocks created with the [add_clocks](#) command or all SDC-defined clocks created by an SDC file loaded with the [read_sdc](#) command or both.

Arguments

- **-All | -User | -Sdc**

A 1-of-3 choice of optional switches that report user-defined clocks or SDC clocks or both. User-defined clocks are created by the [add_clocks](#) command and SDC clocks are created by the SDC file loaded with the [read_sdc](#) command. The default option is -User. Note that the -Sdc switch is valid only when the flat model is available.

For information about the user-defined clocks report, refer to [Example 3](#). For information about the SDC clocks report, refer to [Example 4](#).

- **-Display | [FLAt_schematic] | [HIEarchical_schematic] | [DAta] | [Wave] | ALl} [APpend]**
An optional switch and repeatable literal that specify to display the instance(s) in the specified window; if Append is specified, the instances are added to the existing contents of the window instead of replacing the contents. The window choices are as follows:

FLAt_schematic — Specifies the Flat Schematic window. This is the default.

HIEarchical_schematic — Specifies the Hierarchical Schematic window.

DAta — Specifies the Data window.

Wave — Specifies the Wave window.

ALl — Specifies all supported windows.

- **> file_pathname**

An optional redirection operator and pathname pair for creating *or* replacing the contents of file_pathname.

- **>> file_pathname**

An optional redirection operator and pathname pair for appending to the contents of file_pathname.

Examples

Example 1

The following example adds two clocks to the clock list and then displays a list of the clocks:

```
SETUP> add_clocks 1 I1
SETUP> add_clocks 0 I2
SETUP> report_clocks

User-defined Clocks (2) :
=====
Sync and Async Source Clocks
=====

----- ----- ----- -----
Name Off State Constraints Internal
----- ----- ----- -----
'I1' 1 No
'I2' 0 No
```

Example 2

The following example adds two internal clocks to the clock list and merges them into a new primary input:

```
SETUP> add_clocks 1 u2/CLK u4/u5/u2/CLK -pseudo_port_name group_clk
// Note: Primary input 'group_clk' is added, merging 2 pins.

SETUP> report_clocks

User-defined Clock (1) :
=====
Sync and Async Source Clocks
=====

----- ----- ----- ----- ----- -----
Name Off State Constraints Internal Other Properties Pin(s)
----- ----- ----- ----- -----
group_clk 1 Yes Merged internal pin u2/CLK
u4/u5/u2/CLK
```

Example 3

The following example reports only user-defined clocks:

```
SETUP> add_clocks 1 u2/CLK u4/u5/u2/CLK -pseudo_port_name group_clk
// Note: Primary input 'group_clk' is added, merging 2 pins.
SETUP> add_clocks 0 I1 -period 50 ns
SETUP> add_clocks 1 I2 -pulse_always
SETUP> add_clocks I3 -pulse_in_capture -label clock_3
SETUP> report_clocks -user
```

User-defined Clocks (4) :							
Sync and Async Source Clocks							
Name	Label	Off State	Constraints	Internal	Period	Other Properties	Pin(s)
group_clk	group_clk	1			Yes	Merged internal pin u2/CLK u4/u5/u2/CLK	
I1	I1	-	Asynchronous	No	50.00ns		
I2	I2	1	Pulse always	No			
I3	clock_3	0	Pulse in capture	No			

The following explains the columns in the report:

- Name — Lists the name of the clock defined with the -pseudo_port_name switch or by default.
- Label — Lists the label name specified with the -label switch or assigned by default.
- Off State — Lists the off state of the clock as defined by the add_clocks command.
- Constraints — Lists the special constraint of the clock specified with the add_clocks command:
 - Pulse always — The clock is defined with the -pulse_always switch.
 - Asynchronous — The clock is defined with the -period switch.
 - Pulse in capture — The clock is defined with the -pulse_in_capture switch.
- Internal — Indicates whether the clock is defined on an internal pin.
- Period — Lists the clock period defined with the -period switch.
- Other Properties — Lists any additional properties of the clock.
- Pin(s) — Lists one or more internal pins that are connected to the clock.

Example 4

The following example reports only SDC clocks:

> report_clocks -sdc

SDC-defined Clocks (3) :					
Type	Add_clocks	Create_clock	Divide_by	Name	Nodes
Source	X	X		clk1x /clk1 (1)	
Generated			2	clk2x /CG/occicg_clk2x_top_inst/gclk (26)	
Generated			4	clk4x /CG/occicg_clk4x_top_inst/gclk (36)	

The report groups the generated clocks under the source clock from which they're derived. The following explains the columns in the report:

- Type— Lists the type of SDC clock, which is either a Source clock (from SDC `create_clock` command) or a Generated clock (from the SDC command `create_generated_clock`).
- Add_clocks — Indicates if the clock is also defined with the `add_clocks` command.
- Create_clock — Indicates when a source clock is defined using SDC `create_clock` command.
- Divide_by — Lists the `divide_by` ratio of the clock (from the SDC command “`create_generated_clock -divide_by`”).
- Name — Lists the name of the clock.
- Nodes — Lists the target nodes of the clock.

Example 6

The following example adds two internal clocks and then shows the output of the `report_clocks` command:

```
SETUP> add_clocks 0 clk1_inst/Y clk2_inst/Y clk3_inst/Y -pseudo_port_name clock_1x_int
SETUP> add_clocks 0 clk4_inst/Y clk5_inst/Y clk6_inst/Y -pseudo_port_name clock_2x_int
SETUP> report_clocks

User-defined Clocks (2):
-----
Name      Off State Constraints Internal Other Properties   Pin(s)
-----
'clk4_inst'  0       Yes           Merged internal pi  clk4_inst/Y
                                         clk5_inst/Y
                                         clk6_inst/Y
'clk5_inst'  0       Yes           Merged internal pin clk1_inst/Y
                                         clk2_inst/Y
                                         clk3_inst/Y
```

Example 7

The following example adds and then reports a clock branch:

```
SETUP> add_clocks u4/u5/u2/CLK -branch -label branch_2
SETUP> report_clocks

User-defined Clock (1):
Branch Clock
=====
Off State  Pin(s)      Label
-----
-          u4/u5/u2/CLK branch_2
```

Example 8

The following example uses the [set_clock_options](#) command to specify a TCK MUX insertion point using the -dft_inject_node switch, introspects the status, and reports the clocks:

```
SETUP> add_clocks 0 clk
SETUP> set_clock_options clk2 -dft_inject_node udff15/CLK
SETUP> set_clock_options clk3 -dft_inject_node udff20/CLK
SETUP> puts [get_name_list [get_clock_option clk2 -dft_inject_node]] udff15/CLK
SETUP> puts [get_name_list [get_clock_option clk3 -dft_inject_node]] udff20/CLK
SETUP> report_clocks

User-defined Clocks (3) :
=====
Sync and Async Source Clocks
=====
-----
Name      Off State   Constraints     Internal    Period      DFT Inject Node
-----
'clk'      0           Asynchronous   No          10.00ns    'clk'
'clk2'     -           Asynchronous   No          10.00ns    'dff15/CLK'
'clk3'     -           Asynchronous   No          10.00ns    'dff20/CLK'
```

report_compactor_connections

Context: dft -edt, patterns -scan (EDT On), patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup, analysis

Displays defined scan chain connections for each EDT scan channel output.

Usage

```
report_compactor_connections [-All_blocks | {-CHANnel channel_number} |  
{-CHAIn chain_name} ] [{>|>>} file_pathname]
```

Description

Displays defined scan chain connections for each EDT scan channel output. If issued from Setup mode, the report_compactor_connections command lists scan chain connections for EDT scan channel outputs previously defined using the [set_compactor_connections](#) command.

If issued from analysis mode, all compactor connections are reported, whether defined by Tesson TestKompress or with the set_compactor_connections command.

You can display the chain connection information for all scan channel outputs, or optionally include the -Channel or -Chain switch to display the information only for a particular scan chain or channel.

The -All_blocks switch is only for the top-level Pattern Generation Phase of modular Tesson TestKompress, where the netlist read in includes multiple EDT blocks. In this case, the command by default reports the chain connection information as described above, but only for the EDT block you have specified as the current EDT block. If you include the -All_blocks switch, the command displays information for all the EDT scan channel outputs in every EDT block. You set the current EDT block using either the [add_edt_blocks](#) or [set_current_edt_block](#) command. “EDT block” is the term used for a decompressor/compactor pair and the scan chains it controls/observes. For more information, refer to the “[Modular Compressed ATPG](#)” chapter of the *Tesson TestKompress User’s Manual*.

Arguments

- -All_blocks

Note

 This switch is only for the top-level Pattern Generation Phase of modular Tesson TestKompress, where the netlist read in includes multiple EDT blocks. If you are using a standard (non-modular) Tesson TestKompress flow, you do not need this switch.

An optional switch that specifies to display all chain connection information for all EDT blocks. Without this switch, the tool displays the information for only the current EDT block, if it is defined. If a current EDT block is not defined, the tool displays the information for all EDT blocks.

- **-CHANnel *channel_number***
An optional switch and positive integer pair that specify to display the scan chain connections for only the scan channel identified by *channel_number*.
- **-CHAIn *chain_name***
An optional switch and string pair that specify to display the scan chain connections for only the scan channel whose compactor group includes *chain_name*. Use this switch to see which scan channel is associated with a particular chain.
- **> *file_pathname***
An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file_pathname*.
- **>> *file_pathname***
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

Example 1

Assume a design has eight scan chains named “chain1” through “chain8”, whose outputs currently have user-specified connections through the compactor to two EDT scan channels. These user-defined connections are the result of previous `set_compactor_connections` commands.

The following example displays the compactor connection information for the chain3 scan chain. You can see from the report that chain3 is part of a compactor group that also includes chain4 and chain5; also that the outputs of these three chains are currently specified to be compacted into the output of scan channel number 2.

```
report_compactor_connections -chain chain3
```

```
//Reporting user-defined compactor connections:  
//  
//      Channel      Chains  
//      -----      -----  
//          2      chain3 - chain5  
//
```

Example 2

The following example looks up the connection information for scan channel number 1.

```
report_compactor_connections -channel 1
```

```
//Reporting user-defined compactor connections:  
//  
//      Channel      Chains  
//      -----      -----  
//          1      chain1, chain2, chain6, chain7, chain8  
//
```

[set_compactor_connections](#)

report_config_data

Context: unspecified, all contexts

Mode: all modes

Reports the content of configuration wrappers in the transcript as it appears inside the file when the configuration data is written to a file using the write_config_data command.

Usage

```
report_config_data [config_object] [-in_wrapper wrapper_object_spec]  
    [-partition partition] [-show_unspecified]  
    [-levels integer / all] [-indent integer]  
    [-left_indent left_indent]
```

Description

Reports the contents of configuration wrappers in the transcript as it appears inside the file when the configuration data is written to a file using the [write_config_data](#) command.

Like all report commands, you can use the greater than symbol “>” to redirect the output into a file.

Arguments

- ***config_object***

A required value that specifies the name of a configuration element or a collection containing one configuration element. When config_object is a collection, the -in_wrapper and -partition options cannot be used because the object contains all of the information about the configuration element. In order to use the -in_wrapper option, the config_object value must be a name and the name must be relative to the specified wrapper element. You can use a positional id for any level of hierarchy. You can also replace the id of a leaf name by the position. For example, the path “tmp(1)/<0>/wrp<1>” means “tmp(1)/wrp(abc)/wrp(def)” if “wrp(abc)” is the first element found inside “tmp(1)” and “wrp(def)” is the second instance of a wrapper with a base name of “wrp” inside “tmp(1)/wrp(abc)”.

- **-in_wrapper *wrapper_object_spec***

An optional switch and value pair that specifies the parent wrapper in which the configuration element exists. The wrapper_object_spec value is the name of a wrapper or a collection containing a wrapper element. The names in config_object are relative to the specified parent wrapper.

- **-partition *partition***

An optional switch and value pair that specifies the parent wrapper in which the configuration element exists. When the option is unspecified, the default partition is used which is where all specifications ([DftSpecification](#) and [DefaultsSpecification](#)/[DftSpecification](#)) are located. You can access the Core wrappers comprising the Tesson Core Description syntax in the tcd partition. Using the partition names meta: and meta:tcd

allows you to access the metadata configuration elements that define the default and tcd partitions. [Table 5-7](#) summarizes the available partition names.

Table 5-7. Available Partition for Introspection

Partition name	Configuration data contained
	When the -partition option is unspecified, the Default partition is accessed which is where the DftSpecification and DefaultsSpecification/DftSpecification configuration data is located.
tcd	When the -partition option is specified with the tcd value, the Core wrappers comprising the Tesson Core Description syntax is accessed
meta	When the -partition option is specified with the meta value, the metadata configuration data defining the allowed syntax of the DftSpecification and DefaultsSpecification/DftSpecification is accessed.
meta:tcd	When the -partition option is specified with the meta:tcd value, the metadata configuration data defining the allowed syntax of the Core wrappers is accessed.

- `-show_unspecified`

An optional Boolean switch that specifies to include all properties and wrappers of type Repeatable:single, as described in the documentation for the [Wrapper](#) command, in the reported data as opposed to only those that are currently specified. The unspecified properties are shown with their default values.

- `-levels integer / all`

A property that specifies the number of sub-wrapper levels to display. By default, the “all” value is used which specifies to display the full content of all sub-wrappers. When an integer N value is specified, the contents of the sub-wrapper that is N levels below the top wrapper being reported is left empty.

- `-indent left_indent`

An optional switch and integer pair that specifies the indentation to use for the inner wrappers. When this switch is not specified, each inner wrapper is indented two white spaces relative to their parent wrapper. This switch enables you to control the number of white spaces used when indenting a lower wrapper relative to its parent wrapper.

- `-left_indent left_indent`

An optional switch and integer pair that specifies to add a number of white spaces in front of every row in the report. By default, the outer wrapper of the report has zero white spaces and each subsequent inner wrapper adds two white spaces. When `-left_indent` is specified, the outer wrapper has N number of white spaces, as specified by `left_indent`, and each inner wrapper adds two white spaces on top of N. This is useful when you want to report the

contents of a wrapper and insert it inside a “read_config_data -from_string” command as shown in [Example 3](#).

Examples

Example 1

The following example creates some configuration elements and then reports them. The last command uses the “> myfile” to output the reported data into a file called *myfile*.

```
add_config_element tmp(1)
{/tmp(1)}

add_config_element tmp(1)/p1 -value v1 -type property
{/tmp(1)/p1}

add_config_element tmp(1)/p2 -value v2 -type property
{/tmp(1)/p2}

add_config_element tmp(1)/w1 -type wrapper
{/tmp(1)/w1}

add_config_element tmp(1)/w1/P1 -value v1 -type property
{/tmp(1)/w1/P1}

add_config_element tmp(1)/w1/P2 -value v2 -type property
{/tmp(1)/w1/P2}

add_config_element tmp(1)/w2 -copy_from tmp(1)/w1
{/tmp(1)/w2}

report_config_data

tmp(1) {
    p1 : v1;
    p2 : v2;
    w1 {
        P1 : v1;
        P2 : v2;
    }
    w2 {
        P1 : v1;
        P2 : v2;
    }
}
```

report_config_data tmp(1) -level 1

```
tmp(1) {
    p1 : v1;
    p2 : v2;
    w1 {
        // Not shown
    }
    w2 {
        // Not shown
    }
}
```

report_config_data tmp(1) -level 1 > myfile

Example 2

This example shows how config data is reported when it is of type CSV. The `read_config_data` command is used to parse a CSV file generated from Excel. Notice how the format of the data is changed when only reporting the content of the CSV wrapper as opposed to the CSV Wrapper itself. The same feature exists in the `write_config_data` command such that you can export CSV data back into a spreadsheet application.

add_config_element csv(1)

CDV(1)

read_config_data mydata.csv -in csv(1)

report_config_data

```
csv(1) {
    "", "", "", "", "";
    a, b, c;
    "a,c", d;
    "", "", "";
}
```

report_config_data csv(1)

```
'''
a,b,c
"a,c",d
'''
```

Example 3

The following example uses the `-left_indent` switch to report the content of a wrapper and insert it inside a “`read_config_data -from_string`” command. Notice in the second invocation of the `report_config_syntax` command how the `HostScanInterface(ijtag)` wrapper is pushed to the right two white spaces because the command included the `-left_indent` option.

```
ANALYSIS> report_config_data \
    DftSpecification(blockA,rtl)/IjtagNetwork/HostScanInterface(ijtag)
```

```

HostScanInterface(ijtag) {
    Sib(sti) {
        Attributes {
            tesson_dft_function : scan_tested_instrument_host;
        }
        Sib(mbist) {
        }
    }
}

ANALYSIS> report_config_data \
DftSpecification(blockA,rtl)/IjtagNetwork/HostScanInterface(ijtag) \
-left_indent 2

HostScanInterface(ijtag) {
    Sib(sti) {
        Attributes {
            tesson_dft_function : scan_tested_instrument_host;
        }
        Sib(mbist) {
        }
    }
}

```

You can then easily add the content of the reported config data into the “read_config_file -from_string” wrapper to have it automatically added.

```

ANALYSIS> read_config_file \
-in DftSpecification(blockA,rtl)/IjtagNetwork/HostScanInterface(ijtag) \
-from_string

HostScanInterface(ijtag) {
    Sib(sti) {
        Attributes {
            tesson_dft_function : scan_tested_instrument_host;
        }
        Sib(mbist) {
        }
    }
}

```

[report_config_syntax](#)
[write_config_data](#)

report_config_messages

Context: all contexts

Mode: all modes

Reports messages associated to a configuration element. When the -hierarchical option is used, it also reports the messages associated to elements below the specified wrapper.

Usage

```
report_config_message config_object
    [-hierarchical]
    [-all | [-error] [-warning] [-info]]
```

Description

Reports messages associated to a configuration element. When the -hierarchical option is used, it also reports the messages associated to elements below the specified wrapper.

Arguments

- ***config_object***

A required value that specifies the name of a configuration element or a collection containing one configuration element.

- **-hierarchical**

An optional switch that can only be used when the config_object_spec is a wrapper and specifies that the command should also return elements below the specified wrapper having at least one config message of the specified types.

- **-all**

An optional Boolean option that specifies that all message types are to be returned. The use of the -all option is mutually exclusive to the specification of the -error, -warning, and -info options. When none of the four options is specified, -all is assumed.

- **-error**

An optional Boolean option that specifies that the messages to be returned are of type error. The use of the -error option is mutually exclusive to the specification of the -all, -warning, and -info options. When none of the -error, -warning, and -info options is specified, -all is assumed.

- **-warning**

An optional Boolean option that specifies that the messages to be returned are of type warning. The use of the -error option is mutually exclusive to the specification of the -all, -warning, and -info options. When none of the -error, -warning, or -info options are specified, -all is assumed.

- -info

An optional Boolean option that specifies that the messages to be returned are of type info. The use of the -error option is mutually exclusive with the specification of the -all, -warning, and -info options. When none of the -error, -warning, or -info options are specified, -all is assumed.

Examples

The following example adds configuration messages of type error, warning and info on some elements and reports them.

```
add_config_element tmp(1)
{/tmp(1)}

add_config_element tmp(1)/p1 -value v1 -type property
{/tmp(1)/p1}

add_config_element tmp(1)/p2 -value v2 -type property
{/tmp(1)/p2}

add_config_element tmp(1)/w1 -type wrapper
{/tmp(1)/w1}

add_config_element tmp(1)/w1/P1 -value v1 -type property
{/tmp(1)/w1/P1}

add_config_element tmp(1)/w1/P2 -value v2 -type property
{/tmp(1)/w1/P2}

add_config_element tmp(1)/w2 -copy_from tmp(1)/w1
{/tmp(1)/w2}

add_config_message "Message1" -config_object tmp(1)/w1 -error
{/tmp(1)/w1}

add_config_message "Message2" -config_object tmp(1)/w1/P2 -info
{/tmp(1)/w1/P2}

add_config_message "Message3" -config_object tmp(1)/w1/P2 -warning
{/tmp(1)/w1/P2}

report_conf_message tmp(1)/w1
Report for errors, warnings, infos
/tmp(1)/w1
E0) Message1
```

report_conf_message tmp(1)/w1 -hierarchical

```
Report for errors, warnings, infos
/tmp(1)/w1
  E0) Message1
  /tmp(1)/w1/P2
    W0) Message3
    I0) Message2
```

Related Topics

[add_config_message](#)

report_config_syntax

Context: unspecified, all contexts

Mode: all modes

Reports the legal configuration syntax for a specified configuration object.

Usage

```
report_config_syntax config_or_meta_object_spec
    [-properties_only | -wrappers_only]
    [-levels integer]
```

Description

Reports the legal configuration syntax found below the specified config_or_meta_object_spec element.

If you refer to the meta path, you only need to specify the wrapper and property names such as DftSpecification/IjtagNetwork even though the real path name is Wrapper(DftSpecification)/Wrapper(IjtagNetwork). If you have a configuration element such as DftSpecification(corea,rtl)/IjtagNetwork, you can use it too and it will look up the metadata of the element and report its syntax.

Three options limit the amount of syntax displayed to only wrapper, only properties, or to a specified sub-level count.

Arguments

- **config_or_meta_object_spec**

A required string that specifies the configuration wrapper for which you want to see the available syntax. If you refer to the meta path, you only need to specify the wrapper and property names such as “DftSpecification/IjtagNetwork” even though the real meta path name is “Wrapper(DftSpecification)/Wrapper(IjtagNetwork)”. If you have a configuration element such as DftSpecification(corea,rtl)/IjtagNetwork, you can use it too and it will look up the metadata of the element and report its syntax.

- -properties_only

An optional Boolean option that restricts the command to only show the properties at the top level of the specified wrapper.

- -wrappers_only

An optional Boolean option that restricts the command to only show the wrappers and exclude the properties.

- -level *integer*

An optional value pair that specifies the number of sub-wrappers to show. When unspecified, all sub-levels are shown.

Examples

Example 1

The following example uses the report_config_syntax command to show the available syntax, limited to two levels, currently available in the DftSpecification wrapper.

```
set_context dft -rtl
report_config_syntax DftSpecification -level 2

DftSpecification(<module_name>,<id>) {
    rtl_extension           : <string> ; // default: v
    gate_extension          : <string> ; // default: vg
    reuse_modules_when_possible : <boolean> ; // default: auto
    IJtagNetwork {
        DataInPorts {
        }
        DataOutPorts {
        }
        HostScanInterface(<id>) {
        }
    }
}
```

Example 2

The second example shows the entire syntax available in the Tdr wrapper.

```
report_config_syntax \
DftSpecification/IJtagNetwork/HostScanInterface/Tdr
```

```
DftSpecification(<module_name>,<id>) {
    IjtagNetwork {
        HostScanInterface(<id>) {
            Tdr(<id>) {
                Interface {
                    tck          : <port_name>           ; // default: ijtag_tck
                    reset       : <port_name>           ; // default: ijtag_reset
                    select      : <port_name>           ; // default: ijtag_sel

report_context

Context: unspecified, all contexts

Mode: all modes

Reports the current context as specified by the set_context command and any inferred subcontexts.

Usage

```
report_context
```

Description

Reports the current context as specified by the set_context command and any inferred subcontexts.

This command also provides information about inferred sub-contexts as shown in the examples below.

Arguments

None

Return Values

None

Examples

Example 1

In the following example, the command reports that it ran in uncompressed ATPG mode.

```
report_context
// Context: patterns -scan -no_rtl
// Uncompressed ATPG (no EDT) mode active.
```

Example 2

In the following example, the command reports that it is in extraction mode.

```
report_context
// Context: patterns -ijtag -no_rtl
// ICL extraction mode active.
```

Example 3

In the following example, the command reports that it is in compressed ATPG mode.

```
report_context
// Context: patterns -scan -no_rtl
// Compressed ATPG (EDT) mode active.
```

Example 4

In the following example, the command reports that it is in Logic BIST mode.

```
report_context
// Context: patterns -scan -no_rtl
// Logic BIST mode active.
```

Related Topics

[set_context](#)

report_control_signals

Context: dft -scan

Mode: analysis

Displays the rules checking results for control signals consisting of clocks added with the `add_clocks` command and pins identified for gating scannable memory elements with test logic.

Usage

```
report_control_signals {[-All] | {[pin_pathname...]} [-Clock] [-Set] [-Reset] [-Write] [-Read]  
[-Tristate_enable]} [-Verbose] [-NOSTABLE_High] [-NOSTABLE_Low]
```

Description

Displays the rules checking results for control signals consisting of clocks added with the `add_clocks` command and pins identified for gating scannable memory elements with test logic.

Arguments

- **-All**
An optional switch that outputs all control signals to the report. Default setting.
- ***pin_pathname***
An optional, repeatable string that specifies the pathnames of control signals to report on.
- **-Clock**
An optional switch that outputs clock control signals in the report.
- **-Set**
An optional switch that reports on all set control signals.
- **-Reset**
An optional switch that reports on all reset control signals.
- **-Write**
An optional switch that reports on all write control signals.
- **-Read**
An optional switch that reports on all read control signals.
- **-Tristate_enable**
An optional switch that reports on all tristate enable signals.
- **-Verbose**
An optional switch that includes all memory elements associated with each control signal in the report.
- **-NOSTABLE_High**
An optional switch that disables the report on any stable-high memory elements.

- -NOSTABLE_Low

An optional switch that disables the report on any stable-low memory elements.

report_core_descriptions

Context: all contexts
Mode: all modes
Reports all core description files.

Usage

```
report_core_descriptions [-all]
```

Description

Reports all core description files.

The tool uses the information in this file to retarget patterns for instances of the associated core. Since it is useful have know the *design_id* for cores, the report includes the *design_id* value taken from memory or the TSDB container. The core description report is sorted by core name, then the *design_id* value and finally by mode name.

The *design_id* for TCD instruments are not stored in memory, but is included in the instrument's name.

Arguments

- **-all**
An optional literal that reports the core descriptions in the open [Tessent Shell Data Base \(TSDB\)](#) as well as the core descriptions in memory.

Examples

The following example shows the output of the report_core_descriptions command in two modes:

Example 1

This command in setup mode:

```
report_core_descriptions
Name          Mode Name      Type
-----        -----
* chip        retargeting   retargeting
Note: * denotes current design
```

Example 2

This command in analysis mode:

```
report_core_descriptions
```

Command Dictionary (R) report_core_descriptions

Name	Mode Name	Type	Instantiations	Chain Patterns	Scan Patterns
* chip	retargeting	retargeting		8	117
piccpu_maxlen16	internal	internal	1		

Note: * denotes current design

Example 3

In this example, there are two cores inside the opened TSDBs: coreA and coreB. Every core has multiple views specified with mode and design_id values. The report sorts the cores by core name, then by *design_id* value, and finally by the mode name.

Name	Design ID	Mode Name	Type	In Memory	TCD File
* top		unwrapped	unwrapped	Yes	
coreA	id1	m1	internal	No	tsdbA/logic_test_cores/coreA_id1.logic_test_core/coreA_atpg_mode_m1/coreA_m1.tcd.gz
	id1	m2	internal	No	tsdbA/logic_test_cores/coreA_id1.logic_test_core/coreA_atpg_mode_m2/coreA_m2.tcd.gz
	id1	m3	external	No	tsdbA/logic_test_cores/coreA_id1.logic_test_core/coreA_atpg_mode_m3/coreA_m3.tcd.gz
	id2	m1	internal	No	tsdbA/logic_test_cores/coreA_id2.logic_test_core/coreA_atpg_mode_m1/coreA_m1.tcd.gz
	id2	m2	internal	No	tsdbA/logic_test_cores/coreA_id2.logic_test_core/coreA_atpg_mode_m2/coreA_m2.tcd.gz
	id2	m3	external	No	tsdbA/logic_test_cores/coreA_id2.logic_test_core/coreA_atpg_mode_m3/coreA_m3.tcd.gz
coreA_id1_tessent_edt_blk1		edt	No		tsdbA/instruments/coreA_id1_edt.instrument/coreA_id1_tessent_edt_blk1.tcd
coreA_id1_tessent_edt_blk2		edt	No		tsdbA/instruments/coreA_id1_edt.instrument/coreA_id1_tessent_edt_blk2.tcd
coreB	rt11	bcd	internal	No	tsdbB/logic_test_cores/coreB_rt11.logic_test_core/coreB_atpg_mode_bcd/coreB_bcd.tcd.gz
	rt12	bcd	internal	No	tsdbB/logic_test_cores/coreB_rt12.logic_test_core/coreB_atpg_mode_bcd/coreB_bcd.tcd.gz
coreB_id2_tessent_edt		edt	No		tsdbB/instruments/coreB_id2_edt.instrument/coreB_id2_tessent_edt.tcd

Note: * denotes current design

Example 4

In this example, a number of TCDs have been loaded into memory for coreA and coreB. Every mode has an associated *design_id* value.

report_core_descriptions

Name	Design ID	Mode Name	Type
* top		unwrapped	unwrapped
coreA	id1	m1	internal
	id1	m2	internal
	id2	m3	external
coreA_id1_tessent_edt_blk1		edt	
coreA_id2_tessent_edt_blk1		edt	
coreB	rt12	bcd	internal
coreB_id2_tessent_edt		edt	

Note: * denotes current design

report_core_instance_parameters

Context: patterns -scan, patterns -scan_retargeting, patterns -failure_mapping

Mode: all modes

Reports the instrument configuration parameters and their values that were specified when the core instance was added with the add_core_instances commands -parameter_values switch.

Usage

```
report_core_instance_parameters {-cores core_names | -modules module_objects |  
-instances instance_objects} [-silent]
```

Description

Reports the EDT instrument configuration parameters and their values that were specified when the core instance was added with the add_core_instances commands -parameter_values switch. By default, the command reports all parameters when you have no filters defined.

Arguments

- **-cores *core_names***

A required switch and Tcl list that specify the core names of the core descriptions from which all instrument configuration parameters should be reported.

- **-modules *module_objects***

A required switch and string pair that specify a Tcl list of one or more object names (hierarchical names), or a collection of one or more objects. This command reports the instance instrument configuration parameters for each instantiation of those modules in the design.

- **-instances *instance_objects***

A required switch and string pair that specify a Tcl list of one or more object names (hierarchical names), or a collection of one or more objects. This command reports the instance EDT instrument configuration parameters for each instance in the list.

- **-silent**

An optional switch that specifies to suppress warning messages.

Examples

```
SETUP> report_core_instance_parameters -core  
{m8051_edt m8051_G_tessent_occ_NX1 m8051_G_tessent_occ_NX2}
```

Core instance 'm8051_edt_i' (core 'm8051_edt', instrument type 'edt')

Parameter Name	Parameter Value	Legal Override Values	Read Only
edt_bypass	off	off, on	
edt_single_bypass_chain	off	off, on	
tessent_chain_masking			Yes
tessent_chain_masking	off	off, on	

Related Topics

[add_core_instances](#)

[set_core_instance_parameters](#)

report_core_instances

Context: patterns -scan, patterns -scan_retargeting, patterns -failure_mapping

Mode: setup, analysis

Reports the instance bindings created with the add_core_instances command, as well as the pattern count for patterns read in for each core.

Usage

```
report_core_instances [-cores core_names | -modules module_objects |  
-instances instance_objects] [-silent]
```

Description

Reports the instance bindings created with the [add_core_instances](#) command, as well as the pattern count for patterns read in for each core. If this command is invoked in analysis mode, the pattern count for each core is also reported.

You can specify the absolute instance path names or the module or core names. You can either report all core instances that have been added (the default), or filter by modules, instances, or core names.

This command also reports the *design_id* values if they are available. TCD files incoming from TSDBs that have logic_test_core containers created with an empty *design_id* will be reported with an empty value. Since it is useful to know the *design_id* for cores, the report includes the *design_id* value taken from memory or the TSDB container. The core description report is sorted by core name, then the *design_id* value and finally by mode name.

Arguments

- **-cores *core_names***

A switch and Tcl list that specifies the core names of the core descriptions from which all instance bindings should be reported.

- **-modules *module_objects***

An optional switch and string pair that specifies a Tcl list of one or more object names (hierarchical names), or a collection of one or more objects. This command reports the instance bindings for each instantiation of those modules in the design.

- **-instances *instance_objects***

An optional switch and string pair that specifies a Tcl list of one or more object names (hierarchical names), or a collection of one or more objects. This command reports the instance bindings for each instance in the list.

- **-silent**

An optional switch that specifies to suppress warning messages.

Examples

Example 1

The following example reports all existing core instances while in setup mode.

report_core_instances

Instance	Core	Mode Name	Type	Module
core_1	my_core_1	internal	internal	my_module_1
core_2	my_core_2	internal	internal	my_module_2
core_3	my_core_3	internal	internal	my_module_3

Example 2

The following example reports all existing core instances while in analysis mode.

report_core_instances

Instance	Core	Mode Name	Type	Module	Chain Patterns	Scan Patterns
core_1	my_core_1	internal	internal	my_module_1	12	10
core_2	my_core_2	internal	internal	my_module_2	12	10
core_3	my_core_3	internal	internal	my_module_3	6	74

Example 3

The following example first reports all core instances for modules my_module_1 and my_module_2 while in setup mode; it then reports the same while in analysis mode.

report_core_instances -modules {my_module_1 my_module_2}

Instance	Core	Mode Name	Type	Module
core_1	my_core_1	internal	internal	my_module_1
core_2	my_core_2	internal	internal	my_module_2

set_system_mode analysis

...

report_core_instances -modules {my_module_1 my_module_2}

Instance	Core	Mode Name	Type	Module	Chain Patterns	Scan Patterns
core_1	my_core_1	internal	internal	my_module_1	12	10
core_2	my_core_2	internal	internal	my_module_2	12	10

Example 4

The following example reports all EDT IP instances:

report_core_instances

Instance	Core	Type	Module
blk1_edt_i	blk1_edt	edt	blk1_edt
blk2_edt_i	blk2_edt	edt	blk2_edt
blk3_edt_i	blk3_edt	edt	blk3_edt
blk4_edt_i	blk4_edt	edt	blk4_edt

Example 4

The following example first reports core instances core_1 and core_3 while in setup mode; it then reports the same while in analysis mode.

```
report_core_instances -instances {core_1 core_3}
```

Instance	Core	Mode	Name	Type	Module
core_1	my_core_1	internal	internal	internal	my_module_1
core_3	my_core_3	internal	internal	internal	my_module_3

```
set_system_mode analysis
```

```
...
```

```
report_core_instances -instances {core_1 core_3}
```

Instance	Core	Mode	Name	Type	Module	Chain Patterns	Scan Patterns
core_1	my_core_1	internal	internal	internal	my_module_1	12	10
core_3	my_core_3	internal	internal	internal	my_module_3	6	74

Example 5

In this example, the tool reports the core instances with the *design_id* values.

```
SETUP> report_core_instances
Instance          Core           Design ID Mode Name Type   Module
-----          -----
'coreA_inst1'    coreA          id1      m1    internal 'coreA'
|_ 'coreA_inst1/coreA_id1_tessent_edt_blk1_i' coreA_id1_tessent_edt_blk1
|_ 'coreA_inst1/coreA_id1_tessent_edt_blk2_i' coreA_id1_tessent_edt_blk2
'coreA_inst2'    coreA          id1      m1    internal 'coreA'
|_ 'coreA_inst2/coreA_id1_tessent_edt_blk1_i' coreA_id1_tessent_edt_blk1
|_ 'coreA_inst2/coreA_id1_tessent_edt_blk2_i' coreA_id1_tessent_edt_blk2
'coreB_inst1'    coreB          rtl2     bcd   internal 'coreB'
|_ 'coreB_inst1/coreB_id2_tessent_edt_i'       coreB_id2_tessent_edt
```

report_core_parameters

Context: patterns -scan, patterns -scan_retargeting, patterns -failure_mapping

Mode: all modes

Reports all core parameters and their values.

Usage

```
report_core_parameters {-cores core_names | -modules module_objects |  
-instances instance_objects} [-silent]
```

Description

Reports all core parameters and their values. By default, the command reports all parameters when you have no filters defined.

Arguments

- **-cores *core_names***

A required switch and Tcl list that reports core parameters for the specified *core_names*.

- **-modules *module_objects***

A required switch and string pair that reports core parameters for the specified *module_objects*, which is a Tcl list of one or more object names (hierarchical names), or a collection of one or more objects.

- **-instances *instance_objects***

A required switch and string pair that reports core parameters for the specified *instance_objects*, which is a Tcl list of one or more object names (hierarchical names), or a collection of one or more objects.

- **-silent**

An optional switch that specifies to suppress warning messages.

Examples

```
SETUP> rep_core_param -cores piccpu_maxlen16_1_edt  
Core 'piccpu_maxlen16_1_edt' (instrument type 'edt')  
-----  
Parameter Name          Default Value  Legal Values  
-----  
edt_bypass              off           off, on  
edt_configuration        high, low  
edt_low_power_shift_en   on            off, on  
used_input_channels      4             2..4
```

report_design_sources

Context: all contexts

Mode: all modes

Reports the pathnames or file extensions previously specified with the set_design_sources command.

Usage

```
report_design_sources
```

Description

Reports the pathnames or file extensions previously specified with the set_design_sources command.

Arguments

None.

Examples

Example 1

The following example shows a report generated by this command:

```
set_design_sources -format icl -y ..\data\icl_primitives -extension icl
set_design_sources -y ..\data\verilog_primitives -extension v
report_design_sources

// ICL search_design_load_path: activated
// -----
// format      type    path                                file extensions
// -----      ----
// Verilog     dir     '..\data\verilog_primitives'   'v v.gz'
// ICL         dir     '..\data\icl_primitives'       'icl icl.gz'
```

Example 2

The following example reports information about all formats:

```
SETUP> set_design_sources -format tcd_scan -y ..\data -extension tcd_scan
SETUP> report_design_sources
```

```
// Search design load path settings
// =====
// format          value
// -----  -----
// icl            on
// tcd_bscan      on
// tcd_scan       on

report_dfm_rules

Context: patterns -scan_diagnosis

Mode: analysis

Returns a tabular report of the DFM rules contained in the layout database.

Usage

```
report_dfm_rules [-header | -col columns...]
```

Description

Returns a tabular report of the DFM rules contained in the layout database.

By default, all columns are listed. These are: id, rule, layer, and type.

For more information about DFM rules, see “[Diagnosis for Design for Manufacturability Analysis](#).”

Arguments

- **-header**
An optional switch that returns a list of available column names.
- **-col *columns...***
An optional switch that specifies the column names you want to use for the DFM rule information in the report.

Examples

Example1

The following example creates a report that contains all available columns.

```
report_dfm_rules
```

id	rule	layer	type
1	minimum_space_4_line_route1	route_1	BRIDGE
2	metal_cross_edge_route1	route_1	OPEN
3	low_density_min_space_route2	route_2	BRIDGE
4	half_comb_route3	route_2	OPEN
5	metal_cross_edge_route1	route_3	OPEN
6	corner_to_interior_metal4	route_4	BRIDGE
7	divergent_line_with_jog_metal5	route_5	BRIDGE
8	metal_cross_edge_route1	route_5	OPEN
9	route_5_barbell	route_5	OPEN
10	route_2_between_vias	route_2	OPEN

Example 2

The following example creates a report that contains the rule name and the type.

report_dfm_rules -col rule type

rule	type
minimum_space_4_line_route1	BRIDGE
metal_cross_edge_route1	OPEN
low_density_min_space_route2	BRIDGE
half_comb_route3	OPEN
metal_cross_edge_route1	OPEN
corner_to_interior_metal4	BRIDGE
divergent_line_with_jog_metals5	BRIDGE
metal_cross_edge_route1	OPEN
route_5_barbell	OPEN
route_2_between_vias	OPEN

Prerequisites: The current design must be set with the `set_current_design` command.

Reports the currently defined DFT clock enables.

Usage

```
report_dft_clock_enables [-post_drc] [-usage func_en | test_en]
```

Description

Reports the currently defined DFT clock enables.

A DFT clock enable signal is either automatically learned on the ports of clock gating cells, or is specified using the `add_dft_clock_enable` command on a pin or port of the design.

The `-post_drc` switch can be specified in analysis mode, when the `-usage` switch defaults to or is specified as “`func_en`”, to report the `func_en` pin that will be intercepted to enable the clock gaters that are in the fanin of the memory clocks during memory BIST testing.

Arguments

- `-usage func_en | test_en`

An optional switch and value pair that specifies the usage of the clock enable pins and ports to report. When you specify the “`func_en`” value, the report includes the ports on clock gating cells that have the *function* attribute set to “`func_enable`”. The report also includes the ports or pins defined with the `add_dft_clock_enables` -usage `func_en` option. When you specify the “`test_en`” value, the report includes the ports on clock gating cells that have the *function* attribute set to “`test_enable`”. The report also includes the ports or pins defined with the `add_dft_clock_enables` -usage `test_en` option.

- `-post_drc`

An optional Boolean switch that can be specified in analysis mode, when the `-usage` switch defaults to or is specified as “`func_en`”, to report the `func_en` pin that will be intercepted to enable the clock gaters that are in the fanin of the memory clocks during memory BIST testing. Without this switch, the command reports the clock enable ports or pins as defined or learned in the cell library or as defined by the “`add_dft_clock_enables` -usage `func_en`” command. When the `-post_drc` switch is specified, the ports are mapped to pins and only those fanning out to memory clock pins are reported.

Examples

The following example uses the `add_dft_clock_enables` command to identify the en ports of clock gating modules whose module name starts with “`my_clock_gate`”, and to define the pin on an instance as a clock enable signal with a polarity of 0. The source of the clock enable signal is a special TDR that is scan tested with the rest of the functional logic. The

[add_dft_control_points](#) command is used to control the select signal of an existing clock multiplexer; the [add_dft_clock_enable](#) command is not used to control that signal because the clock multiplexer must be controlled in scan test mode too.

The [report_dft_clock_enables](#) command is used in analysis mode with and without the [-post_drc](#) option to show the specified clock enables and those extracted during DRC. The specified clock enables can exist on pins or ports of the current design or on ports of any sub-module. During DRC, the clock enables specified on the ports of sub-modules are mapped to pins. Only the clock enable signals that affect the memory clocking are kept.

report_dft_clock_muxes

Context: dft, patterns

Mode: all modes

Prerequisites: The current design must be set with the `set_current_design` command.

Reports the currently defined DFT clock muxes that were previously added using the `add_dft_clock_muxes` command.

Usage

```
report_dft_clock_muxes
```

Description

Reports the currently defined DFT clock muxes that were previously added using the [add_dft_clock_mux](#) command.

Arguments

None

Examples

The following example adds three DFT clock muxes and then reports them.

```

add_dft_clock_muxes clkb -test_clock_source mem1/clk -dft_signal_source_name all_test
register_static_dft_signal_names pll_bypass
add_dft_clock_muxes pll1/vco -test_clock_source pll1/ref \
    -dft_signal_source_name pll_bypass
add_dft_clock_muxes pll1/ref -test_clock_source clkb -dft_signal_source_name alt_ref
report_dft_clock_muxes

// Dft clock muxes
// =====
// ----- -----
//   Node      Test clock source  Control source name
// ----- -----

report_dft_control_points

Context: dft, patterns

Mode: all modes

Prerequisites: The current design must be set with the `set_current_design` command.

Reports the currently defined DFT control points that were previously added using the `add_dft_control_points` command.

Usage

```
report_dft_control_points
```

Description

Reports the currently defined DFT control points that were previously added using the `add_dft_control_points` command.

Arguments

None

Examples

Example 1

The following example adds three DFT control points and then reports them.

```
add_dft_control_point portb -dft_signal_source_name all_test
register_static_dft_signal_names pll_bypass
add_dft_control_point pll1_mux/s -dft_signal_source_name pll_bypass
add_dft_control_point ref_mux/s -dft_signal_source_name alt_ref
report_dft_control_points

// DFT Control points
// =====
// -----
//     Node      Control source name
// -----
// 'portb'    all_test
// 'pll1_mux/s' pll_bypass
// 'ref_mux/s' alt_ref
//
```

Example 2

If you issue the `report_dft_control_points` command in analysis mode, the report shows if the added `add_dft_control_points`-type AsyncSetReset nodes are ignored or reached by the [DFT_C9](#) DRC as follows:

The report shows the following *before* analysis:

```
// '<node>'    async_set_reset    scan_en    User Added
```

The report shows the following *after* analysis:

```
// '<node>'    async_set_reset    scan_en    User Added, Ignored
```

when the node was not reached by DFT_C9.

When the node was reached by DFT_C9, then the report shows the following:

```
// '<node>'    async_set_reset    scan_en    User Added, Used by DFT_C9,  
Active High
```

-or-

```
// '<node>'    async_set_reset    scan_en    User Added, Used by DFT_C9,  
Active Low
```

The reported polarity is the polarity that activates the reset/set at the flops.

The DFT control logic uses scan_en to force the node inactive during shift mode.

report_dft_modal_connections

A command to report the cumulative effect of the previously invoked add_dft_modal_connections and delete_dft_modal_connections commands

Usage

```
report_dft_modal_connections
```

Description

This command reports the cumulative effect of the previously invoked add_dft_modal_connections and delete_dft_modal_connections commands. The report has four optional sections. If called before any DFT modal connections are specified, the command echos:

```
SETUP> report_dft_modal_connections
There are no DFT_modal connections to report
```

Once there are input and/or output DFT modal connections specified, the report includes the “Modes” section which lists all the used modes and the ports/auxiliary data pins used by each mode. It also includes the “Input connections” and/or the “Output connections” sections showing the destination/source of the port or auxiliary data pins in each mode. Finally, if the specification implies the presence of multiplexing at one or more input data destination nodes, the “Input destinations” section is added and the multiplexing at the destination nodes that include multiplexing are shown. See the example below showing the four sections in the report.

Arguments

None

Examples

The following example shows the four sections of the report representing the effect of the used add_dft_modal_connections commands.

```
set mode edt_mode
add_dft_modal_connections -ports gpio[1:0] \
    -input_data_destination_nodes * \
    -enable_dft_signal $mode -pipeline_stages 2

report_dft_signal_names

Context: unspecified, all contexts

Mode: all modes

Reports all registered DFT signal names and identifies their attributes as well as what was the source of registration.

Usage

`report_dft_signal_names`

Description

Reports all registered DFT signal names and identifies their attributes as well as what was the source of registration. The report separates the static and dynamic DFT signals into two tables. The table for the static DFT signals includes six columns that show the specific information about each signal. The table for the dynamic DFT signals includes two columns that show the specific information about each signal.

Arguments

None

Examples

The command has no arguments, and creates two tables showing the static and the dynamic DFT signals. The static DFT signals table has six columns, which makes the table wider than this page. For an example of the actual report, issue the `report_dft_signal_names` command in any context. The list of built-in DFT signals shows the complete variation of the report. The actual report generated by the command is not shown here because it is too wide to fit in this narrow page.

`report_dft_signal_names`

[report_dft_signals](#)

report_dft_signals

Context: dft, patterns

Mode: setup, analysis, insertion

Reports all the DFT signals added or to-be-created in the design.

Usage

```
report_dft_signals
```

Description

Reports all the DFT signals added or existing in the design. The report is a table with five columns.

- The first column is the name of the DFT signal.
- The second column uses either “To be created” or “Existing” based on whether the DFT signal is scheduled to be created or already exists.
- The third column reports one of these values: “User added”, “Imported from DesignInfo”, “ICL attributes”.
 - “User added” means the DFT signal exists because the [add_dft_signals](#) command was issued for the signal in the current insertion pass.
 - “Imported from DesignInfo” means the DFT signal was added on a Port or is a Dynamic DFT signal. During the insertion pass that added the signal, the information was stored in the *.tcd* file located in the [dft_inserted_designs](#) directory inside the [Tessent Shell Data Base \(TSDB\)](#) directory and was automatically re-imported when using [read_design](#) for the next insertion pass.
 - “ICL attributes” means the signal is a static DFT signal defined as an attributed DataOutPort of an ICL module.
- The forth and fifth column report the type and location, respectively.

See “[Example 2](#)” on page 217 of the [add_dft_signals](#) command description to see the attributes that define static DFT signals.

Arguments

None

Examples

The following example shows the report generated when the command is issued after certain DFT signals were defined using the [add_dft_signals](#) command, but prior to issuing the [process_dft_specification](#) command. Rerunning the [report_dft_signals](#) command after issuing the [process_dft_specification](#) command changes the status to “Existing”, and the null locations become the pin on the TDR that sources the DFT signal.

```

report_diagnosis

Context: patterns -scan_diagnosis

Mode: analysis

Writes the scan diagnosis report to standard I/O.

Usage

```
report_diagnosis [-ENCoded] [-SHORT]
```

Description

Writes the scan diagnosis report to standard I/O.

Arguments

- **-ENCoded**
An optional switch encoding the suspect's pin pathname, net name, and cell name in the diagnosis report.
- **-SHORT**
An optional switch that suppresses the display of layout-aware diagnosis information in the diagnosis report.

Related Topics

[write_diagnosis](#)

report_display_instances

Context: all contexts

Mode: setup, analysis

Shows netlist information for the specified instances displayed in the Flat Schematic, Hierarchical Schematic, or Data window.

Usage

```
report_display_instances {gate_id# | instance_name} ... | -All  
[-Display {FLAt_schematic | HIEarchical_schematic | DAta}] [-Full]
```

Description

Shows netlist information for the specified instances displayed in the Debug, Design, or Data window. The report_display_instances command reports, in the session transcript, netlist information for the specified instances currently displayed in the DFTVisualizer, Flat Schematic, Hierarchical Schematic, or Data window. The default report includes the information listed in the following table:

Table 5-8. Default Netlist Information Reported for Instances

“set_gate_level Design” in effect	“set_gate_level Primitive” in effect
Instance name	Instance name
DFT library model name	Gate identification number
	Gate type

You can display the same information from a tool’s command line using the report_gates command, whether or not DFTVisualizer is open.

Arguments

- ***gate_id#***

A repeatable integer that specifies a gate whose netlist information you are reporting. The value of the *gate_id#* argument is the unique identification number the tool automatically assigns to every gate within the design during the model flattening process.

- ***instance_name***

A repeatable string that specifies the name of an instance whose netlist information you are reporting.

- **-All**

A switch that specifies to report all instances in the current display netlist (including the compacted gates).

- -Display {FLAt_schematic | HIErarchical_schematic | Data}

A switch and literal that specify the window containing the instance(s) you are reporting. The window choices are as follows:

FLAt_schematic — Specifies the Flat Schematic window. This is the invocation default.

HIErarchical_schematic — Specifies the Hierarchical Schematic window.

Data — Specifies the Data window.

- -Full

A switch that specifies to include the following information for each pin on each reported instance:

- Pin name
- Pin type (input or output)
- Simulated pin data (if appropriate)
- Gates to which that pin connects

Examples

The following example analyzes a DRC violation (automatically invoking DFTVisualizer in the process and displaying the part of the netlist related to the violation in the Flat Schematic window):

```
set_gate_level design analyze_drcViolation c3-1
// command: open_visualizer -display flat_schematic
// Note: Gate report now set to clock_cone (clock=/tck).
// Creating Schematic for 5 instances
```

The DFTVisualizer Transcript window shows the following information for the violation:

```
===== (Violation ID = c3-1) =====
// Note: Clock /tck failed rule C3 on input 3 of /reg_enable (76). (C3-1)
// Note: Source of violation: input 3 of /reg_pstate_2_ (70).
// Note: Gate report now set to clock_cone (clock=/tck).
Creating Schematic for 5 instances
```

The next example shows the differences between the default and the detailed report for the gate where clock /tck failed the C3 DRC:

```
report_display_instances /reg_enable
// /reg_enable dffr
report_display_instances /reg_enable -full
```

```
// /reg_enable dffr
//      D      I  (E)  /ix130/Y
//      CLK    I  (C)  /ix473/Y
//      R      I  (-)  /ix475/Y
//      Q      O  (-)  /tri_pin/E
//      QB     O  (-)
```

report_drc_rules

Context: all contexts

Mode: all modes

Displays either a summary of DRC violations (fails) or violation occurrence message(s).

Usage

```
report_drc_rules [-Fails_summary | -Summary | rule_id... | rule_id-occurrence#... | -All_fails]
[ {> | >>} file.pathname ]
```

C1 Usage:

```
report_drc_rules C1 [-EXcluded]
```

D5 Usage:

```
report_drc_rules D5
[ { [-TYpe {I0 | I1 | IX | T0 | T1 | TX | TLA}...]
  [-NOType {I0 | I1 | IX | T0 | T1 | TX | TLA}...]
  [-EDge_triggered | -LEvel_sensitive] } | -Summary ]
[ {> | >>} file.pathname ]
```

E5 Usage:

```
report_drc_rules E5 [-TIMing_exceptions]
```

Description

Displays either a summary of DRC violations (fails) or violation occurrence message(s). This command can display a report in one of two formats:

- **Summary Report** — Lists for each reported design rule, one line of data per rule, the current number of DRC violations (fails), the violation handling, and a brief description of the rule. When you request a summary of D5 violations, the report lists the number of D5 violations of each type (INIT-0, INIT-1, INIT-X, TIE-0, TIE-1, TIE-X, TLA).
- **Occurrence Report** — Lists one or more violation occurrence messages that give details of specific DRC violations

Table 5-9 provides a summary of the available information displayed and the arguments you use to obtain them. Refer to the Arguments subsection for complete details about the arguments.

Table 5-9. Available Information Displayed and Arguments

Desired Display	Rules/Occurrences Covered	Argument
Summary report	Design rules that resulted in violations (fails) during DRC	-Fails_summary
	All design rules	-Summary

Table 5-9. Available Information Displayed and Arguments (cont.)

Desired Display	Rules/Occurrences Covered	Argument
Occurrence report	Specific rule, specific occurrence	<i>rule_id-occurrence#</i>
	Specific rule, all occurrences ¹	<i>rule_id</i>
	All occurrences	-All_fails

1. Additional D5-specific arguments enable you to further customize the D5 information display.

You can use the [set_drc_handling](#) command to change the handling of many of the A (RAM), C (clock), D (data), E (extra), K (EDT), T (trace), and W (timing) rules.

For more information about the design rules, refer to “[Design Rule Checking](#)” on page 2639.

Arguments

- **-Fails_Summary**

A switch that specifies to display the following for each user-controllable rule that resulted in a violation (fail) during DRC:

- Rule identification (ID)
- Number of failures of the rule
- Current handling status of the rule
- Brief description of the rule

This is the default.

Note

 This switch does not display anything if there are no rule violations or the tool has not yet performed DRC.

- **-Summary**

A switch that specifies to display a summary report that varies depending on whether you are reporting on all design rules or just on the D5 rule. (The latter reporting is available only in Tessent FastScan and Tessent TestKompress.)

When you report on all rules (report_drc_rules -Summary), the following is reported for each user-controllable rule, whether or not it resulted in a violation (fail) during DRC:

- Rule identification (ID)
- Number of failures of the rule
- Current handling status of the rule
- Brief description of the rule

When you report on just the D5 rule (report_drc_rules D5 -Summary) in Tessent FastScan or Tessent TestKompress, the tool displays the number of non-scan memory elements of each type (INIT-0, INIT-1, INIT-X, TIE-0, TIE-1, TIE-X or TLA) that resulted in a D5 violation during DRC. Refer to the description of the -Type switch for the meaning of the types. See also the “[D5](#)” section for detailed information about the D5 rule.

- *rule_id*

A repeatable string that specifies the identification literal (ID) of a particular design rule for which you want to display the violations. For information about the design rules and their ID, refer to the appropriate section:

- [RAM Rules \(A Rules\)](#)
- [BIST Rules \(B Rules\)](#)
- [Clock Rules \(C Rules\)](#)
- [Scan Cell Data Rules \(D Rules\)](#)
- [Extra Rules \(E Rules\)](#)
- [EDT Finder Rules \(F Rules\)](#)
- [Flattening Rules \(FN, FP, and FG Rules\)](#)
- [General Rules \(G Rules\)](#)
- [EDT Rules \(K Rules\)](#)
- [Procedure Rules \(P Rules\)](#)
- [Scannability Rules \(S Rules\)](#)
- [Scan Chain Trace Rules \(T Rules\)](#)
- [Power-Aware Rules \(V Rules\)](#)
- [Timing Rules \(W Rules\)](#)
- [ICL Extraction Rules \(I Rules\)](#)
- [ICL Semantic Rules \(ICL Rules\)](#)
- [Core Mapping for ATPG and Scan Pattern Retargeting Rules \(R Rules\)](#)

- *rule_id-occurrence#*

A repeatable string that specifies the identification literal (ID) of a particular design rule and the violation occurrence for which you want to display the occurrence message. This argument must include the specific design rule ID (*rule_id*), the specific occurrence number of the violation, and the hyphen between them. For example, you can analyze the second violation occurrence of the C3 rule by specifying C3-2. Numbers to occurrences of rule violations are assigned as they are encountered; you cannot change the number assigned to a specific occurrence.

- **-All_Fails**

A switch that specifies to display all occurrence messages for all occurrences of rule violations. The displayed information can be lengthy, as it is the same information you would get if you consecutively entered a “`report_drc_rules <rule_id>`” command for each rule that had a violation. Use this switch to output a report of all violation occurrences (most likely to a log file) for later analysis.

- **>file.pathname**

An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of `file.pathname`.

- **>>file.pathname**

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of `file.pathname`.

C1-Only Arguments

- **C1**

A required literal that specifies reporting C1 DRC rule violations.

- **-EXcluded**

An optional switch for use only with a C1 violation. Specifying this switch reports the C1 violations that have been excluded from the default C1 list because these C1 violations can be handled by the tool without causing potential mismatch.

D5-Only Arguments

- **-TYpe I0 | I1 |IX | T0 | T1 | TX | TLA**

An optional switch and repeatable literal that displays D5 occurrence messages for only the specified type(s) of non-scan sequential elements. The literal choices for the type of element are as follows (the term you will see in occurrence messages for each type is shown in parentheses):

I0 — If the element is at 0 at the beginning of the first capture cycle and may go to any state during capture. (INIT-0)

I1 — If the element is at 1 at the beginning of the first capture cycle and may go to any state during capture. (INIT-1)

IX — If the element’s state is unknown at the beginning of the first capture cycle and may go to any state during capture. (INIT-X)

T0 — If the element is always at 0 during capture. (TIE-0)

T1 — If the element is always at 1 during capture. (TIE-1)

TX — If the element is always at an unknown state during capture. (TIE-X)

TLA — If the element is always transparent when its clock is at its off state. (TLA)

Tip

 Except for TLAs, you can also direct the tool to display information for only those D5 elements that are edge-triggered or level-sensitive. See the `-Edge_triggered` and `-Level_sensitive` switch descriptions for details.

- `-NOType I0 | I1 |IX | T0 | T1 | TX | TLA`

An optional switch and repeatable literal that specify not to display occurrence messages for the particular type(s) of D5 violations. See the description of the `-Type` switch for the meaning of the literal choices.

- `-EDge_triggered | -LEvel_sensitive`

Optional switches that specify to display D5 occurrence messages either for edge-triggered or level-sensitive elements only. The default (when neither option is specified) is to display information for both edge-triggered and level-sensitive elements.

E5-Only Arguments

- `-TIMing_exceptions`

An optional switch that specifies to report only on E5 violations due to timing exceptions. In order to use this switch you must first issue a “`set_drc_handling -timing_exception_check ON`” command in setup mode (see “[Example 8](#)” on page 1491).

Examples**Example 1**

The following example displays a summary of the rules that resulted in violations during an attempted ATPG run:

report_drc_rules

```
C3: #fails=2 handling=warning (clock may capture data affected by its
     captured data)
C5: #fails=1 handling=error (clock is connected to multiple ports of same
     latch)
C7: #fails=19 handling=warning (scan cell capture ability check)
C8: #fails=2 handling=warning (PO connected to a clock line)
C9: #fails=2 handling=warning (PO connected to a clock line gated by scan
     cell that uses same clock)
D5: #fails=23 handling=warning (non-scan memory element)
D6: #fails=22 handling=warning (non-transparent non-scan latches)
D7: #fails=22 handling=warning (stable high edge-triggered clock ports)
```

Example 2

The following example displays the occurrence message for the two C3 violations, and the first C7, and first D7 violation reported in the preceding example:

report_drc_rules c3 c7-1 d7-1

```
// Warning: Clock /sgst failed rule C3 on input 3 of /sp_b_i0.latch  
    (1501). (C3-1)  
// Source of violation: input 3 of /sp_c_i1.slave (1482).  
// Warning: Clock /sgst failed rule C3 on input 3 of /sp_c_i0.latch  
    (1527). (C3-2)  
// Source of violation: input 3 of /sp_c_i1.slave (1482).  
// Warning: Clock input 5 of /c8.master (1495) cannot capture data  
    with single clock on. (C7-1)  
// Warning: Flipflop /FF1 (103) has clock port set to stable high. (D7-1)
```

Example 3

The following example changes the handling of data rule 7 (D7) from warning to error and also specifies execution of a full test generation analysis when performing the rules checking for the clock (C) rules:

```
set_drc_handling d7 error atpg_analysis  
set_system_mode analysis  
  
//-----  
//Begin scan chain identification process, memory elements=8.  
//-----  
// Reading group test procedure file /user/design/tpf.  
// Simulating load/unload procedure in g1 test procedure file.  
// Chain = c1 successfully traced with scan_cells = 8.  
// Error: Flipflop /FF1 (103) has clock port set to stable high. (D7-1)  
// Error: Rules checking unsuccessful, cannot exit SETUP mode.
```

Example 4

The following example displays the occurrence message for the D7 violation:

```
report_drc_rules d7-1  
//Error: Flipflop /FF1 (103) has clock port set to stable high. (D7-1)
```

Example 5

The following example displays a summary of the non-scan memory elements that resulted in D5 rule violations:

```
report_drc_rules d5 -summary  
  
// -----  
// 44 non-scan memory elements are identified.  
// -----  
//      9 non-scan memory elements are identified as TIE-0. (D5)  
//      2 non-scan memory elements are identified as TIE-1. (D5)  
//      5 non-scan memory elements are identified as TIE-X. (D5)  
//      3 non-scan memory elements are identified as INIT-0. (D5)  
//     11 non-scan memory elements are identified as INIT-1. (D5)  
//      4 non-scan memory elements are identified as INIT-X. (D5)  
//     10 non-scan memory elements are identified as TLA. (D5)  
// -----
```

Example 6

The following example displays details about the preceding example's D5 violations that occurred on non-scan memory elements the tool identified as type INIT-X:

report_drc_rules d5 -type ix

```
// Warning: /U1 (78) is a non-scan flip-flop identified as INIT-x. (D5-1)
// Warning: /U6 (56) is a non-scan flip-flop identified as INIT-x. (D5-7)
// Warning: /U7 (82) is a non-scan flip-flop identified as INIT-x. (D5-8)
// Warning: /U9 (11) is a non-scan latch identified as INIT-x. (D5-9)
// Number of non-scan memory elements reported = 4.
```

Example 7

The following example displays the information for just the INIT-X non-scan latch:

report_drc_rules d5 -type ix -level_sensitive

```
// Warning: /U9 (11) is a non-scan latch identified as INIT-x. (D5-9)
// Number of non-scan memory elements reported = 1.
```

You could obtain the same information using the -Notype switch:

report_drc_rules d5 -notype i1 i0 tx t1 t0 tla -level_sensitive

```
// Warning: /U9 (11) is a non-scan latch identified as INIT-x. (D5-9)
// Number of non-scan memory elements reported = 1.
```

Example 8

The following example reads timing exception paths and enables the timing exception check for E5. Next, the example enters analysis mode and reports E5 due to timing exceptions.

```
SETUP> read_sdc my_design.sdc
SETUP> set_drc_handling E5 -timing_exception_check on
SETUP> set_system_mode analysis

...
// 9 gates may have an observable X-state, 2 of which are due to timing
// exception paths. (E5)

ANALYSIS> report_drc_rules e5 -timing_exceptions

// DFF gate /M3S004FP/VALIDDEVCHIRPK_REG (59193) may have an observable
// X-state due to timing exception paths. (E5-8)
// DFF gate /M3S014FP0/TXVALIDDH_REG (59220) may have an observable
// X-state due to timing exception paths. (E5-9)
```

[set_drc_handling](#)

report_edt_abort_analysis

Context: dft -edt, patterns -scan (EDT On)

Mode: analysis

Reports the results of EDT Aborted fault analysis.

Usage

```
report_edt_abort_analysis [-block block_name]
    [-from from_cube_id] [-to to_cube_id]
    [-statistics [-cells_most_commonly_specified number_of_cells]
    [-shift_positions_most_commonly_specified number_of_shift_positions]]
    [-cubes]
```

Description

Reports the results of EDT Aborted (EAB) fault analysis. Without any arguments, the report_edt_abort_analysis command generates a summary report containing the cells most commonly specified and the shift positions most commonly specified. The classification of a EAB test cube is meant to identify the EDT block in which the encoding first failed.

See “[EDT Aborted Fault Analysis](#)” in the *Tessent TestKompress User’s Manual* for a complete discussion.

Arguments

- **-block *block_name***

An optional switch and string pair that specifies the name of an EDT block on which to perform the analysis.

- **-from *from_cube_id***

An optional switch and positive integer pair that specifies which EAB test cube the tool should analyze first. The default is 1.

This option is only meaningful when either the -block switch pair is used or all EAB test cubes are from one EDT block. If multiple EDT blocks contain EAB test cubes and -block is not used, then the tool produces an error message.

Used in conjunction with the complementary -to *to_cube_id* switch and positive integer pair.

- **-to *to_cube_id***

An optional switch and positive integer that specifies where to end the EAB analysis. By default, *to_cube_id* is the total number of collected EAB test cubes.

This option is only meaningful when either the -block switch pair is used or all EAB test cubes are from one EDT block. If multiple EDT blocks contain EAB test cubes and -block is not used, then the tool produces an error message.

Used in conjunction with the complementary -from *from_cube_id* switch and positive integer pair.

- -statistics

An optional switch that reports the statistics for the selected block and EAB cubes. This is the default unless you specify the -cubes keyword.

The tool-generated report shows statistics for each EDT block that has EAB cubes. For each such EDT block, the report contains the following sections:

- EAB cube size distribution
- Most specified scan cells by EAB test cubes
- Most specified shift positions by EAB test cubes

Optionally, you can control the number of displayed scan cells and shift positions by using the -cells_most_commonly_specified and -shift_positions_most_commonly_specified options.

- -cells_most_commonly_specified *number_of_cells*

An optional switch and positive integer pair that specifies the number of cells to report. Used in conjunction with the -statistics switch.

- -shift_positions_most_commonly_specified *number_of_shift_positions*

An optional switch and positive integer pair that specifies the number of shift positions to report. Used in conjunction with the -statistics switch.

- -cubes

An optional literal that reports the smallest test cubes for the selected block and test cubes.

Examples

Example 1

The following example shows the default report.

In this example, two EDT blocks contain EAB cubes. The first one contains 3EAB cubes and the second one contains 49. It can be seen from the first one that none of the EAB cubes in the block are “oversized” (>100%).

Note that in this example, the “Gate” column entries are shortened with /*gate_path*, which represents the following:

```
/edt_top_core2_maxlen90/piccpu_maxlen90_i
```

This is done for presentation purposes.

//7 2(66.67%)  '/gate_path/inst_reg_6/' (31088)  piccpu_90_chain1 8  
//8 2(66.67%)  '/gate_path/status_reg_6/' (31056) piccpu_90_chain5 17  
//9 2(66.67%)  '/gate_path/inst_reg_3/' (31085)  piccpu_90_chain1 5  
//10 2(66.67%) '/gate_path/inst_reg_2/' (31084)  piccpu_90_chain1 4  
//  
//Top specified shift positions are:  
//Shift position  Specified times  Average specified times per cube  
//-----  
//4           4                  1  
//5           4                  1  
//12          4                  1  
//16          4                  1  
//3           3                  1  
//22          3                  1  
//7           3                  1  
//8           3                  1  
//9           3                  1  
//13          3                  1
```

In the next report block, 8 out of 49 EAB cubes are beyond the encoding capacity. This means that the specified bits of these 8 cubes are over the encoding capacity of the block. It is more or less expected that they cannot be compressed. The other 41 EAB cubes are within normal cube size range.

Note that in this example, the “Gate” column entries are shortened with */gate_path*, which represents the following:

/m8051_5channels/m8051_i

This is done for presentation purposes.

//
// Total analysis time = 0.00 sec.

```

In the above example, we focus on the cubes whose size is below or near encoding capacity. As noted earlier, EAB cubes are ordered in ascending order of their size in the failing block. The tool listed 30 top specified scan cells. For each scan cell, the tool reports its specified times among the selected EAB cubes, gate name and id, scan chain, shift position counted from scan input, block name and known constraint on the gate.

From the constraint column, we can see that a number of top specified bits have constraints on them. For example, the 4th scan cell has a cell constraint, the 2nd one is a condition bit of an NCP and so on. You may see the following constraint types in this column:

- **Cell Constraint** — A C0/C1 cell constraint is on this scan cell.
- **ATPG Constraint** — The scan cell's value is determined due to some added atpg constraints. Note, the atpg constraint may not be added on the cell directly. E.g. if an AND gate is constrained to 1, both of its inputs must be 1. If one of the inputs happens to be a scan cell, it will have this constraint.
- **Condition Bit of an NCP** — This scan cell needs to load a pre-determined value for the NCP.
- **Condition Bit of a Clock Under Control** — The bit is part of the clock control definition of an internal clock.
- **Equivalent Scan Cell** — The scan cell is equivalent to another scan cell that is constrained.
- **Design Constraint** — The scan cell does not have a “hard” constraint. However, when we try to satisfy all the ATPG constraints and prevent all the bus contentions in the design, this scan cell is part of the solution. If this type of scan cell is in the top list, the encoding problem may come from busses or ATPG constraints in the design.

Example 3

The following example shows a design that suffers from excessive EAB faults due to clock control condition bits.

Note that in this example, the “Gate” column entries are shortened with */gate_path*, which represents the following:

/core_0/dig_core_0/wrap_0/test_clock_ctrl_test_clk_bp_0

This is done for presentation purposes.

//'/gate_path/u5/TMPDAT_reg_5_/' (31493)  0    m8051_5ch_chain27  6
//'/gate_path/u4/L_ACCDAT_reg_5_/' (31466) 1    m8051_5ch_chain30  5
```

```
///'/gate_path/u1/Q4_reg/' (31164)          0      m8051_5ch_chain23   6
///'/gate_path/u4/L_ACCDAT_reg_6_/' (31465)  0      m8051_5ch_chain30   6
///'/gate_path/u4/L_ACCDAT_reg_4_/' (31467)  1      m8051_5ch_chain30   4
// Total bits specified = 11
//
// Total analysis time = 0.00 sec.
```

The test cubes are represented in a similar way as the cells in the top specified cell list. A little different is that the bit in an EAB cube has a value field. We can see that the number of EAB cubes is pretty small. For example, the first reported EAB cube contains only 8 bits. In certain situations such as linear dependency, it may not be possible to encode these 8 bits even though the encoding capacity of the block is over 60. If detection of a fault requires specification of these 8 bits, the fault may be classified as EAB.

Example 5

When multiple EDT blocks share the same EDT channel input pins, analysis of EAB cubes must consider such blocks together.

Note that in this example, the “Gate” column entries are shortened with */gate*, which represents the following:

/EngineX4_i

This is done for presentation purposes.

The generated report displays such blocks as a composite EDT block named COMPOSITE_BLOCK_N. The following example shows EAB analysis for 6 EDT blocks that share EDT input channels and are reported as COMPOSITE_BLOCK_0 and another 2 blocks reported as COMPOSITE_BLOCK_1:

ANALYSIS> report_edt_abort_analysis

```

//
// EAB test cube analysis results for composite EDT block 'COMPOSITE_BLOCK_0':
// This composite EDT block contains the following EDT blocks:
// blk1
// blk2
// blk7
// blk8
// blk3
// blk4
// EDT configurations:
// Number of channels      = 13
// Number of scan chains    = 600
// Number of scan cells     = 18899
// Longest scan chain length = 32
// Approximate encoding capacity = 310
//
// EAB test cube size distribution:
// Specified bits   Specified bits / Capacity (%)   EAB cubes

```

Related Topics

[set_edt_abort_analysis_options](#)

report_edt_blocks

Context: dft -edt, patterns -scan (EDT On), patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup, analysis

Displays a list of the current user-defined EDT block names (also referred to as block tags) and indicates which one, if any, represents the current block.

Usage

`report_edt_blocks`

Description

Displays a list of the current user-defined EDT block names (also referred to as block tags) and indicates which one, if any, represents the current block.

When the display shows “current block” by a name, it indicates relevant tool commands apply only to the EDT block associated with that name.

You can transfer this restriction (also referred to as the EDT context) to another EDT block with the [set_current_edt_block](#) or [add_edt_blocks](#) commands.

Arguments

None

Examples

The following example lists currently defined EDT block names:

```
report_edt_blocks
// my_core1_block
// my_core2_block
// my_core3_block
// my_core4_block    (current block)
```

Related Topics

[add_edt_blocks](#)

[delete_edt_blocks](#)

[set_current_edt_block](#)

report_edt_configurations

Context: dft -edt, patterns -scan (EDT On), patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup, analysis

Displays configuration information for the current compression logic.

Usage

```
report_edt_configurations [-ALL_blocks] [<> | >>] file_pathname]
```

Description

Displays configuration information for the current compression logic.

Among the items reported are the version, compactor type, power controller status, low-power pipeline stages, number of scan channels and related information, multiple compression configurations, and whether the tool is set up to insert bypass logic and lockup cells. This command only displays a partial report from Setup mode. To produce a complete report, you must exit Setup mode to run DRC and flatten the model before issuing this command.

Note

 The report_edt_configurations command does not list the names of EDT pins. To display the names of EDT pins, use the [report_edt_pins](#) command.

The -all_blocks switch is useful where the netlist read in includes multiple EDT blocks. In this case, the command by default reports the EDT configuration information as described above, but only for the EDT block you have specified as the current EDT block. If you include the -all_blocks switch, the command displays configuration information for every EDT block. You set the current EDT block using either the [add_edt_blocks](#) or [set_current_edt_block](#) command. “EDT block” is the term used for a decompressor/compactor pair and the scan chains it controls/observes. For more information, refer to the [Modular Compressed ATPG](#) chapter of the *Tessent TestKompress User’s Manual*.

Arguments

- `-ALL_blocks`

An optional switch that displays EDT configuration information for all EDT blocks. Without this switch, only information for the current EDT block displays. If a current EDT block is not defined, configuration information for all EDT blocks displays.

- `>file_pathname`

An optional redirection operator and pathname pair for creating or replacing the contents of `file_pathname`.

- `>>file_pathname`

An optional redirection operator and pathname pair for appending to the contents of `file_pathname`.

Examples

Example 1

The following example reports configuration details for a non-modular design with eight scan chains and one scan channel; first while in Setup mode, then again after DRC:

```
report_edt_configurations

// IP version: 1
// External scan channels: 1
// Bypass logic: On
// Lockup cells: On
// Clocking: edge-sensitive

set_system_mode analysis

...
# -----
# Begin EDT rules checking.
# -----
# Running EDT logic creation Phase.
# 5 pin(s) will be added to the EDT wrapper. (K11)
# EDT rules checking completed, CPU time=0.01 sec.
# All scan input pins were forced to TIE-X.
# All scan output pins were masked.
# -----
...

report_edt_configurations

// IP version: 1
// Shift cycles: 381, 373 (internal scan length)
// + 8 (additional cycles)
// External scan channels: 1
// Internal scan chains: 8
// Masking bits: 2
// Longest chain range: 2 - 373
// Decompressor size: 32
// Shift power controller: Enabled and inactive(shift power control
// is off)
// Min switching threshold: 25%
// Compactor type: Xpress
// Scan cells: 18650
// Compression per pattern: 16.01x (ATPG bypass = 3 x 6341, EDT = 3 x
// 396)
// Clocking: edge-sensitive
// Compactor pipelining: Off
```

Example 2

The following example defines two EDT blocks in the patterns -scan context, then reports configuration details first for the current block and then for all blocks:

```
# Define the block name "my_block1" for an EDT block
# and automatically set it as the current EDT block.
```

```
add_edt_blocks my_block1
# Define the location (instance name) of the top-level EDT logic for this
#   block; also the decompressor and compactor.

report_edt_configurations

// EDT block "my_block2"
// -----
// IP version:                      3
// External scan channels:          1
// Decompressor size:               10
// Compactor type:                 Xpress
// Clocking:                        edge-sensitive
//
// Note: Only current EDT block "my_block2" is reported. Use "report edt
// configuration -all_blocks" to report the configurations of all blocks.
```

report_edt_configurations -all_blocks

```
// EDT block "my_block1"
// -----
// IP version: 3
// External scan channels: 3
// Decompressor size: 12
// Compactor type: Xpress
// Clocking: edge-sensitive
//
// EDT block "my_block2"
// -----
// IP version: 3
// External scan channels: 1
// Decompressor size: 10
// Compactor type: Xpress
// Clocking: edge-sensitive
```

Example 3

The following example reports all EDT blocks. Channel sharing information is shown in red font. Note that “// Blocks sharing input channels:” means the blocks having at least one input channel that is shared with this channel.

report_edt_configurations -all

Command Dictionary (R) **report_edt_configurations**

```
// EDT block "B1"
// -----
// IP version: 4
// Shift cycles: 53, 19 (internal scan length) + 11
// (additional cycles) + 23 (pad cycles due to blocks with longer chains)
// External scan channels: 2 (1 control input channel)
// Internal scan chains: 32
// Masking bits: 25
// Longest chain range: 2 - 19
// Decompressor size: 16
// Compactor type: Xpress
// Blocks sharing input channels: B2
// Scan cells: 573
// Clocking: edge-sensitive
// Compactor pipelining: 0 stages
//
// EDT block "B2"
// -----
// IP version: 4
// Shift cycles: 53, 2 (internal scan length) + 13
// (additional cycles) + 38 (pad cycles due to blocks with longer chains)
// External input channels: 3 (1 control input channel)
// External output channels: 2
// Internal scan chains: 4
// Masking bits: 5
// Longest chain range: 2 - 2
// Decompressor size: 8
// Compactor type: Xpress
// Blocks sharing input channels: B1, B3
// Scan cells: 8
// Clocking: edge-sensitive
// Compactor pipelining: 0 stages
//
// EDT block "B3"
// -----
// IP version: 4
// Shift cycles: 53, 2 (internal scan length) + 13
// (additional cycles) + 38 (pad cycles due to blocks with longer chains)
// External scan channels: 2 (1 control input channel)
// Internal scan chains: 4
// Masking bits: 5
// Longest chain range: 2 - 2
// Decompressor size: 8
// Compactor type: Xpress
// Blocks sharing input channels: B2
// Scan cells: 8
// Clocking: edge-sensitive
// Compactor pipelining: 0 stages
```

Example 4

In this example, the tool reports while in non-setup mode if there is an EDT low-power controller:

report_edt_configurations

```
//  
// IP version: 6  
// Shift cycles: 148, 143 (internal scan length) + 5 (additional cycles)  
// External scan channels: 23 (4 control input channels)  
// Internal scan chains: 1827  
// Masking bits: 254  
// Decompressor size: 92 (4 segments)  
// Scan cells: 258561  
// Compression per pattern: 76.33x (ATPG bypass = 23 x 11297, EDT = 23 x 148)  
// Bypass logic: On  
// Lockup cells: On  
// Clocking: edge-sensitive  
// Compactor pipelining: Off  
// Low power shift controller: Enabled and active  
//   Min switching threshold: 25%  
//   Low power bits: 30
```

[set_edt_pins](#)

report_edt_finder

Context: patterns -scan (EDT On), patterns -scan_diagnosis

Mode: setup, analysis

Reports information about the EDT logic contained in a design.

Usage

To report decompressors

```
report_edt_finder -Decompressors [-Type {ACtive | Inactive | ALL}]  
[-Id decompressor_id#] [-Filter instance_name_wildcard]  
[-Verbose [instances]] [{>} | >>] file_pathname
```

To report scan chain segments

```
report_edt_finder -Chain_segments  
[-Id decompressor_id#] [-Type {ALL | ACcessible | COMpressed | Uncompressed  
| CONtrol | Inaccessible}] [-Min_length integer] [-Max_length integer] [-Bins integer]  
[-Endpoints {instance_name_wildcard | gate_id#}]  
[-Details {SUMmary | Endpoints | Full}] [{>} | >>] file_pathname
```

To report masking logic

```
report_edt_finder -Masking_logic [-Id decompressor_id#] [-Filter instance_name_wildcard]  
[-Verbose [instances]] [{>} | >>] file_pathname
```

To report low-power shift controller logic

```
report_edt_finder -Low_power_shift_controller [-Id decompressor_id#]  
[-Filter instance_name_wildcard] [-Verbose [instances]] [{>} | >>] file_pathname
```

Description

Reports information about the EDT logic contained in a design. Depending on the specified switches, the following columns can be reported:

- Length — Specifies the length of the identified scan chains. For example, (16-101) means the smallest scan chain has 16 cells and the longest scan chain has 101 cells.
- Count — Specifies the number of scan chains. For example, the first line of this report shows there are 40 chains that are compressed with length 16-101.

```
// Type          Length        Count  
// -----  
// compressed    16-101      40  
// compressed    102-188     50  
// inaccessible  1-94       7520  
// inaccessible  95-189      1160
```

- Type — Specifies the type of chain segment as defined by the Type argument description.

- Begin/End — Specifies the first scan cell or last scan cell of the scan chain segment. Defined by the -Details Endpoints switch.

Arguments

- **-Decompressors**

A required switch that reports on decompressors found in the design.

- [-Type {ACtive| Inactive | ALl}]

An optional switch and literal pair that specifies which decompressors to report on. Options include:

ACtive — Reports on all active decompressors identified. This is the invocation default.

Inactive — Reports on all inactive decompressors identified (decompressors that do not reach channel outputs).

ALl — Reports all decompressors identified.

- **-Chain_segments**

A required switch that reports on scan chain segments found in the design.

- [-Type {ALl | ACcessible [Compressed | Uncompressed | CONtrol] | Inaccessible}]}

An optional switch and literal pair that specifies the type of chain segments to report. Literal options include:

ALl — Reports all chain segments found. This is the invocation default.

ACcessible — Reports all scan chain segments accessible via identified EDT logic or primary input/output pins. You can also enter an additional literal option to further sort on the accessible scan chains returned. Literal sort options include:

COMpressed — Reports compressed chains, such as chains accessible via identified EDT logic.

Uncompressed — Reports uncompressed chains such as chains accessible via primary input/output pins.

CONtrol — Reports chain segments of the EDT control logic such as the mask shift registers of Xpress compactors.

Inaccessible — Reports chain segments that are not accessible via identified EDT logic or primary input/output pins.

- **-MIn_length *integer***

An optional switch and integer pair that specifies the minimum length of chain segments to display. The default is 1.

- **-MAx_length *integer***

An optional switch and integer pair that specifies the maximum length of chain segments to display. The default is unlimited.

- **-Endpoints {*instance_name_wildcard* | *gate_id#*}**
An optional switch and string or integer that specifies the endpoints of the chain segments to display. The string may include asterisk (*) and/or question mark (?) wildcard characters.
- **-Details {SUMmary | Endpoints | Full}**
An optional switch and literal pair that specifies the details to display. Options include:
 - SUMmary — Reports only a summary such as the number of chains that belong to a certain category. This is the invocation default.
 - Endpoints — Reports the endpoints of the chain segments.
 - Full — Reports all available information about the chain segments, including the instance name of each chain element.
- **-Bins *integer***
An optional switch and integer pair that specifies the maximum number of bins that scan chain data is sorted by in the summary report.
Each type (accessible/compressed/uncompressed/control/inaccessible) of scan chain reported is sorted by scan chain lengths determined by the number of bins specified with this switch. By default, 10 bins are used.
- **-Masking_logic**
A required switch that reports details about specified Xpress mask registers identified by EDT Finder.
- **-Low_power_shift_controller**
A required switch that reports details about low-power shift and hold registers identified by EDT Finder.
- **-Id *decompressor_id#***
An optional switch and integer pair that specifies the identification number of the decompressor to report. The value of the *decompressor_id#* is the unique identification number automatically assigned to every decompressor by EDT Finder.
- **-Filter*instance_name_wildcard***
An optional switch and string pair that specifies the instance name of the decompressors or masking logic to report. You can use regular expressions that include asterisk (*) and/or question mark (?) wildcard characters.
- **-Verbose [instances]**
An optional switch and literal that transcribes informational messages about the EDT logic found in a design. Depending on the EDT logic specified, this switch reports informational messages about decompressors, low power registers, and masking logic found in the design. If the *instances* literal is specified, only the names of instances are reported. By default, these messages are disabled.

- **>file.pathname**

An optional redirection operator and pathname pair that creates or replaces the contents of *file.pathname* with the output.

- **>>file.pathname**

An optional redirection operator and pathname pair that appends the output to the contents of *file.pathname*.

Examples

Example 1

The following example displays a summary of decompressors found in a design:

report_edt_finder -decompressors

```
// Decomp. Id# #Bits #Inputs #Chains Block Type
// -----
// 1 16 4 28 m1_28x16 active
// 2 16 4 4 m2_4x32 active
// 3 16 4 50 m3_50x187 active
// 4 10 1 8 m4_8x16 active
```

Example 2

The following example displays a summary of all the masking logic found:

report_edt_finder -masking_logic

```
// Decomp. Id# Length Type Block
// -----
// 1 9 xpress piccpu_40
// 2 31 xpress my_core_5ch
// 3 31 xpress my_core_5ch_2
```

Example 3

This example displays a summary of all found chain segments grouped into 2 bins per type:

report_edt_finder -chain_segments -bins 2

```
// Type Length Count
// -----
// compressed 16-101 40
// compressed 102-188 50
// inaccessible 1-94 7520
// inaccessible 95-189 1160
```

Example 4

The following example displays the scan inputs and outputs of the accessible chain segments with a minimum length of 50:

report_edt_finder -chain_segments -type accessible compressed -min_length 50

```
// EDT Control          Length  Type           Name
// -----
// edt controllable    50     compressed   picccpu_90_chain2
// edt controllable    90     compressed   picccpu_90_chain3
// edt controllable    50     compressed   picccpu_90_2_chain2
// edt controllable    90     compressed   picccpu_90_2_chain3
```

Example 5

The following example displays a summary of the low-power shift controller logic in blk1:

```
report_edt_finder -low_power_shift_controller -id 2 -verbose instances
```

```
// Decomp. Id # Registers      Block
// -----
// 2             5               blk1
// Shift reg.  /top/blk1_i/.../low_power_shift_reg_0_reg[4]/UD1 (16171)
// Hold reg.   /top/blk1_i/.../control_hold_reg_0_reg[4]/DFF1 (16166)
// Shift reg.  /top/blk1_i/.../low_power_shift_reg_0_reg[3]/UD1 (16172)
// Hold reg.   /top/blk1_i/.../low_power_hold_reg_0_reg[3]/DFF1 (16167)
// Shift reg.  /top/blk1_i/.../low_power_shift_reg_0_reg[2]/UD1 (16173)
// Hold reg.   /top/blk1_i/.../low_power_hold_reg_0_reg[2]/DFF1 (16168)
// Shift reg.  /top/blk1_i/.../low_power_shift_reg_0_reg[1]/UD1 (16174)
// Hold reg.   /top/blk1_i/.../low_power_hold_reg_0_reg[1]/DFF1 (16169)
// Shift reg.  /top/blk1_i/.../low_power_shift_reg_0_reg[0]/UD1 (16175)
// Hold reg.   /top/blk1_i/.../low_power_hold_reg_0_reg[0]/DFF1 (16170)
```

[set_edt_finder](#)

report_edt_instances

Context: dft -edt, patterns -scan (EDT On), patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup, analysis

Displays the instance pathnames of the top-level EDT logic, decompressor, and compactor.

Usage

```
report_edt_instances [-All_blocks] [-Errors_only] [{> | >>} file.pathname]
```

Description

Displays the instance pathnames of the top-level EDT logic, decompressor, and compactor.

Note

 For modular Tessent TestKompress, the report_edt_instances command operates only on the current EDT block (the EDT block that is the current target of EDT-specific commands). This is the EDT block specified by the last add_edt_blocks or last [set_current_edt_block](#) command, whichever you issued most recently.

The report_edt_instances command lists the names of the instances where the tool expects to find the top-level EDT logic, decompressor, and compactor. It also reports the pathnames of these instances when known. If the display lists any instance paths as “NOT FOUND,” the tool will not be able to provide the maximum amount of detail in the debugging information for K19-K22 DRC violations. You can use the [set_edt_instances](#) command to update the instance information.

The -All_blocks switch is only for the top-level Pattern Generation Phase of modular Tessent TestKompress, where the netlist read in includes multiple EDT blocks. In this case, the command by default reports the information described above, but only for the EDT block you have specified as the current EDT block. If you include the -All_blocks switch, the command displays this information for every EDT block. You set the current EDT block using either the [add_edt_blocks](#) or [set_current_edt_block](#) command. “EDT block” is the term used for a decompressor/compactor pair and the scan chains it controls/observes. For more information, refer to the “[Modular Compressed ATPG](#)” chapter of the *Tessent TestKompress User’s Manual*.

Arguments

- -All_blocks

Note

 This switch is only for the top-level Pattern Generation Phase of modular Tessent TestKompress, where the netlist read in includes multiple EDT blocks. If you are using a standard (non-modular) Tessent TestKompress flow, you do not need this switch.

An optional switch that specifies to display instance information for all EDT blocks. Without this switch, the tool displays information for only the current EDT block, if it is defined. If a current EDT block is not defined, the tool displays the information for all EDT blocks.

- **-Errors_only**

An optional switch that specifies to display instance information only if the tool is unable to positively identify at least one of the instance names. This could be because the tool either cannot find the instance name/path, or the instance name is not unique.

- **>file.pathname**

An optional redirection operator and pathname pair for creating *or* replacing the contents of *file.pathname*.

- **>>file.pathname**

An optional redirection operator and pathname pair for appending to the contents of *file.pathname*.

Examples

The following example displays the current EDT instance data for a design, updates the information, then displays the updates:

```
report_edt_instances

// edt_logic_top
//   Setting: edt_i
//   Path    : NOT FOUND
//
// decompressor
//   Setting: edt_decompressor_i
//   Path    : NOT FOUND
//
// compactor
//   Setting: edt_compactor_i
//   Path    : NOT FOUND

set_edt_instances -edt_logic_top my_core_edt_i \
                  -decompressor my_core_edt_decompressor_i \
                  -compactor my_core_edt_compactor_i

// Found edt_logic_top at path: "/my_core_edt_top/my_core_edt_i".
// Found compactor at path:
//   "/my_core_edt_top/my_core_edt_i/my_core_edt_compactor_i".
// Found decompressor at path:
//   "/my_core_edt_top/my_core_edt_i/my_core_edt_decompressor_i".
```

```
report_edt_instances
```

```
// edt_logic_top
//   Setting: my_core_edt_i
//   Path    : /my_core_edt_top/my_core_edt_i
//
// decompressor
//   Setting: my_core_edt_decompressor_i
//   Path    : /my_core_edt_top/my_core_edt_i/my_core_edt_decompressor_i
//
// compactor
//   Setting: my_core_edt_compactor_i
//   Path    : /my_core_edt_top/my_core_edt_i/my_core_edt_compactor_i
```

report_edt_lockup_cells

Context: dft -edt, patterns -scan (EDT On), patterns -scan_diagnosis

Mode: setup, analysis

Displays a tabular report of the lockup cells in the EDT logic.

Usage

```
report_edt_lockup_cells [-All_blocks] [{> | >>} file.pathname]
```

Description

Displays a tabular report of the lockup cells in the EDT logic.

The report_edt_lockup_cells command reports details about the lockup cells in the EDT logic.

The command only reports lockup cells that will be included in the generated IP. Specifically, when lockup cell insertion is turned off (which is not recommended), the report does not include any lockup cells.

Note

 During pattern generation, the command reports the expected lockup cells and not the actual lockup cells in the design.

The reported information is arranged in tables that cover the following:

Note

 If you invoke this command in Setup mode because EDT DRC failed, some data will not be available, and hence, will not be reported.

- Scan clocking — Details about the first and last scan cell in each scan chain. For each flip-flop (FF), the report lists whether it is leading edge triggered (LE) or trailing edge triggered (TE). For each latch, the report lists whether it is active high (HI) or active low (LO). The names of the first and last cell's clocks and their capture timing are also provided. The capture time is listed in the “Cap” column for the first cell, and in the “Chg” column for the last cell.
- Location — Each lockup cell is listed under one of the following categories depending on its location in the IP:
 - Decompressor—Lockup cells between the decompressor and the scan chain inputs
 - Compactor — Lockup cells between the scan chain outputs and the compactor
 - Bypass — Lockup cells in the bypass circuitry

- Type of lockup cell — Flip-flop (FF) or latch (LA). For each flip-flop, the report lists whether it is leading edge triggered (LE) or trailing edge triggered (TE). For each latch, the report lists whether it is active high (HI) or active low (LO).
- Clock — Name of the clock for each lockup cell
- Relevant Clocks — Summary of the off state, type, and timing of all clocks listed elsewhere in the report. The timing is based on the shift procedure in the test procedure file.

For more information, see “[Understanding Lockup Cells](#)” in the Tesson TestKompress User’s Manual.

The -All_blocks switch is only for the top-level Pattern Generation Phase of modular Tesson TestKompress, where the netlist read in includes multiple EDT blocks. In this case, the command by default reports the lockup cell information described above, but only for the EDT block you have specified as the current EDT block. If you include the -All_blocks switch, the command displays this information for every EDT block. You set the current EDT block using either the [add_edt_blocks](#) or [set_current_edt_block](#) command. “EDT block” is the term used for a decompressor/compactor pair and the scan chains it controls/observes. For more information, refer to the “[Modular Compressed ATPG](#)” chapter of the *Tesson TestKompress User’s Manual*.

Arguments

- -All_blocks

Note

 This switch is only for the top-level Pattern Generation Phase of modular Tesson TestKompress, where the netlist read in includes multiple EDT blocks. If you are using a standard (non-modular) Tesson TestKompress flow, you do not need this switch.

An optional switch that specifies to display the lockup cell information for all EDT blocks. Without this switch, the tool displays information for only the current EDT block, if it is defined. If a current EDT block is not defined, the tool displays the information for all EDT blocks.

- >*file.pathname*

An optional redirection operator and pathname pair for creating *or* replacing the contents of *file.pathname*.

- >>*file.pathname*

An optional redirection operator and pathname pair for appending to the contents of *file.pathname*.

Examples

Example 1

The following example reports lockup details for a design with eight scan chains and one scan channel. The EDT logic is FF-based and includes bypass circuitry:

```
set_system_mode analysis
report_edt_lockup_cells

// SCAN Clocking
//-----+-----+
//           | First Cell      | Last Cell
// Chain (#)| Gate (id) Type Cap Clock|Gate (id) Type Chg Clock
//-----+-----+
// chain1(1)|/i7/ (92) FF-TE 20 /clk |/rg0/ (33) FF-TE 20 /clk
...
// chain8(8)|/i5/ (48) FF-TE 20 /clk |/ix8/ (89) FF-TE 20 /clk
//
// DECOMPRESSOR Lockup Cells
//-----+-----+
//           | First cell      | Second cell
// Chain (#)| Type   Clock      | Type   Clock
//-----+-----+
// chain1(1)| FF-TE /edt_clock | -----
// chain2(2)| FF-TE /edt_clock | FF-LE /edt_clock
...
// chain8(8)| FF-TE /edt_clock | -----
//
// COMPACTOR Lockup Cells
//-----+-----+
//           | Lockup cell
// Chain (#)| Type   Clock
//-----+-----+
// chain1(1)| FF-TE /edt_clock
...
// chain8(8)| FF-TE /edt_clock
//
// BYPASS Lockup Cells
//-----+-----+
//           | Lockup cell
// Chain (#) -> Chain (#) | Type   Clock
//-----Channel 1-----+-----+
// chain1 (1) -> chain2 (2) | FF-TE /clk
// chain2 (2) -> chain3 (3) | -----
// chain3 (3) -> chain4 (4) | -----
// chain4 (4) -> chain5 (5) | -----
// chain5 (5) -> chain6 (6) | -----
// chain6 (6) -> chain7 (7) | -----
// chain7 (7) -> chain8 (8) | -----
//
// RELEVANT Clocks
//-----+-----+-----+
//           | Off    |           | Time
// Name      | State  | Type     | LE TE
//-----+-----+-----+
// /edt_clock | 0     | EDT      | 20 30
// /clk       | 0     | Shift Master | 20 30
```

The following is the bypass portion of a report for a design with eight scan chains and two scan channels. Notice that in addition to listing the bypass lockups, the bypass tables show the chain connections to the channels.

```
// BYPASS Lockup Cells
//-----+-----+-----+
//          | Lockup cell
// Chain   (#) -> Chain   (#) | Type   Clock
//-----Channel 1-----+-----+
// chain1   (1) -> chain2   (2) | ----- -----
// chain2   (2) -> chain3   (3) | ----- -----
// chain3   (3) -> chain4   (4) | ----- -----
// chain4   (4) -> chain5   (5) | ----- -----
// chain5   (5) -> chain6   (6) | ----- -----
//-----Channel 2-----+-----+
// chain7   (7) -> chain8   (8) | ----- -----
// chain8   (8) -> chain9   (9) | ----- -----
// chain9   (9) -> chain11  (10) | FF-TE /NX1
// chain11  (10) -> chain10  (11) | FF-TE /NX2
```

Example 2

The following example shows a design with eight scan chains; four of the scan chains are clocked by LE clk1 and the other four scan chains are clocked by TE clk2. The report_edt_lockup_cells output that follows shows the inserted lockup cells at the scan chain inputs and outputs.

```
set_edt_options -lockup on -retime_chain_boundaries on
set_system_mode analysis
report_edt_lockup_cells
```

```
//  
// SCAN Clocking  
// -----+-----+-----+-----+-----+-----+  
// | First cell | Last cell  
// Chain (#) | Gate (id) Type Cap Clock | Gate (id) Type Chg Clock

[report_edt_configurations](#)

[set_edt_options](#)

report_edt_pins

Context: dft -edt, patterns -scan (EDT On), patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup, analysis

Displays the currently defined names and inversion status of EDT channel and control pins.

Usage

```
report_edt_pins [-All_blocks] [-Group_by_pin_name]
[ {> | >>} file.pathname ]
```

Description

Displays the currently defined names and inversion status of EDT channel and control pins. The report_edt_pins command displays the names of all EDT channel and control pins and whether the pin signals are inverted between the chip input pin and the EDT logic.

The -All_blocks switch is only for the top-level Pattern Generation phase of modular Tessent TestKompress, where the netlist read in includes multiple EDT blocks. In this case, the command by default reports the information described above, but only for the EDT block you have specified as the current EDT block. If you include the -All_blocks switch, the command displays this information for every EDT block. You set the current EDT block using either the add_edt_blocks or set_current_edt_block command. “EDT block” is the term used for a decompressor/compactor pair and the scan chains it controls/observes. For more information, refer to the “[Modular Compressed ATPG](#)” chapter of the *Tessent TestKompress User’s Manual*.

Arguments

- -All_blocks

Note

 This switch is only for the top-level Pattern Generation phase of modular Tessent TestKompress, where the netlist read in includes multiple EDT blocks. If you are using a standard (non-modular) Tessent TestKompress flow, you do not need this switch.

An optional switch that specifies to display the EDT channel and control pin information for all EDT blocks. Without this switch, the tool displays information for only the current EDT block, if it is defined. If a current EDT block is not defined, the tool displays configuration information for all EDT blocks.

- -Group_by_pin_name

An optional switch that specifies to display the pin name and all of the blocks that share that pin.

- >*file.pathname*

An optional redirection operator and pathname pair for creating *or* replacing the contents of *file.pathname*.

- **>> file.pathname**

An optional redirection operator and pathname pair for appending to the contents of *file.pathname*.

Examples

Example 1

Assume the tool is in setup mode. The following example reports, for a design with two scan channels and no shared EDT pins, the names and inversion status of the EDT pins. The example then shares the EDT clock pin with a functional pin called “a1”. Following that, it renames the dedicated EDT bypass pin from the default name to “my_bypass” and specifies in the same command that the bypass signal is inverted between the chip input pin and the EDT logic. Afterward, the example again reports the EDT pins.

report_edt_pins

```
//  
//      Pin description          Pin name           Inversion  
//      -----                  -----  
//      Clock                  edt_clock           -  
//      Update                 edt_update           -  
//      Bypass mode            edt_bypass           -  
//      Scan channel 1 input   edt_channels_in1    -  
//      "         " output     edt_channels_out1   -  
//      Scan channel 2 input   edt_channels_in2    -  
//      "         " output     edt_channels_out2   -  
//
```

```
set_edt_pins clock a1  
set_edt_pins bypass my_bypass -inv  
report_edt_pins
```

```
//  
//      Pin description          Pin name           Inversion  
//      -----                  -----  
//      Clock                  a1                  -  
//      Update                 edt_update           -  
//      Bypass mode            my_bypass           inv  
//      Scan channel 1 input   edt_channels_in1    -  
//      "         " output     edt_channels_out1   -  
//      Scan channel 2 input   edt_channels_in2    -  
//      "         " output     edt_channels_out2   -  
//
```

Example 2

The following example reports each pin name and lists all of the blocks that share that pin. Channel sharing information is shown in red font.

report_edt_pins -all -group_by_pin_name

Pin name	Block	Pin Description	Inversion	Channel pipeline stages (mask register)
<hr/>				
edt_clock	A	Clock	-	-
	B	Clock	-	-
	C	Clock	-	-
edt_update	A	Update	-	-
	B	Update	-	-
	C	Update	-	-
channel_in_A	A	Scan channel 1 input (control)	-	7
channel_in_B	B	Scan channel 1 input (control)	-	"
channel_in_C	C	Scan channel 1 input (control)	-	"
channel_in1	A	Scan channel 2 input	-	7
	B	Scan channel 2 input	-	"
	C	Scan channel 2 input	-	"
channel_in2	A	Scan channel 3 input	-	7
	B	Scan channel 3 input	-	"
	C	Scan channel 3 input	-	"
channel_outA	A	Scan channel 1 Output	-	0
channel_outB	B	Scan channel 1 Output	-	"
channel_outC	C	Scan channel 1 Output	-	"

report_environment

Context: unspecified, all contexts

Mode: all modes

Displays the current value(s) of many of the most common “set_...” commands.

Usage

```
report_environment [{> | >>} file_pathname]
```

Description

Displays the current value(s) of many of the most common “set_...” commands.

When you first invoke the tool, the values displayed are the default settings for these commands.

This command shows the [set_gate_report](#) command settings in a field titled “gate report”. The tool reports global on/off options only when the options are enabled. The global on options are reportd in a semi-colon separated list in parenthesis. The tool reports clock_cone clock names in single quotes. The tool only reports the value of time values and not the units. The -max_fanouts and -clock_domains_in_capture_cycles options of set_gate_report do not impact the report_environment output.

Arguments

- *>file_pathname*

An optional redirection operator and pathname pair for creating or replacing the contents of file_pathname.

- *>>file_pathname*

An optional redirection operator and pathname pair for appending to the contents of file_pathname.

Examples

The following example reports the current conditions under which the tool tests the circuit, then performs an ATPG run:

```
set_system_mode analysis
add_faults -all
report_environment
create_patterns
```

The output from the report_environment command may look like the following:

```
abort limit = 30
atpg compression = OFF
atpg limits = none
bist initialization = X
bus simulation method = global
capture clock = none
checkpoint = OFF
clockpo patterns = ON
clock restriction = clock_po
clock_off simulation = OFF
contention check = ON, mode = bus, handling = warning
DRC transient detection = ON -Verbose
fails report = OFF
fault mode = uncollapsed
fault type = stuck
gate level = design
gate report = normal
iddq checks = none, handling = warning
iddq strobe = label
learn reporting = OFF
logfile handling = OFF
net dominance = wired-gate
net resolution = wired-gate
observation point = master
pattern classification = ON
pattern source = internal
possible credit = 50%
pulse generators = ON
RAM initialization = uninitialized
RAM test mode = static_pass_thru

[report_pattern_filtering](#)

report_external_simulator

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Displays the shell command the tool will use to invoke an external simulator for verifying patterns.

Usage

```
report_external_simulator [<> | >>] file_pathname]
```

Description

Displays the shell command the tool will use to invoke an external simulator for verifying patterns.

The report_external_simulator command displays the current setting of the set_external_simulator command. You use the latter to specify the shell command the tool should use to invoke an external time-based simulator for verifying patterns.

Arguments

- `>file_pathname`
An optional redirection operator and pathname pair for creating or replacing the contents of *file_pathname*.
- `>>file_pathname`
An optional redirection operator and pathname pair for appending to the contents of *file_pathname*.

Examples

The following example checks the current external simulator setting, then specifies for the tool to invoke ModelSim in batch mode (-c) with loading messages disabled (-quiet), when verifying simulation results:

```
report_external_simulator  
.../vsim -c  
  
set_external_simulator vsim -c -quiet  
report_external_simulator  
.../vsim -c -quiet
```

Related Topics

[set_external_simulator](#)

report_failures

Context: dft -edt, patterns -scan, patterns -scan_diagnosis,
patterns -failure_mapping

Mode: analysis

Simulates the current design and test patterns and reports the failures in a pattern-based format.

Usage

```
report_failures [{pin_pathname -Stuck_at {0 | 1}}...] [-Pdet | -Exact] [-Max integer] [-Cycle]  
[-MEasure_scan_at {CHANnels | CHAIns}]  
[{> | >>} file_pathname]
```

For “patterns -failure_mapping”

```
report_failures -UNMapped
```

Description

Simulates the current design and test patterns and reports the failures in a pattern-based format.

For failure mapping, reports the unmapped top-level failures.

Arguments

- *pin_pathname* -Stuck_at {0 | 1}

An optional, repeatable string, switch and literal triplet that specifies both the location and the value of a stuck-at fault to check for failing patterns. A fault simulation is run on the specified fault and the results are reported. Argument options include:

pin_pathname — A string that specifies the pin pathname of the fault whose failing patterns you want to identify.

-Stuck_at 0 | 1 — A switch and literal that specify the stuck-at fault value to simulate. The stuck-at options include:

0 — stuck-at-0

1 — stuck-at-1

- -Pdet

An optional switch that directs the tool to report a failure when an X is simulated where a binary value is expected. By default, only the binary detections are reported.

- -Exact

An optional switch directs the tool to report a failure when an X is simulated where a binary value is expected (like the -Pdet switch) and also when a binary value is simulated where an X is expected. By default, only the binary detections are reported.

- -Max *integer*

An optional switch and integer pair that specifies a maximum number of failing patterns before the command stops the simulation. By default, all failing patterns are simulated.

- **-CYClE**
An optional switch that reports the failure file in a cycle-based format. By default, a pattern-based format is output. For more format information, see the “[Input File Requirements](#)” chapter in the *Tessent Diagnosis User’s Manual*.
- **-measure_scan_at {channels | chains}**
An optional switch and literal pair that instructs the tool to report the failing bits of an EDT-enabled design at the scan elements; normally, the tool reports the failing bits at the EDT external channels. For an EDT-enabled design, this switch is only valid for external pattern sets in ASCII or binary format; STIL and WGL formats are not supported.

If EDT is enabled (On), by default, the tool measures at the external channels so that all failing bits are compressed. If you specify the chains option in this case, the tool reports the failing bits at the scan chain cell_number without considering the output compaction logic.

If EDT is disabled (Off), the tool always measures at the scan cells. In this case, specifying the channels option creates an error condition.

Reporting failures using the chains option generates the following information:

`pattern_id` — pattern index where the failure occurs.
`chain/PO_name` — scan chain or the primary output name where the failure occurs.
`cell_number` — scan cell index where the failure occurs. This field will be empty if the failure occurs at a primary output.
`expected_value` — expected value observed at the scan chain output pin from the external pattern set for the failing point.
`simulated_value` — the simulated value from the internal simulation for the failing point.
`cell_path_name` — cell or primary output name of the failing point.

- **>file_pathname**
An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of `file_pathname`.
- **>>file_pathname**
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of `file_pathname`.
- **-unmapped**
A required switch that specifies to report all failures that Tessent Diagnosis could not map to core instances.

Examples

Example 1

The following example loads a test pattern source, runs simulation, and displays the pattern-based failure information.

```

set_system_mode analysis
read_patterns file1
report_failures

// failing_patterns=8 simulated_patterns=36 simulation_time=0.00 sec

```

The pattern-based failure data is written in columns from left to right: pattern_id, chain/PO_name, cell_number, expected_value, simulated_value, cell_path_name as shown in the following example.

```

chain_test
0 chain5 0 H L // uUART/reg_MODE0_CLK
0 chain5 1 H L // uCNTR/reg_PORT_3_SAMPLE_P1_2_
0 chain5 4 H L // uCNTR/reg_PORT_3_SAMPLE_P1_5_
0 chain5 5 H L // uINTR/ix546
0 chain5 8 H L // uINTR/ix476
0 chain5 9 H L // uINTR/ix446
0 chain5 12 H L // uINTR/ix356
0 chain5 13 H L // uINTR/ix326
0 chain5 16 H L // uINTR/ix236
0 chain5 88 H L // padding_cycle
0 chain5 100 H L // padding_cycle
last_pattern_tested 0
scan_test
0 chain5 2 H L // uCNTR/reg_PORT_3_SAMPLE_P1_3_
0 chain5 4 H L // uCNTR/reg_PORT_3_SAMPLE_P1_5_
0 chain5 6 H L // uINTR/ix106
0 chain5 8 H L // uINTR/ix476
0 chain5 9 H L // uINTR/ix446
0 chain5 11 H L // uINTR/ix386
0 chain5 12 H L // uINTR/ix356
0 chain5 13 H L // uINTR/ix326
0 chain5 28 H L // uSTM/reg_WAIT_SYNC/SFFR
0 chain5 100 H L // padding_cycle
last_pattern_tested 2

```

Example 2

The following example shows the output of the report_failures command when the “-measure_scan_at chains” switch and option combination is specified for an EDT-enabled design:

```

FAULT> read_patterns patterns.ascii
FAULT> report_failures -measure_scan_at chains

// pattern_id chain/    cell    expected simulated cell_path_name
//          PO_name   number  value      value
0           chain1    2        H        L          // all_rams_i/sf_0003_1
0           chain4    3        H        L          // all_rams_i/sf_0028_1
0           chain10   1        L        H          // all_rams_i/lf_0055_1
0           chain11   5        L        H          // all_rams_i/lf_0043_1
1           chain7    4        H        L          // all_rams_i/sf_0053_1

// incorrect_patterns=2, simulated_patterns=61, simulation_time=0.04sec.

```

Example 3

The following example returns a list of the top-level failures for core instance logic_die_BOT_inst_logic_die_internal.

report_failures -unmapped

```
//Note: TestSuite[1] '../data/top_flog1', #fail_bits=1Cycle Pin  
      Expected Actual688 bc_2_core_2_q1 L H
```

report_false_paths

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Displays false paths previously defined with the [add_false_paths](#) command.

Usage

```
report_false_paths [-All] [-Error] [-Verbose] [-Debug_error]
  [-From source_node... | -FROM_Clock clock_signal_name...]
  [-TO sink_node... | -TO_Clock clock_signal_name...]
  [{-THrough through_node...}...]
  | [-GATE {{gate_ID# | pin_pathname}...}] ...
  | [-X_Statistics [-PATH_Count {int | All}] [-PATH_X_threshold int]
    [-TO_GATE_Count {int | ALL}] [-TO_GATE_X_threshold int]]
  [{> | >>} file_pathname]
```

Description

Displays false paths previously defined with the [add_false_paths](#) command.

Note that you can display SDC filenames and line numbers by first issuing the “[set_timing_exceptions_handling](#) -line_no” command. To analyze if a pin or a gate is affected by a false path, you can use “[set_gate_report](#) -timing_exceptions on” and [report_gates](#) commands.

If a specified starting point, end point, source node, clock signal name, sink node, or through node does not translate to an internal gate, zero (0) false paths are reported.

Arguments

When using the following arguments, you can include one or more asterisks (*) in pin or instance pathnames. An asterisk is treated as a wildcard character, enabling you to use it to match many pathnames in the design.

- **-All**
An optional switch that displays all previously-defined false paths. This is the default.
- **-Error**
An optional switch that displays only the false paths that have errors and warnings.
- **-Verbose**
An optional switch that displays all the gate information in the from, to, and through gate lists.
- **-Debug_error**
An optional switch that displays all the previously-defined false paths that have errors and warnings, along with their respective error and warning messages.

- -From *source_node*...

An optional switch and repeatable string pair that specifies the starting point of a false path. A valid starting point is a pin pathname, an instance pathname, a clock primary input (PI) or an internal clock pin name. For an instance pathname, all the output pins of the instance are considered to be starting points. For a clock PI, the outputs of all the non-transparent latches, flip-flops, and RAMs associated with the clock PI are considered to be starting points. A pin pathname is considered to be that of an internal clock pin if its fanout reaches only clock ports of sequential elements after traversing through any intervening combinational gates, and the internal clock pin is handled the same as a clock PI.

- -FROM_Clock *clock_signal_name*...

An optional switch and repeatable string pair that specifies the starting point of a false path by its associated clock pin pathname. Any pin pathname you specify with this argument is interpreted to be the source of a clock signal, and the outputs of all non-transparent latches, flip-flops, and RAMs associated with this clock signal are considered to be starting points.

- -TO *sink_node*...

An optional switch and repeatable string pair that specifies the end point of a false path. A valid end point is a pin pathname, an instance pathname, a clock primary input (PI), or an internal clock pin name. For an instance pathname, all the input pins of the instance are considered to be end points. For a clock PI, the data inputs of all non-transparent latches, flip-flops, and RAMs associated with the clock PI are considered to be end points. A pin pathname is considered to be that of an internal clock pin if its fanout reaches only clock ports of sequential elements after traversing through any intervening combinational gates, and the internal clock pin is handled the same as a clock PI.

Note

 For a 2-port latch with ports: Port1 = (D1, CLK1), Port2 = (D2, CLK2), and primary input clocks CLK1 and CLK2, the command “report_false_paths... -to CLK2” would report false paths with an end point at D2.

- -TO_Clock *clock_signal_name*...

An optional switch and repeatable string pair that specifies the end point of a false path by its associated clock pin pathname. Any pin pathname you specify with this argument is interpreted to be the source of an internal clock signal, and the data inputs of all non-transparent latches, flip-flops, and RAMs associated with this clock are considered to be end points.

- {-THrough *through_node*...}...

An optional, repeatable switch and repeatable string pair that specifies circuit node(s) through which the false path must pass. A valid through node is a pin or instance pathname. Clock PIs are not supported as through nodes and no attempt is made to determine if a pin pathname is that of an internal clock pin.

When you use multiple -Through arguments, their order, left-to-right, in the command string is considered to be the order in which a signal would pass through the nodes on the specified path. For example, the following false path specification:

```
add_false_paths -from A -through B C -through D E -to F
```

specifies all paths that start from A, pass through either B or C, then pass through D or E, and end at F. If you do not use the -through argument when specifying a path, all paths from the specified starting points to the specified end points are considered to be false paths.

- **-GAt gate-ID# | pin_pathname**

An optional repeatable switch and repeatable integer or string that filters the report results based on gates or pins that you specify. The tool reports only the false paths and multicycle paths that include the specified gates or pins as the definition points (-from, -to, or -through). You can use multiple -Gate switches to specify additional pins or gates in a single command invocation.

gate-ID# — A repeatable integer that specifies the gate identification number. When you specify multiple gate IDs, the command reports on any path that includes any of those gates as definition points.

pin_pathname — A repeatable string that specifies the name of a pin within the design. When you specify multiple pin_pathnames, the command reports on any path that includes any of those pins as definition points.

- **-X_Statistics [-PATH_Count int | All] [-PATH_X_threshold int] [-TO_GATE_Count {int | ALL}] [-TO_GATE_X_threshold int]**

An optional switch that reports the false or multicycle paths that have the most X masking from [create_patterns](#) or [simulate_patterns](#) after you enable the collection of X statistics with the [set_timing_exceptions_handling](#) command. The command reports the full path only when the path is not associated with the SDC file. Otherwise, the command reports only the SDC filename and line number of the path, as well as the number of cumulative Xs.

-PATH_Count {int | ALL} — An optional switch and integer or literal pair that specifies the number of paths to be reported. The default is to report up to 10 false or multicycle paths that have the greatest number of masking effects propagated to some to-points of the timing exception paths.

int — An optional positive integer that specifies the number of paths for which the tool reports X statistics.

ALL — An optional literal that specifies the tool reports X statistics for all paths that have X statistics.

-PATH_X_threshold int — An optional switch and positive integer pair that specifies the minimum number of accumulated Xs needed for the command to report the path.

-TO_GATE_Count {int | ALL} — An optional switch and integer or literal pair that specifies that the tool reports some or all of the to-gates' X statistics, immediately following each false path, in order from the gate with the greatest number of maskings to the least. The to-gates are the false path defined points from using the -to

option. When the -to option is not specified, path to-gates are derived from the last -through option or the -from option, when the -through option is not specified.

int — An optional positive integer that specifies the number of to-gates for which the tool reports X statistics.

ALL — An optional switch that specifies the tool reports all to-gates with at least one masking.

-TO_GATE_X_threshold *int* — An optional switch and integer pair that specifies the minimum number of accumulated X's needed for the command to report to-gates. When the **-to_gate_x_threshold** option is specified, and the **-to_gate_count** is not specified, the default is 10 gates.

By default, if the **-to_gate_count** option and the **-to_gate_x_threshold** option are both unspecified, the tool does not report any to-gates.

The **-to_gate_count** and the **-to_gate_x_threshold** reporting criteria will be the AND operation of both options. For example, if “**-to_gate_count 5**” and “**-to_gate_x_threshold 8**” are specified, the tool reports the 5 to-gates that have at least 8 accumulated Xs.

- **> *file_pathname***
An optional redirection operator and pathname pair for creating or replacing the contents of *file_pathname*.
- **>> *file_pathname***
An optional redirection operator and pathname pair for appending to the contents of *file_pathname*.

Examples

Example 1

The following example displays all previously-defined false paths.

```
report_false_paths -all
```

```
// False Path -from LINESTATE[1] LINESTATE[0] -to_clock MCLK
// False Path -from_clock UTMICLK[0] -to_clock MCLK
//
// -----
// The false path below has an error.
// -----
// False Path -from dummy1 -to dummy2
//
// -----
// The false paths below have warnings.
// -----
// False Path -from_clock S -to_clock s
// False Path -through I1 I2 I3 I4 I5 SIN CLK1 SEN
// False Path -from CLK1 -through U7/CP CLK1
//
// Total paths reported = 6
// Warning: The last 4 paths reported have 1 error and 3 warnings.
//           Use the command "report_false_paths -debug_error" to report
//           the causes of the errors/warnings.
// Warning: False path defined through all primary inputs, including all
//           clocks, which prohibits at-speed testing. Deleted clocks from
//           this list.
// Warning: There exists a false path that prohibits at-speed testing of
//           clock domain /CLK1.
//           This may result in lower test coverage.
```

Example 2

The following example displays the false paths with error and warning messages.

report_false_paths -error

```
// Error: False Path -from dummy1 -to dummy2
// Warning: False Path -from_clock S -to_clock s
// Warning: False Path -from CLK1 -through U7/CP CLK1
// Warning: False path -through I1 I2 I3 I4 I5 SIN CLK1 SEN
// Total reported false paths = 4
```

Example 3

The following example displays debug information for the false paths with error and warning messages.

report_false_paths -debug_error

```
// Error: False Path -from dummy1 -to dummy2 did not find gates dummy1
// dummy2.
// Warning: False Path -from_clock S -to_clock s has no combinational path
//           between start and end points.
// Warning: False Path -from CLK1 -through U7/CP CLK1 prohibits at-speed
//           testing of clock domain /CLK1.
// Warning: False path -through I1 I2 I3 I4 I5 SIN CLK1 SEN defined
//           through all primary inputs, including all clocks, which
//           prohibits at-speed testing. Deleted clocks from this list.
// False path debug summary: 1 error, 3 warnings
```

Example 4

The following example displays the false paths that start at /my_design/d_in[6]. The second path defined by the user results in an error because there is no sensitized path between the gates. Using the -debug_error option provides additional information about the error.

```
report_false_paths -verbose -from /my_design/d_in[6]

// False path -from /my_design/d_in[6] ( /reg_d_1_7/Q (81)
//      /reg_d_1_6/Q (73) ) -to /my_design/u25 ( /my_design/u25/Y (130) )
//
// -----
// The false path below has an error.
// -----
// Error: False path -from /my_design/d_in[6] ( ) -to /my_design/xray[5] ( )
//
// Total reported false paths = 2
// Warning: The last 1 path reported has an error.
//           Use the command "report_false_paths -debug_error" to report
//           the cause of the error.

report_false_paths -verbose -from /my_design/d_in[6] -debug_error

// Error: False Path -from /my_design/d_in[6] -to /my_design/xray[5] \
//         has no sensitizable combinational path between start and end points.
// False path debug summary: 1 errors, 0 warnings
```

Example 5

The following example displays the false paths and multicycle paths whose definition points (-from, -to, or -through) include the gate top/inst1/A:

```
report_false_paths -gate top/inst1/A
```

Example 6

The following shows false path reporting after turning on reporting of SDC filenames and line numbers:

```
read_sdc timing.sdc
set_timing_exceptions_handling -line_no on
report_false_paths

// False Path -from_clock cmem_fclk1 cmem_fclk1n -to_clock p_clk
//     spm_pci_clk -setup (filename = timing.sdc, line 406)
// False Path -from_clock p_clk spm_pci_clk -to_clock cmem_fclk1
//     cmem_fclk1n -setup (filename = timing.sdc, line 408)
...
// Total reported false paths = 177
```

Example 7

The following shows the commands to enable X statistics functionality and create ATPG patterns. It reports the 3 false paths with the greatest masking effect, in order starting with the path that has the most Xs. For each path, the tool reports the X statistics for the top 5 top-gates, which observe the most masking, in order starting from the gate that has the most Xs.

```

read_sdc mod.sdc
set_timing_exceptions_handling -x_statistics on
create_patterns
report_false_paths -x_statistics -path_count 3 -to_gate_count 5

// Total 249 paths out of 350 paths produced Xs.
// -----
// Path Type Number of Xs File and line number
// -----
// 1 false path 1572811 mod.sdc (line 32761)
// -----
// -----
// Gate (Id) Number of Xs
// -----
// '/u_lspipe/dcuv_valid_dc3_reg/' (253337) 3162
// '/clk_gate_list_phys_id_q_reg_0_/' (218650) 2656
// '/clk_gate_list_phys_id_q_reg_3_/' (218653) 2684
// '/clk_gate_list_phys_id_q_reg_2_/' (218652) 1886
// '/clk_gate_list_phys_id_q_reg_1_/' (218651) 1006
// Only the first 5 to-gates with most masking are reported (21524 out
// of total 26000 to-gates captured X).
// -----
// 2 false path 1107367 mod.sdc (line 32761)
// -----
// -----
// Gate (Id) Number of Xs
// -----

report_fault_sites

Context: dft -edt, patterns -scan

Mode: analysis

Depending on the fault model, displays path definitions, bridge entries, or UDFM entries from the internal list.

Usage

Path Delay Faults Usage:

```
report_fault_sites [-All | path_name] [-Path gate_id_begin gate_id_end]
[-Display {[FLAt_schematic] [HIEarchical_schematic] [DAta] | ALl} [APPend]]
[> | >>} file_pathname]
```

Bridge Faults Usage:

```
report_fault_sites
{[-All | net_pathname_pair | bridge_name... | net_pathname... | instance_name...]
[-NAME | -SINGle] [-NET_pathname] [-PIN_pathname] [-ATtribute] [-NOEQ] | 
[-Histogram {Layer | Type | {Weight [-Sets number]} }]}
[-Display {[FLAt_schematic] [HIEarchical_schematic] [DAta] | ALl} [APPend]]
[> | >>} file_pathname]
```

UDFM Usage:

```
report_fault_sites {[-ALl | instance_name] [-Udfm_type name][-CELL name]
[-MOdule name] [-FAult name]} |
{[-All | instance_name] [-UNDEFined_cells] | [-DEFined_cells]}
[> | >>} file_pathname
```

Description

Depending on the fault model, displays path definitions, bridge entries, or UDFM entries from the internal list.

The report_fault_sites command displays the definitions in the tool's internal list for the specified faults. Fault definitions are loaded into the internal list with the [read_fault_sites](#) command.

For more information about bridge faults, refer to “[The Static Bridge Fault Model](#)” in the *Tessent Scan and ATPG User’s Manual*.

For more information about path delay faults, refer to “[Path Delay Test Set Creation](#)” in the *Tessent Scan and ATPG User’s Manual*.

For more information about UDFM faults, refer to “[About User-Defined Fault Modeling](#)” in the *Tessent Scan and ATPG User’s Manual*.

Path Delay Specifics

The report_fault_sites command also displays unambiguous paths you previously added to the internal path list using the add_ambiguous_paths command. When displaying derived unambiguous paths, report_fault_sites cannot list a gate if it does not have a pin pathname associated with it. For some designs, gates without associated pin pathnames could be fairly common. Therefore, refer to the displayed unambiguous paths for launch and capture points, but be aware the display may not show all the gates in between.

Note

 If you get ambiguous path warnings, then add_ambiguous_paths, those paths when written out lose the information about which of the ambiguous paths they were. Consequently, you cannot reload them and get back to the same set of paths.

UDFM Specifics

The report_fault_sites command doesn't report restricted information about UDFM models generated by Tesson CellModelGen, which protects the IP inside of those models.

Arguments

- **-All**
An optional switch that displays all fault definitions for the currently loaded paths, bridge, or UDFM entries. This is the default.
- ***path_name***
An optional string that specifies the name of a path whose definition you want to display. The path must be one defined in a path definition file that you previously loaded using the read_fault_sites command.
- **-Path *gate_id_begin* *gate_id_end***
An optional switch and two-integer triplet that specifies a particular path or portion of a path whose definition you want to display. Use this argument to report on paths that were not defined in a path definition file, and therefore were not loaded using the read_fault_sites command.
The two integers specify two gate identification numbers that indicate the beginning and ending of the path. The path begins at *gate_id_begin* and ends at *gate_id_end*.
The value of *gate_id_begin* or *gate_id_end* is the unique identification number that the tool automatically assigns to every gate within the design during the model flattening process.
- ***net_pathname_pair***
A string pair that specifies the pathname to the nets or pins in a bridge entry. The first string specifies NET1, and the second string specifies NET2.
- ***bridge_name***
A repeatable string that specifies a bridge name.

- ***net.pathname***
A repeatable string that specifies a single net or pin pathname.
- ***instance.name***
A repeatable string that specifies an instance pathname.
- **-ATtribute**
An optional switch that displays the attributes of the reported bridge entries. Attributes may include distance, weight, layer, and parallel_run.
- **-NAME**
An optional switch that specifies all entered strings are bridge names.
- **-SINGle**
An optional switch that specifies all the entered strings are either a single net or instance. The tool searches for a net first. If a corresponding net cannot be found, the tool searches for a corresponding instance.
If the string is an instance that contains a non-dominant net from a bridge entry, a fault is reported for each bridge entry associated with the instance.
- **-NET.pathname**
An optional switch that reports net pathnames for bridge entries. This is the default.
- **-PIN.pathname**
An optional switch that reports pin pathnames for bridge entries instead of net pathnames.
- **-NOEQ**
An optional switch that reports only the representative fault information: the net pair and fault categories.
- **-Histogram {Layer | Type | {Weight [-Sets *number*]}}**
An optional switch and literal pair that displays a histogram of the number of equivalent classes of bridges based on either their layer, type, or weight attribute. When you specify a weight histogram, you can optionally include the -Sets switch to specify a number of sets into which to distribute the report data. Specifying “-sets 0” forces the tool to display an individual line for each bridge of different weight.
The display for a weight histogram consists of one weight histogram per type of bridge fault, whereas a layer or type histogram is a single histogram.
- **-Display {[FLAt_schematic] [HIErarchical_schematic] [DAta] | ALI} [APpend]**
An optional switch and literal that displays the reported information graphically in the specified DFTVisualizer window(s); if *Append* is specified, the information is added to the existing contents of the window instead of replacing the contents. The choices are as follows:
 - FLAt_schematic — Flat Schematic window
 - HIErarchical_schematic — Hierarchical Schematic window

DAta— Data window

ALl — A literal that displays the information in all of the preceding windows.

- **-Udfm_type *name***

An optional switch and string pair that specifies the name of a UDFM fault type. Use this option to display the faults associated with the specified UDFM fault type. The name string can include any number of asterisk (*) and/or question mark (?) wildcard characters.

- **-Cell *name***

An optional, repeatable switch and string pair that specifies the name of a library cell. Use this option to display all faults associated with a specified library cell. The name string can include any number of asterisk (*) and/or question mark (?) wildcard characters.

- **-Module *name***

An optional switch and string pair that specifies the name of a module. Use this option to display all faults associated with the specified module. The name string can include any number of asterisk (*) and/or question mark (?) wildcard characters.

- **-Fault *name***

An optional switch and string pair that specifies the name of a UDFM defined fault. Use this option to display all faults associated with the specified name. The name string can include any number of asterisk (*) and/or question mark (?) wildcard characters.

- **-UNDEFined_cells**

An optional switch that reports cells without a valid UDFM definition that were added with a previous [read_fault_sites](#) or [add_fault_sites](#) command.

- **-DEFined_cells**

An optional switch that reports cells with a valid UDFM definition that were added with a previous [read_fault_sites](#) or [add_fault_sites](#) command.

- **> *file.pathname***

An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file.pathname*.

- **>> *file.pathname***

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file.pathname*.

Examples

Example 1

The following path delay example reads in (loads) the path information and then displays that data:

```
set_fault_type path_delay
read_fault_sites /user/design/pathfile
report_fault_sites
```

```

PATH "path0" =
  PIN /I$6/Q + ;
  PIN /I$35/B0 + ;
  PIN /I$35/C0 + ;
  PIN /I$1/I$650/IN + ;
  PIN /I$1/I$650/OUT - ;
  PIN /A_EQ_B + ;
END ;
PATH "path1" =
  PIN /I$6/Q + ;
  PIN /I$35/B1 + ;
  PIN /I$35/C1 + ;
  PIN /I$1/I$649/IN + ;
  PIN /I$1/I$649/OUT - ;
  PIN /I$5/D - ;
END ;

```

Example 2

The following bridge example reads the bridge information in the bridge fault definition file, */user/design/bridgefile*, then displays the data for bridge entries added to the fault site list:

```

set_fault_type bridge read_fault_sites /user/design/bridgefile

// Load bridge entries from file "/user/design/bridgefile".
//
// 5 bridge entries were read from file "/user/design/bridgefile".
// 2 bridge entries were skipped due to unknown net name.
// 3 bridge entries were added to the fault site list.

```

report_fault_sites

```

BRIDGE {
  NET1 = "/G5";
  NET2 = "/G10";
  FAULTS = {-, -, -, -};
  NAME = "U7.BRIDGE";
}
BRIDGE {
  NET1 = "/G4";
  NET2 = "/G10";
  FAULTS = {-, -, -, -};
  NAME = "U5.BRIDGE";
}
BRIDGE {
  NET1 = "/G11";
  NET2 = "/G10";
  FAULTS = {-, -, -, -};
  NAME = "U0.BRIDGE";
}

```

Example 3

The following example displays the attribute data for the “U0.BRIDGE” bridge entry:

```
report_fault_sites U0.BRIDGE -name -attribute
```

```
BRIDGE {
    NET1 = "/G11";
    NET2 = "/G10";
    FAULTS = {-, -, -, -, -};
    WEIGHT = 1.0000;
    DISTANCE = 4.93827000e-06 um;
    PARALLEL_run = 6.07500000e-05 um;
    X_COORDINATE = 152500;
    Y_COORDINATE = 739500;
    LAYER = "metall1";
    NAME = "U0.BRIDGE";
}
```

Example 4

The following example displays the UDFM fault definition f01 defined in UDFM type my-udfm-sa-faults of instance /top/inst1:

```
report_fault_sites /top/inst1 -udfmtype my-udfm-sa-faults -fault f01

UDFM {
    Version:1;
    UdfmType("my-udfm-sa-faults") {
        Instance("/top/inst1") {
            // Source reference:
            // File: /home/JohnDoe/myadded.udfm, Line: 145
            Fault("f01") {
                Test { StaticFault{"Z":0;} Conditions{"D":0;"E":1; "F":-;} }
                Test { StaticFault{"Z":1;} Conditions{"D":1;"E":-; "F":0;} }
            }
        }
    }
}
```

If there is more than one UDFM types used, the following command reports all f01 faults on instance /top/inst1:

```
report_fault_sites /top/inst1 -Fault f01
```

```
UDFM {
    Version:1;
    UdfmType("my-udfm-sa-faults") {
        Instance("/top/inst1") {
            // Source reference:
            // File: /home/JohnDoe/myadded.udfm, Line: 145
            Fault("f01") {
                Test { StaticFault{"Z":0;} Conditions{"D":0;"E":1; "F":-;} }
                Test { StaticFault{"Z":1;} Conditions{"D":1;"E":-; "F":0;} }
            }
        }
    }
    UDFMType("intra-cell") {
        Instance("/top/inst1") {
            // Source reference:
            // File: /home/JohnDoe/myadded.udfm, Line: 418
            Fault("f01") {
                Test { StaticFault{"Z":0;} Conditions{"D":0;"E":1; "F":-;} }
                Test { StaticFault{"Z":1;} Conditions{"D":1;"E":-; "F":0;} }
            }
        }
    }
}
```

report_fault_sites -all

```
UDFM {
    Version:1;
    UdfmType("my-udfm-sa-faults") {
        Cell("AOX") {
            // Source reference:
            // File: /home/JohnDoe/myadded.udfm, Line: 145
            Fault("f01") {
                Test { StaticFault{"Z":0;} Conditions{"D":0;"E":1; "F":-;} }
                Test { StaticFault{"Z":1;} Conditions{"D":1;"E":-; "F":0;} }
            }
        }
    }
}
```

Example 5

The following example shows how to display a list of cells both with and without valid UDFM definitions:

report_fault_sites -defined_cells

```
// Report of cells defined by UDFM
//
// Cell Name Instances
// -----
// XNOR2X18      518
// XNOR2X3       139
// XOR2X17       387
// AND2X35       913
// AO112X27        4
// AO12X27      203
// AO22X27      219
// AO312X27        39
// AO31X27         5
// -----
```

report_fault_sites -undefined_cells

```
// Report of cells not defined by UDFM
//
// Cell Name Instances
// -----
// cnhlsx4v      52
// df1qx1v      834
// df4sqx1v        7
// u_noti       68
// u_mux2      7261
// u_mux3       20
// u_mux4      398
// -----
```

report_faults

Context: dft -edt, dft -test_points, patterns -scan

Mode: analysis

Displays fault information from the current fault list.

Usage

Path Delay Usage:

```
report_faults [-Both | -Rise | -Fall] [-VERilog | -VHdl]
[-Class fault_class[fault_subclass]] [object_pathname] [-NO_Subclass]
```

Bridge Usage:

```
report_faults {[-Histogram Weight [-Sets number]]}
| {[-Histogram {Layer | Type}]}
| {net_pathname_pair | {bridge_name ... -NAME}
| {net_pathname ... -SINGLe} | {instance ... -SINGLe}}
[-Class fault_class[fault_subclass]] [-NET_pathname | -PIN_pathname] [-NOEQ]
[-NO_Subclass] [-VERilog | -VHdl] [-ATtribute] [-SCAN_Enable] [-CLOCK_Cones]
[-IO] [-ASYnchronous_controls}]
| {[-CLOCK_Domains {ALL | clock_pathname ...} [-NO_EQUIvalent_clocks]
[-EXCLUDE_FAULTS_BETWEEN_SYNC_clock_domains]]
[-CAPture_procedures {ALL | capture_procedure_name ...}]} [(> | >>) file_name]
```

Toggle/Iddq Usage:

```
report_faults [-Stuck_at [01 | 0 | 1]] [-NO_Subclass]
[{-Class fault_class[fault_subclass]} [{pin_pathname | gate_id} ...] [-NOEQ]
[instance_name ...] [-Hierarchy integer] [-Min_count integer] [-VERilog | -VHdl]
[-CELL_name] [-CLOCK_Domains
{ALL | clock_pathname ...} [-NO_EQUIvalent_clocks]]
[-CAPture_procedures {ALL | capture_procedure_name ...}]}
| {[-SCAN_Enable] [-CLOCK_Cones] [-IO] [-ASYnchronous_controls]}
| {-UNlisted}
[-FRom pin...] [-TThrough pin...] [-TO pin...]
[-STOP_at {sequential_elements | scan_cells | ports_only}] [(> | >>) file_name]
```

Stuck/Transition Usage:

```
report_faults [-Stuck_at [01 | 0 | 1]] [-NO_Subclass]
[{-Class fault_class[fault_subclass]} [{pin_pathname | gate_id} ...] [-NOEQ]
[instance_name ...] [-Hierarchy integer] [-Min_count integer] [-VERilog | -VHdl]
[-CELL_name]
[-CLOCK_Domains {ALL | clock_pathname ...} [-NO_EQUIvalent_clocks]
[-EXCLUDE_FAULTS_BETWEEN_SYNC_clock_domains]]
[-CAPture_procedures {ALL | capture_procedure_name ...}] [-DElay_data]
[-TIMING_CRITICAL}] | {[-SCAN_Enable] [-CLOCK_Cones] [-IO]
[-ASYnchronous_controls]} | {-UNlisted}
```

```
[-FRom pin...] [-THrough pin...] [-TO pin...]  
[-STOP_at {sequential_elements | scan_cells | ports_only}] [(> | >>) file_name]
```

UDFM Usage:

```
report_faults [-NO_Subclass] {[ -Class fault_class[fault_subclass]]  
| instance_pathname | [-Hierarchy integer] [-NOEQ]  
[-CLOCK_Domains {ALL | clock_pathname ...} [-NO_EQUIvalent_clocks]  
[-EXCLUDEFAULTS_BETWEEN_SYNC_clock_domains] {[ -UDFM_type name]  
[-INstance name] [-CELL name] [-MODule name] [-SOurce]} }  
| {-UNlisted} [-FRom pin ...] [-THrough pin ...] [-TO pin ...]  
[-STOP_at [ sequential_elements | scan_cells | ports_only }] [(> | >>) file_name]
```

Power-Aware Options:

(applicable only after you have loaded CPF/UPF power data)

```
[[ON_domains] | [-OFF_domains] | [-POWER_domains {domain_name ...}]]  
[-ISolation_cells] [-LLevel_shifters] [-REtention_cells]
```

Description

Displays fault information from the current fault list. The report_faults command displays all the faults you added to the fault list using the add_faults or read_faults command. You can use the optional arguments to narrow the focus of the report to only specific stuck-at or transition faults that occur on a specific object in a specific class. If you do not specify any arguments, report_faults displays information on all the known faults.

By default, the report_faults command ignores the constraint values implied in the data path when reporting faults in the data path. However, the tool still considers the constraint values for clock path faults.

For more information about UDFM faults, refer to “[About User-Defined Fault Modeling](#)” in the *Tessent Scan and ATPG User’s Manual*.

The power-aware options report_faults based on power domains and/or power features after you have loaded a CPF or UPF file.

The report_faults command displays the following columns of information for each fault:

- fault value - The fault value may be either 0 (for stuck-at-0 or “slow-to-rise” transition faults) or 1 (for stuck-at-1 or “slow-to-fall” transition faults).
- fault code - A code name that indicates the lowest level fault class assigned to the fault (see [Table 5-10](#)). This also includes a fault sub-class code when available (see [Fault Sub-classes](#) in the *Tessent Scan and ATPG User’s Manual*).
- fault site - The pin pathname of the fault site.
- cell name (optional) - The name of the cell corresponding to the fault (displayed only if you include the -Cell_name argument).

You can use the -Hierarchy option to display a hierarchical summary of the selected faults. The summary identifies the number of faults in each level of hierarchy whose level does not exceed the specified level number. You can further specify the hierarchical summary by using the -Min_count option which specifies the minimum number of faults that must be in a hierarchical level before they are displayed.

You may choose to display either collapsed or uncollapsed faults by using the set_fault_mode command. Also, some fault data is large and it would be more appropriate to use the write_faults command, and then read the file contents.

Arguments

- -Class *fault_class*[.*fault_subclass*]

An optional switch and literal pair that specifies the fault class or fault class/sub-class to display. [Table 5-10](#) lists the valid fault class codes and their associated fault class names. [Fault Sub-classes](#) in the *Tessent Scan and ATPG User's Manual* lists the valid fault sub-class names. You should use the code when specifying a fault class or sub-class.

When you have previously issued the “[report_statistics -detailed_analysis](#)” command, report_faults can report specific AU.TC and AU.PC faults by pin pathname or by gate ID. For more information, refer to “[Example 9](#)” on page 1566.

Table 5-10. Fault Class Codes and Names

Fault Class Code	Fault Class Name	Fault Class Coverage
FU	Full	TE+UT
TE	TEstable	DT+PD+AU+UD
DT	DETEcted	DS+DI+DR
DS	DET_Simulation	
DI	DET_Implication	
DR	DET_Robust (Path Delay Testing only)	
DF	DET_Functional (Path Delay Testing only)	
PD	POSDET	PT+PU
PU	POSDET_Untestable	
PT	POSDET_Testable	
AU	Atpg_untestable	
UD	UNDetected	UC+UO
UC	UNControlled	
UO	UNObserved	
UT	UNTestable	UU+TI+BL+RE

Table 5-10. Fault Class Codes and Names (cont.)

Fault Class Code	Fault Class Name	Fault Class Coverage
UU	UNUsed	
TI	TIed	
BL	Blocked	
RE	Redundant	

- **-NO_Subclass**
Prevents the display of fault sub-classes after the fault code. The default is to display fault sub-classes when the tool has analyzed them.
- **-UNlisted**
Displays unlisted fault data. If there are multiple grayboxed instances in the design, this switch reports accumulated fault numbers.
- **-FRom pin ...**
This option sets the start pin(s) of the user-specified cone to report the faults. It directs the tool to perform forward cone tracing from the specified pin(s) until it encounters a stop point. You can specify one or more instance names, rather than pin names. When you specify an instance name with -from, its output pins are used when defining the cone.
- **-THrough pin ...**
This option sets the through pin(s) of the cone of logic used to select faults to report. When specified, the tool performs forward and backward cone tracing from the specified pin(s) until it encounters a stop point in both directions. When you specify an instance name with -through, its output pins are used when defining the cone.
- **-TO pin ...**
This option sets the end pin(s) of the cone of logic used to select faults to report. When specified, the tool performs backward cone tracing from the specified pin(s) until it encounters a stop point. When you specify an instance name with -to, its input pins are used when defining the cone.

Note

When -from, -to, and -through are used with other switches, the selected faults will be the intersection of the cones traced for all specified switches.

- **-STOP_at {sequential_elements | scan_cells | ports_only}**
This option sets the stop condition for tracing of the cone of logic used to select faults to report. By default, the traced logic cone includes only combinational logic, so cone tracing stops at any sequential elements. When you specify “scan_cells”, the cone includes non-scan cells and tracing stops only at scan cells. When you specify “ports_only”, the cone includes any sequential elements and tracing stops only at primary inputs and outputs.

- **-Stuck_at 01 | 0 | 1**

An optional switch and literal pair that specifies the stuck-at or transition faults you want to display. The choices are as follows:

01 — A literal specifying that for stuck-at faults the tool display both “stuck-at-0” and “stuck-at-1” faults; or for transition faults, the tool display both “slow-to-rise” and “slow-to-fall” faults. This is the default.

0 — A literal specifying to display only the “stuck-at-0” faults (“slow-to-rise” faults for transition faults).

1 — A literal specifying to display only the “stuck-at-1” faults (“slow-to-fall” faults for transition faults).

- **object_pathname**

An optional repeatable string that specifies a list of pins, instances, or delay paths whose faults you want to display.

- **-Hierarchy integer**

An optional switch and integer pair that specifies the maximum hierarchy level for which you want to display a summary of the faults. However, note that the reported number of faults depends on other switches, like -class.

- **-Min_count integer**

An optional switch and integer pair that you can use with the -Hierarchy option to specify the minimum number of faults that must be in a hierarchical level to display the hierarchical summary. The default is 1.

- **-NOEQ**

- For stuck-at, transition, toggle, iddq, and udfm faults only, an optional switch that turns off the display of “EQ” as the fault class for any equivalent faults; the fault class displayed is then that of the representative fault. When you do not specify this switch, the tool displays an “EQ” as the fault class for any equivalent faults. This switch is meaningful only when the [set_fault_mode](#) command is set to Uncollapsed. For more information about representative and equivalent faults, see “[Fault Collapsing](#)” in the *Tessent Scan and ATPG User’s Manual*.

- For bridge faults only, an optional switch that writes only the representative bridge fault information: the net pair and fault classes of each corresponding dominant net. The tool does not report physical data.

- **-Both| -Rise | -Fall**

An optional switch that specifies which faults to display for each path already added via the [read_fault_sites](#) command. These switches are used for path delay faults only.

-Both - An optional switch that specifies to display both the slow-to-rise and slow-to-fall faults. This is the default.

-Rise - An optional switch that specifies to display only the slow-to-rise faults.

-Fall - An optional switch that specifies to display only the slow-to-fall faults.

- **-VERilog | -VHdl**

An optional switch pair that output the fault paths in either Verilog or VHDL syntax, rather than using the existing netlist independent format.

- **-CELL_name**

An optional switch that lists the name of the corresponding circuit element (Tessent Cell library cell, Verilog primitive, primary input or primary output) for each fault as listed in [Table 5-11](#). Cell names for equivalent faults are based on the cells associated with the equivalent faults, not the cells associated with the representative faults. This switch is valid for the stuck-at, transition, toggle and IDDQ fault models only.

Table 5-11. Name Conventions Used by report_faults -Cell_name

Corresponding Circuit Element	Listed Cell Name
Tessent Cell library cell	Name of the Tessent Cell library cell
Supported Verilog primitive (for a list, see Table 4-1 in the <i>Tessent Cell Library Manual</i>)	Name of the Verilog primitive
Primary input or output	“primary_input” or “primary_output”

- **-CLOCK_Domains {ALL | clock_pathname...}**

A required switch and literal or repeatable string pair that specifies a list of clocks which is used by the tool to decide the faults to be added to the fault list, given the following requirements are met:

- **Static Faults** — A fault is added to the fault list if it can be captured by any clock in the specified list of clocks or any of its equivalent clocks.
- **Transition Faults** — A fault is added to the fault list:
 - i. If the launch and capture clock are the same clock from the specified list of clocks
 - ii. If the launch and capture clock are synchronous clocks from the specified list of clocks
 - iii. If the launch or capture clock from the specified are equivalent equivalent clocks

When you use this switch, the tool ignores the constraint values implied in the data path when adding faults in the data path. However, the tool still considers the constraint value for the clock cone tracing to determine the state element clock domain.

The argument choices are as follows:

ALL — A literal that specifies all the clocks in the design.

clock_pathname — A repeatable string that specifies a particular clock.

Be aware that a fault reported using this switch might also be detectable by an unspecified clock.

The tool takes user-defined non-race clocks and faults between synchronous clock groups into account when adding or deleting faults by clock domain.

- -NO_EQUIvalent_clocks

An optional switch that prevents the -Clock_domains switch from reporting faults in equivalent clock domains.

- -EXCLUDE_FAULTS_BETWEEN_SYNC_clock_domains

An optional switch used with -Clock_domains to instruct the tool to exclude the inter-clock faults for synchronous clocks. When specified, only faults within clock domains are considered when adding or deleting faults by clock domain.

- -CAPture_procedures {ALL | *capture_procedure_name...*}

An optional switch and literal or repeatable string pair that specifies a list of enabled named capture procedures and directs the tool to report faults that are potentially detectable by any of the specified procedures. The argument choices are as follows:

ALL — A literal that specifies all enabled named capture procedures.

capture_procedure_name — A repeatable string that specifies a particular enabled named capture procedure.

See the [set_capture_procedures](#) command description for information about enabling or disabling named capture procedures.

- -DElay_data

An optional switch that reports the fault list including the slacks of the faulty site. The reported slack is for information only and cannot be loaded back into the system.

- -TIMING_CRITICAL

An optional switch that reports timing-critical faults.

Note

 In order to use the -DElay_data or -TIMING_CRITICAL switches, you must have previously loaded an SDF file containing timing information. See “[Timing-Aware ATPG](#)” in the *Tessent Scan and ATPG User’s Manual* for complete information.

- -SCAN_Enable

An optional switch that specifies to report faults that fan out to the select lines of multiplexers in the scan path. For this switch, a multiplexer is either a MUX simulation primitive or a nonprimitive type multiplexer composed of AND and OR gates. Basically, this switch reports all faults that are in the fanin cone of local scan enable signals and are dominated by them.

- **-CLOCK_Cones**
An optional switch that deletes all faults in the clock cone. The clock cone is the intersection of the fan-in of the sequential element clock ports and the fan-out of the clock sources. This switch considers any sequential elements, such as flops, latches, RAMs, and ROMs, not just scan cells.
- **-IO**
An optional switch that specifies to report faults that are:
 - Only controlled by PIs — To be acted on by the -IO switch, a PI either must not be defined as a clock or, if defined as clock (or read/write control), must be constrained off during capture.
 - Only observed by POs
- **-ASYnchronous_controls**
An optional switch that specifies to report all faults that only fan out to Set/Reset ports of state elements and RAMs.
- **-Histogram Weight [-Sets *number*] -Histogram {Layer | Type}**
An optional switch and literal pair that displays a histogram of the number of equivalent classes of bridges based on either their layer or type, or their weight attributes. When you specify a weight histogram, you can optionally include the -Sets switch to specify a number of sets into which to distribute the report data. Specifying “-sets 0” forces the tool to display an individual line for each bridge of different weight.
The display for a weight histogram consists of one weight histogram per type of bridge fault, whereas a layer or type histogram is a single histogram.
- **> *file_name***
An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_name*.
- **>> *file_name***
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_name*.
- ***net_pathname_pair***
An optional, string pair that specifies the bridge fault site. The first string specifies NET1, and the second string specifies NET2.
- ***bridge_name***
An optional, repeatable string that specifies the bridge name.
- ***net_pathname***
An optional, repeatable string that specifies a single net pathname.

- *instance_name...*
An optional, repeatable string that specifies an instance pathname.
- **-ATtribute**
An optional switch that specifies to display the attributes for bridge entries. Attributes may include distance, weight, layer, and parallel_run.
- **-NAME**
An optional switch that specifies all entered strings are bridge names.
- **-SINGle**
An optional switch that specifies all the entered strings are either a single net or instance. The tool searches for a net first. If a corresponding net cannot be found, the tool searches for a corresponding instance.
If the string specifies an instance that contains a non-dominant net from a bridge entry, a fault is reported for each bridge entry associated with the instance.
- **-NET.pathname**
An optional switch that reports net pathnames for bridge entries. This is the default.
- **-PIN.pathname**
An optional switch that reports pin pathnames for bridge entries instead of net pathnames.
- *instance_pathname ...*
An optional repeatable string that specifies a list of instance names you want to display.
- **-Udfm_type name**
An optional switch and string that specifies the name of a UDFM fault type. Use this option to display the faults associated with a specified UDFM fault type. The name string may include any number of asterisk (*) and/or question mark (?) wildcard characters.
- **-CELL name**
An optional, repeatable switch and string pair that specifies the name of a library cell. Use this option to display all faults associated with a specified library cell. The name string may include any number of asterisk (*) and/or question mark (?) wildcard characters.
- **-Module name**
An optional switch and string pair that specifies the name of a module. Use this option to display all faults associated with a specified module. The name string may include any number of asterisk (*) and/or question mark (?) wildcard characters.
- **-INSTance name**
An optional switch and string pair that specifies the name of an instance. Use this option to display all faults associated with a specified instance. The name string may include any number of asterisk (*) and/or question mark (?) wildcard characters.

- **-S**ource

An optional switch that outputs the UDFM file name and line number where the fault is defined.

Power-Aware Options (applicable only after you have loaded CPF/UPF power data)

- **-ON_domains**

An optional switch that reports faults on all power-on domains.

- **-OFF_domains**

An optional switch that reports faults on all power-off domains.

- **-Power_domains {domain_name ...}**

An optional switch and repeatable string that reports faults on the specified power domains (*domain_name*).

- **-Isolation_cells**

An optional switch that reports faults on all isolation cells.

- **-Level_shifters**

An optional switch that reports faults on all level-shifters.

- **-REtention_cells**

An optional switch that reports faults on all retention cells.

Examples

Example 1

The following example modifies the current fault population in the tool with the contents of the external fault file, *my_detected_faultlist*, then displays the faults:

```
set_system_mode analysis
add_faults -all
read_faults my_detected_faultlist -merge
report_faults
```

Example 2

The following example displays information for the stuck-at-0 fault on pin /mult_8/Y, including the name of the cell associated with the fault:

```
report_faults -stuck_at 0 /mult_8/Y -cell_name
//   type    code    pin.pathname  (cell_name)
//   ----  -----
//     0      DS     /mult_8/Y      (xnor2)
```

Example 3

The following example reports on a fault associated with a primary input:

```
report_faults -stuck_at 1 /ip_scan_en -cell_name
```

```
// type code pin.pathname (cell_name)
// ---- -----
// 0 AU /ip_scan_en primary_input
```

Example 4

The following example shows a fault list with the static test slack and the actual minimum test slack. Only DS faults contain the actual minimum test slack data.

report_faults -delay_data

```
// type code pin.pathname
// ----- -----
// 0 DS /CORE_i/IRQA_B/A 10.1010 12.3000
// 1 DS /CORE_i/IRQA_B/B 20.1480 25.4820
// 0 AU.BB /CORE_i/IRQA_B/C 12.1890 -
// 1 AU.BB /CORE_i/IRQA_B/C 18.8770 -
```

Example 5

The following example displays information for the stuck-at-0 fault on pin /mult_8/Y plus all isolation cells:

report_faults -stuck_at 0 /mult_81/Y -isolation_cells

Example 6

The following example shows the reporting of unlisted faults:

report_faults -unlisted

	detections	collapsed_fault_count	uncollapsed_fault_count
UC	0	1252	2079
UC.EAB	0	452	543
DS	1	69873	87232
DS	2	12873	21432
DS	3	9752	11974
DS	4+	4487	6293
AU.BB	0	8708	10046
AU	0	2374	3782

Example 7

The following example displays the fault data for *ds* class faults associated with library cells that start with *mux* or *an* to the *my_fault_list* file:

report_faults -class ds -cell mux* -cell an*

```
// Command output
```

```
FaultInformation {
    version : 1;
    FaultType (UDFM) {
        FaultList {
            Format : Identifier, Class;
            UdfmType ("intra-cell-bridges_1") {
                Cell ("MUX2") {
                    Instance ("/top/i1/i4") {
                        "F2", DS;
                    }
                }
                Cell ("AND3") {
                    Instance ("/top/i1/i456") {
                        "F2", DS;
                        "F4", DS;
                        "F5", DS;
                        "F7", DS;
                    }
                }
            }
        }
    }
}
```

Example 8

The following example shows the default format of the fault report when the fault type is specified as UDFM using the set_fault_type command:

report_faults

Class	UdfmType	Fault	instance
UC	my-added-sa	f01	/top/i1/i4
DS	my-added_sa	f02	/top/i1/i4
DS	intra-cell	f01	/top/i3
AU.BB	intra-cell	f02	/top/i3

Adding the -source switch to the command extends the report with references to the definition sources:

report_faults -source

Class	UdfmType	Fault	instance	File	Line
UC	my-added-sa	f01	/top/i1/i4	/home/JohnDoe/myadded.udfm	14
DS	my-added_sa	f02	/top/i1/i4	/home/JohnDoe/myadded.udfm	145
DS	intra-cell	f01	/top/i3	/home/JohnDoe/intra.udfm	217
AU.BB	intra-cell	f02	/top/i3	/home/JohnDoe/intra.udfm	67

Example 9

The following examples shows how to report specific AU.TC and AU.PC faults:

```
report_statistics -detailed_analysis # you must first run this command
```

```
report_faults -class au.tc /tap_i/tap_ctrl_i/reg_enable #specified using a pin pathname
```

type	code	pin.pathname
0	AU.TC	/pad_i1/tdo_buf/tri_pin/A
0	EQ	/pad_i1/tdo_buf/ix68/Y
1	EQ	/pad_i1/tdo_buf/ix68/A
1	AU.TC	/pad_i1/tdo_buf/tri_pin/A
1	EQ	/pad_i1/tdo_buf/ix68/Y
0	EQ	/pad_i1/tdo_buf/ix68/A
0	AU.TC	/tdo
0	EQ	/pad_i1/tdo_buf/tri_pin/Y
1	AU.TC	/tdo
1	EQ	/pad_i1/tdo_buf/tri_pin/Y
0	AU.TC	/pad_i1/tdo_buf/tri_pin/E

report_faults -class au.tc 1196 #specified using a gate ID.

type	code	pin.pathname
0	AU.TC	/pad_i1/tdo_buf/tri_pin/A
0	EQ	/pad_i1/tdo_buf/ix68/Y
1	EQ	/pad_i1/tdo_buf/ix68/A
1	AU.TC	/pad_i1/tdo_buf/tri_pin/A
1	EQ	/pad_i1/tdo_buf/ix68/Y
0	EQ	/pad_i1/tdo_buf/ix68/A
0	AU.TC	/tdo
0	EQ	/pad_i1/tdo_buf/tri_pin/Y
1	AU.TC	/tdo
1	EQ	/pad_i1/tdo_buf/tri_pin/Y
0	AU.TC	/pad_i1/tdo_buf/tri_pin/E

report_faults -class au.pc test_en #specified using a pin pathname

type	code	pin.pathname
1	AU.PC	/test_en
1	AU.PC	/core_i/test_design_i/senmux/ix9/S0
0	AU.PC	/core_i/test_design_i/senmux/ix9/A0
1	AU.PC	/core_i/test_design_i/senmux/ix9/A0

report_faults -class au.pc 35 #specified using a gate ID

type	code	pin.pathname
1	AU.PC	/test_en
1	AU.PC	/core_i/test_design_i/senmux/ix9/S0
0	AU.PC	/core_i/test_design_i/senmux/ix9/A0
1	AU.PC	/core_i/test_design_i/senmux/ix9/A0

Example 10

The following example shows the format of the fault report when the fault type is specified as UDFM and you have enabled multiple detections:

report_faults

//	Class	Detections	UdfmType	Fault	Instance
//	-----	-----	-----	-----	-----
//	DS	2	intra-cell	F1	ip_inst/pio_i/i_42/inst
//	DS	1	intra-cell	F2	ip_inst/pio_i/i_42/inst
//	DS	2	intra-cell	F3	ip_inst/pio_i/i_42/inst
//	DS	3+	intra-cell	F4	ip_inst/pio_i/i_42/inst
//	DS	1	intra-cell	F5	ip_inst/pio_i/i_42/inst
//	DS	1	intra-cell	F6	ip_inst/pio_i/i_42/inst

Example 11

The following example shows the format of the fault report when you specify that you want to display faults from a maximum of two levels of hierarchy:

report_faults -hierarchy 2

// /clk_ctrl_clk_testshell	48
// /clk_ctrl_clk_testshell/gated_ccb_inst4	6
// /clk_ctrl_clk_testshell/gated_ccb_inst2	6
// /clk_ctrl_clk_testshell/i_ipoHold_10275	4
// /clk_ctrl_clk_testshell/gated_ccb_inst1	10
// /clk_ctrl_clk_testshell/antiskeew_clock_inv	4
// /clk_ctrl_clk_testshell/antiskeew_1	6
// /clk_ctrl_clk_testshell/gated_ccb_inst3	12
// /ip_inst	240366
// /ip_inst/dsp_periph_em_ccb_i	960
// /ip_inst/siox_i	8336
// /ip_inst/dio_i	25218

report_feedback_paths

Context: all contexts

Mode: all modes

Prerequisites: You can use this command only after the tool performs the learning process, which happens immediately after flattening a design to the simulation model. Flattening occurs when you first attempt to exit Setup mode or when you issue the `create_flat_model` command.

Displays a report of currently identified feedback paths.

Usage

```
report_feedback_paths [-All | loop_id#...] [-Display {[FLAt_schematic] | [HIEarchical_schematic] | [-Hierarchical] | DAData | ALL} [APPend]] [{> | >>} file.pathname]
```

Description

Displays a report of currently identified feedback paths.

The `report_feedback_paths` command displays feedback paths the tool identified during the last circuit learning process. By default, the command displays a textual report of all currently identified feedback paths and their identification numbers. Issuing the command with the identification numbers of specific paths of interest will limit the display to just those paths.

You can use the identification numbers with the `report_loops -Display` command to schematically display specific feedback paths. When you issue this command for specific feedback paths, DFTVisualizer transcribes the same information as the `report_feedback_paths` command, but only for the specified paths.

Note

 Feedback paths include, by default, any duplicated gates.

Arguments

- **-ALL**
An optional switch that specifies to report all currently identified feedback paths. This is the default.
- ***loop_id#***
An optional, repeatable, non-negative integer that specifies the identification number of a particular feedback path to report. The tool assigns the numbers consecutively, starting with 0.
- **-Display {[FLAt_schematic] | [HIEarchical_schematic] | [Hierarchical] | DAData | ALL}**
An optional switch, repeatable literal, and literal that displays the reported information graphically in the specified DFTVisualizer window(s); if *Append* is specified, the

information is added to the existing contents of the window instead of replacing the contents.

The choices are as follows:

FLAt_schematic — A literal that specifies the Flat Schematic window.

HIErarchical_schematic — A literal that specifies the Hierarchical Schematic window.

If the Hierarchical literal is specified, only the top-level hierarchical instances are displayed in the Hierarchical Schematic window; if the Hierarchical literal is not specified, the child instances of the corresponding hierarchical instances are also displayed.

DATa — A literal that specifies the Data window.

ALl — A literal that specifies all the preceding windows.

The default when you specify -Display without including a window name is to add feedback paths to the Flat Schematic window.

- >file_pathname

An optional redirection operator and pathname pair for creating *or* replacing the contents of *file_pathname*.

- >>file_pathname

An optional redirection operator and pathname pair for appending to the contents of *file_pathname*.

Examples

The following example enters analysis mode (which flattens the simulation model and performs the learning process), reports the identification numbers of all learned feedback paths, and then displays one of the reported feedback paths (loop #1):

```
set_system_mode analysis
report_feedback_paths

Loop#=0, feedback_buffer=26, #gates_in_network=5
    INV /I_956_I_582/ (51)
    PBUS /I_956_I_582/N1/ (96)
    ZVAL /I_956_I_582/N1/ (101)
    INV /I_956_I_582/ (106)
    TIEX /I_956_I_582/ (26)
Loop#=1, feedback_buffer=27, #gates_in_network=5
    INV /I_962_I_582/ (52)
    PBUS /I_962_I_582/N1/ (95)
    ZVAL /I_962_I_582/N1/ (100)
    INV /I_962_I_582/ (105)
    TIEX /I_962_I_582/ (27)
```

```
report_feedback_paths 1 -display hierarchical_schematic
```

Related Topics

[report_loops](#)

set_loop_handling

report_flattener_rules

Context: all contexts

Mode: setup, analysis

Displays either a summary of all the flattening rule violations or the data for a specific violation.

Usage

```
report_flattener_rules [rule_id [{occurrence_id | -Verbose}]] [{> | >>} file.pathname]
```

Description

Displays either a summary of all the flattening rule violations or the data for a specific violation.

The report_flattener_rules command displays the following information for a specific violation:

- Rule identification number
- Current number of rule failures
- Violation handling

You can use the [set_flattener_rule_handling](#) command to change the handling of the net, pin, and gate rules.

Arguments

- *rule_id*

A literal that specifies the flattening rule violation for which you want to display information. The flattening rule violations and their identification literals are divided into the following three groups: net, pin, and gate rules violation IDs.

- Net flattening violations are described in sections “[FN1](#)” through “[FN9](#)”.
- Pin flattening violations are described in sections “[FP1](#)” through “[FP13](#)”.
- Gate flattening violations are described in sections “[FG1](#)” through “[FG8](#)”.

- *occurrence_id*

A literal that specifies the identification of the exact flattening rule violation (the occurrence) for which you want to display information. For example, you can analyze the second occurrence of the FG4 rule by specifying the rule_id and the occurrence_id, FG4 2. The tool assigns the occurrences of the rules violations as it encounters them; you cannot change either the rule identification number or the ordering of the specific violations.

- -Verbose

A switch that displays the following for each flattening rule:

- Rule identification number
- Number of failures of each rule

- Current handling status of that rule
- Brief description of that rule
- **>file_pathname**
An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file_pathname*.
- **>>file_pathname**
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

The following example shows the summary information of the FG3 rule:

```
report_flattener_rules fg3
/   FG3: fails=2 handling=warning/noverbose
```

Related Topics

[set_flattener_rule_handling](#)

report_gates

Context: all contexts

Mode: setup, analysis

Displays the netlist information and simulation results for the specified gates and the simulation results for the specified user-defined ATPG functions.

Usage

```
report_gates {pin_or_net_pathname | gate_id# | instance_name}...  
  {-Value_trace [position] [-TRANSition] [-Endpoints] [-DISplay]  
   [-STOP_ambiguous] | -GO_One_ambiguous | -GO_All_ambiguous]}
```

```
report_gates {-Type {gate_type | ALLF | ALL}}... [-SUMmary]
```

```
report_gates {{-Sequential_test_depth | -0Control_depth | -1Control_depth | -Observe_depth}  
  depth_number}...
```

```
report_gates {-Path {pin_pathname | gate_id} {pin_pathname | gate_id}}
```

```
report_gates {-GLitch_masked_cells}
```

```
report_gates {[ -Endpoints] [-COnstraints] [-Forward | -Backward] {pin_pathname | gate_id}...}
```

All of the above forms can redirect their output with: [{> | >>} *file_pathname*]

Description

Displays the netlist information and simulation results for the specified gates and the simulation results for the specified user-defined ATPG functions.

The report_gates command displays the netlist information for either the design-level or the primitive-level gates you specify. You designate the gate by its gate identification number (ID#), a pathname of a pin connected to a gate, an instance name (design level only), or a gate type. You can specify a design cell by the pathname of a pin on the design cell. If you use a gate ID# or gate type, the command always reports the primitive-level gate. You must flatten the netlist before issuing this command.

The *pin_or_net_pathname* and *instance_name* arguments support regular expressions, which may include any number of '*' or '?' wildcard characters embedded in the pathname string. The '*' character matches any sequence of characters (including none) in a name, and the '?' character matches any single character. If a wildcard name is specified, the command will search for matching instance names from the top library cell level down to the primitive gates.

The format for the design-level gate report is:

```
instance_name      cell_type
    input_pin_name   I   (data)   pin_pathname...
...
    output_pin_name  O   (data)   pin_pathname...
...
```

The data field displays the pin information as selected by the “[set_gate_report](#)” command.

The format for the primitive-level report is:

```
instance_name      (gate_ID#)      gate_type
    input_pin_name   I   (data)   gate_ID#-pin_pathname...
...
    output_pin_name  O   (data)   gate_ID#-pin_pathname...
...
```

When you provide the name or identification number (ID#) of a user-defined ATPG function, the command reports simulation data of the function. The data reported is that specified by the Parallel_pattern option of the [set_gate_report](#) command.

The format for the function report is:

```
function_name      (function_ID#)      function_type
    input_pin_name   I   (data)   gate_ID#-pin_pathname...
...
    output_pin_name  O   (data)   gate_ID#-pin_pathname...
...
```

The list associated with the input and output pin names indicate the pins to which they connect. For the primitive level, this also includes the gate index number of the connecting gate and only includes the pin pathname if one exists at that point. There is a limitation on reporting gates at the design level. If some circuitry inside the design cell is completely isolated from other circuitry, the command only reports the circuitry associated with the pin pathname.

You can also report the fan-in or fan-out cone of a specified gate. The endpoints of a cone are defined as the primary inputs, primary outputs, tied gates, rams, roms, flip-flops, and latches. All gates reported are at the primitive level.

You can change the output of the [report_gates](#) command by using the [set_gate_report](#) command.

Note

 The tool does not explicitly simulate the EDT logic during scan loading and capture cycles. Therefore, [report_gates](#) cannot report simulation values for the EDT logic during these cycles. This is true regardless of the option set with the [set_gate_report](#) command.

Backslashes (\), Periods (.) and Spaces in Hierarchical Names

When reading hierarchical names into its internal database, the tool hides backslashes (\), converts periods (.) to slashes (/), and ignores spaces. For example, the tool reads the cell name, “FFH.\E/MY_SCAN_FF .SCAN_FF5” in a WGL pattern, as “FFH/E/MY_SCAN_FF/ SCAN_FF5”, and stores the latter in its internal database. To report on this cell, you must reference it by the name that is stored internally.

Note

 The difference between the internal hierarchical name and the name in the WGL file of the preceding example does not alter the correctness of the tool. That is, the output pattern file remains consistent with the original netlist.

The following example reports on a Verilog gate named “FFH.\E/MY_SCAN_FF .SCAN_FF5”.

report_gates FFH/E/MY_SCAN_FF/SCAN_FF5

```
//  /FFH/E/MY_SCAN_FF/SCAN_FF5 FD1SF
//    D      I  /FFH/E/MY_SCAN_FF/GATE00/Z
//    A      I  /C-4/Z
//    SI     I  /FFG/SO
//    CP     I  /INPBUF1/Z
//    B      I  /C-5/Z
//    Q      O  /GATE20/C
//    QN    O
//    SO     O  /C-7/A
```

Reporting Power Data of Gates

When you issue the [read_cpf](#) or [read_upf](#) command, power data is loaded into the tool. The **report_gates** command enables power data reporting by default and shows the power on (PON) or power off (POFF) status as well as the power domain of the gate. For example:

read_upf upf_file

report_gates /lp_case_si_rst_sms/ati_rst_sync/sync_r/U3/Udff

```
//  /lp_case_si_rst_sms/ati_rst_sync/sync_r  sync3msfqxss1ul
//    SDI    I(PON)  /vl_sms_lp_case_si_sms_proc_sms_1_stp/
U_lp_case_si_sms_proc_bist/uu5/Z
//    D      I(PON)  /lp_case_si_rst_sms/ati_rst_sync/sync_buf/Z
//    SEN    I(PON)  /se
//    CLK    I(PON)  /lp_case_si_rst_sms/ati_rst_sync/uu1/Z
//    Q      O(PON)  /lp_case_si_rst_sms/ati_rst_sync/uu2/A  /
lp_case_si_rst_sms/and_r/B
//    in power domain PD_P2
```

Reporting on the First Input of a Gate

The report_gates command provides a shortcut to display data on the gate connected to the first input of the previously-reported gate. This lets you quickly and easily trace backward through circuitry. To use report_gates in this manner, first report on a specific gate and then enter:

b

The following example shows how to use report_gates and B commands to trace backward through the first input of the previously reported gate.

report_gates 26

```
// /u1/inst_565_ff_d_1_13 (26)  BUF
//   "I0"    I  269-
//   "OUT"   O  268-  75-
```

b

```
// /u1/inst_565_ff_d_1_13 (269)  LA
//   "S"    I  14-
//   "R"    I  145-
//   SCLK  I  4-/clk
//   D     I  265-/u1/_g32/X
//   ACLK  I  2-/scan_mclk
//   SDI   I  20-/u1/inst_565_ff_d_0_dff/Q2
//   "OUT"  O  26-  27-
```

b

```
// /u1/inst_565_ff_d_1_13 (14)  TIE0
//   "OUT"  O  269-  268-
```

If you include an integer argument with “b”, the trace will be backward through the specified input. For example, “b 3” will trace backward through the third input of the previously specified gate. When using integer arguments with the B and F commands in the tool, all arguments must be given at the primitive level.

For pins that are not at the library cell boundary (pins internal to the model), the pin name is enclosed in double quotes (""). The following example displays this issue.

set_gate_level primitive**report_gates /I_20/I_226/q**

```
// /I_20/I_226 dffsr
//   clk    I  (HX)  /I_20/I_225/out
//   d      I  (X)   /I_20/I_222/out
//   pre   I  (H1)  /PRE
//   clr   I  (H1)  /CLR
//   q     O  (X)   /I_16/io  /I_23/I_221/io  /I_6/io
//   qb   O  (X)
```

set_gate_level primitive

```
// Creating schematic for 5 instances (1 was compacted).
```

report_gates /I_20/I_226/q

```
// /I_20/I_226 (12) BUF
//   "I0" I (0) 39-
//   q     O (X) 16-/I_16/io 31-/I_23/I_221/io
//           17- /I_6/io
```

b

```
// /I_20/I_226 (39) DFF
//   "S" I (LX) 26-
//   "R" I (LX) 23-
//   clk I (HX) 20-/I_20/I_225/out
//   d   I (X) 36-/I_20/I_222/out
//   "OUT" O (0) 12- 13-
//   MASTER cell_id=1 chain=c1 group=g1 invert_data=FFFF
```

Reporting on the First Fanout of a Gate

Similar to tracing backward through circuitry, you can also use a shortcut to trace forward through the first fanout of the previously reported gate. To use report_gates in this manner, first report on a specific gate and then enter:

f

The following example shows how to use Report Gate and F commands to trace forward through the first fanout of the previously reported gate.

report_gates 269

```
// /u1/inst_565_ff_d_1_13 (269) LA
//   "S" I 14-
//   "R" I 145-
//   SCLK I 4-/clk
//   D   I 265-/u1/_g32/X
//   ACLK I 2-/scan_mclk
//   SDI I 20-/u1/inst_565_ff_d_0_dff/Q2
//   "OUT" O 26- 27-
```

f

```
// /u1/inst_565_ff_d_1_13 (26) BUF
//   "I0" I 269-
//   "OUT" O 268- 75-
```

f

```
// /u1/inst_565_ff_d_1_13 (268) LA
//   "S" I 14-
//   "R" I 145-
//   BCLK I 1-/scan_sclk
//   "D0" I 26-
//   "OUT" O 24- 25-
```

If you include an integer argument with “f”, the trace will be forward through the specified fanout of the previously reported gate. For example, “f 2” will trace forward through the second fanout of the previously specified gate. When using integer arguments with the B and F commands in the tool, all arguments must be given at the primitive level.

Note

 When reporting gates, be aware that a reported X may not have been captured. For example, when the tool uses scan chain masking, it records the actual measured value for each cell only in the unmasked, selected scan chain in a compactor group; the rest of the scan chains in the group are masked, so the tool records all Xs for their scan cells. When not using scan chain masking, the tool records an X for a scan cell if it is made unmeasurable as a result of the actual occurrence of an X in the corresponding cell of a different scan chain in the same compactor group. For more information, see “[Understanding Scan Chain Masking in the Compactor](#)” in the Tesson TestKompress User’s Manual.

When using the tool to report on RAM or ROM gates, the report_gates command displays the RAM and ROM data that describes their behavior. You can use the set_gate_report command to customize the content of the reported data. For example, assume you add_faults on a RAM pin, then generate RAM sequential patterns. If you follow that with a set_gate_report command, specifying the Parallel_pattern argument, the report_gates output shows for the specified pattern, the address and data written to the RAM. A hyphen (-) separates the information for each cycle. The following example shows how this information is displayed for an 8-bit output named “OUT” and a 4-cycle pattern.

```
"OUT" O (S [0]=00000011-S [0]=00001001-S-SX) 5353- 5354- 5355-
      5356- 5357- 5358-
      5359- 5360-
```

In the first cycle, the pattern writes 00000011 to address 0, in the second, it writes 00001001 to address 0. The pattern does not write anything in the third cycle. The fourth cycle is a “don’t care” cycle.

The RAM and ROM simulation primitives are the same as the library primitives with the outputs being OUT gates in the RAM/ROM fanout list. The report_gates command gives RAM behavior summary information at the end of the displayed data. The report displays messages similar to the following:

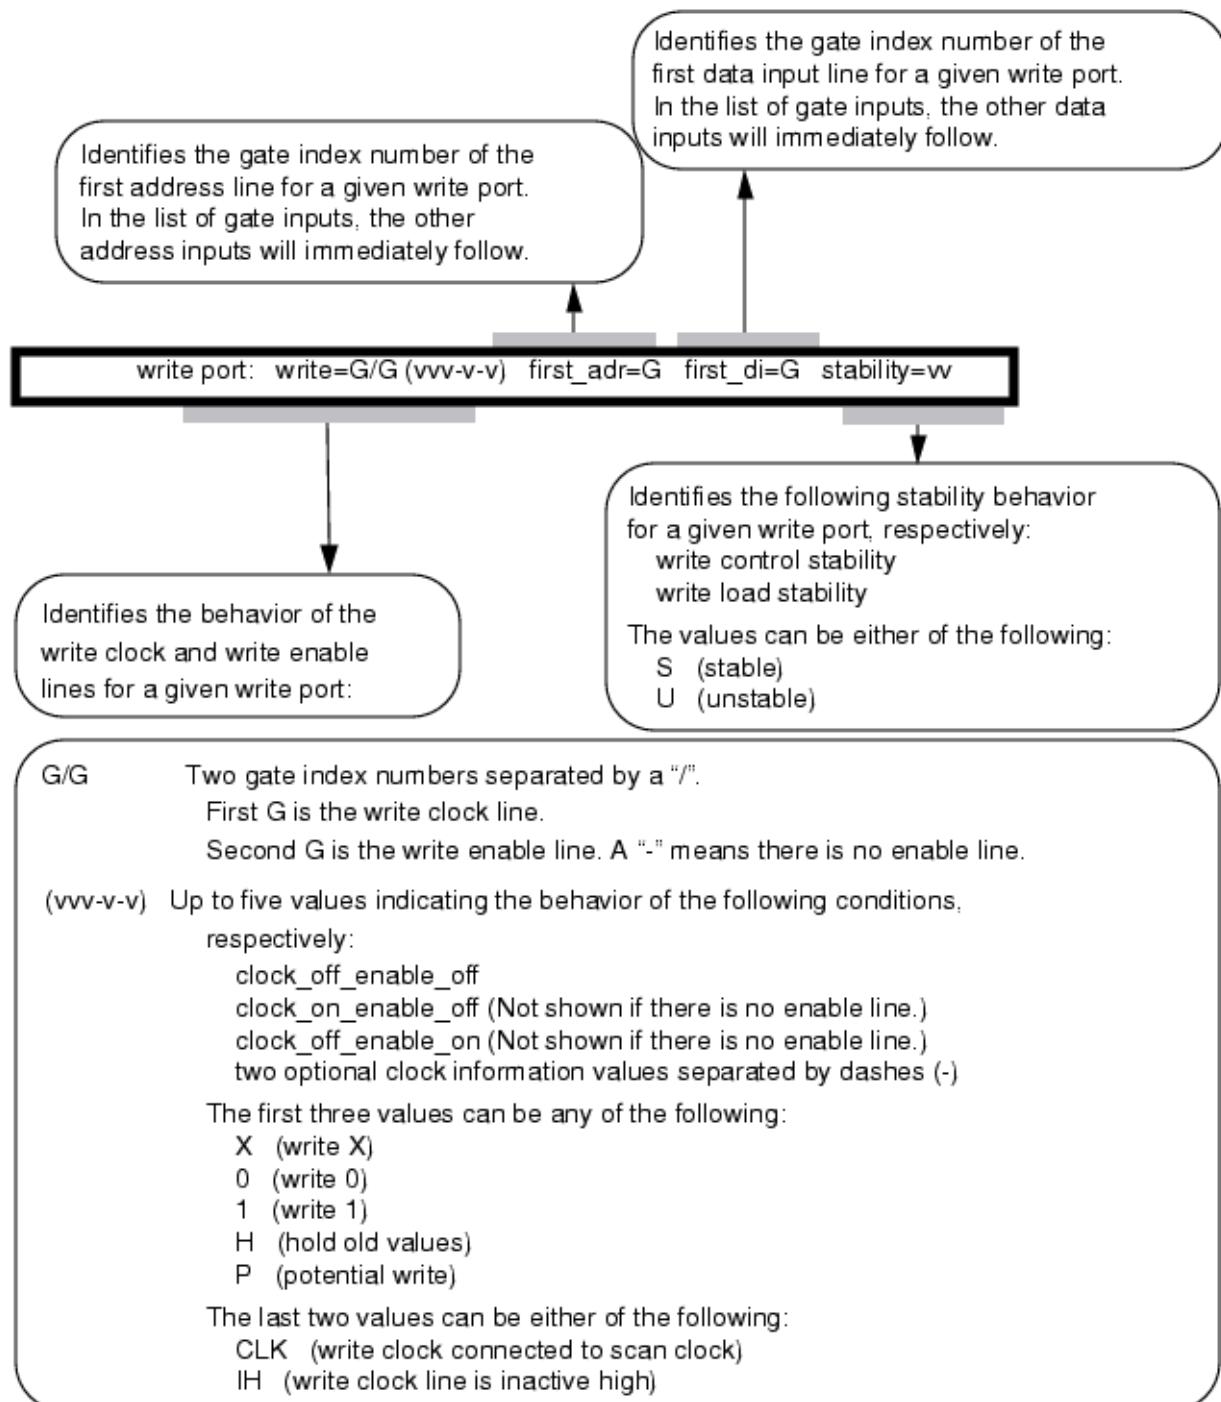

```
write port: write=G/G (vvv-v-v) first_addr=G first_di=G stability=vv
read port: read=G/G (vvv-v-v) first_addr=G first_do=G stability=vv
Test behavior: stability=vvvv tiex-X=v read_only=v
                  ram_sequential=v/v seq_transparent=v/v
Contention Behavior: write_write=v/v read_read=v read_write=v/v
```

A RAM is classified as a read-only RAM if all three of the following conditions are met:

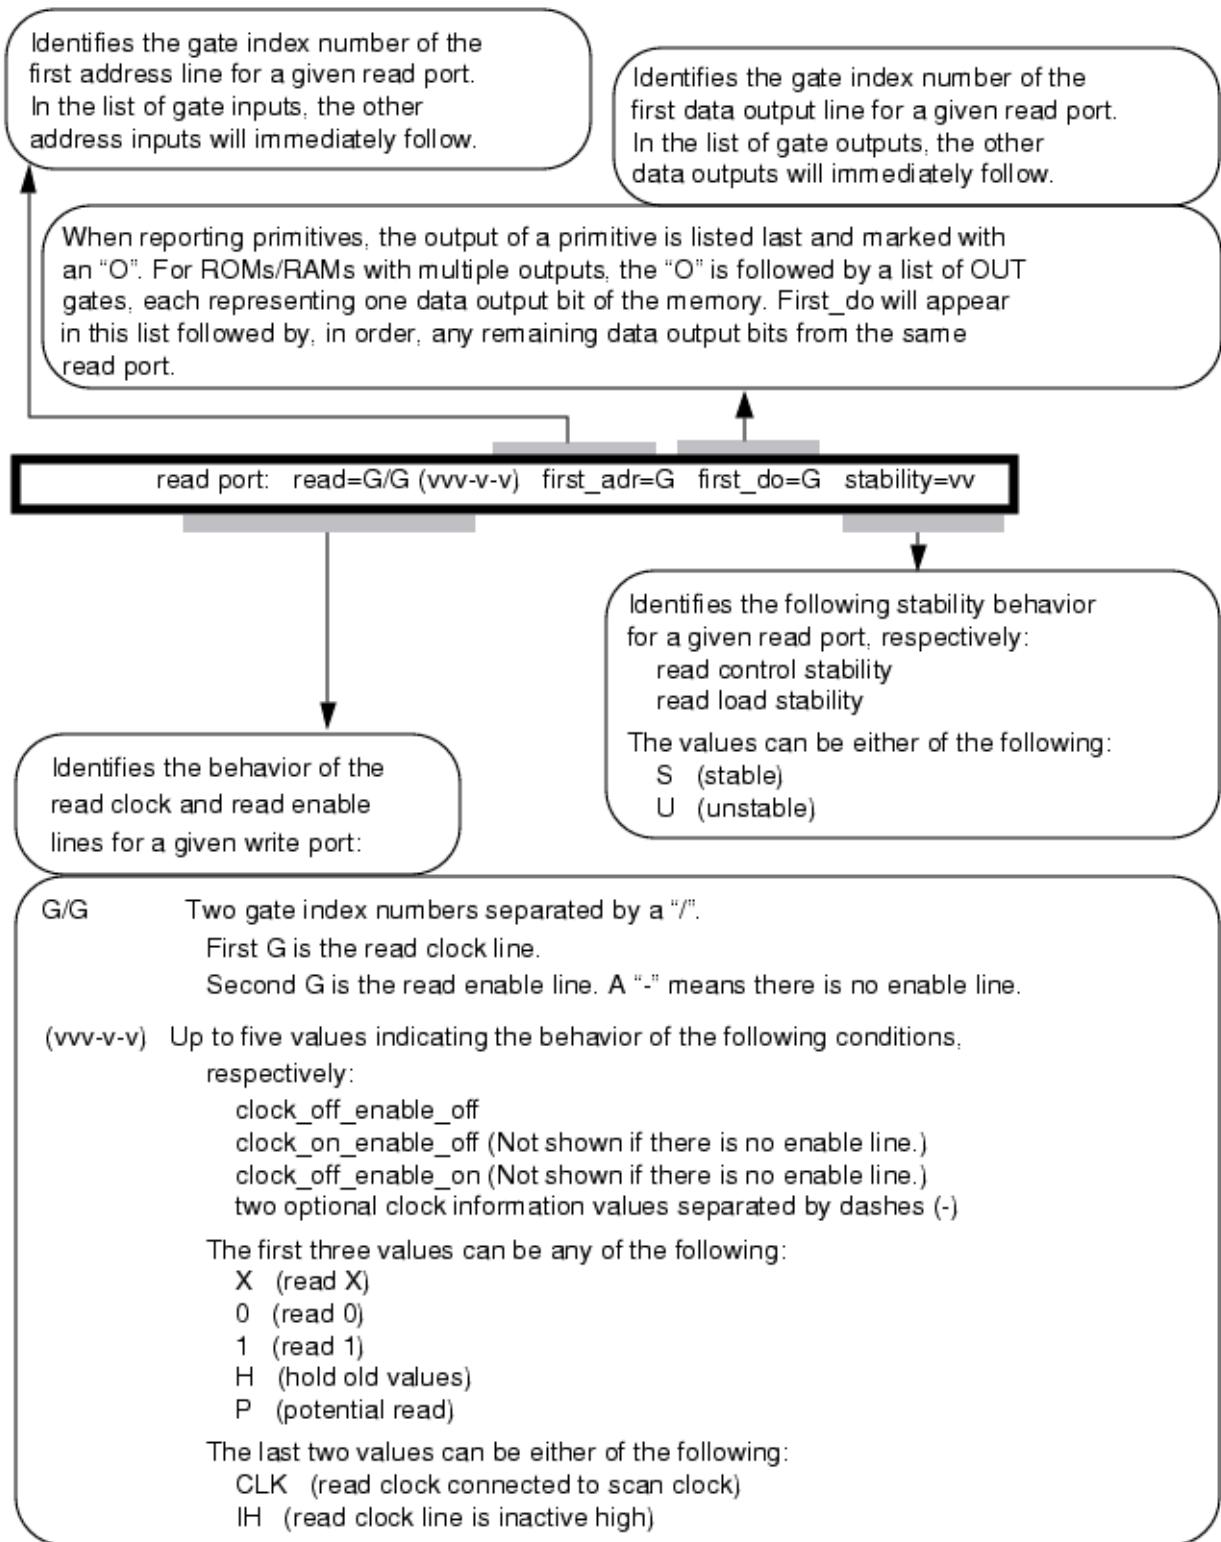

- its contents cannot be disturbed by any procedure except test setup;
- its set, reset and write ports must hold at an inactive state in the capture window;

- it has an initialization file defined in the Tessent Cell library.

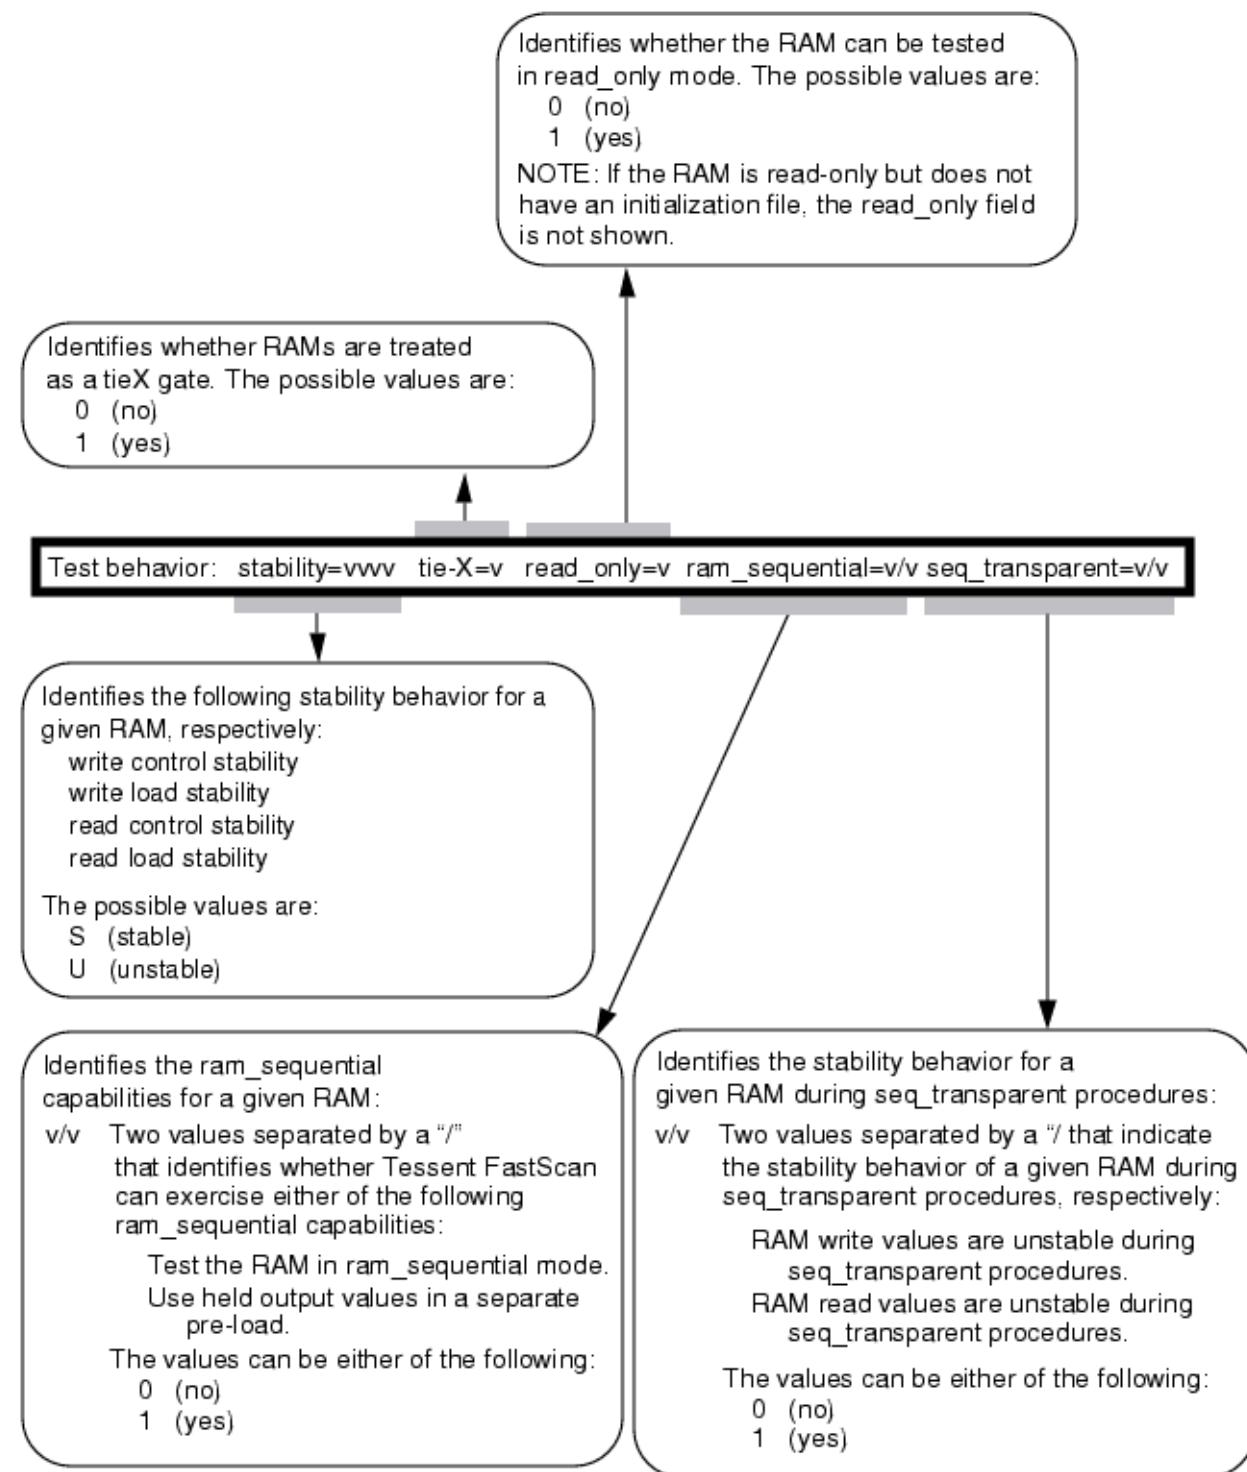

The following describes the fields for the write port message line:

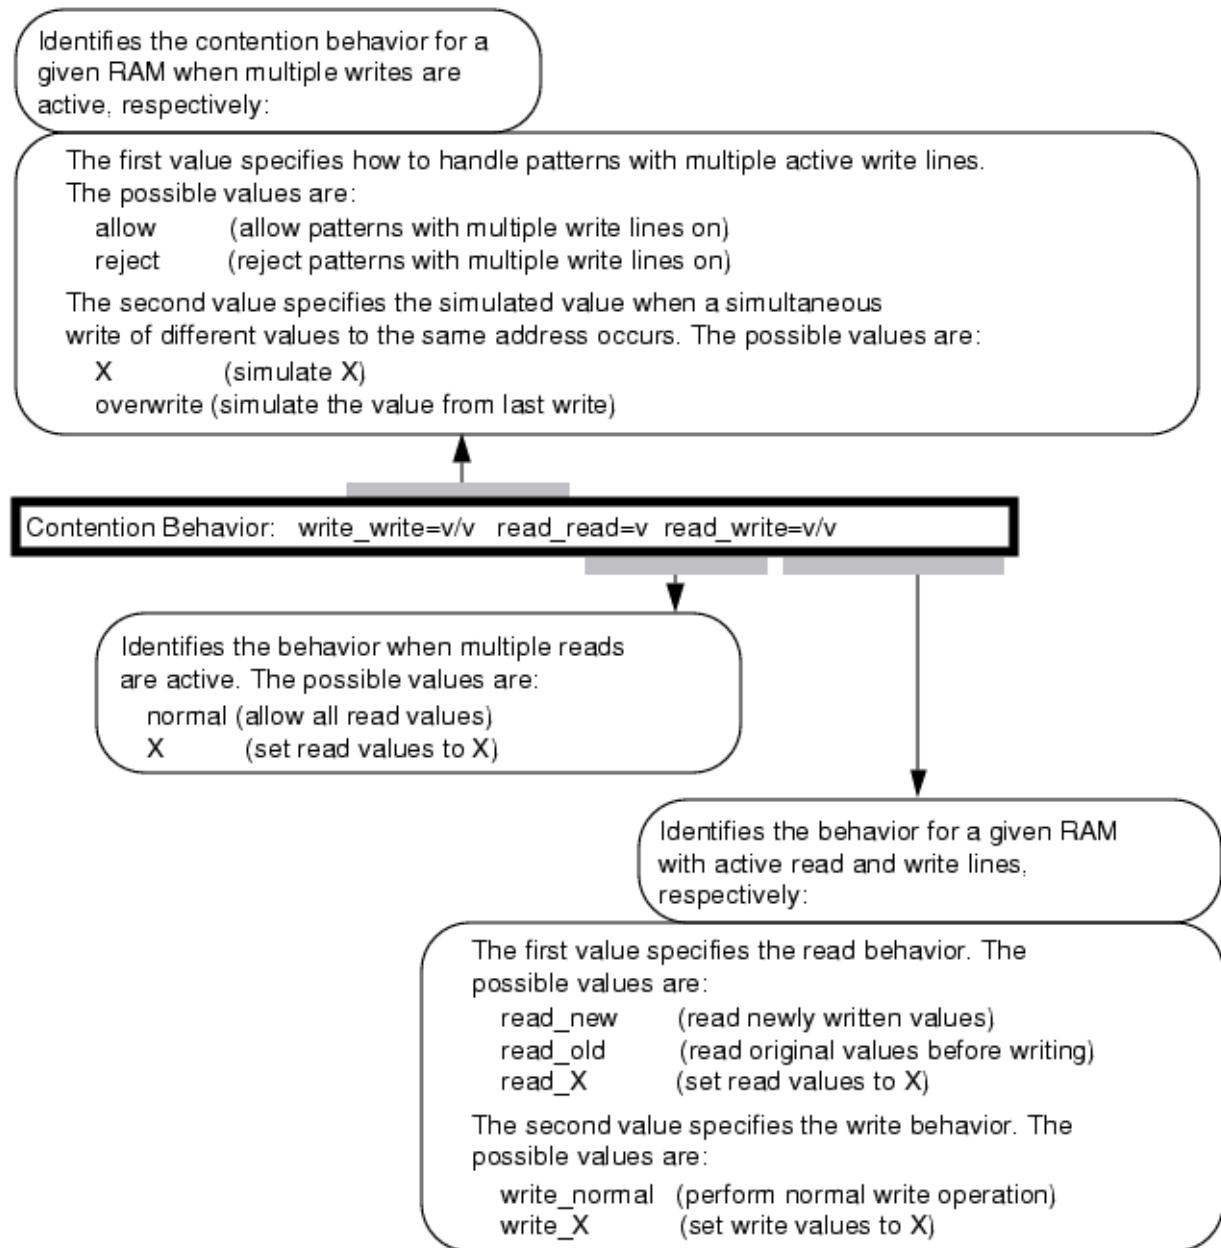

The following describes the fields for the read port message line:

The following describes the fields for the Test behavior message line:

The following describes the fields for the Contention Behavior message line:

Arguments

The following four arguments list the four methods for naming the objects on which you want the tool to display information. You can use any number of the four argument choices, in any order.

- ***function_name***

A repeatable string that specifies a user-defined ATPG function.

- **gate_id#**

A repeatable integer that specifies the gate identification numbers of the objects. The value of the *gate_id#* argument is the unique identification number that the tool automatically assigns to every gate within the design during the model flattening process.

The tool also accepts gate_pin IDs specified in the following format:

'*gate_id:port_index*'

- **pin_or_net.pathname**

A repeatable string that specifies the pathnames of pins or nets in the design netlist. You may use wildcard characters to match multiple pin or net pathnames.

For a hierarchical pathname, the display will include information describing how that pathname maps to the driving design level pin(s) and gate(s) for which data is displayed.

- **instance_name**

A repeatable string that specifies the hierarchical pathname of an instance of a library cell within the design. If a valid library instance pathname is given when in primitive level, all pins on that library cell are reported. When in primitive level, *instance_name* may also be the pathname of a primitive instance.

- **-Value_trace [position] [-TRANsition] [-Endpoints] [-DISplay] [-STOP_ambiguous | -GO_One_ambiguous | -GO_All_ambiguous]**

An optional switch that specifies to trace backward from the output pin of the gate to the source of a value. The -Value_trace option only supports the primitive report level; therefore, all arguments must be specified at the primitive level.

position

An optional value that specifies which bit to trace on for multi-bit data. For example, if a clock signal is 0X0 for a shift cycle, you can specify the tracing is on the second bit (X). The default is to use position 0 (the first bit).

-TRANsition

An optional switch that specifies to trace backward to the source of the transition of a pair of values. When using the *position* option, *position* specifies the first bit of the transition.

-Endpoints

An optional switch that specifies to report only endpoints that control the specified gate. The result of using this option also depends on the tracing mode. Only when using the -GO_All_ambiguous tracing mode are all endpoints reported.

-DISplay

An optional switch that displays all tracing gates in the Flat Schematic window of DFTVisualizer.

Note

The -Display switch cannot be used in conjunction with the -Path switch.

The following three optional switches let you choose the tracing mode of operation.

-STOP_ambiguous

An optional switch that specifies to stop if either input could cause the value on the output. This is the default setting if -go_one_ambiguous or -go_all_ambiguous is not specified.

-GO_One_ambiguous

An optional switch that specifies to trace one input if multiple input could cause the output value. For example, if the output of an OR is X, input A is X, input B is X, then the source of X is represented by both A and B. The tool will pick one controlling input, say B, and continue tracing input B.

then the source of X is represented by B. The tool will continue tracing input B.

-GO_All_ambiguous

An optional switch that specifies to trace all inputs if multiple input could cause the output value.

- **-Type {gate_type | ALLF | ALL}**

An optional repeatable switch where *gate_type* is a name pair that specifies the gate types for which you want to display the gate information. [Table 5-12](#) lists the supported types.

The **ALLF** option lets you report gates on all primitive level gates and ATPG functions. This feature supports users who require access to the tool's flat models. The **ALL** option lets you report gates on all primitive level gates (but not functions).

- **-SUMmary**

An optional switch that reports only the number of gates found when using the -Type switch.

- **-Forward {pin_pathname | gate_id}...**

An optional switch that reports the fan-out cone of the specified gate.

- **-Backward {pin_pathname | gate_id}...**

An optional switch that reports the fan-in cone of the specified gate.

- **-Endpoints [-Forward | -Backward] {pin_pathname | gate_id}...**

An optional switch that reports only the endpoint of the cone.

Note

 Immediately after -Endpoints, you must specify either -Forward or -Backward followed by the specified gate. When using -Endpoints or -COnstraints simultaneously, -Forward or -Backward followed by the specified gate need only be entered once.

- -COnstraints [-Forward | -Backward] {pin.pathname | gate_id}...

An optional switch that takes into account the effects of pin and cell constraints.

For a gate whose output is constrained to a fixed value, the tools report only other gates whose output is also constrained. For a gate whose output is not constrained to a fixed value, the tools report only other gates whose outputs are not constrained. During backwards tracing, a mux input, which is always blocked by a constrained value on the select line of the mux, will never be backtraced.

Note

 Immediately after -Constraints, you must specify either -Forward or -Backward followed by the specified gate. When using -Endpoints or -COnstraints simultaneously, -Forward or -Backward followed by the specified gate need only be entered once.

- -Path {gate_id# | pin.pathname} {gate_id# | pin.pathname}

Note

 This switch cannot be used in conjunction with the -Display switch.

An optional switch that reports on the path between the first gate_id# or pin.pathname and the second gate_id# or pin.pathname. All paths must be specified at the primitive level. Paths do not extend through sequential elements. The output generates a report on each primitive in the path(s), in order of increasing gate_id#.

- -GLitch_masked_cells

An optional switch that specifies for the tool to report the sequential elements that have been masked due to glitches on the set or reset port. It also reports the number of patterns for which the cells are masked. This is an example of the report:

```
// 30 state elements are masked due to set/reset port glitches,  
// which may impact the test coverage.  
// #-pat-cycles-masked state-element  
// -----  
// 1 '/cm0507/cm2304/' (7956)  
// 1 '/cm0507/cm2305/' (7959)
```

- -Sequential_test_depth *depth_number*

An optional switch and integer pair that specifies for the tool to report gates with a sequential test depth greater than the specified *depth_number*. The sequential test depth is the greater of the control 0 and control 1 depths plus the observe depth for the primitive

output. This is the minimum depth required to test stuck faults at the primitive output. This is also the number used to determine the maximum sequential test depth of the circuit.

- **-0Control_depth *depth_number***

An optional switch and integer pair that specifies for the tool to report gates with a control 0 depth greater than the specified *depth_number*. The control 0 depth is the minimum sequential depth required to set the primitive output to a 0.

- **-1Control_depth *depth_number***

An optional switch and integer pair that specifies for the tool to report gates with a control 1 depth greater than the specified *depth_number*. The control 1 depth is the minimum sequential depth required to set the primitive output to a 1.

- **-Observe_depth *depth_number***

An optional switch and integer pair that specifies for the tool to report gates with an observe depth greater than the specified *depth_number*. The observe depth is the minimum sequential depth required to observe the output of the primitive at either a primary output or scan cell.

- **> *file_pathname***

An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.

- **>> *file_pathname***

An optional redirection operator and pathname pair used, at the end of the argument list, for appending to the contents of *file_pathname*.

Reference Tables

- These are the reference tables for gate types and clock port categories:
 - [Table 5-12](#) lists all of the types of gates that you can specify with the -Type switch.
 - [Table 5-13](#) lists the various categories of clock ports on state elements that can appear in report_gates output.

Table 5-12. Reportable Gate Types

gate_type	Description
BUF	buffer
INV	inverter
AND	and
NAND	inverted and
OR	or
NOR	inverted or
XOR	exclusive-or

Table 5-12. Reportable Gate Types (cont.)

gate_type	Description
NXOR	inverted exclusive-or
DFF	D flip-flop, same as _dff library primitive
LA	latch, same as _dlat library primitive
PI	primary input
PO	primary output
TIE0	tied low
TIE1	tied high
TIEX	tied unknown
TIEZ	tied high impedance
HIST	histogram of each primitive type used
TSD	tri-state driver, first input is active high enable line
BUS	tri-state bus
ZVAL	Z converter gate, converts Z to X
WIRE	undetermined wired gate
MUX	2-way multiplexer, first line is select line
SW	switch gate, first input is active high enable line
PBUS	pulled bus gate, where the second input is the pulled value
OUT	memory model gate, created for each read data bit
RAM	random access memory
ROM	read only memory
XDET	X detector, gives 1 when input is X
ZDET	Z detector, gives 1 when input is Z
TLA	transparent latch
STLA	seq_transparent latch
STFF	seq_transparent flip-flip
FB_BUF	internal gate type to break combinational loops in the design
MASTER	the primary memory element of a scan cell
SLAVE	an independently-clocked scan cell memory element; resides in the scan chain path.

Table 5-12. Reportable Gate Types (cont.)

gate_type	Description
SHADOW	non-scan flip-flop that has the D input connected to the Q output of a scan flip-flop
COPY	a memory element that lies in the scan chain path and can contain the same (or inverted) data as the associated master or slave element in the scan cell

Table 5-13. Clock Port Categories

Category	Description
IL	inactive low
IH	inactive high
AHS	active high slave
ALS	active low slave

For more information about using the clock port options, refer to “[The ATPG Analysis Option](#)” on page 2692.

Examples

Example 1

The following example displays the simulated values of the gate and its inputs at the primitive level:

```
set_system_mode analysis
set_gate_report error_pattern
set_gate_level primitive
report_gates i_1006/o
```

The gate report for the design level may look like the following:

```
/P2.13P ND2
A I /LD.1
B I /M1.1
Z O /P2.2P/S
```

The gate report for the primitive level may look like the following:

```
/P2.13P (23) NAND
A I 9-/LD.1
B I 6-/M1.1
Z O 33-/P2.2P/S
```

The gate report for the primitive level of a RAM gate may look like the following:

```
//  /P1.RAM/U1  (67)  RAM
//    "I0"    I  27-
//    "I1"    I  20-
//    RCK0   I  36-
//    "I3"    I  26-
//    "I4"    I  42-
//    "I5"    I  43-
//    "I6"    I  44-
//    "I7"    I  45-
//    "I8"    I  46-
//    WCK0   I  28-
//    "I10"   I  19-
//    A14    I  29-
//    A13    I  30-
//    A12    I  31-
//    A11    I  32-
//    A10    I  34-
//    D14    I  66-/P1.RAM/D1[0]
//    D13    I  65-/P1.RAM/D1[1]
//    D12    I  64-/P1.RAM/D1[2]
//    D11    I  63-/P1.RAM/D1[3]
//    D10    I  62-/P1.RAM/D1[4]
//    "OUT"   O  68-  69-  70-
//                  71-  72-
//    address size =      5
//    data size =       5
//    minimum address =    0
//    maximum address =   31
//    number write ports =  1
//    number read ports =  1
//    edge_triggered =     no
//    initialization file = ram.init_file
//    write port: write=28/- (H)  first_adr=29  first_di=66
//                                stability=SS
//    read port:  read=36/- (0)  first_adr=42  first_do=68
//                                stability=SS
//    Test behavior: stability=SSSS  tie-X=0  read_only=1
//                                ram_sequential=1/0  seq_transparent=0/0
//    Contention behavior: write_write=allow/X  read_read=normal
//                                read_write=read_new/write_normal
```

Example 2

The following example defines a function named “my_function” and displays all its simulation results from the last simulation pass:

```
set_system_mode analysis
add_atpg_functions my_function or /g1 ~/g2
set_gate_report parallel_pattern all
report_gates my_function

//  my_function  (44)  USER_OR
//    "I0"    (0/0/0/0/0/0/0/0.../0) 12-/g1
//    ~"I1"    (1/1/1/1/1/1/1.../1) 13-/g2
//    "OUT"   (0/0/0/0/0/0/0.../0)
```

Example 3

The following example shows the use of wildcards:

```
report_gates /xscan_0_0_cch_scan_32x/ix15*
// /xscan_0_0_cch_scan_32x/ix151 NOR2XL
// A I /myop1<0> [1]
// B I /myop2[1]
// Y O /xscan_0_0_cch_scan_32x/sum_add_0_ix27/A0
// /xscan_0_0_cch_scan_32x/ix153 NAND2X1
// A I /myop1<0> [0]
// B I /myop2[0]
// Y O /xscan_0_0_cch_scan_32x/sum_add_0_ix1/A \
// /xscan_0_0_cch_scan_32x/ sum_add_0_ix23/B \
// /xscan_0_0_cch_scan_32x/sum_add_0_ix27/A1
// /xscan_0_0_cch_scan_32x/ix155 NAND2X1
// A I /myop1<0> [1]
// B I /myop2[1]
// Y O /xscan_0_0_cch_scan_32x/ix166/B0 \
// /xscan_0_0_cch_scan_32x/ sum_add_0_ix27/B0
// /xscan_0_0_cch_scan_32x/ix157 NAND2X1
// A I /myop1<0> [3]
// B I /myop2[3]
// Y O /xscan_0_0_cch_scan_32x/ix174/B0 \
// /xscan_0_0_cch_scan_32x/ sum_add_0_ix55/B0
```

```
report_gates /xscan_0_0_cch_scan_32x/ix159
```

```
// /xscan_0_0_cch_scan_32x/ix159 NAND2X1
// A I /myop1<0> [5]
// B I /myop2[5]
// Y O /xscan_0_0_cch_scan_32x/ix188/B0 \
// /xscan_0_0_cch_scan_32x/ sum_add_0_ix83/B0
```

set_gate_level primitive

```
report_gates /xscan_0_0_cch_scan_32x/ix157
```

```
// /xscan_0_0_cch_scan_32x/ix157 (43) NAND
// A I 7-/myop1<0> [3]
// B I 17-/myop2[3]
// Y O 60-/xscan_0_0_cch_scan_32x/ix174/B0 \
// 75-/xscan_0_0_cch_scan_32x/ sum_add_0_ix55/B0
// /xscan_0_0_cch_scan_32x/ix157 (43) NAND
// A I 7-/myop1<0> [3]
// B I 17-/myop2[3]
// Y O 60-/xscan_0_0_cch_scan_32x/ix174/B0 \
// 75-/xscan_0_0_cch_scan_32x/ sum_add_0_ix55/B0
// /xscan_0_0_cch_scan_32x/ix157 (43) NAND
// A I 7-/myop1<0> [3]
// B I 17-/myop2[3]
// Y O 60-/xscan_0_0_cch_scan_32x/ix174/B0 \
// 75-/xscan_0_0_cch_scan_32x/ sum_add_0_ix55/B0
```

Example 4

The following example shows how the output report will change if the input pathname is a hierarchical pin or net. In this case, an additional line is output at the top of the report, indicating the mapping that was found.

set_gate_level design

report_gates /sub3/in2

```
// Hierarchical pin /sub3/in2 maps to /sub1/gate4/Y
// /sub1/gate4 nand02
//   A1 I /in1
//   A0 I /sub1/gate2/Y
//   Y O /sub3/gate1/A1 /sub3/micro1/gate1/A1 /sub2/gate3/A1
//     /sub3/gate3/A1 /sub3/micro1/gate2/A1 /sub2/gate1/A1
```

report_gates /w2

```
// Hierarchical net /w2 maps to /sub1/gate4/Y
// /sub1/gate4 nand02
//   A1 I /in1
//   A0 I /sub1/gate2/Y
//   Y O /sub3/gate1/A1 /sub3/micro1/gate1/A1 /sub2/gate3/A1
//     /sub3/gate3/A1 /sub3/micro1/gate2/A1 /sub2/gate1/A1
```

Example 5

The following example traces backward to the source of a DRC error:

```
// Error: clock input of /ff2 (35) set to X. (T5-1)
// Error: Scan chain c0 blocked at gate /ff2 (35) after tracing 1 cells.
// (T3-1)
// Error: Rules checking unsuccessful, cannot exit SETUP mode.
```

set_gate_level prim

set_gate_report drc shift

report_gates 35

```
// /ff2 (35) DFF
//   "S" I (000) 10-
//   "R" I (000) 9-
//   CLK I (0X0) 27-/gate8/Y
//   "D0" I (XXX) 32-
//   "OUT" O (XXX) 14- 15-
```

report_gates 27 -v 1

```
//  /gate8 (27)  AND
//    A0      I  (010)  6-/clk1
//    A1      I  (XXX)  21-/ff4/Q
//    Y       O  (0X0)  35-/ff2/CLK
//
//  /ff4 (21)  INV
//    "I0"    I  (XXX)  11-
//    Q       O  (XXX)  27-/gate8/A1
//
//  /ff4 (11)  INV
//    "I0"    I  (XXX)  33-
//    "OUT"   O  (XXX)  21-  22-
//
//  /ff4 (33)  DFF
//    "S"     I  (000)  10-
//    "R"     I  (000)  9-
//    CLK     I  (010)  7-/clk2
//    D       I  (XXX)  3-/in3
//    "OUT"   O  (XXX)  11-
//
// Total 4 gates traced which controls gate /gate8 (27) to X (bit 1).
```

Example 6

The following example traces backward to the first ambiguous gate where multiple source control the values:

```
set_gate_level prim
set_gate_report drc shift
report_gates 29

//  /sgate1 (29)  AND
//    A0      I  (XXX)  25-/sgate2/Y
//    A1      I  (111)  10-
//    Y       O  (XXX)  31-/ff1/SI

report_gates29 -v 1

//  /sgate1 (29)  AND
//    A0      I  (XXX)  25-/sgate2/Y
//    A1      I  (111)  10-
//    Y       O  (XXX)  31-/ff1/SI
//
//  /sgate2 (25)  OR
//    A0      I  (XXX)  21-/ff0/Q
//    A1      I  (XXX)  16-/ff2/QB
//    Y       O  (XXX)  29-/sgate1/A0
// Total 2 gates traced which controls gate /sgate1 (29) to X (bit 1).
```

Example 7

The following example traces backward to all ambiguous gates:

```
report_gates 29 -v 1 -go_all
```

```

//  /sgate1 (29)  AND
//    A0      I  (XXX)  25-/sgate2/Y
//    A1      I  (111)  10-
//    Y       O  (XXX)  31-/ff1/SI
//
//  /sgate2 (25)  OR
//    A0      I  (XXX)  21-/ff0/Q
//    A1      I  (XXX)  16-/ff2/QB
//    Y       O  (XXX)  29-/sgate1/A0
//
//  /ff0 (21)  INV
//    "I0"    I  (XXX)  12-
//    Q       O  (XXX)  25-/sgate2/A0
//
//  /ff0 (12)  INV
//    "I0"    I  (XXX)  35-
//    "OUT"   O  (XXX)  21-  22-
//
//  /ff0 (35)  DFF
//    "S"     I  (000)  11-
//    "R"     I  (000)  9-
//    CLK     I  (010)  6-/clk1
//    D       I  (XXX)  3-/in3
//    "OUT"   O  (XXX)  12-
//
//  /ff2 (16)  INV
//    "I0"    I  (XXX)  37-
//    QB     O  (XXX)  25-/sgate2/A1
//
//  /ff2 (37)  DFF
//    "S"     I  (000)  11-
//    "R"     I  (000)  9-
//    CLK     I  (010)  6-/clk1
//    "D0"    I  (XXX)  34-
//    "OUT"   O  (XXX)  15-  16-
// Total 7 gates traced which controls gate /sgate1 (29) to X (bit 1).

```

Example 8

The following example traces backward from the output of gate 122 to the origin of the transition:

```

// Fault type is transition

set_gate_level prim
set_gate_report pattern_index 3
report_gates 122 -value_trace -transition

```

```
// /top_i/sf_0002_2 (122) MUX
//   SE    I  (111-111)  6-/sen
//   D     I  (111-000)  3-/pi[0]
//   SI    I  (011-111)  36-/top_i/sf_0001_2/Q
//   "OUT"  O  (011-111)  419-
// /top_i/sf_0001_2 (36)  BUF
//   "I0"   I  (011-111)  418-
//   Q     O  (011-111)  115-/top_i/an_2/A2  122-/top_i/sf_0002_2/SI
// /top_i/sf_0001_2 (418)  DFF
//   "S"    I  (000-000)  12-
//   "R"    I  (000-000)  136-
//   CLK   I  (010-000)  5-/clk
//   "D0"   I  (111-111)  404-
//   "OUT"  O  (011-111-[1]) 36- 37-
//   MASTER cell_id=5 chain=chain1 group=grp1 invert_data=FFFF
//
// Total 3 gates traced which control gate '/top_i/sf_0002_2/' (122) to
L_H transition (bit 0-1).
```

Example 9

The following example displays the status of the faults on the gate and its inputs:

```
set_gate_report fault_status
report_gates /ram1/address<4>

// /ram1 picdram
//   clk    I  (AU.SEQ:AU.SEQ)  /gater2/an_4/Y
//   address<6> I  (AU.SEQ:AU.SEQ)  /address1[6]
//   address<5> I  (AU.SEQ:AU.SEQ)  /address1[5]
//   address<4> I  (AU.SEQ:AU.SEQ)  /address1[4]
//   address<3> I  (AU.SEQ:AU.SEQ)  /address1[3]
//   address<2> I  (AU.SEQ:AU.SEQ)  /address1[2]

report_gates /an_10/A1

// /an_10 and03
//   A0    I  (AU.BB:AU.BB)  /sf_1_6/Q
//   A1    I  (AU.BB:AU.BB)  /sf_3_6/Q
//   A2    I  (AU.BB:AU.BB)  /sf_5_6/Q
//   Y     O  (AU.BB:AU.BB)  /po6

report_gates /gater11/an_1/Y

// /gater11/an_1 inv02
//   A    I  (AU.TC:AU.TC)  /an_13/Y
//   Y    O  (AU.TC:AU.TC)  /gater11/lat1/CLK
```

In the example, the tool reports the following untestable (AU) fault sub-classes:

- BLACK_BOXES (BB) — Untestable faults due to black boxes.
- SEQUENTIAL_DEPTH (SEQ) — Untestable faults with the current sequential_depth and may be testable with a higher depth.
- TIED_CELLS (TC) — Untestable faults due to tied or blocked tied non-scan cells.

For a complete list of these AU fault sub-classes, see [Table 6-18](#).

Example 10

The following example shows how a launch-off-shift transition pattern can be created and reported:

```
set_fault_type transition -allow_shift_launch
create_patterns
set_gate_report pattern_index 0
report_gates /top_i/sf_0001_1

// /top_i/sf_0001_1 sffr
//   D      I  ((0)-111)  /pi[0]
//   SI     I  ((1)-000)  /top_edt_i/top_edt_bypass_logic_i/U18/Y
//   SE     I  ((1)-000)  /sen
//   CLK    I  ((0)-010)  /clk
//   R      I  ((1)-111)  /rst
//   Q      O  ((1)-111-[1])  /top_i/an_2/A1  /top_i/sf_0002_1/SI
//   QB    O  ((0)-000-[0])
```

In the example, the first value in parentheses is the value from the last scan-shift event. The next values (following the dash “-”) are the first capture-cycle values. In this case there are three events for the first capture cycle.

Example 11

The following example shows how the value used to simulate a gate is displayed (in **bold**) when that gate is reported as not simulated:

```
// command: rep gate /piccpu_i/status_reg_7/DFF1/D      // not simulated
// /piccpu_i/status_reg_7/DFF1 (2520)  DFF
//   "S"    I  66-
//   "R"    I  67-
//   CP    I  543-
//   D      I  2301-/piccpu_i/status_reg_7/MUX2/Q
//   "OUT"  O  235-
//   MASTER  cell_id=0  chain=chain7  group=grp1  invert_data=FFFF
//
// Proc: shi 1 sh 2 sh 3 sh 4 sh 5 sh 6 sh 7 sh 8 sh 9 sh10 sh11 cap
// -----
//   i
//   n 123  123  123  123  123  123  123  123  123  123  123  o  o
// Time: i 000  000  000  000  000  000  000  000  000  000  000  f  f
//       t0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000  fxf
// -----
// Sim: XXXXX XXXX XXXX XXXX XXXX XXXX XXXX XXXX XXXX XX11 1XX
//
// Inputs:
// "S"    00000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 000
// "R"    00000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 000
// CP    00010 0010 0010 0010 0010 0010 0010 0010 0010 0010 0010 0X0
// D    was not simulated during shift procedure in DRC K19. Simulation
// value used = X.
```

Example 12

The following example shows how to report only the total number of master gates:

```
ANALYSIS> report_gates -type master -summary  
// Total number of master gates = 376034
```

Example 13

This example demonstrates how to report the simulated values from all natural, tied gates, and learned constant value non-scan cells.

Use the “set_gate_report -constrain_value on” command. Then report_gates is used.

The report shows that the INV gate in /sdff2/lat is unreachable from any observation point, as indicated by UU value.

```
set_gate_report -constrain_value on  
report_gates sdff2/lat  
  
// /sdff2/lat (18)  BUF  
//   "I0"    I  (X/01/-)  34-  
//   Q      O  (X/01/-)  36-/so  
// /sdff2/lat (19)  INV  
//   "I0"    I  (X/01/-)  34-  
//   QN    O  (X/01/-/UU)  
// /sdff2/lat (34)  TLA  
//   "S"    I  (0/1/-)  9-  
//   "R"    I  (0/1/-)  8-  
//   CLK    I  (-/-/B)  26-/sdff2/u0/OUT  
//   D      I  (-/-/-)  29-/sdff2/u1/OUT  
//   "OUT"  O  (X/01/-)  18-  19-  
// Reported all gates in instance 'sdff2/lat'
```

Example 14

This procedure file defines four events in the shift procedure (force_pi is set to occur at 5 ns rather than at the beginning of the cycle).

report_gates

```

set time scale 1.000000 ns ;
set strobe_window time 1 ;
timeplate gen_tp1 =
    force_pi 5 ;
    measure_po 10 ;
    pulse CLOCK 20 10;
    period 40 ;
end;
procedure shift =
    scan_group grp1 ;
    timeplate gen_tp1 ;
    // cycle 0 starts at time 0
    cycle =
        force_sci ;
        measure_sco ;
        pulse CLOCK ;
    end;
end;
procedure load_unload =
    scan_group grp1 ;
    timeplate gen_tp1 ;
    // cycle 0 starts at time 0
    cycle =
        force scan_en 1 ;
        force CLOCK 0 ;
    end ;
    apply shift 3;
end;
procedure test_setup =
    timeplate gen_tp1 ;
    // cycle 0 starts at time 0
    cycle =
        force IN1 0 ;
    end;
end;

```

The report_gates command reports four values, one for each event in the cycle.

```

set_gate_level design
set_gate_report drc shift
report_gates .reg1

// /reg1 dfsc
// CK I (0010) /CLOCK
// D0 I (XXXX) /gate1/OUT
// D1 I (SSSS) /reg2/QBAR
// SC I (1111) /scan_en
// Q O (XXXX) /gate2/B
// QBAR O (SSSS) /scan_out1

```

report_graybox_statistics

Context: patterns -scan

Mode: analysis

Reports the statistics gathered by graybox analysis.

Usage

```
report_graybox_statistics {[ -top integer] | [-percentage_exceeds integer] |  
[-exceeds_max_sequential_levels]}
```

Description

Reports the statistics gathered by graybox analysis. This command works only after running graybox analysis using the -collect_reporting_data switch of the [analyze_graybox](#) command.

Arguments

- **-top *integer***

An optional switch and integer pair that lists the graybox analysis backward tracing origins with the highest number of leaf instances. The *integer* argument specifies how many tracing origins from the top will be listed in the report output. A tracing origin can be a PO, a wrapper cell input pin, or a preserve instance.

- **-percentage_exceeds *integer***

An optional switch that lists all tracing origins that exceed the specified percentage of leaf instances (with respect to all leaf instances in design) covered during backtracing.

- **-exceeds_max_sequential_levels**

An optional switch that lists the tracing origins that exceed the maximum sequential levels limit specified by “analyze_graybox -max_sequential_levels”. The default value for maximum sequential levels is 2 unless specified by the -max_sequential_levels switch.

Examples

The following example shows the command output for the top four tracing origins with the highest number of leaf instances:

```
report_graybox_statistics -top 4
```

Start Point	Pin Type	Number of Leaf Instances	Percentage of Design	Sequential Levels Limit Reached
sff2/D, SI	WrapperCellDataPin	3	50.00	yes
sff1/D	WrapperCellDataPin	2	33.33	-
po	PrimaryOutput	1	16.67	-
so	PrimaryOutput	1	16.67	-

The explanation of the columns are as follows:

- Start Point is the pathname of the tracing origin.
- Pin Type is one of the following: PrimaryOutput, WrapperCellDataPin, WrapperCellSetPin, WrapperCellResetPin, WrapperCellClockPin, PreserveInstanceInputPin.
- Number of Leaf Instances is the number of leaf instances marked for the tracing origin.
- Percentage of Design is the percentage of covered leaf instances with respect to the leaf instances in the entire design.
- Sequential Levels Limit Reached is “yes” when the specified or default maximum sequential levels limit is exceeded, and is “-” otherwise.

report_icl_extraction_options

Context: all contexts

Mode: all modes

Provides a human readable report of the ICL extraction options.

Usage

```
report_icl_extraction_options
```

Description

Provides a human readable report of the ICL extraction options.

Arguments

None

Examples

The following command displays the ICL extraction settings in a human readable form:

```
report_icl_extraction_options
//  Option          | Type | Value
//  -----+-----+-----+
//  extract_learned_muxes | BOOL |    on
//  extract_library_muxes | BOOL |    on
```

Related Topics

[get_icl_extraction_options](#)

[set_icl_extraction_options](#)

report_icl_modules

Context: dft, patterns

Mode: all modes

Reports loaded and extracted ICL modules in either ICL syntax or human readable form. The output can be redirected to a file.

Usage

```
report_icl_modules [-all | -modules modules [-hierarchical]]
```

Description

Reports loaded and extracted ICL modules in either ICL syntax or human readable form. The output can be redirected to a file.

If you invoke this command without any arguments, the names of all loaded and extracted ICL modules are reported in human readable form.

Note

 If you invoke this command during setup mode, before ICL extraction has taken place, only the loaded ICL modules will be reported. If you invoke this command in the analysis mode, the tool may have performed ICL extraction, and the report_icl_modules command will report the loaded and extracted ICL modules.

Arguments

- **-all**
An optional switch that reports all loaded and extracted ICL modules in ICL syntax.
- **-modules *modules***
An optional switch that reports the specified modules in ICL syntax. The switch can take an *object_spec* (TCL string list or object list).
- **-hierarchical**
An optional switch that reports the listed modules, as well as a recursive listing of all modules that are instantiated by the listed modules and their child modules.

Examples

Example 1

In the following example, when you issue this command without any arguments, it reports the names of all the ICL modules in human readable form:

```
report_icl_modules
```

```
//      pll1
//      pll2
//      pll3
//      pll4
//      block
```

If the current design is set when you issue this command, the current design will be marked as shown in the following example:

```
set_current_design top
report_icl_modules

//      pll1
//      pll2
//      pll3
//      pll4
//      block
//      top      (current iProcsForModule ICL module)
//      Middle
//      bottom
```

Example 2

The following example reports the ICL syntax for the module chip:

```
report_icl_modules -modules chip
```

```
Module chip {
    // ICL module read from source on or near line 1 of file './data/icl/
    chip3.icl'
    TCKPort tck;
    ScanInPort tdi;
    ScanOutPort tdo {
        Source MyTap.tdo;
    }
    TMSPort tms;
    TRSTPort trst;
    Instance MyTap Of tap {
        InputPort tck = tck;
        InputPort tdi = tdi;
        InputPort tms = tms;
        InputPort trst = trst;
        InputPort fromTdr1 = MySib2.so;
    }
}
```

Example 3

The following example reports the ICL syntax for the module chip as well as a recursive listing of all modules instantiated by chip and its child modules.

```
report_icl_modules -modules chip -hierarchical
```

```
Module chip {
    // ICL module read from source on or near line 1 of file './data/icl/
chip.icl'
    TCKPort tck;
    ScanInPort tdi;
    ScanOutPort tdo {
        Source MyTap.tdo;

report_iclock

Context: dft, patterns -ijtag, patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: In the patterns -ijtag context, a pattern set has been opened by the open_pattern_set command.

Reports the ICL ClockPort specified by the iClock command as well as their extracted sources and cumulative freqMultiplier and freqDivider values.

Usage

report_iclock [-overridden]

Description

Reports the ICL ClockPort specified by the iClock command as well as their extracted sources and cumulative freqMultiplier and freqDivider values.

Arguments

- **-overridden**

Specifies to return the ICL port and pin names on which an iClockOverride command was issued as opposed to the iClock command when the option is not specified.

Return Values

None

Examples

The following example shows the result of the report_iclock command specified inside a pattern set in which two iClock commands have been issued. The first iClock command is on the reference pin of a PLL. The root-level clock port called CLK is its source and the connection is direct. The second one is on the CLK input of a memory BIST instance.

The report reflects the fact that the source tracing went through the PLL and picked up a FreqMultiplier value of 10 and a FreqDivider value of 2 either from the ICL definition or from an **iClockOverride** command that could have been specified on the output clock port of the PLL as shown in the example provided for the **iClock** command.

```
report_iclock
// iClock      Source  FreqMultiplier  FreqDivider      Period
// ======  =====  ======  ======  =====
// PLL.ref    CLK        1            1       100ns
// mbist.clk  CLK        10           2       20ns
```

report_id_stamp

Context: dft -edt, patterns -scan

Mode: analysis

Displays the unique identifier that the tool assigns each internal pattern set.

Usage

`report_id_stamp [{> | >>} file_pathname]`

Description

Displays the unique identifier that the tool assigns each internal pattern set.

The report_id_stamp command displays the current internal pattern set's unique identification stamp which consists of five fields, each separated by a colon (:). Due to the length of three of the fields, the tool encodes those fields and displays the encoded information. The tool encodes the three fields using 4 bytes of hexadecimal numbers. This encoding's primary use is to ensure that each pattern set has a unique identification stamp. The following list shows the information each field provides:

1. Tool version number
2. Encoded environment settings
3. Encoded DRC rules data
4. Number of patterns in the internal pattern set
5. Encoded pattern data

The tool generates the identification stamp each time you issue either the report_id_stamp command or the write_patterns -Environment command. You can use the identification stamp to tag identical patterns saved in different formats.

Arguments

- `> file_pathname`

An optional redirection operator and pathname pair for creating *or* replacing the contents of *file_pathname*.

- `>> file_pathname`

An optional redirection operator and pathname pair for appending to the contents of *file_pathname*.

Examples

The following example displays the unique identification stamp for the current pattern set:

`report_id_stamp`

2012.3:5c95:3e10:16:1bf2

report_iddq_exceptions

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Displays current exceptions to Iddq restrictions.

Usage

```
report_iddq_exceptions [<> | >>] file_pathname]
```

Description

Displays current exceptions to Iddq restrictions.

The report_iddq_exceptions command displays Iddq exceptions added with the [add_iddq_exceptions](#) command. For more information about IDDQ, refer to “[IDDQ Test Set Creation](#)” in the *Scan and ATPG User’s Manual*.

Arguments

- `> file_pathname`
An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.
- `>> file_pathname`
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

The following example displays Iddq exceptions on sites for which the tool would report Iddq check violations if the exceptions did not exist.

```
report_iddq_exceptions
```

report_ijtag_instances

Context: dft patterns

Mode: setup analysis insertion

Reports options of instances for which there is a matched ICL module.

Usage

```
report_ijtag_instances [name_spec] [-below_instances below_instances]
    [-filter filter] [-limit limit]
    [-silent]
```

Description

Reports options of instances for which there is a matched ICL module.

You can restrict the report to instances below a given collection of instances and filter the collection based on an attribute filtering equation involving other attributes registered against or inherited by the instance object type.

The -silent option suppresses the warning that is normally generated if there are no Ijtag instances to report.

Arguments

- *name_spec*

An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of instances. The string is a Tcl list of patterns separated by spaces and enclosed in braces {}. If no name_patterns are specified, the tool searches all instances.

If you specify the -below_instances options, the name patterns are hierarchical name patterns relative to the specified instance objects; otherwise the name patterns are relative to the current design.

- *-below_instances instance_objects*

An optional switch and value pair that constrains the command to search for instances below the specified instance_objects. The specified name_patterns are searched relative to each instance found in the instance_objects list.

- *-filter attribute_equation*

An optional switch and string that specify to filter results based on the expression specified by the attribute_equation string. The attributes used within the equation must exist for the instance object type. See section “[Attribute Filtering Equation Syntax](#)” on page 3162 for more details on filtering attribute equation format.

- *-silent*

An optional switch that suppresses the warning message normally generated when the command does not find any instances to report. The warning message is intended to indicate

a probable mistake when specifying patterns. You can use the -silent switch to suppress the warning. This -silent option has no effect on any other error reporting.

Examples

The following example uses the report_ijtag_instances command to report the options of the first three instances of the Ijtag module. The command [create_dft_specification](#) provides access to those features if they are not already connected to the network.

report_ijtag_instances -l 3

```
//  
// ijtag instance: pb_di_do  
// -----  
// use_in_dft_specification : auto  
// scan_interface_count      : 1  
// data_in_port_count        : 4  
// data_out_port_count       : 0  
//  
// ijtag instance: pb_di_do/dido_bus  
// -----  
// use_in_dft_specification : auto  
// scan_interface_count      : 1  
// data_in_port_count        : 16  
// data_out_port_count       : 16  
//  
// ijtag instance: pb_si  
// -----  
// use_in_dft_specification : auto  
// scan_interface_count      : 1  
// data_in_port_count        : 0  
// data_out_port_count       : 0  
//  
// Reached limit of 3, skipping remaining 9 instances.
```

report_ijtag_logical_connections

Context: patterns -ijtag

Mode: setup, analysis

Reports the logical paths that exist within the current design between the specified source and destination pins/ports, as well as all connections from or to the specified pins/ports.

Usage

```
report_ijtag_logical_connections [-from source_pin_or_port_name]  
                                [-to destination_pin_or_port_name]
```

Description

Reports the logical paths that exist within the current design between the specified source and destination pins/ports, as well as all connections from or to the specified pins/ports. If no pin or port connections are specified, all logical connections are listed.

Arguments

- **-from *source_pin_or_port_name***

An optional switch and value pair that specifies the source pin/port for the logical connections, which should be a top level module port or a hierarchical instance pin in the current top design module.

- **-to *destination_pin_or_port_name***

An optional switch and value pair that specifies the destination pin/port for the logical connections, which should be a top level module port or a hierarchical instance pin in the current top design module.

Examples

Example 1

The following example will list the logical connections between the pins /i1/in and /i32/u11/x10, as well as all logical connections from /i1/in and all connections to /i32/u11/x10.

```
report_ijtag_logical_connections -from /i1/in -to /i32/u11/x10  
// IJTAG Logical Connections:  
// From Source To Destination Inversion  
// ====== ====== ======  
// /i1/in /i32/u11/x10 no
```

Example 2

The following example will list all the logical connections in the current design.

```
add_ijtag_logical_connection -from tap1_I1/ue -to block3_I1/ue -inverted  
add_ijtag_logical_connection -from tap1_I1/ue -to logical_out -inverted
```

```
add_ijtag_logical_connection -from tdi -to tdo -inverted
add_ijtag_logical_connection -from tdi -to tms
add_ijtag_logical_connection -from tdo -to tms -inverted
report_ijtag_logical_connections

// IJTAG Logical Connections:
// From Source    To Destination   Inversion
// ======  ======  ======
// /tap1_I1/ue   /block3_I1/ue    yes
// /tap1_I1/ue   logical_out     yes
// tdi           tdo             yes
// tdi           tms             no
// tdo           tms             yes
```

[report_ijtag_retargeting_options](#)

Context: all contexts

Mode: all modes

Reports the type and value of each option of the previous [set_ijtag_retargeting_options](#) command or their default values if the [set_ijtag_retargeting_options](#) command was not issued.

Usage

`report_ijtag_retargeting_options`

Description

Reports the type and value of each option of the previous [set_ijtag_retargeting_options](#) command or their default values if the [set_ijtag_retargeting_options](#) command was not issued.

Arguments

None

Examples

Example 1

The following example sets the context “patterns –ijtag” and reports the current retargeting options:

```
SETUP> set_context patterns -ijtag -no_rtl  
SETUP> report_ijtag_retargeting_options
```

Command Dictionary (R)
report_ijtag_retargeting_options

report_input_constraints

Context: all contexts

Mode: setup, analysis

Displays the present constraint status of primary input pins.

Usage

Context: dft -scan and dft -test_points

```
report_input_constraints  
[-ALl | primary_input_pin_name... | -BIDI_Only | -BIDI_Exclude | -SCAN_INputs |  
-EQuivalent] [constraint_switch] [-Display {[FLAt_schematic] [HIEarchical_schematic]  
[DAta] | ALl} [APpend]]
```

Context: patterns -scan

```
report_input_constraints  
[-ALl | primary_input_pin_name... | -BIDI_Only | -BIDI_Exclude | -SCAN_INputs |  
-EQuivalent] [constraint_switch] [-HOLD] [-NO_Z] [-SLOW_pad [-CELL model_name]]  
[-Display {[FLAt_schematic] [HIEarchical_schematic] [DAta] | ALl} [APpend]]
```

Context: patterns -ijtag

```
report_input_constraints  
[-ALl | primary_input_pin_name... | -BIDI_Only | -BIDI_Exclude |  
-EQuivalent] [constraint_switch] [-Display {[FLAt_schematic] [HIEarchical_schematic]  
[DAta] | ALl} [APpend]]
```

Description

Displays the present constraint status of primary input pins.

The report_input_constraints command displays the constraint status of primary input pins to which you have applied constraints using the [add_input_constraints](#) command.

Arguments

- **-ALl**
An optional switch that specifies to display the current constraint status of every primary input pin to which you previously applied an input constraint using the [add_input_constraints](#) command. Pins from which you removed the constraint with the [delete_input_constraints](#) command prior to reporting the status are included in the report.
- ***primary_input_pin_name***
An optional, repeatable string that specifies the name of a primary input pin for which to display the constraint status.
- **-BIDI_Only**
An optional switch that specifies to display the constraint status of bidirectional pins only.

- **-BIDI_Exclude**
An optional switch that specifies to display the constraint status only of primary input pins that are not bidirectional.
- **-SCAN_INputs**
An optional switch that specifies to display the constraint status of scan input pins only.
- **-EQuivalent**
An optional switch that specifies to display the constraint status of primary input pins that have a pin equivalence definition applied to them. These are pins for which you used the -Equivalent switch with the add_input_constraints command. The -C_all constraint switch is the only constraint switch you can include in the same command line with -Equivalent.
- **constraint_switch**
An optional switch that specifies to report only on primary input pins that have a particular type of constraint applied. The choices, from which you can specify only one, are as follows:
 - C0 — Constant 0
 - C1 — Constant 1
 - CX — Constant X (unknown)
 - CZ — Constant Z (high-impedance)
 - CT0 — Constant TIE0
 - CT1 — Constant TIE1
 - CTZ — Constant TIEZ

Note

 For additional information about the constraints associated with the preceding switches, refer to the same switches under the [add_input_constraints](#) command.

- C_All** — All C-type constraints
- **-HOld**
An optional switch that specifies to report only input constraints that currently exhibit hold behavior. For information about what hold behavior is, refer to the -Hold argument under the add_input_constraints command.
- **-NO_Z**
An optional switch that specifies to report only input constraints that currently exhibit no-Z behavior. For information about what no-Z behavior is, refer to the -No_z argument under the add_input_constraints command.

- **-Slow_pad**

An optional switch that specifies to report only input constraints that currently exhibit slow-pad behavior. For information about what slow-pad behavior is, refer to the **-Slow_pad** argument under the **add_input_constraints** command.

- **-CELL *model_name***

An optional switch and string pair that, together with the **-Slow_pad** switch, specifies to prefix the instance name of each instance of the Tessent Cell library model, *model_name*, to the *primary_input_pin_name* and look up each resulting name as the pin on which to report.

- **-Display {[FLAt_schematic] [HIEarchical_schematic] [DAta] | ALl} [APpend]**

An optional switch, repeatable literal, and literal that specify to display the primary input(s) in the specified window. The “Append” option adds the primary inputs to the existing contents of the window instead of replacing the contents. The window choices are as follows:

FLAt_schematic — Specifies the Flat Schematic window. This is the invocation default.

HIEarchical_schematic — Specifies the Hierarchical Schematic window.

DAta — Specifies the Data window.

ALl — Specifies all supported windows (Flat Schematic, Hierarchical Schematic, and Data).

APpend — Adds the primary inputs to the existing contents of the window instead of replacing the contents.

Examples

The following example reports input constraints for a primary input.

report_input_constraints indata2

// Primary Input	C-Type	Hold	No-Z	Slow-Pad
// -----	-----	-----	-----	-----
// indata2	C0	No	Undetermined	No

report_insert_test_logic_options

Context: dft -scan, dft -test_points

Mode: setup, analysis, insertion

Reports the prefix/infix values that will be used when logic is created by the insert_test_logic command.

Usage

```
report_insert_test_logic_options
```

Description

The report_insert_test_logic_options command reports the prefix/infix values that will be used when logic is created by the insert_test_logic command.

Arguments

None

Examples

This example reports the current prefix/infix values.

```
set_context dft -scan
report_insert_test_logic_options

SETUP> set_context dft -scan
SETUP> report_insert_test_logic_options
// 'insert_test_logic' Command Option      Current Value
// -----
// -inserted_object_prefix                ts_

report_iprocs

Context: all contexts

Mode: all modes

Displays a table listing of all iProcs and their related namespace iProcNameSpace for each ICL module.

Usage

report_iprocs

Description

Displays a table listing of all iProcs and their related namespace iProcNameSpace for each ICL module. The iProcNameSpace column is not displayed if all iProcs are defined in the global namespace.

Arguments

None

Examples

The following is an example of the report generated by this command:

```
report_iprocs
// Module  iProcNameSpace  iProcs
// =====
// chip          chipProc1  chipProc2  chipProc3  chipProc4
//           Bar      chipProc1  chipProc3
//           Foo      chipProc2  chipProc4
// block         blockProc1 blockProc2  blockProc3
//           Bar      blockProc4 blockProc5
//           Foo      blockProc1 blockProc3  blockProc5
//           Bar      blockProc2 blockProc4
```

report_layout_core_information

Context: patterns -scan_diagnosis

Mode: analysis

In hierarchical layout-aware diagnosis, lists the instance pathnames of a core stored in an instance-aware core-level LDB.

Usage

```
report_layout_core_information [-chip_design_name name]
```

Description

In hierarchical layout-aware diagnosis, lists the instance pathnames of a core stored in an instance-aware core-level LDB.

To use this command you must have a valid LDB that you previously opened using the open_layout command.

By default, this command lists the instance pathnames for all the designs stored in the LDB.

This command reports the pathnames, placement and orientation for all core instances for all top-level SoC designs stored in the currently opened LDB. It also reports the top-level DEF design name for the SoC design set in the current tool run.

See “[Diagnosis for Hierarchical Design](#)” in the *Tessent Diagnosis User's Manual* for more information.

Arguments

- `-chip_design_name name`

An optional switch and string pair that returns only the instance pathnames for the specified design.

Examples

The following example shows the reporting format for the report_layout_core_information command.

```
report_layout_core_information
```

```
// Top design name: <top DEF design name-1>
// Instances of <core DEF design name>
//   '<Instance Path Name-1>' Placed at: <Placement-x>, <Placement-y>
//   Oriented: <Orientation>
//   '<Instance Path Name-2>' Placed at: <Placement-x>, <Placement-y>
//   Oriented: <Orientation>
//   ...
//
// Top design name: <top DEF design name-2>
// Instances of <core DEF design name>
//   '<Instance Path Name-1>' Placed at: <Placement-x>, <Placement-y>
//   Oriented: <Orientation>
//   '<Instance Path Name-2>' Placed at: <Placement-x>, <Placement-y>
//   Oriented: <Orientation>
//   ...
//
// Current design set to: <top DEF design name for current tool run>
```

Related Topics

[add_layout_core_information](#)

[delete_layout_core_information](#)

report_layout_files

Context: patterns -scan_diagnosis

Mode: setup, analysis

Returns the flat models and pattern sets associated with RCD constants stored in the LDB.

Usage

```
report_layout_files [-include_file_paths]
```

Arguments

- `-include_file_paths`

An optional switch that displays the full pathnames of the files.

Description

When generating RCD constants for RCD analysis, you may run the `create_feature_statistics` command multiple times on different combinations of flat models and pattern sets. Similarly, you may have verified the LDB against multiple flat models. The `report_layout_files` command reports which flat models and pattern sets are associated with the RCD constants stored in the LDB. It also reports the flat models that have been verified against the LDB.

The report displays the following information:

- `VERIFY_DB`: Within the LDB, the tool generates a verification database (.verifydb) after layout verification against a flat model.
- `RCD_DB`: Within the LDB, the tool generates RCD database (.rcddb) files every time you run `create_feature_statistics` to create RCD constants.
- `flat model`: The flat model name associated with `VERIFY_DB`.
- `flat MD5`: The MD5 signature for the flat model.
- `design MD5`: The structural MD5 of the design represented in the flat model.
- `pattern`: The pattern file name associated with `RCD_DB`. There may be multiple pattern files for each `RCD_DB`.
- `pattern MD5`: The MD5 signature for the pattern.
- `pattern set MD5`: The MD5 signature for the collective set of patterns in `RCD_DB`.

Examples

In the following example, the `report_layout_files` report shows that there are two verification databases within the current LDB. The first one is marked Active because the loaded flat model (current design) and pattern (current pattern) match its `RCD_DB` MD5 signatures.

```
read_flat_model design0.flat.gz
```

read_pattern pattern.wgl.gz

open_layout layoutDB

report_layout_files

RCD constants match for current design & pattern:

current design : design0.flat.gz MD5: c5ce18a2cfa9a98e3654a2d52b361c43

report_layout_rules

Context: patterns -scan_diagnosis

Mode: analysis

Provides detailed reporting of layout rule violations.

Usage

```
report_layout_rules [-Fails_summary | -Summary | layout_rule_id... |  
layout_rule_id-occurrence#... | -All_fails | -MISmatch_report | -NO_LAYOUT_names]  
{[-INClude design_module_name...] | [-EXClude design_module_name...]}  
[{> | >>} file.pathname]
```

Description

Provides detailed reporting of layout rule violations. Before using this command, you must run layout verification as part of the [create_layout](#) command or use the [open_layout](#) command with an existing Layout Database.

Note

 Use this command in conjunction with the [create_layout](#) command to debug layout rule violations before you create the diagnosis Layout Database.

See “[Layout-Aware Diagnosis and Reporting](#)” in the *Tessent Diagnosis User’s Manual* for complete information.

Arguments

- -Fails_summary

A switch that specifies to display the following for each user-controllable rule that resulted in a violation (fail) during layout verification:

- Rule identification (ID)
- Number of failures of the rule
- Current handling status of the rule
- Brief description of the rule

This is the default.

- -Summary

A switch that specifies to display a summary report of layout rule violations. When you report on all rules (report_layout_rules -Summary), the following is reported for each user-controllable rule, whether or not it resulted in a violation (fail) during layout verification:

- Rule identification (ID)
- Number of failures of the rule

- Current handling status of the rule
- Brief description of the rule
- *layout_rule_id*
A repeatable string that specifies the identification literal (ID) of a particular layout rule for which you want to display the violations.
- *layout_rule_id-occurrence#*
A repeatable string that specifies the identification literal (ID) of a particular layout rule and the violation occurrence for which you want to display the occurrence message. This argument must include the specific design rule ID (*rule_id*), the specific occurrence number of the violation, and the hyphen between them. Numbers to occurrences of layout rule violations are assigned as they are encountered; you cannot change the number assigned to a specific occurrence.
- -All_Fails
A switch that specifies to display all occurrence messages for all occurrences of layout rule violations. The displayed information can be lengthy, as it is the same information you would get if you consecutively entered a “`report_layout_rules <layout_rule_id>`” command for each rule that had a violation. Use this switch to output a report of all violation occurrences (most likely to a log file) for later analysis.
- -Mismatch_report
An optional switch that re-generates the [layout verification rule violation report](#). Normally, you use this switch in conjunction with the `report_layout_rules` command’s -INClude and -EXClude switches to filter the layout rule violations—see “[Guidelines for Including or Excluding Design Modules From Mismatch Reporting](#)” in the *Tessent Diagnosis User’s Manual*.
- -NO_LAYOUT_names
An optional switch that suppresses the reporting of instance/net/pin path names in layout format for selected layout rule violations. See “[Instance, Net, and Pin Path Names in Layout Rule Violation Reports](#)” in the *Tessent Diagnosis User’s Manual* for complete information.
- -INClude *design_module_name*
A switch and repeatable string that defines an excluded area of the design’s hierarchy when performing layout-to-design verification. The excluded area comprises all design elements that are *not* below instances of the included modules.

The *design_module_name* is a space-delimited list of design modules. For example:

```
report_layout_rules -include moduleA moduleB moduleD
```

The -INClude and -EXClude switches are mutually exclusive.

For detailed usage of this switch, see “[Guidelines for Including or Excluding Design Modules From Mismatch Reporting](#)” in the *Tessent Diagnosis User’s Manual*.

- -EXClude **design_module_name**

A switch and repeatable string that defines an excluded area of the design's hierarchy when performing layout-to-design verification. The excluded area comprises all design elements contained below instances of the excluded modules.

The **design_module_name** is a space-delimited list of design modules. For example:

```
report_layout_rules -include moduleA moduleB moduleD
```

The -INClude and -EXClude switches are mutually exclusive.

For detailed usage of this switch, see “[Guidelines for Including or Excluding Design Modules From Mismatch Reporting](#)” in the *Tessent Diagnosis User's Manual*.

- >*file.pathname*

An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file.pathname*.

- >>*file.pathname*

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file.pathname*.

Examples

Example 1

report_layout_rules

```
// Warning: Rule DesignCellPinMatch violated 1 times out of 226 checks.  
// Warning: Rule DesignInstanceMatch violated 48 times out of 5344  
// checks.  
// Warning: Rule DesignNetPinMatch violated 139 times out of 18630 checks.  
// Warning: Rule LayoutNetPinMatch violated 66 times out of 18557 checks.  
// Warning: Rule PinExistenceMacro violated 3 times out of 44202 checks.
```

Without any switches a summary of all layout rule violations is printed. In addition to the number of violations, the total number of times a particular rule was checked is also printed. As an example, for the DesignInstanceMatch rule above, this rule was checked 5344 times (specifically there must be 5344 library cell instances in this design) and it was violated 48 out of these 5344 checks.

Example 2

report_layout_rules PinExistenceMacro

```
PinExistenceMacro: #fails=3 #checks=44202 handling=warning (pin not exist  
in macro).  
// Warning: PinExistenceMacro-1: The specified NET cpu_i/uOPD/nx104 is  
// connected to MACRO oai222 which uses a PIN C0 which is not defined in  
// the LEF files.  
// Warning: PinExistenceMacro-2: The specified NET cpu_i/INTR_PRI1_7_ is  
// connected to MACRO oai222 which uses a PIN C0 which is not defined in  
// the LEF files.  
// Warning: PinExistenceMacro-3: The specified NET cpu_i/INTR_PRI1_0_ is  
// connected to MACRO oai222 which uses a PIN C0 which is not defined in  
// the LEF files.
```

By specifying a rule name all the violations of that rule will be printed. First a summary for the user specified rule is printed and then each rule violation is printed in detail.

Example 3

report_layout_rules PinExistenceMacro-2

```
PinExistenceMacro: #fails=3 #checks=44202 handling=warning (pin not exist  
in macro).  
// Warning: PinExistenceMacro-2: The specified NET cpu_i/INTR_PRI1_7_ is  
// connected to MACRO oai222 which uses a PIN C0 which is not defined in  
// the LEF files.
```

This prints one particular violation of a given rule.

Example 4

In this case the instance name in DFT format differs from that in layout format since the last part of the name is flattened. Since the layout is being created from the LEF/DEF the instance path name in layout format is expected to be as follows:

```
/core0/cntl_1/mac\adder\AND0
```

Note that in LEF/DEF naming convention individual hierarchy delimiters are escaped.

Report the corresponding Instance Rules rule violation using the following command:

report_layout_rules DesignInstanceMatch-1

```
// DesignInstanceMatch-1: Design instance /core0/cntl_1/mac/adder/AND0  
// (Expected Layout Name: /core0/cntl_1/mac\adder\AND0) not found in  
// layout.
```

You can suppress reporting of the layout name for this violation using the report_layout_rules command as follows:

report_layout_rules DesignInstanceMatch-1 -no_layout_names

```
// DesignInstanceMatch-1: Design instance /core0/cntl_1/mac/adder/AND0 not  
// found in layout.
```

report_lbist_configuration

Context: dft -logic_bist

Mode: setup, analysis

Reports the global LogicBIST controller configuration parameters.

Usage

```
report_lbist_configuration [> | >>file_pathname] [-hardware_default_compatibility]
```

Description

Reports the global LogicBIST controller configuration parameters. To report the parameters for individual EDT/LogicBist blocks, use the [report_edt_configurations](#) command. This command is used with the hybrid TK/LBIST flow—refer to the *Hybrid TK/LBIST Flow User's Manual* for complete information.

Arguments

- `>file_pathname`
An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.
- `>>file_pathname`
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.
- `-hardware_default_compatibility`
An optional switch that specifies to report hardware default configuration values. This switch is only available for fault simulation. When used in setup mode, it reports the hardware default values. When used in analysis mode, it reports these values plus fault simulation settings and compatibility on a per setting and composite basis. The tool issues a warning if you specify this switch outside of the TCD flow.

Examples

Example 1

The following example shows how to configure the LBIST controller parameters and then report on what has been specified.

```
set_lbist_controller_options -max_shift 400 -max_capture 3 -max_pattern 100000 \
    -capture {clk1P 30 clk2P 60 rstP 10}
report_lbist_configuration
```

```
// IP version: 1
// Max Shift cycles: 400
// Max Capture cycles: 3
// Max pattern count: 100000
// Capture procedures: clk1P 30%//
// clk2P 60%
// rstP 10%
```

Example 2

The following snippet shows the report format that the tool returns when you specify the `-hardware_default_compatibility` switch while in analysis mode. The report indicates that some settings are compatible with hardware default mode and others are not.

```
// -----
// Core Instance
// -----
// LBIST
// -----
// shift length      56          40      no
// capture width    4           15      no
// pattern count    500         1024    yes
// masked chains    0           0       yes
// NCP 1 count     154 (60%)   103 (40%) no
// NCP 2 count     26 (10%)    102 (40%) no
// NCP 3 count     76 (30%)    51 (20%) no
// ...
// ...
// -----
// Current fault simulation settings are not compatible with hardware default mode
```

report_lbist_pins

Context: dft -logic_bist

Mode: setup, analysis

Reports the LogicBIST controller pins using the set_lbist_pins command.

Usage

```
report_lbist_pins [> | >> file_pathname]
```

Description

Reports the LogicBIST controller pins using the set_lbist_pins command.

When you have renamed pins using the set_lbist_pins -on_controller_module command, the report includes a column entitled “Name on LBIST module.” By default, this column is hidden.

This command is used with the hybrid TK/LBIST flow—refer to the [Hybrid TK/LBIST Flow User’s Manual](#) for complete information.

Arguments

- *>file_pathname*
An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.
- *>>file_pathname*
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

This example reports all the design pins to which the LogicBIST controller’s control signals, including the TAP interface signals are connected.

```
report_lbist_pins

//          PinType           Connection
//  -----   -----
//  Clock      refclk
//  Scan enable scan_en
//  TCK        tck
//  Xbounding enable lbist_en
//  Setup Shift Scan in tdi
//  Setup Shift Scan out tdo jtag/scanCfgReg_so
//  Shift DR    - jtag/shift_dr
//  Capture DR  - jtag/capture_dr
//  Update DR   - jtag/update_dr
//  Test logic reset - jtag/tlr
//  TAP instruction decode - jtag/scanCfgReg_en
```

report_lfsr_connections

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Displays a list of all the connections between Linear Feedback Shift Registers (LFSRs) and primary pins.

Usage

```
report_lfsr_connections
```

Description

Displays a list of all the connections between Linear Feedback Shift Registers (LFSRs) and primary pins.

The report_lfsr_connections command displays all of the connections between the LFSRs and the primary pins. These connections were specified with the add_lfsr_connections commands.

Arguments

None

Examples

The following example displays the connections between the LFSRs and primary pins:

```
add_lfsrs lfsr1 prpg 5 15 -serial -in
add_lfsrs lfsr2 prpg 5 13 -serial -in
add_lfsrs misr1 misr 5 11 -parallel -in
add_lfsr_taps lfsr1 1 3
add_lfsr_taps lfsr2 2 3
add_lfsr_connections scan_in.1 lfsr1 3
add_lfsr_connections scan_out.0 misr1 2
report_lfsr_connections
```

Related Topics

[add_lfsr_connections](#)

[delete_lfsr_connections](#)

report_lfsrs

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Displays a list of definitions for all the current Linear Feedback Shift Registers (LFSRs).

Usage

```
report_lfsrs
```

Description

Displays a list of definitions for all the current Linear Feedback Shift Registers (LFSRs).

The report_lfsrs command displays all of the LFSRs with their current values and tap positions that you specified using the add_lfsrs and add_lfsr_taps commands.

Arguments

None

Examples

Example 1

The following example displays the definitions of all the current LFSRs:

```
add_lfsrs lfsr1 prpg 5 15 -serial -in
add_lfsrs lfsr2 prpg 5 13 -serial -in
add_lfsrs misr1 misr 5 11 -parallel -in
report_lfsrs
```

Example 2

The following example defines a 24-bit PRPG with self-feedback cells at positions 3, 7, 12, 15, and 23 and then lists the LFSRs:

```
add_lfsrs my_prpg prpg 24 FFFFFFFF -CA
add_lfsr_taps my_prpg 3 7 12 15 23
report_lfsrs
```

Output:

```
list of LFSRs
my_prpg  PRPG  length=24  shift=serial  ca_taps=3,12,15,23
my_prpg_pre_unload_value = 111111111111111111111111
my_prpg_post_unload_value = 111111111111111111111111
```

[set_lfsrs](#)

report_licenses

Context: unspecified, all contexts

Mode: all modes

Reports the license features currently checked out by the tool.

Usage

`report_licenses`

Description

Reports the license features currently checked out by the tool.

Arguments

None

Examples

The following example displays the licenses currently being used by the automatic diagnosis session.

`report_licenses`

The following report displays:

```
Licenses:  
4 yieldascandiag  
1 yieldaylearn
```

report_lists

Context: dft -edt, patterns -scan

Mode: analysis

Displays the list of pins whose values the tool will report during simulation.

Usage

report_lists [**>** | **>>**] *file_pathname*

Description

Displays the list of pins whose values the tool will report during simulation.

The **report_lists** command displays pins the tool is currently set up to report on during simulation. Use the [add_lists](#) command to add pins to the list and the [delete_lists](#) command to remove pins from the list.

When you switch to Setup mode, the tool discards all pins from the list.

Arguments

- **> *file_pathname***
An optional redirection operator and pathname pair for creating or replacing the contents of *file_pathname*.
- **>> *file_pathname***
An optional redirection operator and pathname pair for appending to the contents of *file_pathname*.

Examples

The following example displays the pins whose values the tool will report during simulation:

```
add_lists /i_1006/o /i_1007/o
report_lists

2 pins are currently monitored.
i_1006/o
i_1007/o
```

report_loadboard_loopback_pairs

Context: patterns -ijtag, -scan, -scan_diagnosis, -scan_retargeting

Modes: Setup, analysis

Prerequisites: Design must be elaborated prior to using this command.

Reports the loopback connections and the ac_delay, if any, that were created using the add_loadboard_loopback_pairs command.

Usage

```
report_loadboard_loopback_pairs
```

Description

This command reports any loopback connection pairs created using the [add_loadboard_loopback_pairs](#) command. It will also report the ac_delay for the loopback pairs.

Arguments

None

Examples

This example shows the report of loopback pairs and ac_delay values for the elaborated design:

```
add_loadboard_loopback_pairs -inputs {din[4] ue} -outputs {dout[5] dout[0]}
```

```
report_loadboard_loopback_pairs
```

```
-----
Inputs   Outputs   AC Time to Z
-----  -----
din[4]   dout [5]  N/A
ue       dout [0]  N/A
-----
```

report_loops

Context: all contexts

Mode: setup, analysis

Displays information about circuit loops.

Usage

```
report_loops [-All | loop_id#...]  
[-Display {HIERarchical_schematic [-Hierarchical]} [DAta] | ALl} [APpend] ]  
[{> | >>} file.pathname]
```

Description

Displays information about circuit loops.

The report_loops command displays information about currently identified loops in the circuit. For each loop, the report indicates whether the loop was broken by duplication. The report shows loops unbroken by duplication to be broken instead by a constant value, which means the loop is either a coupling loop or has a single multiple-fanout gate. The report also includes the pin pathname and gate type of each gate in each loop.

You can write the loops report information to a file by using the command's redirection operators or the [write_loops](#) command.

Arguments

- **-ALl**
An optional switch that specifies to report all the loops in the circuit. This is the default.
- ***loop_id#***
An optional, repeatable, positive integer that specifies the identification number of a particular loop to report. The tool assigns loop identification numbers consecutively, starting with 1.
- **-Display {HIERarchical_schematic [-Hierarchical]} [DAta] | ALl} [APpend]**
An optional switch, repeatable literal, and literal that specify to display the primary input(s) in the specified window; if *Append* is specified, the primary inputs are added to the existing contents of the window instead of replacing the contents.

The choices are as follows:

HIERarchical_schematic — A literal that specifies the Hierarchical Schematic window. If the *-Hierarchical* literal is specified, only the top-level hierarchical instances are displayed in the Hierarchical Schematic window; if the *-Hierarchical* literal is not specified, the child instances of the corresponding hierarchical instances are also displayed.

DAta— A literal that specifies the Data window.

All — A literal that displays the information in all the preceding windows.

- `>file.pathname`
An optional redirection operator and pathname pair for creating *or* replacing the contents of `file.pathname`.
- `>>file.pathname`
An optional redirection operator and pathname pair for appending to the contents of `file.pathname`.

Examples

Example 1

The following example displays a list of all the loops in the circuit:

```
set_system_mode analysis
report_loops

Loop = 1: not_duplicated (coupling loop)
    my_design/my_minibus (SBUS)
    my_design/PAD (BUF)
    my_design/my_minibus (Z2X)
Loop = 2: not_duplicated (coupling loop)
...
Loop = 8: not_duplicated (single multiple fanout)
    my_design/al/pl/padx (BUF)
    my_design/al/pl/pad (BUF)
    my_design/pad (WIRE)
```

Example 2

The following example displays loop 8 only:

```
report_loops 8

Loop = 8: not_duplicated (single multiple fanout)
    my_design/al/pl/padx (BUF)
    my_design/al/pl/pad (BUF)
    my_design/pad (WIRE)
```

Example 3

The following example writes the display information for loop 8 to a new file named `my_loop_file`:

```
report_loops 8 > my_loop_file
... writing to file my_loop_file
```

Related Topics

[report_feedback_paths](#)

report_lpct_configuration

Context: dft -edt, patterns -scan (EDT On), patterns -scan_diagnosis

Mode: setup, analysis

Reports the current low pin count test controller (LPCT) parameters to the standard display output.

Usage

`report_lpct_configuration [> | >> filename]`

Description

Reports the current low pin count test controller (LPCT) parameters to the standard display output.

After saving the patterns, you can use the [report_register_value](#) command to report the different fields of the test configuration registers such as shift_length, capture_depth, scan_pattern_count, and chain_pattern_count.

For more details on the values reported by this command, see the [set_lpct_controller](#) command.

Arguments

- `> file_pathname`
An optional redirection operator and pathname pair used at the end of an argument list to create or replace the contents of *file_pathname* with command output.
- `>> file_pathname`
An optional redirection operator and pathname pair used at the end of the argument list to append the command output to the contents of *file_pathname*.

Examples

The following example shows a report generated from Setup mode during EDT logic creation:

```
report_lpct_configuration
// Controller type:           Type 3
// Max Shift cycles:          1000
// Max Capture cycles:        8
// Max Scan patterns:         1048575
// Max Chain patterns:        1023
// Test mode detect sequence: 1010000101001
// Test mode detect period:   100 cycles
// Scan shift control:        internally generated clock
```

Related Topics

[report_lpct_pins](#)

[set_lpct_controller](#)

report_lpct_pins

Context: dft -edt, patterns -scan (EDT On), patterns -scan_diagnosis

Mode: setup, analysis

Reports the low pin count test (LPCT) controller pins and connection information to the standard display output.

Usage

```
report_lpct_pins [{> | >>} filename]
```

Description

Reports the low pin count test (LPCT) controller pins and connection information to the standard display output.

Arguments

- *> file_pathname*
An optional redirection operator and pathname pair used at the end of an argument list to create or replace the contents of *file_pathname* with command output.
- *>> file_pathname*
An optional redirection operator and pathname pair used at the end of the argument list to append the command output to the contents of *file_pathname*.

Examples

The following example shows a report generated from Setup mode during EDT logic creation:

```
report_lpct_pins

// Input pin      Pin name      Inversion Internal connection
// -----        -----
// Clock          port_clock    -
// Reset (Active High)   -        -      pwr_up/reset
// Data in        lpct_data_in  -
// Test mode      lpct_test_mode -
// 
// Output pin     Connection
// -----        -----
// Capture enable
// Clock mux select
// Shift clock
// Scan enable    scan_en
// Reset out
// Test end
// Data out
// Test active
```

Related Topics

[report_lpct_configuration](#)
[set_lpct_controller](#)

report_measure_cycles

Prerequisites: A WGL or STIL pattern set must be loaded.

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: analysis

Displays data for the specified components/cycles/patterns from the test patterns loaded for the current session. If nothing is specified, data for all the test patterns is reported.

Usage

```
report_measure_cycles [-All_cycles] [-Suite test_suite_ID] [{-Pattern_range | -Cycle_range}  
begin end] | [-List cycles ...] [observe_point...] [> | >> filename]
```

Description

Displays data for the specified components/cycles/patterns from the test patterns loaded for the current session. If nothing is specified, data for all the test patterns is reported.

Depending on the arguments used with this command, you can report expect bits, masked bits, cycle padding, cycles, patterns, and chain cells and lengths.

You can use this command to troubleshoot data verification errors that occur before diagnosis. Only WGL and STIL test patterns are supported by this command.

Use this command to debug failure file mismatches reported by the tool. You can use this command to report the failing cycle, failing pattern, expect values, and boundary cycles related to a specific mismatch.

Arguments

- **-All_cycles**

An optional switch that generates a full report for all cycles.

The tool assigns each cycle to a specific category, and groups the neighboring cycles belonging to the same category into a cycle block, which include one or more cycles.

For each cycle block, the tool reports the following in columnar format:

- **First** — First cycle.
- **Last** — Last cycle (unless the cycle is the same as the first cycle).
- **#Cycle** — Count of cycles.
- **Pid** — Pattern ID.
- **Type** — Pattern type.
- **Sid** — Suite ID. Reported if there is more than one test suite.
- **RelPid** — Relative Pattern ID. Reported if there is more than one test suite.

- **Operation** — Function of the cycle block, for example “Test setup”, “Setup shift”, “Force PI”, “Measure PO” and “Shift and measure SCO”.
- **-Suite** *test_suite_ID*
An optional switch and string pair that specifies the targeted test suite when you use more than one test suite. When you specify a valid test suite ID, the pattern IDs (begin end) specified are treated as relative IDs for this targeted test suite. Otherwise, the pattern IDs (begin end) are considered as absolute numbers.
By default, if you omit this switch, then the pattern IDs (begin end) are considered as absolute numbers. If only the -suite switch is used and the -pattern is omitted, then the tool reports all patterns of the specified test suite.
- **-Pattern_range** *begin end*
Optional switch and value pair that specifies a range of patterns.
- **-Cycle_range** *begin end*
Optional switch and value pair that specifies a range of cycles. This option cannot be used with -All_cycles because a full cycle-oriented report is generated; the tool ignores the -all_cycles option, if supplied.
- **-List** *cycles*
Optional, repeatable switch and value pair used to specify one or more specific cycles.
- **observe_point**
Optional value that specifies the name of one or more components to focus the report on. Observe points are usually pin names, but may also represent any of the following:
 - chain
 - scanout_pin
 - edt_channel
 - edt_scanout_pin
 - POpin
- **>** *file_pathname*
An optional redirection operator and pathname pair for creating *or* replacing the contents of *file_pathname*. Use this argument to write the report to a file.
- **>>** *file_pathname*
An optional redirection operator and pathname pair for appending to the contents of *file_pathname*. Use this argument to append the report to the specified file.

Examples

Example 1

The following example displays a specified range of patterns:

```
report_measure_cycles -pattern 10 20
```

```
total cycles = 41103
pattern set # 1 total cycles: 41103 last chain: 9 last scan: 382
( pat/pat.wgl )
  Pattern   Measure_PO   Measure_SCO (first,last,step)
  -----  -----
  10 (S)    2277    { (2279,2380,+1) }
  11 (S)    2381    { (2383,2484,+1) }
  12 (S)    2485    { (2487,2588,+1) }
  13 (S)    2589    { (2591,2692,+1) }
  14 (S)    2693    { (2695,2796,+1) }
  15 (S)    2797    { (2799,2900,+1) }
  16 (S)    2901    { (2903,3004,+1) }
  17 (S)    3005    { (3007,3108,+1) }
  18 (S)    3109    { (3111,3212,+1) }
  19 (S)    3213    { (3215,3316,+1) }
  20 (S)    3317    { (3319,3420,+1) }
```

Example 2

The following example displays the cycles, patterns, and expect bits information for the chain test for chain3:

```
report_measure_cycles chain3
```

```
total cycles = 41103
cycle  pattern  chain{cell}:scanout  expect
-----  -----
 105      0      chain3{0}:scan_out3 L  chaintest
 106      0      chain3{1}:scan_out3 L  chaintest
 107      0      chain3{2}:scan_out3 H  chaintest
 108      0      chain3{3}:scan_out3 H  chaintest
 109      0      chain3{4}:scan_out3 L  chaintest
 110      0      chain3{5}:scan_out3 L  chaintest
 111      0      chain3{6}:scan_out3 H  chaintest
 112      0      chain3{7}:scan_out3 H  chaintest
 113      0      chain3{8}:scan_out3 L  chaintest
 114      0      chain3{9}:scan_out3 L  chaintest
 115      0      chain3{10}:scan_out3 H  chaintest
 116      0      chain3{11}:scan_out3 H  chaintest
 117      0      chain3{12}:scan_out3 L  chaintest
 118      0      chain3{13}:scan_out3 L  chaintest
 119      0      chain3{14}:scan_out3 H  chaintest
 120      0      chain3{15}:scan_out3 H  chaintest
```

Example 3

The following example reports all cycles based on cycle blocks.

report_measure_cycles -all_cycles

```
total cycles = 41103
pattern set # 1 total cycles: 41103 last chain: 9 last scan: 382
( pat/pat.wgl )
```

First	Last	#Cycle	Pid	Type	Operation
0		1	0	C	Test setup
1		1	0	C	Setup shift
2	103	102	0	C	Shift (load only)
104		1	0	C	Setup shift
105	206	102	0	C	Shift and measure SCO
207		1	1	C	Setup shift
208	309	102	1	C	Shift and measure SCO
310		1	2	C	Setup shift
311	412	102	2	C	Shift and measure SCO
413		1	3	C	Setup shift
414	515	102	3	C	Shift and measure SCO
516		1	4	C	Setup shift
517	618	102	4	C	Shift and measure SCO
619		1	5	C	Setup shift
620	721	102	5	C	Shift and measure SCO
722		1	6	C	Setup shift
723	824	102	6	C	Shift and measure SCO
825		1	7	C	Setup shift
826	927	102	7	C	Shift and measure SCO
928		1	8	C	Setup shift
929	1030	102	8	C	Shift and measure SCO
1031		1	9	C	Setup shift
1032	1133	102	9	C	Shift and measure SCO
1134		1	0	S	Setup shift
1135	1236	102	0	S	Shift (load only)
1237		1	0	S	Measure PO and pulse clock
1238		1	0	S	Setup shift
1239	1340	102	0	S	Shift and measure SCO
1341		1	1	S	Measure PO and pulse clock

Example 4

The following example reports the measurement cycles for test suite 1.

report_measure_cycles -suite 1

```

total cycles = 82206
pattern set # 1 total cycles: 41103 last chain: 9 last scan: 382
( pat/pat.wgl )
pattern set # 2 total cycles: 41103 last chain: 9 last scan: 382
( pat/pat.wgl )
  Pattern (Suite/Pid)  Measure_PO  Measure_SCO (first,last,step)
  -----
  0 ( 1/ 0) (C)  ---- { (105,206,+1) }
  1 ( 1/ 1) (C)  ---- { (208,309,+1) }
  2 ( 1/ 2) (C)  ---- { (311,412,+1) }
  3 ( 1/ 3) (C)  ---- { (414,515,+1) }
  4 ( 1/ 4) (C)  ---- { (517,618,+1) }
  5 ( 1/ 5) (C)  ---- { (620,721,+1) }
  6 ( 1/ 6) (C)  ---- { (723,824,+1) }
  7 ( 1/ 7) (C)  ---- { (826,927,+1) }
  8 ( 1/ 8) (C)  ---- { (929,1030,+1) }
  9 ( 1/ 9) (C)  ---- { (1032,1133,+1) }
  0 ( 1/ 0) (S) 1237 { (1239,1340,+1) }
  1 ( 1/ 1) (S) 1341 { (1343,1444,+1) }
  2 ( 1/ 2) (S) 1445 { (1447,1548,+1) }
  3 ( 1/ 3) (S) 1549 { (1551,1652,+1) }
  4 ( 1/ 4) (S) 1653 { (1655,1756,+1) }
  5 ( 1/ 5) (S) 1757 { (1759,1860,+1) }
  6 ( 1/ 6) (S) 1861 { (1863,1964,+1) }

```

Example 5

The following example reports in blocks, all cycles between 0 and 200, and shows that cycles 105-206 are measure cycles for the first chain pattern.

report_measure_cycles -cycle_range 0 200

```

total cycles = 41103
pattern set # 1 total cycles: 41103 last chain: 9 last scan: 382
( pat/pat.wgl )

First  Last   #Cycle  Pid  Type  Operation
  0        1      0    C  Test setup
  1        1      0    C  Setup shift
  2     103    102    0    C  Shift (load only)
  104      1      0    C  Setup shift
  105    206    102    0    C  Shift and measure SCO

```

report_memory_cluster_configuration

Context: dft, patterns

Mode: all modes

Reports the configuration of cluster memories tested in subsequent controller steps for a specified memory cluster and memory access level.

Usage

Context: dft

```
report_memory_cluster_configuration
{ [-design_name] [design_name]
  [-design_id] [design_id]
  [-controller_id] [controller_id]
  [-cluster_id] [cluster_id] }
| { [-tcd_memory_cluster_name] [cluster_module_name]
    [-memory_access_level] {from_defaults_specification|logical|auto|physical} } }
```

Context: patterns

```
report_memory_cluster_configuration
{ [-design_name] [design_name]
  [-design_id] [design_id]
  [-pattern_id] [pattern_id] }
| { [-patterns_name] [patterns_name]
    [-test_step_name] [test_step_name]
    [-controller_icl_instance] [controller_icl_instance] }
| [-tcd_memory_bist_controller_name] [tcd_memory_bist_controller_name]
```

Description

Creates a tabular report with steps and lists of cluster memories tested in consecutive controller steps. In the dft context, the report is based on the memory cluster library description and the selected memory expansion (access) level. In the patterns context, the report is based on the MemoryBIST controller TCD description associated with the given MemoryBIST controller instance.

Context : dft

The command accepts a minimum set of options to uniquely identify the reported memory cluster instance in either the [DftSpecification](#) or the [/Core/MemoryCluster](#), in case the DftSpecification was not loaded. When a design contains a single memory cluster, it is not necessary to specify any options with the command. When multiple memory clusters exist in a design, an error is reported if it is not possible to uniquely identify a memory cluster_id with the provided command options. In this case, the DftSpecification can be consulted with the [report_config_data](#) command to identify the available memory clusters

If the reported memory cluster is included in the DftSpecification, it is accompanied with the memory expansion level value defined either explicitly with the [/DftSpecification/MemoryBist/MemoryCluster/memory_access_level](#) property, or inferred from the [/DefaultsSpecification/DftSpecification](#) settings.

If no DftSpecification is present, Tesson Shell reports the memory cluster configuration of the [/Core/MemoryCluster](#) defined in the tcd partition. Similarly to the DftSpecification generation, the cluster memory access level is assumed from the DefaultsSpecification, unless the “-memory_access_level” option is used.

Context : patterns

The command accepts a minimum set of options to uniquely identify a MemoryBIST controller TCD loaded in the tcd partition. Alternately, you may directly specify a controller TCD using the “-tcd_memory_bist_controller_name” option. When a design contains a single memory cluster, it is not necessary to specify any options with the command. When multiple memory clusters exist in a design, an error is reported if it is not possible to uniquely identify a memory cluster_id with the provided command options. In this case, the DftSpecification can be consulted with the [report_config_data](#) command to identify the available memory clusters.

Arguments

- **-design_name *design_name***

An optional switch and value pair that specifies which DftSpecification or PatternsSpecification wrapper the reported memory cluster is located in. This is used in case multiple DftSpecifications or PatternsSpecifications for different design names are loaded in memory. In the dft context, this switch is mutually exclusive with the “-tcd_memory_cluster_name” switch. In the patterns context, this switch is mutually exclusive with the “-tcd_memory_bist_controller_name” switch.

- **-design_id *design_id***

An optional switch and value pair that narrows down the search of the DftSpecification or PatternsSpecification when multiple DftSpecifications or PatternsSpecifications are loaded in memory for the same design. In the dft context, this switch is mutually exclusive with the “-tcd_memory_cluster_name” switch. In the patterns context, this switch is mutually exclusive with the “-tcd_memory_bist_controller_name” switch.

- **-controller_id *controller_id***

An optional switch and value pair to narrow down the search to only a single DftSpecification/MemoryBist/Controller wrapper containing the reported memory cluster. This switch is mutually exclusive with the “-tcd_memory_cluster_name” switch.

- **-cluster_id *cluster_id***

An optional switch and value pair that informs which /DftSpecification/MemoryBist/Controller/MemoryCluster to select for the memory cluster report. This switch is mutually exclusive with the “-tcd_memory_cluster_name” switch.

- **-tcd_memory_cluster_name *cluster_module_name***
An optional switch and value pair to reference the reported memory cluster in /Core/MemoryCluster. This switch is mutually exclusive with the following switches referencing DftSpecification location: “-design_name”, “-design_id”, “-controller_id”, “-cluster_id”.
- **-memory_access_level {from_defaults_specification | logical | auto | physical}**
An optional switch and enumeration symbol pair used together with the “-tcd_memory_cluster_name” switch to assume the given cluster memory expansion level when generating the report. If the switch is not provided, Tesson Shell assumes the expansion level currently defined in the /DefaultSpecification/DftSpecification.
- **-pattern_id *pattern_id***
An optional switch and value pair to specify a particular PatternsSpecification to further narrow down the search for the memory cluster report. This switch is mutually exclusive with the “-tcd_memory_bist_controller_name” switch and is only available in the patterns context.
- **-patterns_name *patterns_name***
An optional switch and value pair to specify a particular /PatternsSpecification/Patterns wrapper to further narrow down the search for the memory cluster report. This switch is mutually exclusive with the “-tcd_memory_bist_controller_name” switch and is only available in the patterns context.
- **-test_step_name *test_step_name***
An optional switch and value pair to specify a particular /PatternsSpecification/Patterns/TestStep wrapper to further narrow down the search for the memory cluster report. This switch is mutually exclusive with the “-tcd_memory_bist_controller_name” switch and is only available in the patterns context.
- **-controller_icl_instance *controller_icl_instance***
An optional switch and value pair to specify a particular /PatternsSpecification/Patterns/TestStep/MemoryBist/Controller wrapper to further narrow down the search for the memory cluster report. This switch is mutually exclusive with the “-tcd_memory_bist_controller_name” switch and is only available in the patterns context.
- **-tcd_memory_bist_controller_name *tcd_memory_bist_controller_name***
An optional switch and value pair to reference the reported memory controller in the /Core/MemoryBistController configuration data. This switch only available in the patterns context, and is mutually exclusive with the following switches referencing PatternsSpecification location: “-patterns_name”, “-pattern_id”, “-test_step_name”, and “-controller_icl_instance”.

Examples

Example 1 (Context: dft)

Given the following DftSpecification:

```
DftSpecification(WIRELESS_CORE,rtl) {
    MemoryBist {
        Controller(c1) {
            MemoryCluster(c1) {
                instance_name: top/a/b/mc;
                memory_access_level: physical;
            }
        }
    }
}
```

The following command can be used to report the test scheduling for memory cluster instance top/a/b/mc:

```
report_memory_cluster_configuration -design_name WIRELESS_CORE -controller_id c1
```

Note

 The cluster will be tested at the physical memory access level in this example.

Example 2 (Context: dft)

Assuming no design is loaded, but the following DftSpecification exists (no_insertion mode):

```
DftSpecification(WIRELESS_CORE,rtl) {
    MemoryBist {
        Controller(c1) {
            MemoryCluster(c1) {
                memory_cluster_library_name: CLUSTER;
            }
        }
    }
}
```

The same command given in Example 1 can be used to print the test scheduling. Please note however, this time the memory access level defined in the /DefaultsSpecification/ DftSpecification applies.

Example 3 (Context: dft)

If the DftSpecification is not available, one may print the test scheduling with the following command:

```
report_memory_cluster_configuration -tcd_memory_cluster_name CLUSTER \
-memroy_access_level physical
```

Example 4 (Context: patterns)

Given the following PatternsSpecification loaded in memory:

```
PatternsSpecification(WIRELESS_CORE,rtl,signoff) {
    Patterns(ICLNetwork) {
        ICLNetworkVerify(WIRELESS_CORE) {
        }
    }
    Patterns(MemoryBist_P1) {
        TestStep(run_time_prog) {
            MemoryBist {
                run_mode : run_time_prog;
                reduced_address_count : off;
                Controller(mbist_c1_controller_inst) {
                    DiagnosisOptions {
                        compare_go : on;
                        compare_go_id : on;
                    }
                }
            }
            Controller(mbist_c2_shared_bus_assembly_inst.mbist_c2_controller_inst) {
                DiagnosisOptions {
                    compare_go : on;
                    compare_go_id : on;
                }
            }
        }
    }
}
```

The following command invocation can be used to print the report for the second controller:

```
report_memory_cluster_configuration -controller_icl_instance \
mbist_c2_shared_bus_assembly_inst.mbist_c2_controller_inst
```

Example 5 (Context: patterns)

If the controller TCD is loaded in the tcd partition in memory, the report can be printed with the following command:

```
SETUP> report_memory_cluster_configuration \
-tcd_memory_bist_controller_name mbist_c2_controller
```

This command results in the following table report:

```
// controller id: mbist_c2_controller
// =====
// Step  Access  Logical  Physical  Cluster   Logical  Physical  Memory
//      level    access    access    interface  memory   memory   id
//           code     code     id
// -----
// 0    logical  3'b001   -        I1       LM_0
// 1    logical  3'b010   -        I1       LM_1
// 2    logical  3'b011   -        I1       LM_2
// 3    logical  3'b100   -        I1       LM_3
//
```

report_memory_identification

Context: dft

Mode: analysis, insertion

Reports the validation results of the memory module matching performed from the name patterns specified with the set_memory_identification_options command.

Usage

report_memory_identification

Description

Creates a tabular report showing the memory module matching results. It is required to have previously used the [set_memory_identification_options](#) command with a valid match expression before requesting the report created by report_memory_identification.

The report contains a Memory Identification Report table with the following information:

- **Design module** — The name of the memory design module identified either by the pattern(s) specified with the set_memory_identification_options command, or recognized by the tool by matching a provided memory TCD.
- **TCD name** — If found, the name of the memory TCD associated with the design memory module is reported.
- **Pattern match** — A “yes” or “no” report as to whether a design memory module matches any pattern specified with the set_memory_identification_options command.
- **Instance count** — The number of instances associated with a design memory module.
- **Action** — Recommended actions for the user to review. The reported actions are:
 - **missing pattern** — The listed design module has not been identified by a matching pattern expression specified with the set_memory_identification_options command, but has been recognized as memory because the memory TCD for the module exists. The pattern matching expression specified for set_memory_identification_options needs to be verified.
 - **missing TCD** — The listed design module has been identified as memory by a matching pattern expression specified with the set_memory_identification_options command, but the corresponding memory TCD has not been found. The memory TCD needs to be provided, or the pattern expression needs to be updated if the design module is not a memory module.

The report also contains a Matching Patterns Expressions table with the following information:

- **Matching pattern expression** — The regular or wildcard matching pattern specified with the set_memory_identification_options command.

- **Matched modules count** — The number of design modules that are matched by the corresponding regular or wildcard matching pattern.

Arguments

None

Examples

During the setup mode for this example design, the following design module matching patterns are specified:

```
set_memory_identification_options "{(.SYNC_1.*)} {(.SYNC_2.*)} {(.SYNC_3.*)}" -regexp
```

When [check_design_rules](#) is run, the report will automatically be generated if errors or warning exist between design module matching and memory TCD.

Later in the flow, while in either the analysis or insertion mode, the [report_memory_identification](#) command can be run to view the report as shown in the example below:

```
report_memory_identification

// Memory identification report table
// =====
// Design module      TCD name    Pattern match   Instance count   Action
// -----      -----
// SYNC_1R1W_16x8     -          yes            5               missing TCD
// SYNC_2R2W_12x8     -          yes            3               missing TCD
//
// Actions legend:
//
// Action 'missing TCD':
//   Memory has been identified by matching pattern expression, but
//   corresponding memory TCD library has not been found. Provide the
//   missing TCD library file or correct the matching pattern expression
//   if identified design module is not a memory module.

// Matching pattern expressions table
// =====
// Matching pattern expression  Matched modules count
// -----
// (.SYNC_1.*)
// (.SYNC_2.*)
// (.SYNC_3.*)
//
// Error: Memory validation by matching pattern expression (enabled with
//        set_memory_identification_options) has identified potentially
//        untested memories due to missing TCD library file.
//        Refer to the above memory identification report table.
```

Related Topics

[set_memory_identification_options](#)

report_memory_instances

Context: dft, patterns

Mode: all modes

Prerequisite: The current design must be set with the `set_current_design` command.

Reports the options of all instances for which there is a matched TCD Memory description.

Usage

```
report_memory_instances [name_patterns] [-below_instances below_instances]  
[-filter filter] [-limit limit]  
[-silent]
```

Description

Reports the options of all instances for which there is a matched TCD Memory description. See “[Tessent Core Description](#)” on page 3755.

You can restrict the report to instances below a given collection of instances, and filter the collection based on an attribute filtering equation involving other attributes registered against or inherited by the instance object type.

The `-silent` option suppresses the warning that is normally generated if there are no memory instances to report.

Arguments

- `name_patterns`

An optional string or Tcl list of strings that specifies one or more patterns to be used to filter the returned list of instances. The string is a Tcl list of patterns separated by spaces and enclosed in braces `{}`. If no `name_patterns` are specified, the tool searches all instances.

If you specify the `-below_instances` options, the name patterns are hierarchical name patterns relative to the specified instance objects; otherwise, the name patterns are relative to the current design.

- `-below_instances instance_objects`

An optional switch and value pair that constrains the command to search for instances below the specified `instance_objects`. The specified `name_patterns` are searched relative to each instance found in the `instance_objects` list.

- `-filter attribute_equation`

An optional switch and string pair that specifies to filter results based on the expression specified by the `attribute_equation` string. The attributes used within the equation must exist for the instance object type. See “[Attribute Filtering Equation Syntax](#)” on page 3162 for more details on the attribute filtering equation format.

- **-limit *limit***

An optional switch and number pair that defines the maximum number of memory instances the tool should report. The default of limit is 10.

- **-silent**

An optional switch that suppresses the warning message normally generated when the command does not find any instances to report. The warning message is intended to indicate a probable mistake when specifying patterns. You can use the -silent switch to suppress the warning. This -silent option has no effect on any other error reporting.

Examples

The following example uses the report_memory_instances command to report the options of the first three instances of the memory module.

SETUP> report_memory_instances -limit 3

```
//  
// Memory Instance: blockA_l1_i1/blockA_l2_i1/mem1  
// -----  
// bist_data_in_pipelineing : off  
// physical_cluster_override :  
// power_domain_island :  
// test_clock_override :  
// use_in_memory_bist_dft_specification : auto  
// use_in_memory_bisr_dft_specification : auto  
//  
// Memory Instance: blockA_l1_i1/blockA_l2_i1/mem2  
// -----  
// bist_data_in_pipelineing : off  
// physical_cluster_override :  
// power_domain_island :  
// test_clock_override :  
// use_in_memory_bist_dft_specification : auto  
// use_in_memory_bisr_dft_specification : auto  
//  
// Memory Instance: blockA_l1_i1/blockA_l2_i1/mem3  
// -----  
// bist_data_in_pipelineing : off  
// physical_cluster_override :  
// power_domain_island :  
// test_clock_override :  
// use_in_memory_bist_dft_specification : auto  
// use_in_memory_bisr_dft_specification : auto  
//  
// Reached limit of 3, skipping remaining 15 instances.
```

report_memory_repair_groups

Context: dft

Mode: setup, analysis

Reports information about the repair groups from a DftSpecification.

Usage

```
report_memory_repair_groups [-show_memory_instances]
    {[-design_name design_name -insertion_id id]}
```

Description

The report_memory_repair_groups command reports information about the repair groups from a DftSpecification. By default, the command reports the repair groups from the DftSpecification for the current elaborated design and insertion id.

If it is desired to report the repair groups from a DftSpecification of a different design than the one that is currently elaborated, or if there isn't one currently elaborated, the -design_name and -insertion_id arguments must be specified.

The report contains the controller for each group and its size, expressed in terms of total memory bits that are sharing a spare element. If the -show_memory_instances argument is specified, the report will also provide an additional list of all memory instances within each repair group.

Arguments

- **-show_memory_instances**
An optional switch that specifies a list of all memory instances with each repair group will also be reported.
- **-design_name *design_name***
An optional switch and value pair that specifies the module design name from which the repair groups will be reported. The -insertion_id argument must also be specified to uniquely identify the design module.
- **-insertion_id *id***
An optional switch and value pair that specifies the module id associated with the design module from which the repair groups will be reported. The -design_name argument must also be specified to uniquely identify the design module.

Examples

The following example shows the reporting of repair group information from the DftSpecification for the currently elaborated design. The use of the -show_memory_instances argument provides the additional list of memory instances within each repair group.

```
report_memory_repair_groups -show_memory_instances
```

report_mismatch_sources

Context: dft -edt, patterns -scan

Mode: analysis

Displays the sources of simulation mismatches.

Usage

```
report_mismatch_sources [src-id | -All] [-Display [FLAt_schematic]  
[HIEarchical_schematic] [DAta] [Wave] | All] [(> | >>) file_pathname]
```

Description

Displays the sources of simulation mismatches.

The report_mismatch_sources command displays detailed information about the sources of simulation mismatches found by a previous analyze_simulation_mismatches command or a write_patterns -Debug command. For each mismatch source you specify, the command reports the following information in columnar format:

- ID# — Positive integer that identifies a specific mismatch source. The tool numbers mismatch sources consecutively, starting at 1.
- Instance name — Hierarchical instance name of the mismatch source.
- Pattern number — The number of the first failing pattern caused by a mismatch source. In the ModelSim Wave window, the pattern number is the value of the “_pattern_count” variable at the time the mismatch occurred. This variable is displayed in the top line of the Wave window and increments as each pattern is simulated. This number corresponds to the pattern number in ASCII patterns.
- Time (ns) — First simulation time where the source causes a value in the external simulator that is inconsistent with what the tool expected.
- Capture cycle — The capture cycle where the first mismatch occurs (starting from 0).
- Expected value (ATPG_val) — Expected output value from the tool.
- Simulated value (VCD_val) — Simulated output value from the external simulator. Possible values are:
 - 0 — Logic 0
 - 1 — Logic 1
 - Z — Tristate
 - X — Unknown
 - U — Unused
 - . — No VCD data was saved.

- Reason — The following is a list of possible mismatch reasons:
 - “incorrect input”: Mismatch is due to wrong force values at PI.
 - “incorrect PO measure”: Mismatch is due to wrong measure PO time.
 - “incorrect loading”: Mismatch is due to incorrect scan load.
 - “incorrect capture”: Mismatch is due to incorrect capture clock even at the state element.
 - “incorrect unloading”: Mismatch is due to incorrect scan unload.
 - “wrong clock pulse”: Mismatch is due to incorrect clock pulse.
 - “setup time violation”: Mismatch is due to setup time violation, specifically the combinational path is not stable in one clock cycle.
 - “incorrect logic”: Mismatch is due to difference logic between Tesson Cell library model and the Verilog model. This includes different netlists used between ATPG tool and Verilog simulator, or Tesson Cell library model difference to the corresponding Verilog model.
 - “mismatched RAM model”: Mismatch is due to difference on RAM model between Tesson Cell library and Verilog library.
 - “incorrect library cell”: Mismatch is due to difference between Tesson Cell library model and Verilog library cell.
 - “incorrect ATPG setting”: Mismatch is due to improper setting on ATPG tool. Most common mistakes are incorrect setting of set_split_capture and set_clock_off_simulation.
 - “hold time violation”: Mismatch is due to hold time violation. The sink flop of the hold time violation is reported as the mismatch source gate.
 - “clock/data port race”: mismatch is due to clock and data racing. Common clock racing situations include C6 and C4 violation.

Arguments

- *src-id*
An optional positive integer that specifies the identification number of the mismatch source to report. The tool assigns source IDs to mismatch sources consecutively, starting with 1.
- -Display [FLAt_schematic] [HIEarchical_schematic] [DAta] [Wave]
An optional switch that specifies to display the specified source(s) in the Flat Schematic, Hierarchical Schematic, Data, or Wave window of DFTVisualizer. If the *Display* switch is specified without an argument, the Flat Schematic, Data, and Wave windows are displayed.
- -All
An optional switch that specifies to display all the mismatch sources. This is the default.

Note

 In the Flat Schematic window, pin names assigned to the value “.” indicate that the VCD debug test bench did not capture the VCD value for that location. It is not possible to capture VCD values for every node in the design due to very large file sizes and run time; the test bench only captures values in the combination cone behind the failure location, which in most cases provides sufficient information to explain the mismatch.

- *>file.pathname*

An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file.pathname*.

- *>>file.pathname*

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file.pathname*.

Examples

The following example assumes the pathname of the ModelSim bin directory is defined by the PATH variable and patterns are generated but not yet saved. The example first specifies the invocation command for the external simulator, then saves the generated pattern set. Next, it creates the Verilog library *my_mismatch_work*, compiles the source for the top-level design and supporting simulation parts library into the library, and analyzes the simulation mismatches. Finally, DFTVisualizer is invoked and displays the simulation, test pattern, and design data with the mismatch sources highlighted in red.

```
set_external_simulator vsim -c -voptargs+=acc=npr
write_patterns results pat_p.v -verilog -parallel -replace
sys vlib my_mismatch_work
sys vlog -work my_mismatch_work my_design_source/my_design.v -v \
    my_verilog_source/verilog_lib.v

report_misrs

Context: pattern -scan

Mode: setup, analysis

Reports the MISRs you have added to your design.

Usage

```
report_misrs {-all | misr_name ...} [> | >> file_pathname]
```

Description

Reports the MISRs you have added to your design.

This command is used with the hybrid TK/LBIST flow—refer to the [Hybrid TK/LBIST Flow User's Manual](#) for complete information.

Arguments

- **-all**
A required switch that reports all MISRs.
- **misr_name**
A required repeatable string that specifies the name of the MISR.
- **> *file_pathname***
An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.
- **>> *file_pathname***
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

Example 1

This example reports all the MISRs defined across all the EDT/logicBIST blocks.

```
report_misrs -all
```

```
list of MISRs
A_misr_0  MISR  length=24  in_stream_taps=20,21,23
  A_misr_0_pre_unload_value = 00000000000000000000000000000000
A_misr_1  MISR  length=32  in_stream_taps=4,5,31
  A_misr_1_pre_unload_value = 00000000000000000000000000000000
A_misr_2  MISR  length=32  in_stream_taps=4,5,31
  A_misr_2_pre_unload_value = 000000000001000100010001000100000000
A_misr_3  MISR  length=32  in_stream_taps=4,5,31
  A_misr_3_pre_unload_value = 00000000000000000000000000000000
B1_misr  MISR  length=24  in_stream_taps=20,21,23
  B1_misr_pre_unload_value = 00000000000000000000000000000000
B2_misr_0  MISR  length=24  in_stream_taps=20,21,23
  B2_misr_0_pre_unload_value = 00000000000000000000000000000000
B2_misr_1  MISR  length=24  in_stream_taps=20,21,23
  B2_misr_1_pre_unload_value = 00000000000000000000000000000000
```

Example 2

This example reports a specific MISR: A_misr_2:

```
report_misrs A_misr_2
```

```
list of MISRs
A_misr_2  MISR  length=32  in_stream_taps=4,5,31
  A_misr_2_pre_unload_value = 00000000000100010001000100000000
```

report_misr_connections

Context: patterns -scan

Mode: setup, analysis

Reports MISR connections.

Usage

```
report_misr_connections misr_name [> | >>file.pathname]
```

Description

Reports MISR connections.

This command is used with the hybrid TK/LBIST flow—refer to the [Hybrid TK/LBIST Flow User's Manual](#) for complete information.

Arguments

- **misr_name**
A required repeatable string that specifies the name of the MISR.
- **>file.pathname**
An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file.pathname*.
- **>>file.pathname**
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file.pathname*.

Examples

This example shows the connection between the LBIST scan chain output and the MISR input for a 24-bit MISR named 'misr'. The 16 scan chains are compacted with a 4-to-1 XOR and connected to the first 4 inputs of the MISR.

```

report_module_matching

Context: dft, patterns -ijtag

Mode: all modes

Reports design modules and their matching modules of the specified format, if the set_current_design command has already been executed.

Usage

```
report_module_matching -icl | -format { icl | tcd_bscan | tcd_scan | tcd_fusebox | tcd_memory  
| tcd_memory_cluster }
```

Description

Reports design modules and their matching modules of the specified format, if the set_current_design command has already been executed.

Arguments

- -icl

An optional switch that specifies to report matching ICL modules.

If the attribute “ignore_during_icl_extraction” is defined for any instance, an additional column “Ignored” is added to the report specifying whether the instance was ignored during ICL extraction. However, the “Ignored” column is not included if the value of the attribute is set to “false” for all instances for which the attribute is defined.

- - format { icl | tcd_bscan | tcd_scan | tcd_fusebox | tcd_memory | tcd_memory_cluster }

An optional switch that specifies the format of the matching modules to be reported.

Return Values

None

Examples

Example 1

The following example shows an example report generated by this command.

```
read_icl ./data/icl/block3.icl  
set_design_sources -format icl -search_design_load_path On  
set_module_matching_options -suffix_pattern_list "\[0-9\]" -regexp  
set_current_design chip  
report_module_matching -icl
```

report_multicycle_paths

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Displays multicycle path definitions you previously read into the tool using the [read_sdc](#) command.

Usage

```
report_multicycle_paths [-All] [-Error] [-Verbose] [-Debug_error]  
[-From source_node... | -FROM_Clock clock_signal_name...]  
[-TO sink_node... | -TO_Clock clock_signal_name...]  
[-Through through_node...]...  
[{> | >>} file.pathname]
```

Description

Displays multicycle path definitions you previously read into the tool using the [read_sdc](#) command.

Note that you can display SDC filenames and line numbers by first issuing the “[set_timing_exceptions_handling](#) -line_no” command. To analyze if a pin or a gate is affected by a multicycle path, you can use “[set_gate_report](#) -timing_exceptions on” and [report_gates](#) commands.

If a specified starting point, end point, source node, clock signal name, sink node, or through node does not translate to an internal gate, zero (0) multicycle paths are reported.

Arguments

Tip When using the following arguments, you can include one or more asterisks (*) in pin or instance pathnames. The command treats an asterisk as a wildcard character, enabling you to use it to match many pathnames in the design.

- **-All**
An optional switch that displays all previously-defined multicycle paths. This is the default.
- **-Error**
An optional switch that displays only the multicycle paths that have errors and warnings.
- **-Verbose**
An optional switch that displays all the gate information in the from, to, and through gate lists.

- **-Debug_error**
An optional switch that displays all the previously-defined multicycle paths that have errors and warnings, along with their respective error and warning messages.
- **-From *source_node*...**
An optional switch and repeatable string pair that specifies the starting point of a multicycle path. A valid starting point is a pin pathname, an instance pathname, a clock primary input (PI), or an internal clock pin name. For an instance pathname, all the output pins of the instance are considered to be starting points. For a clock PI, the outputs of all the non-transparent latches, flip-flops, and RAMs associated with the clock PI are considered to be starting points. A pin pathname is considered to be that of an internal clock pin if its fanout reaches only clock ports of sequential elements after traversing through any intervening combinational gates, and the internal clock pin is handled the same as a clock PI.
- **-FROM_Clock *clock_signal_name*...**
An optional switch and repeatable string pair that specifies the starting point of a multicycle path by its associated clock pin pathname. Any pin pathname you specify with this argument is interpreted to be the source of a clock signal, and the outputs of all non-transparent latches, flip-flops, and RAMs associated with this clock signal are considered to be starting points.
- **-TO *sink_node*...**
An optional switch and repeatable string pair that specifies the end point of a multicycle path. A valid end point is a pin pathname, an instance pathname, a clock primary input (PI), or an internal clock pin name. For an instance pathname, all the input pins of the instance are considered to be end points. For a clock PI, the data inputs of all non-transparent latches, flip-flops, and RAMs associated with the clock PI are considered to be end points. A pin pathname is considered to be that of an internal clock pin if its fanout reaches only clock ports of sequential elements after traversing through any intervening combinational gates, and the internal clock pin is handled the same as a clock PI.

Note

 For a 2-port latch with ports: Port1 = (D1, CLK1), Port2 = (D2, CLK2), and primary input clocks CLK1 and CLK2, the command “report_multicycle_paths... -to CLK2” would report multicycle paths with an end point at D2.

- **-TO_Clock *clock_signal_name*...**
An optional switch and repeatable string pair that specifies the end point of a multicycle paths by its associated clock pin pathname. Any pin pathname you specify with this argument is interpreted to be the source of an internal clock signal and the data inputs of all non-transparent latches, flip-flops, and RAMs associated with this clock are considered to be end points.
- **{-THrough *through_node*...}...**
An optional, repeatable switch and repeatable string pair that specifies circuit node(s) through which the multicycle path must pass. A valid through node is a pin or instance

pathname. Clock PIs are not supported as through nodes and no attempt is made to determine if a pin pathname is that of an internal clock pin.

When you use multiple -Through arguments, their order left-to-right in the command string is considered to be the order in which a signal would pass through the nodes on the specified path. For example, the following multicycle path specification:

```
report multicycle paths -from A -through B C -through D  
E -to F
```

specifies all paths that start from A, pass through either B or C, then pass through D or E, and end at F. If you do not use the -Through argument when specifying a path, all paths from the specified starting points to the specified end points are considered to be multicycle paths.

- *>file_pathname*
An optional redirection operator and pathname pair for creating or replacing the contents of *file_pathname*.
- *>>file_pathname*
An optional redirection operator and pathname pair for appending to the contents of *file_pathname*.

Examples

Example 1

The following example displays all previously-defined multicycle paths.

```
report_multicycle_paths -all
```

```
// Multicycle Path -from -from /cpu/d_in[7] -through /cpu/u1 -cycles 2
// Multicycle Path -to /cpu/c -cycles 2
//
// -----
// The multicycle path below has an error.
// -----
// Multicycle Path -from dummy1 -to dummy2 -cycles 2
//
// -----
// The multicycle paths below have warnings.
// -----
// Multicycle Path -from /cpu/d_in[7] -through /cpu/d_in_[6]
//   /cpu/u25 -cycles 2
// Multicycle Path -through I1 I2 I3 I4 I5 SIN CLK1 SEN -cycles 3
// Multicycle Path -from CLK1 -through /cpu/xray[6] CLK1 -cycles 2
//
// Total reported multicycle paths = 6
// Warning: The last 4 paths reported have 1 error and 3 warnings.
//           Use the command "report_multicycle_paths -debug_error" to
//           report the causes of the errors/warnings.
// Warning: Multicycle path defined through all primary inputs, including
//           all clocks, which prohibits at-speed testing. Deleted clocks
//           from this list.
// Warning: There exists a multicycle path that prohibits at-speed testing
//           of clock domain /CLK1.
//           This may result in lower test coverage.
```

Example 2

The following example displays the multicycle paths with error and warning messages.

report_multicycle_paths -error

```
// Error: Multicycle Path -from dummy1 -to dummy2 -cycles 2
// Warning: Multicycle Path -through /cpu/d_in_[6] /cpu/u25 -cycles 2
// Warning: Multicycle Path -through I1 I2 I3 I4 I5 SIN CLK1 SEN -cycles 3
// Warning: Multicycle Path -from CLK1 -through /cpu/xray[6]
//   CLK1 -cycles 2
// Total reported multicycle paths = 4
```

Example 3

The following example displays debug information for the multicycle paths with error and warning messages.

report_multicycle_paths -debug_error

```
// Error: Multicycle Path -from dummy1 -to dummy2 -cycles 2 did not find
//         gates dummy1 dummy2
// Warning: Multicycle Path -from /cpu/d_in[7]-through /cpu/d_in[6]
//           /cpu/u25 -cycles 2 has no combinational path between start and
//           through points.
// Warning: Multicycle Path -through I1 I2 I3 I4 I5 SIN CLK1 SEN -cycles 3
//           defined through all primary inputs, including all clocks,
//           which prohibits at-speed testing.
//           Deleted clocks from this list.
// Warning: Multicycle Path -from CLK1 -through /cpu/xray[6] CLK1
//           -cycles 2 prohibits at-speed testing of clock domain /CLK1.
// Multicycle path debug summary: 1 error, 3 warnings.
```

Example 4

The following example displays a verbose report of multicycle paths that start from /cpu/d_in[7]. Notice the empty “()” for the incorrectly defined path.

```
report_multicycle_paths -verbose -from /cpu/d_in[7]

// Multicycle Path -from /cpu/d_in[7] (/reg_d_1_7_/Q (81)) -through
//   /cpu/u1 (/reg_d_1_6_/Q (73)) -cycles 2
//
// -----
// The multicycle path below has an error.
// -----
// Error: Multicycle Path -from /cpu/d_in[7] ( ) -through /cpu/xray[6] ( )
//   -cycles 2
//
// Total reported false paths = 2
```

For examples of how to use the asterisk (*) character to specify multiple pathnames with one pathname string, see the [add_false_paths](#) command.

Example 5

The following shows multicycle path reporting after turning on reporting of SDC filenames and line numbers:

```
read_sdc sdc2
set_timing_exceptions_handling -line_no on
report_multicycle_paths

// Multicycle Path -from sff108/Q -to sff209/D -cycles 3 -setup
//   (filename = sdc2, line 1)
```

set_timing_exceptions_handling

report_multiprocessing_options

Context: unspecified, dft -edt, patterns -scan

Mode: setup, analysis, insertion

Displays the values of all variables used when executing multiprocessing commands for ATPG or fault simulation.

Usage

`report_multiprocessing_options`

Description

Displays the values of all variables used when executing multiprocessing commands for ATPG or fault simulation. The `report_multiprocessing_options` command displays in human-readable format the values of multiprocessing variables that affect the behavior of the tool's built-in multiprocessing manager. These are values that you can set with the `set_multiprocessing_options` command. To obtain the values of multiprocessing processing variables for Tcl scripting, use the `get_multiprocessing_option` command.

For more information, refer to “[Multiprocessing to Reduce Runtime](#)” in the *Tessent Scan and ATPG User’s Manual* and “[The Tessent Tcl Interface](#)” in the *Tessent Shell User’s Manual*.

Arguments

None

Examples

The following example displays the current settings of the multiprocessing variables:

`report_multiprocessing_options`

// Multiprocessingoptions:// Option	Type	Value	Description
// -----			
// generic_delete	string		generic job scheduler delete
// generic_scheduler	string		generic job scheduler
// license_timeout	number	5	A positive integer to specify in minutes how long to queue for a license, 'unlimited', or 'no-queue'
//			
//			
// lsf_heuristics	on/off	on	true for LSF job scheduler heuristic learning
// lsf_learning	on/off	on	true for LSF job scheduler learning
// lsf_options	string		options for LSF job scheduler
// multithreading	on/off	on	turn on/off multithreading flow
// processors_per_grid_request	number	-1	# processors grouped for one grid request (default: 1 for SGE and GENERIC, 4 for LSF)
//			
// remote_shell	string	rsh	rsh or ssh remote_shell setting
// result_time_limit	float	45	time limit (min) used to detect non-responsive slaves.
//			
// scheduler_timeout	number	10	# mins for job scheduler
// sge_options	string		options for SGE job scheduler

report_nofaults

Context: dft -edt, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Displays the nofault settings for the specified pin pathnames or pin names of instances.

Usage

```
report_nofaults pathname... | -All [-Instance] [-Stuck_at {01 | 0 | 1}] [-Class {Full | User | System}] [{> | >>} file_pathname]
```

Description

Displays the nofault settings for the specified pin pathnames or pin names of instances.

The report_nofaults command displays, for pin pathnames or pin names of instances, the nofault settings that you previously specified with the add_nofaults command.

Arguments

- ***pathname***

A repeatable string that specifies the pin pathnames or the instance pathnames for which you want to display the nofault settings. If you specify an instance pathname, you must also specify the -Instance switch.

- ***-All***

A switch that displays the nofault settings on either all pin pathnames or, if you also specify the -Instance switch, all pin names of instances.

- ***-Instance***

An optional switch that specifies that the *pathname* or -All argument indicates instance pathnames.

- ***-Stuck_at* 01 | 0 | 1**

An optional switch and literal pair that specifies the stuck-at or transition nofault settings you want to display. The choices are as follows:

01 — A literal that specifies to display both the “stuck-at-0” and “stuck-at-1” nofault settings for stuck-at faults; or both the “slow-to-rise” and “slow-to-fall” nofault settings for transition faults. This is the default.

0 — A literal that specifies to display only the “stuck-at-0” nofault settings (“slow-to-rise” nofault settings for transition faults).

1 — A literal that specifies to display only the “stuck-at-1” nofault settings (“slow-to-fall” nofault settings for transition faults).

- -Class Full | User | System

An optional switch and literal pair that specifies the source (or class) of the nofault settings which you want to display. The literal choices are as follows:

Full — A literal that displays all the nofault settings in the user and system class. This is the default.

User — A literal that displays only the user-entered nofault settings.

System — A literal that displays only the netlist-described nofault settings.

- $>file_pathname$

An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file.pathname*.

- $>>file_pathname$

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file.pathname*.

Examples

The following example displays all pin names of the instances that have the nofault settings:

```
add_nofaults i_1006 i_1007 i_1008 -instance  
report_nofaults
```

report_nonscan_cells

Context: dft -edt, patterns -scan

Mode: analysis

Displays the non-scan cells whose model type you specify.

Usage

```
report_nonscan_cells [-All | -TIE0 | -TIE1 | -TIEX | -TLatch | -Clock_sequential |  
-INIT0 | -INIT1] [-VERilog] [{> | >>} file_pathname]
```

Description

The report_nonscan_cells command displays the instance name, gate number, and model type of the non-scan cells that you specify. The tool assigns a model type to the non-scan cells during the Design Rules Check (DRC) in order to model non-scan memory behavior more exactly.

During scan loading, scan clocks can affect non-scan memory elements. The worst case is to assume that all non-scan memory elements will have an unknown state right after scan loading, which makes some faults difficult to test. Therefore, the tool assigns an appropriate model type to the non-scan cells, which sets them to known values. The following argument descriptions describe the conditions that the tool uses to make the various model type assignments.

Arguments

- **-All**
An optional switch that displays all non-scan cells. This is the default.
- **-TIE0**
An optional switch that displays the non-scan cells which are always 0 after each loading and before the next unloading.
Non-scan cells that the tool models as TIE0 indicate that the pin constraints hold the cell's value during non-scan operation.
- **-TIE1**
An optional switch that displays the non-scan cells which are always 1 after each loading and before the next unloading.
Non-scan cells that the tool models as TIE1 indicate that the pin constraints hold the cell's value during non-scan operation.
- **-TIEX**
An optional switch that displays the non-scan cells which are always unknown (X) after each loading and before the next unloading.
- **-TLatch**
An optional switch that displays the non-scan cells which the tool models as transparent latches.

- **-Clock_sequential**
An optional switch that displays all clock_sequential cells that are valid when the sequential depth is set to non-zero.
- **-INIT0**
An optional switch that displays a list of cells which DRC has identified as being initialized to 0 by scan load but has failed to prove that it is tied to 0.
Non-scan cells that the tool models as INIT0 indicate one of the following:
 - The test procedure can set the memory element to 0 after scan loading.
 - The non-off clock is a reset.
- **-INIT1**
An optional switch that displays a list of cells which DRC has identified as being initialized to 1 by scan load, but has failed to prove that it is tied to 1.
Non-scan cells that the tool models as INIT1 indicate one of the following:
 - The test procedure can set the memory element to 1 after scan loading.
 - The non-off clock is a set.
- **-VERilog**
An optional switch that outputs the cell instance and pin pathnames in Verilog syntax, rather than using the default netlist independent format.
- **> *file_pathname***
An optional redirection operator and pathname pair, used at the end of the argument list, for creating *or* replacing the contents of *file_pathname*.
- **>> *file_pathname***
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

The following example reports only the non-scan cells that the tool models as transparent latches.

```
add_scan_groups g1 proc.g1
add_scan_chains c1 g1 scin scout
add_clocks 0 clk
set_system_mode analysis
report_nonscan_cells -tlatch
```

report_nonscan_models

Context: dft -scan, dft -test_points

Mode: setup, analysis

Displays the sequential non-scan model list.

Usage

```
report_nonscan_models [-Class { User | System}]
```

Description

Displays the sequential non-scan model list.

Displays sequential models that you added by using the [add_nonscan_instances](#) command.

Arguments

-Class {User | System}

An optional switch and literal pair that specifies the class code of the non-scan model that you specify. The valid literal names are as follows:

User — A literal that specifies that the list of non-scan models were previously added by using the [add_nonscan_instances](#) command. This is the default class.

System — A literal that specifies that the list of non-scan models were added by the tool.

Examples

The following example displays all sequential non-scan models from the non-scan model list:

```
set_system_mode analysis
add_nonscan_instances -modules d_flip_flop1 d_flip_flop2
report_nonscan_models
```

report_notest_points

Context: dft -scan, dft -test_points

Mode: setup, analysis

Displays all the circuit points for which you do not want the tool to insert controllability and observability.

Usage

```
report_notest_points [-Paths] [-tool_identified]
```

Description

Displays all the circuit points for which you do not want the tool to insert controllability and observability.

The report_notest_points command displays the circuit points added using the [add_output_masks](#) command and which therefore, the tool cannot use for testability insertion.

You can also list the critical path definitions that added notest points by using the -Paths switch.

Arguments

- *>file_pathname*

An optional redirection operator and pathname pair for creating or replacing the contents of file_pathname.

- *>>file_pathname*

An optional redirection operator and pathname pair for appending to the contents of file_pathname.

- **-Paths (dft -test_points context only)**

An optional switch that displays the definitions for all currently loaded critical paths that have marked notest points. If this switch is not specified, the tool reports only the resulting notest points.

- **-tool_identified**

An optional switch that displays only the notest points added by the tool.

Note that if you issue the report_notest_points command without any switch, it will display the notest points added by the user.

Examples

The following example displays the list of all circuit points that the tool cannot use for testability insertion:

```
add_notest_points i_1006/o i_1007/o  
add_notest_points i_1009/o  
report_notest_points
```

Related Topics

[add_output_masks](#)

[delete_nottest_points](#)

report_output_masks

Context: dft, dft -edt, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup, analysis

Displays a list of the currently masked primary output pins.

Usage

```
report_output_masks [[{> | >>} file_pathname] [-Display {FLAt_schematic}]]
```

Description

Displays a list of the currently masked primary output pins.

The report_output_masks command displays the masked primary output pins using the [add_output_masks](#) command. When you mask a primary output pin, the tool marks that pin as an invalid observation point during the fault detection process. The tool uses all unmasked primary output pins as possible observation points to which the effects of all faults propagate for detection.

Arguments

- `>file_pathname`
An optional redirection operator and pathname pair for creating or replacing the contents of *file_pathname*.
- `>>file_pathname`
An optional redirection operator and pathname pair for appending to the contents of *file_pathname*.
- `-Display FLAt_schematic`
An optional switch and literal that specify to display the mask information for the primary output(s) as callouts in the Flat Schematic window.

Examples

The following example masks two primary outputs and then displays the results:

```
add_output_masks qb1 qb2
report_output_masks

TIEX qb1
TIEX qb2
```

Related Topics

- [add_output_masks](#)
- [delete_output_masks](#)
- [set_output_masks](#)

report_pattern_filtering

Context: dft -edt, patterns -scan

Mode: analysis

Displays the current pattern filtering configuration.

Usage

`report_pattern_filtering [<> | >>] file_pathname]`

Description

Displays the current pattern filtering configuration.

The report_pattern_filtering command displays the pattern filtering configuration set previously with the set_pattern_filtering command.

Note

 The report_environment command reports if pattern filtering is on, but shows no status for pattern filtering when it is turned off.

Arguments

- `>file_pathname`

An optional redirection operator and pathname pair for creating *or* replacing the contents of *file_pathname*.

- `>>file_pathname`

An optional redirection operator and pathname pair for appending to the contents of *file_pathname*.

Examples

The following example displays the current pattern filtering configuration:

report_pattern_filtering

```
Current pattern filtering configuration
-----
original_patterns (internal) = 125
current_filtered_pattern(s) = 7
sampled_patterns_per_type = 2
sample_capture_clock = on
sample_pattern_type(s) = all
-----
```

Related Topics

[report_environment](#)

[write_patterns](#)

set_pattern_filtering

report_pattern_sets

Context: patterns ijttag

Mode: analysis

Creates a report of a specified pattern set or of all pattern sets.

Usage

```
report_pattern_sets [-sort_by {declaration_order | name}] [pattern_set_list]
```

Description

Creates a report of a specified pattern set or of all pattern sets.

This command creates a human-readable report of all pattern sets when the pattern_set_list argument is omitted. The report contains the names of the pattern sets, the associated timeplates, the number of vectors, the TAP start and TAP end states, and whether the pattern set has been saved.

Arguments

- `-sort_by {declaration_order | name}`

An optional switch and keyword pair that sorts the patterns in the report by order of declaration or by name. By default, the command sorts the patterns in the order of declaration. If you do not specify this switch, but do specify a pattern_set_list, the command reports pattern sets in the order specified by the list.

- `pattern_set_list`

An optional Tcl list of pattern set names. If this list is present, the report is restricted to the pattern sets in the list. Otherwise, the report contains all pattern sets.

Return Values

None

Examples

Example 1

The following example creates a report of all pattern sets sorted by name:

```
report_pattern_sets -sort_by name
```

Example 2

The following example creates a report of the pattern sets returned by the lsearch command:

```
report_pattern_sets [lsearch -inline -all [get_pattern_set_list] p*]
```

For a detailed example, refer to “[Create Pattern Sets](#)” in the *Tessent IJTAG User’s Manual*.

Related Topics

[close_pattern_set](#)

[get_pattern_set_list](#)
[open_pattern_set](#)
[reset_open_pattern_set](#)

report_patterns

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: analysis

Displays information about patterns.

Usage

```
report_patterns [-EXTernal] [-PATtern_index pattern_index]  
    [-PATH_faults] [-CHain_test]  
    [-UNLoad_x]  
    [-INClude_always_pulsed_clocks]  
    [-X_Cell_report_limit { 20 | d | unlimited }]  
    [{>|>>} file_pathname]
```

Additional switches available only when EDT is on:

```
report_patterns  
    [-EDT [[-COnstant_chains] [-Verbose]]]
```

Description

Displays information about patterns.

You can display information for all patterns, or use the -Pattern_index switch to report on a single pattern. When you use the [set_pattern_filtering](#) command to create a temporary subset of sampled patterns, the report_patterns command reports only on patterns in the filtered subset. By default, information for internal patterns is reported, but you can report on patterns in an external pattern set by first specifying the external pattern file with the [read_patterns](#) command.

Also, by default, the report information will show pulse_always and pulse-in-capture clocks as an *. In that case, a note follows the report to identify the clock information.

The following information is reported for each pattern when the -EDT switch is not used:

- Pattern # — Pattern index
- Pre-filtering pattern # — Pattern index in the original unfiltered pattern set (reported only when filtering by the [set_pattern_filtering](#) command is in effect, causing “Pattern #” to show pattern indexes in the filtered subset).
- Pattern type — Basic, Clock PO, Clock sequential, MacroTest, Multi-load, RAM sequential or Iddq
- Cycles — An integer indicating how many capture cycles there are in the pattern
- Loads — An integer indicating how many scan loads there are in the pattern
- Observe procedure — Name of the observe procedure (Master_Observe or Shadow_Observe), if applied in the pattern

- Capture procedure — Name of the named capture procedure, if applied in the pattern
- Capture clock sequence — Sequence the clocks are pulsed in during capture

When you use the -EDT switch to report a pattern created with Tessent TestKompress (EDT On), the information content of the report changes to display the following EDT-specific information:

- EDT block name if applicable
- EDT channel index number
- EDT channel names
- EDT input channel pin names
- EDT output channel pin names
- Observed core scan chain name(s)

If a channel is masked in the reported pattern, the name of the single scan chain observed for that channel is listed. If the channel is not masked in the pattern, this means that all connected chains are observed and the “<all connected chains>” string displays.

Arguments

- **-EXTernal**
An optional switch that displays pattern information for external patterns instead of internal patterns. Before using this switch, you must specify the name of the external pattern file with the [read_patterns](#) command.
- **-PATtern_index *pattern_index***
An optional switch and integer pair that displays information only for the pattern with the specified index, not all patterns.
- **-PATH_faLts**
An optional switch that displays the path faults detected by the internal patterns. This switch cannot be used with the -external switch and is only valid when the current fault type is set to path_delay.
- **-CHain_test**
An optional switch that, together with -pattern_index switch, reports a particular chain test pattern in the pattern set. Without this switch, the tool reports scan test pattern information. Note that you can use this switch only when chain test patterns exist. Chain test patterns are created by the [write_patterns](#) command or if loaded as part of external patterns. If no chain test patterns exist, the tool issues an error message.
- **-EDT (Available only when EDT is on)**
An optional switch that (1) reports which of the internal scan chains connected to each scan channel are observed by the specified EDT pattern when used in conjunction with the

-Pattern_index switch, or (2) reports one line per pattern when used without the -Pattern_index switch. On each line, the pattern ID is followed by the pattern masking status for this pattern. This switch is valid only for Tesson TestKompress patterns created with Tesson TestKompress (EDT On).

- **-Constant_chains (Available only when EDT is on)**

An optional switch that together with the -EDT and -Pattern_index switches lists the actual data source (decompressor or constant 0) for the specified internal pattern. Use this switch to display test pattern information for the low-power decompressor.

- **-Verbose (Available only when EDT is on)**

An optional switch that together with the -EDT and -Pattern_index switches lists the actual names of all the connected chains in the observed_chains column. Without this switch, the summary message “<all connected chains>” is displayed rather than the names of all the connected chains.

- **-UNLoad_x**

An optional switch that reports patterns that contain some scan cells with X unload values. For EDT patterns, X values due to EDT masking are not considered as unload X. When you specify this switch with the -pattern_index switch, the command also reports the scan cells that capture X values (see “[Example 8](#)” on page 1706).

You can use the -unload_x switch for debugging purposes if you issue a “set_simulation_option -report_x_capturing_cells on” command and notice some patterns that capture X on scan cells. You should first use the -unload_x switch to see patterns that unload X, and then add the -pattern_index switch to further see which scan cells capture X of the specified pattern.

Use the -x_cell_report_limit switch to control the number of cells that get reported.

- **-INClude_always_pulsed_clock**

An optional switch that will enable the report to include the full names of the pulse-always and pulse-in-capture clocks. This changes the behavior from the default which is to represent these clocks as “*” in the report and follow the report with a note to identify the clocks.

- **-X_Cell_report_limit { 20 | d | unlimited }**

An optional switch that limits the number of capture X cells included in the report. You can limit the number of cells reported to a nonnegative integer (by default, 20), or you can specify no limit to the number of cells reported. If the report is truncated, a message indicates that the limit was reached and provides the total number of X captured cells from the report.

- **> file_pathname**

An optional redirection operator and pathname pair for creating or replacing the contents of *file_pathname*.

- `>>file.pathname`

An optional redirection operator and pathname pair for appending to the contents of `file.pathname`.

Examples

Example 1a

The following example of scan pattern reporting displays all patterns in the current internal pattern set. [Table 5-14](#) summarizes the display notation.

Table 5-14. Notation Used in report_patterns Display

Notation	Column	Meaning
master_obs	observe_proc	Pattern applies a master_observe procedure.
shadow_obs	observe_proc	Pattern applies a shadow_observe procedure.
-	observe_proc	No master_observe or shadow_observe procedure is applied.
-	capture_proc	No named capture procedure is applied.
-	capture_clock_sequence	No clock is pulsed in the capture window.
[-]	capture_clock_sequence	No clock is pulsed in the capture window, but primary inputs are being forced.
[clock1][clock2] ...	capture_clock_sequence	Sequence (left to right) in which <i>clock1</i> and <i>clock2</i> , etc. are pulsed.
[clock1, *]	capture_clock_sequence	By default, pulse-always and pulse-in-capture clocks are shown as *. A note is added at the end of the report to identify these clocks.
[clock1, clock2, ...]	capture_clock_sequence	Shows <i>clock1</i> and <i>clock2</i> , etc. are pulsed at the same time.
S	capture_clock_sequence	A scan load occurs in the corresponding cycle. ¹

1. The first cycle always has a scan load, so no S is displayed for the first cycle.

[report_patterns](#)

patt #	type	cycles	loads	observe_proc	cap_proc	cap_clk_seq
0	basic	1	1	master_obs	-	[clk1]
1	basic	1	1	-	-	[clk1]
2	clock_po	1	1	-	-	-
3	clock_seq	2	1	shadow_obs	named_cap1	[clk1] [clk1]
4	multi_load	3	3	-	-	[ramclk] S[clk1] S[clk2]
5	clock_seq	2	1	-	-	[clk1,clk2] [-]
6	clock_seq	2	1	-	-	[clk1] [-]
7	multi_load	3	2	-	-	[clk1] S[clk1] [clk1]
8	basic	1	1	-	-	[clk1]
9	basic	1	1	-	-	[-]
10	basic	1	1	-	-	[scn_rst]

Pattern 0 is a basic pattern that applies a master_observe procedure. Pattern 2 is a clock PO pattern; therefore, no clock is pulsed in the capture window. Pattern 3 is a clock sequential pattern that uses the named capture procedure “nmd_cap1” in which the clock sequence is [clk1] [clk1]. Pattern 4 is a multiple-load pattern. The S in the capture clock sequence indicates there is a scan load in the corresponding cycle (the first cycle always has a scan load, so no S is displayed there). Pattern 5 is a clock sequential pattern that pulses two clocks simultaneously in the first capture cycle, then in the cycle that follows, forces primary inputs without pulsing any clocks. Pattern 6 differs from pattern 5 in that it pulses just one clock in the first capture cycle.

Example 1b

Another example of report_patterns showing the case with pulse-always and pulse-in-capture clocks.

```
report_patterns

// pattern # type      cycles  loads   observe_proc  cap_proc  cap_clock_sequence
// -----
// 0    clock_sequential 2       1       -           -         [core_clk200,*] [core_clk200,*]
// 1    clock_sequential 2       1       -           -         [core_clk200,*] [core_clk200,*]
//
//Note: [*] = "int_shift_reg_clk1,int_shift_reg_clk2,int_shift_reg_clk3", which are pulse-
always clocks.
```

The “Note” line only appears if there are pulse-in-capture or pulse-always clocks in the design.

Example 2

The following example shows how you can use the [set_pattern_filtering](#) command to display a subset of patterns. The example first displays just the non-basic patterns of the preceding example, then displays just the patterns that use ramclk as a capture clock:

set_pattern_filtering -range 2 7

```
// Internal pattern filtering is on: 6 selected pattern(s), 11 original
// pattern(s).
```

report_patterns

		pre-filter		patt #	patt #	type	cycles	loads	observe_proc	cap_proc	cap_clk_s
0	2	clock_po	1	1	-	-	-	-	-	-	-
1	3	clock_seq	2	1	shadow_obs	named_cap1	[clk1]	[clk1]	[clk1]	S[clk1]	S[clk2]
2	4	multi_load	3	3	-	-	-	-	-	S[clk1]	S[clk2]
3	5	clock_seq	2	1	-	-	-	-	-	[clk1,clk2]	[-]
4	6	clock_seq	2	1	-	-	-	-	-	[clk1] [-]	[clk1]
5	7	multi_load	3	2	-	-	-	-	-	S[clk1]	[clk1]

set_pattern_filtering -clocks ramclk

```
// Warning: The previous filter options have been reset.
// Internal pattern filtering is on: 1 selected pattern(s), 11 original
// pattern(s).
```

report_patterns

		pre-filter		patt #	patt #	type	cycles	loads	observe_proc	cap_proc	cap_clk_s	
0	4	multi_load	3	3	-	-	-	-	-	[ramclk]	S[clk1]	S[clk2]

Example 3

The following EDT pattern reporting example reports EDT chain test pattern 9. The design is a **Modular Compressed ATPG** design with two EDT blocks, p1 and p2. Block p1 has one channel and all chains connected to this channel are observed with this pattern. Block p2 has three channels. For each of them, only one chain is observed with this pattern.

report_patterns -pattern_index 9 -edt -chain_test

```
// block ch# channel_name channel_input_pin channel_output_pin obs_chains
// -----
// p1      1  p1_channel1  core1_edt_ch_in1  core1_edt_ch_out1  <all conn.
//                                         chains>
// -----
// p2      1  p2_channel1  core2_edt_ch_in1  core2_edt_ch_out1  core2_chain1
// "      2  p2_channel2  core2_edt_ch_in2  core2_edt_ch_out2  core2_chain4
// "      3  p2_channel3  core2_edt_ch_in3  core2_edt_ch_out3  core2_chain7
```

Example 4

The following example is the same as the preceding example except that the -Verbose switch is included in the command. This expands the “<all connected chains>” summary information to the names of all chains connected to p1_channel1.

```
report_patterns -pattern_index 9 -edt -chain_test -verbose
// block ch# channel_name channel_input_pin channel_output_pin obs_chains
// -----
// p1      1 p1_channel1  core1_edt_ch_in1  core1_edt_ch_out1 core1_chain1
//                                core1_chain2
//                                core1_chain3
//                                core1_chain4
//                                core1_chain5
// -----
// p2      1 p2_channel1  core2_edt_ch_in1  core2_edt_ch_out1 core2_chain1
// "      2 p2_channel2  core2_edt_ch_in2  core2_edt_ch_out2 core2_chain4
// "      3 p2_channel3  core2_edt_ch_in3  core2_edt_ch_out3 core2_chain7
```

Example 5

The following example reports on a particular pattern in an external pattern set for a design that has both **uncompressed scan chains** (direct access chains) and compressed scan chains. The direct access chains are reported in lines that begin “<uncompressed chain>”. As the design consists of just one block, the “block” column is unnecessary and it is not displayed.

```
read_patterns my_edt_patts
report_patterns -external -pattern_index 199 -edt -chain_test
// ch# channel_name channel_input_pin channel_output_pin obs_chains
// -----
// 1 pic_channel1 core1_edt_ch_in1  core1_edt_ch_out1  core1_chain1
// 2 pic_channel2 core1_edt_ch_in2  core1_edt_ch_out2  core1_chain4
// 3 pic_channel3 core1_edt_ch_in3  core1_edt_ch_out3  core1_chain7
// -----
// <uncompressed chain> core2_edt_ch_in1  core2_edt_ch_out1  core2_chain1
// <uncompressed chain> core2_edt_ch_in2  core2_edt_ch_out2  core2_chain2
```

Example 6

The following example sets the fault type to path_delay, loads path data into the system, and creates patterns to test the path delay faults. It uses the report_patterns command to check which path faults are detected by the internal patterns.

```
set_fault_type path_delay
read_fault_sites paths.txt
set_pattern_type -sequential 2
create_patterns
report_patterns -path_faults
```

```
// Pattern 0 detects following path fault(s):
//   Detected path = path1, edge = rise, detection = robust
//   Detected path = path44, edge = fall, detection = robust
// Pattern 1 detects following path fault(s):
//   Detected path = path3, edge = rise, detection = robust
//   Detected path = path12, edge = fall, detection = robust
//   Detected path = path16, edge = fall, detection = robust
//   Detected path = path21, edge = fall, detection = robust
//   Detected path = path33, edge = fall, detection = robust
//   Detected path = path34, edge = fall, detection = robust
//   Detected path = path45, edge = fall, detection = robust
//   Detected path = path52, edge = fall, detection = robust
// Pattern 2 detects following path fault(s):
//   Detected path = path5, edge = fall, detection = robust
//   Detected path = path44, edge = rise, detection = robust
...
...
```

Example 7

The following example shows the data source for scan chains associated with the 101 test pattern index.

```
report_patterns -edt -constant_chains -pattern_index 101
```

```

//          block           data source statistics
//  -----  -----
// piccpu1  8 of 8 scan chains are driven by constant value
//  -----
// piccpu2  3 of 8 scan chains are driven by constant value
//  -----
// piccpu3  8 of 8 scan chains are driven by constant value
//
// command: rep patterns -edt -constant_chains -patt 101 -verbose
//
//          block      chain      data source
//  -----  -----
// piccpu1 core1_chain1 constant 0
//          "       core1_chain2 constant 0
//          "       core1_chain3 constant 0
//          "       core1_chain4 constant 0
//          "       core1_chain5 constant 0
//          "       core1_chain6 constant 0
//          "       core1_chain7 constant 0
//          "       core1_chain8 constant 0
//  -----
// piccpu2 core2_chain1 decompressor
//          "       core2_chain2 decompressor
//          "       core2_chain3 constant 0
//          "       core2_chain4 constant 0
//          "       core2_chain5 decompressor
//          "       core2_chain6 constant 0
//          "       core2_chain7 decompressor
//          "       core2_chain8 decompressor
//  -----
// piccpu3 core3_chain1 constant 0
//          "       core3_chain2 constant 0
//          "       core3_chain3 constant 0
//          "       core3_chain4 constant 0
//          "       core3_chain5 constant 0
//          "       core3_chain6 constant 0
//          "       core3_chain7 constant 0
//          "       core3_chain8 constant 0
//

```

Example 8

The following example shows how to report patterns that contain some scan cells with X unload values:

report_patterns -unload_X

pattern #	type	cycles	loads	unload_X	observe_proc	capture_proc	capture_clock_seq
0	basic	1	1	yes	-	-	[clock]
1	basic	1	1	yes	-	-	[clock]
4	basic	1	1	yes	-	-	[clock]
5	basic	1	1	yes	-	-	[clock]
7	basic	1	1	yes	-	-	[clock]

You can then further investigate one of these patterns and report the scan cells that capture X values:

```
report_patterns -pattern_index 1 -unload_x
```

```
// pattern # type  cycles loads unload_X observe_proc capture_proc capture_clock_seq
// -----
//      0  basic    1      1     yes      -          -           [clock]
// Scan cell dff1 (233) captures X
// Scan cell dff3 (235) captures X
```

Example 9

The following example shows the default limit of 20 X captured cells reported:

```
report_patterns -unload_x -pattern_index 0
```

```
// pattern # type  cycles loads unload_x observe_proc capture_proc capture_clock_sequence
// -----
//      0  basic    1      1     Yes      -          cap1        [clk1,clk4]
//
// Scan cell '/reg_result_add_clk4_29/Q' (1274) captures X
// Scan cell '/reg_result_add_clk4_18/Q' (1262) captures X
...
// Scan cell '/reg_result_add_clk4_7/Q' (1170) captures X
// Only the first 20 out of 98 X captured cells are reported. Add "-X_cell_report_limit
// unlimited" to show all cells capturing X.
```

report_power_data

Context: all contexts

Mode: all modes

Reports the power data currently loaded in the system from either a [read_cpf](#) or [read_upf](#) command.

Usage

```
report_power_data {[ -Summary | -All | -DOmains [domain_name ...] |  
    -SStates [state_name ...] } [-ISolation_cells] [-LLevel_shifters] [-Always_on_cells]  
    [-REtention_cells]
```

Description

Reports the power data currently loaded in the system from either a [read_cpf](#) or [read_upf](#) command.

Arguments

- **-Summary**

An optional switch that specifies the content of power data to be reported. By default, the command reports the summary of loaded power data.

- **-All**

An optional switch that reports the details of the loaded power data, including all power domains and all power modes. When executing the command in non-setup mode, the tool reports the count of low power cells associated with each power domain and the gate count of every power domains.

- **-DOmains [domain_name ...]**

An optional switch and optional repeatable string that reports only the specified power domains (*domain_name*) and the data associated with the specified power domains. If no power domain is specified, all power domains are reported.

- **-SStates [state_name ...]**

An optional switch and optional repeatable string that reports only the specified power mode and power data related to the specified power modes. If no power mode is specified, all power modes will be reported.

- **-ISolation_cells**

An optional switch that reports the detailed information of the isolation cells.

- **-LLevel_shifters**

An optional switch that reports the detailed information of the level shifters.

- **-Always_on_cells**

An optional switch that reports the detailed information of the always-on cells.

- **-REtention_cells**

An optional switch that reports the detailed information of the retention cells.

Examples

The following example displays detailed power data for isolation cells:

`report_power_data -isolation_cells`

report_power_metrics

Context: dft -edt, patterns -scan

Mode: analysis

Displays shift and capture power metrics for specified test patterns.

Usage

```
report_power_metrics [-PATterns {ALL | pattern_index... | PAD
| RANGE first_pattern_index last_pattern_index}
[{-SORT_Capture [ST_Peak | ST_Average | WSA_Peak | WSA_Average]
|-SORT_Shift [LOAD | RESPonse]} [-ASCending | -DESCending]]
[-INTERNAL | -EXTernal] [-EVERY_CAPTURE_cycle]
[-INSTance instance_pathname...] [-MODULE module_name...]
[-SHIFT [-SCan_test | -CHain_test | -ALl_test]
-CYCLE {ALL | PEAK | cycle_index... | RANGE first_cycle_index last_cycle_index}]]]
[{> | >>} file_pathname]
```

Description

Displays shift and capture power metrics for specified test patterns.

Use this information to identify the test patterns that may cause chip failure due to power issues. Enter this command without any arguments to display a summary of shift and capture power metrics for all test patterns.

Note

 You can use this command when the [set_power_metrics](#) command is set to
-Shift off -Capture off and the test patterns are automatically resimulated to calculate shift and capture power if necessary.

Arguments

- **-PATterns {ALL | pattern_index... | PAD | RANGE *first_pattern_index* *last_pattern_index*...}**

An optional switch and literal, list of positive integers, or literal and list of positive integers that display the shift power and capture power for specified test patterns. Options include:

ALL — Displays the shift power and capture power for all patterns.

pattern_index — Displays the shift power and capture power for the specified patterns.
Pattern index starts from 0.

PAD — Displays the shift power consumed by the unloading of the last test pattern in the specified test patterns. This value is only available when [set_power_metrics -composite_shift_power](#) is enabled.

RANGE *first_pattern_index* *last_pattern_index* — Displays the shift power and capture power for all patterns from *first_pattern_index* to *last_pattern_index*.

- **-SORT_Capture [ST_Peak | ST_Average | WSA_Peak | WSA_Average]**

An optional switch and literal pair that sorts specified test patterns based on their switching activity during capture. Literal options include:

ST_Peak — Peak of state transitions. Default.

ST_Average — Average of state transitions.

WSA_Peak — Peak of weighted switching activity.

WSA_Average — Average of weighted switching activity.

For more information, on WSA and ST values, see Example 1 below and the [set_power_metrics](#) command.

- **-SORT_Shift [LOAD | RESPonse]**

An optional switch and literal pair that sorts the specified test patterns based on their function during test pattern application. This option is only valid when the -SHIFT option is specified. Literal options include:

LOAD — Switching activity during the loading of test pattern stimuli.

RESPonse — Switching activity during the unloading of test responses.

- **-ASCending | -DESCending**

An optional switch that sorts the specified test patterns in an ascending or descending order based on switching activity. By default, test patterns with the lowest switching activity are listed first (ascending order).

- **-INTernal | -EXTernal**

An optional switch that specifies whether power metrics are reported for the internal or external test pattern set. By default, the internal test pattern set is used.

- **-EVERY_CApture_cycle**

An optional switch that reports the weighted switching activity and the “state element transition” for every capture cycle on a per pattern basis. By default, the tool reports only the average and peak capture activity for the test pattern.

- **-INSTance *instance.pathname*...**

An optional switch and repeatable string that reports the shift and capture power usage for one or more specified design instances. The instance_pathname may include any number of asterisk (*) and/or question mark (?) wildcard characters in a name.

- **-MODULE *module.name*...**

An optional switch and repeatable string that reports the shift and capture power usage for all instances of a specified design module(s).

- [-SHIFT {-SCan_test | -CHain_test | -ALL_test}]

An optional pair of switches that reports shift and capture power metrics for a specific pattern type. By default, the power metrics for scan test patterns are reported. Options include:

-SCan_test— Scan test patterns. Default.

-CHain_test — Chain test patterns.

-ALL_test — Scan and chain test patterns.

- [-CYCLE {ALL | PEAK | *cycle_index* ... | RANGE *first_cycle_index* *last_cycle_index*}]

An optional switch and literal, list of integers, or a literal and a pair of integers that reports shift power for the specified test pattern cycles. You must enable the composite shift power calculation with [set_power_metrics](#) to calculate these values. Options include:

ALL — Shift transitions for all cycles.

PEAK — Shift transitions for the cycle with the peak shift power.

cycle_index — Shift transitions for the specified cycles.

RANGE *first_cycle_index* *last_cycle_index* — Shift transitions for a specified range of cycles.

- >*file_pathname*

An optional redirection operator and pathname pair for creating or replacing the contents of *file_pathname*.

- >>*file_pathname*

An optional redirection operator and pathname pair for appending the contents of *file_pathname*.

Examples

Example 1

The following example displays the shift power and capture power for pattern 15.

```
report_power_metrics -patterns 15
```

Pattern	Shift			Capture		
	Load	Response	WSA	State	Element	Tran.
15	45.29%	40.56%	13.89% (15.49%)	14.32%	(18.13%)	

- The Shift Load number (45.29%) is the percentage of the number of scan cell transitions during the loading of the test stimuli over the worst case. The worst case is calculated by assuming that every scan cell is toggled in every shift cycle.
- The Shift Response number (40.59%) is the percentage of the number of scan cell transitions during the unloading of the test response over the worst case. The worst case is calculated by assuming that every scan cell is toggled in every shift cycle.

- The first Capture WSA (Weighted Switching Activity) number (13.89%) is the average of the weighted switching activity per capture cycle. The second number (15.49%) is the weighted switching activity for the peak capture cycle. The peak capture cycle is the cycle with the highest weighted switching activity among all capture cycles in a test pattern.

The WSA calculation includes the switching activity of the combinational logic, state elements, as well as factoring in gate output fanout for capture cycles.

- The first Capture State Element Tran. number (14.32%) is the average number of state element transitions per capture cycle. The second number (18.13%) is the number of state element transitions in the peak capture cycle. The peak capture cycle is the cycle with the highest number of state element transitions among all capture cycles in a test pattern.

Example 2

The following example displays a summary of capture power and shift power for all patterns:

report_power_metrics

Power Metrics	Min.	Average	Max.
WSA	9.03%	18.74%	36.82%
State Element Transitions	8.99%	25.44%	47.33%
Load Shift Transitions	39.06%	44.62%	51.66%
Response Shift Transitions	6.45%	39.38%	50.54%

Example 3

The following example calculates and reports the power metrics for external test patterns, *mypat.ascii*:

read_patterns mypat.ascii report_power_metrics -external

Power Metrics	Min.	Average	Max.
WSA	10.62%	12.54%	13.65%
State Element Transitions	13.59%	18.71%	20.94%
Peak Cycle			
WSA	10.62%	12.54%	13.65%
State Element Transitions	13.59%	18.71%	20.94%
Load Shift Transitions	15.38%	25.00%	30.77%
Response Shift Transitions	17.95%	21.15%	25.64%

Example 4

The following example reports the power metrics with composite shift for both scan tests and chain tests for all test patterns in the internal test pattern set:

```
set_power_metrics -composite_shift on
report_power_metrics -shift -all_test -patterns all

// Chain test :
//
//      Pattern      Shift
// Pat. loaded Pat. unloadedAverage
// -----
// 0      -          32.89%
// 1      0          48.60%
// 2      1          54.20%
// pad   2          49.56%
//
// Scan test :
//
//      Pattern      Shift
// Pat. loaded Pat. unloadedAverage
// -----
// 0      -          10.60%
// 1      0          8.60%
// 2      1          14.20%
// 3      2          8.20%
// pad   3          9.56%
```

Example 5

The following example shows the composite shift power for a specified range of cycles in the second and third test pattern in the internal test pattern set. In this example, the peak shift power for test pattern 1 occurs in cycle 6 as indicated by the asterisk cycle index:

```
set_power_metrics -composite_shift on
report_power_metrics -pattern 1 2 -shift -cycle range 4 6

//      Pattern      Cycle | Shift Transitions
// Pat. loaded Pat. unloaded
// -----
// 1      0          4      | 43.82%
//                   5      | 40.76%
//                   6      (*) | 47.64%
// 2      1          4      | 38.82%
//                   5      | 39.54%
//                   6      | 37.56%
//
// (*) indicates the cycle with the peak shift power.
```

Example 6

The following example reports the peak shift power for test pattern 1 and 2:

```
set power metric -composite_shift on
report_power_metrics -pattern 1 2 -shift -cycle peak
```

Pattern	Peak Cycle	Shift Transitions
// Pat. loaded Pat. unloaded		
// -----	-----	-----
// 1	0	5
// 2	1	114

Example 7

The following example shows the switching activity for capture when the -every_capture_cycle argument is specified. In this example, there are three capture cycles in pattern 10.

report power metrics -pattern 10 -every_capture_cycle

Pattern	Capture
//	WSA State Element Tran.
// -----	-----
// 10	8.23%, 25.21%, 24.68% 1.69%, 22.16%, 19.53%

The following example has patterns with different numbers of capture cycles. This occurs when NCPs or clock control definitions are used. This example shows patterns with 1, 2, and 3 capture cycles.

report power metrics -pattern range 12 15 -every_capture_cycle

Pattern	Capture
//	WSA State Element Tran.
// -----	-----
// 12	8.16%, 21.91%, 23.22% 1.54%, 16.64%, 19.08%
// 13	8.22%, 25.06%, 1.74%, 21.28%
// 14	8.17%, 21.47%, 23.40% 1.52%, 15.78%, 14.42%
// 15	8.21%, 1.61%,

[set_power_metrics](#)

report_primary_inputs

Context: all contexts

Mode: analysis, setup

Displays a list of the primary inputs of a circuit.

Usage

```
report_primary_inputs [-All | net.pathname... | primary_input_pin...]  
[-Class {Full | User | System}] [-Verbose] [{> | >>} file.pathname]
```

Description

Displays a list of the primary inputs of a circuit.

You can choose to display either the user class, system class, or full classes of primary inputs. Additionally, you can display all of the primary inputs or a specific list of primary inputs. If you issue the command without specifying any arguments, then the tool displays all the primary inputs.

Arguments

- **-All**
An optional switch that displays all the primary inputs. This is the default.
- **net.pathname**
An optional repeatable string that specifies the circuit connections whose user-class primary inputs to display.
- **primary_input_pin**
An optional repeatable string that specifies a list of system-class primary input pins to display.
- **-Class Full | User | System**
An optional switch and literal pair that specifies the source (or class) of the primary input pins to display. The literal choices are as follows:
 - Full** — Displays all the primary input pins in the user and system class. This is the default.
 - User** — Displays only the user-entered primary input pins.
 - System** — Displays only the netlist-described primary input pins.
- **-Verbose**
An optional switch that displays all the nets grouped under a primary input.
- **> file.pathname**
An optional redirection operator and pathname pair used at the end of the argument list for creating or replacing the contents of *file.pathname*.

- *>> file_pathname*

An optional redirection operator and pathname pair used at the end of the argument list for appending to the contents of *file_pathname*.

Examples

Example 1

The following example displays the full classes of primary inputs:

```
add_primary_inputs indata2 indata4
report_primary_inputs -class full
```

Example 2

The following example displays the user classes of primary inputs:

```
add_primary_inputs /dut/*/CLK_X-pseudo_port_name MYCLKX
//Note: Adding primary input MYCLKX merging 224 nets.

report_primary_inputs -class user

USER: '/MYCLKX' (merged internal pin)
Merges 224 nets
```

Example 3

The following dft -scan example displays all of the primary inputs:

```
report_primary_inputs -all

SYSTEM:      '/clk'
SYSTEM:      '/datain'
```

The label “system” means that these are primary inputs that the tool automatically recognizes because they were in the netlist.

Related Topics

report_primary_outputs

Context: all contexts

Mode: analysis, setup

Displays the specified primary outputs.

Usage

```
report_primary_outputs [-All | net.pathname... | primary_output_pin...]  
[-Class {Full | User | System}] [{> | >>} file.pathname]
```

Description

Displays the specified primary outputs.

The report_primary_outputs command displays a list of primary outputs of a circuit. You can choose to display either the user class, system class, or full classes of primary outputs.

Additionally, you can display all of the primary outputs or a specific list of primary outputs. If you issue the command without specifying any arguments, then the tool displays all the primary outputs.

Arguments

- **-All**
An optional switch that displays all primary outputs. This is the default.
- **net.pathname**
An optional, repeatable string that specifies the circuit connections whose user-class primary outputs you want to display.
- **primary_output_pin**
An optional, repeatable string that specifies a list of system-class primary output pins that you want to display.
- **-Class Full | User | System**
An optional switch and literal pair that specifies the source (or class) of the primary output pins that you want to display. The literal choices are as follows:
 - Full** — A literal that displays all of the primary output pins in the user and system class. This is the default.
 - User** — A literal that displays only the user-entered primary output pins.
 - System** — A literal that displays only the netlist-described primary output pins.
- **> file.pathname**
An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file.pathname*.

- *>> file.pathname*

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file.pathname*.

Examples

Example 1

The following example displays all primary outputs in the user class:

```
add_primary_outputs outdata1 outdata3 outdata5
report_primary_outputs -class user
```

Example 2

The following dft -scan example displays all of the primary outputs:

```
report_primary_outputs -all
SYSTEM:      '/dataout'
SYSTEM:      '/dataout1'
```

The label “system” means that these are primary outputs that the tool automatically recognizes because they were in the netlist.

report_procedures

Context: dft -edt, dft -scan, patterns -scan, patterns -ijtag,
patterns -scan _retargeting, patterns -failure _mapping

Mode: setup, analysis

Displays the specified procedure.

Usage

```
report_procedures {procedure_name [group_name] [-Display Wave] | -All} [-COre  
    core_name [-MOde mode_name]]  
    [{>} | >>} file.pathname] [-EXpand_iprocs]
```

Description

Displays the specified procedure.

The report_procedures command displays all procedures or the specified procedure.

Arguments

- ***procedure_name***
A string that specifies which procedure to display.
- ***group_name***
An optional string that specifies a particular scan group from which to display the specified procedure.
- **-Display Wave**
An optional switch that displays the specified procedure in the Wave window of DFTVisualizer. This is for unoptimized NCPs. Use the [report_capture_procedures](#) command to display optimized NCPs.
- **-All**
A switch that specifies for the tool to display all procedures. This is the default.
- **-COre *core_name***
An optional switch and string pair that specifies that the tool reports the procedures for a given core. The core must exist, or an error will be issued.
- **-MOde *mode_name***
An optional switch and string pair that specifies that the tool reports the procedures for the given mode of a core defined by the -core *core_name* switch. The tool reports an error if this switch is specified without the -core switch. This switch is not necessary when there is only one mode for a core. If a core has more than one mode, an error will be issued if the mode is not specified.

- **>file.pathname**
An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of file.pathname.
- **>>file.pathname**
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of file.pathname.
- **-EXPAND_iprocs**
An optional switch that reports the final solution that is used in the test_setup or test_end procedures for any embedded iCalls and iMerge in those procedures. If an iCall is used within an iMerge, then that entire iMerge is expanded. The start and end of the expanded cycles is marked by comments in the reported procedure or procedure file. Use this switch to when debugging E14 DRC violations.

Examples

Example 1

The following example displays all procedures:

report_procedures -all

Example 2

The following example shows using the -EXPAND_iprocs switch to work with the set of used ports and vector callbacks in:

ANALYSIS> report_procedure test_setup -expand_iprocs

```
procedure test_setup =
    timeplate tp1 ;
    iReset;
    // Begin expanded iCall m8051_B1_edt_i.setup edt_low_power_shift_en on ;
    // cycle 1 start at time 40
    cycle =
        annotate "+ Targets: ..."
        ...
        end;
    // End expanded iCall
    // cycle 5 starts at time 200
    cycle =
        ...
        end;
    end;
```

Example 2

This is an example of using -core and -mode.

report_procedures -core piccpu maxlen16_1 -mode

```
procedure capture my_cap =
    timeplate gen_tp1 ;
    // cycle 0 starts at time 0
    cycle =
        force_pi ;
        force core_1_edt_clock 0 ;
        force core_1_ramclk 0 ;
        pulse core_1_clk ;
    end;
end;
procedure capture =
    timeplate gen_tp1 ;
    // cycle 0 starts at time 0
    cycle =
        force_pi ;
        measure_po ;
        pulse_capture_clock ;
    end;
end;
procedure ram_sequential =
    timeplate gen_tp1 ;
    // cycle 0 starts at time 0
    cycle =
        force_pi ;
        pulse_read_clock ;
        pulse_write_clock ;
    end;
end;
procedure clock_sequential =
    timeplate gen_tp1 ;
    // cycle 0 starts at time 0
    cycle =
        force_pi ;
        pulse_capture_clock ;
        pulse_read_clock ;
        pulse_write_clock ;
    end;
end;
procedure shift =
    timeplate gen_tp1 ;
    // cycle 0 starts at time 0
    cycle =
        force_sci ;
        force core_1_edt_update 0 ;
        measure_sco ;
        pulse core_1_clk ;
        pulse core_1_edt_clock ;
    end;
end;
procedure load_unload =
    timeplate gen_tp1 ;
    // cycle 0 starts at time 0
    cycle =
        force core_1_clk 0 ;
        force core_1_edt_clock 0 ;
        force core_1_edt_update 1 ;
        force core_1_ramclk 0 ;
        force core_1_reset 0 ;
```

```
        force core_1_scan_enable 1 ;
        pulse core_1_edt_clock ;
    end ;
    apply shift 16;
end;
procedure test_setup =
    timeplate gen_tp1 ;
// cycle 0 starts at time 0
cycle =
    force core_1_edt_clock 0 ;
    force core_1_reset 0 ;
    force core_1_scan_enable 0 ;
end;

end;
```

Example 3

This is an example of using -code with a specific procedure.

```
report_procedures load_unload -core piccpu maxlen16_1
```

```
procedure load_unload =
    timeplate gen_tp1 ;
// cycle 0 starts at time 0
cycle =
    force core_1_clk 0 ;
    force core_1_edt_clock 0 ;
    force core_1_edt_update 1 ;
    force core_1_ramclk 0 ;
    force core_1_reset 0 ;
    force core_1_scan_enable 1 ;
    pulse core_1_edt_clock ;
end ;
apply shift 16;

end;
```

report_processors

Context: unspecified, all contexts

Mode: setup, analysis, insertion (dft -edt context only)

Displays information about the processors used for the current multiprocessing environment.

Usage

```
report_processors [-Verbose]
```

Description

Displays information about the processors used for the current multiprocessing environment.

For more information, refer to “[Multiprocessing to Reduce Runtime](#)” in the *Tessent Scan and ATPG User’s Manual*.

The report_processors command displays the information listed in [Table 5-15](#) for the current multiprocessing environment:

Table 5-15. Default report_processors Information Display

Column Name	Description
hosts	Network names of host machines
threads	The number of threads launched on that host
arch	Architecture of host machines (similar to entering “uname -m” on each host)
CPU(s)	Number of hardware processors and their speed for each host machine
%idle	Current CPU idle percentage (a small interval of time is sampled)
free RAM	A machine’s total free memory
process size	Size of the master or slave process

This information enables you to determine whether to use the current set of host machines for slave processes or whether to use different machines. For example, a host machine with a low %idle is not as likely to provide as much CPU time to slave processes as one that is 100% idle. The free RAM may also help you decide which machines to avoid at the present time.

Note

 Be sure to consider the number of processors on the host machine when evaluating the idle percentage (%idle), as a partially idle machine may have one or more completely idle processors available to run slave processes.

Arguments

- **-Verbose**

An optional switch that adds the data listed in [Table 5-16](#) to the normal display.

The master CPU time reported is cumulative. The slave CPU time reported is the sum of the CPU time for all the threads reported for the most recent distribution session.

Table 5-16. Additional Data Displayed by -Verbose

Column Name	Description
free swap	Total available swap space minus the swap space currently in use
total RAM	Total available RAM
total swap	Total available swap space
user CPU	Current sum of the time spent executing the master or slave process
sys CPU	Current sum of the time spent in system routines on behalf of the master or slave process

Examples

Example 1

The following example summarizes the performance statistics for the current multiprocessing environment:

report_processors

```
// hosts          threads   arch      CPU(s)    %idle    free
RAM   process size
// ----- -----
// nemo (master)    1 x86-64  24 x 2.8 GHz    6%     70229.83 MB  19320.18 MB
// ahab            4 x86-64  16 x 3.0 GHz   39%     15463.78 MB   458.61 MB
// master with 1 thread and 1 slave with 4 threads running.
```

Example 2

This example uses the **-verbose** switch for this command. The first “**report_processors -verbose**” command reports that the cumulative CPU time for the master prior to running **create_patterns** is 18m.

When you subtract the 18m CPU time reported by that command from the 11h 51m CPU time for the master reported by the second instance of the command, you have the total master CPU time for the **create_patterns** command, 11h 33m.

Please be aware that the CPU time reported for the slave threads is the sum of the thread CPU times for the latest distribution session.

The tabular output of this example is wrapped, as indicated with an ellipsis (...), for easy reading.

report_processors -verbose

```
// sub-command: report_processors -verbose
// hosts      threads      arch      CPU(s)      %idle      free RAM      ...
// -----  -----  -----  -----  -----  -----
// nemo (master)      1      x86-64    24 x 2.8 GHz      6%    70229.83 MB      ...
// ahab             4      x86-64    16 x 3.0 GHz     39%   15463.78 MB      ...

      free swap      total RAM      total swap      process size      user CPU      sys CPU
-----  -----  -----  -----  -----  -----

[add_processors](#)[delete_processors](#)

report_read_controls

Context: dft -edt, dft -scan, dft -test_points, patterns -scan,
patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup, analysis

Displays all of the currently defined read control lines.

Usage

`report_read_controls [> | >>] file_pathname]`

Description

Displays all of the currently defined read control lines.

The report_read_controls command displays all the read control lines specified using the add_read_controls command. The display also includes the corresponding off-state with each read control line.

Arguments

- `> file_pathname`
An optional redirection operator and pathname pair for creating or replacing the contents of `file_pathname`.
- `>> file_pathname`
An optional redirection operator and pathname pair for appending to the contents of `file_pathname`.

Examples

The following example displays a list of the current read control lines:

```
add_read_controls 0 r1 r3
add_read_controls 1 r2 r4
report_read_controls
```

Related Topics

report_read_verilog_options

Context: unspecified, all contexts

Mode: all modes

Reports options specified with the [set_read_verilog_options](#) command.

Usage

```
report_read_verilog_options
```

Description

Reports options specified with the [set_read_verilog_options](#) command.

Arguments

None.

report_register_value

Context: all contexts

Mode: setup, analysis

Reports register information for each register name.

Usage

```
report_register_value [(> | >>) file_pathname]
```

Description

Reports register information for each register name.

In the report, the columns contain the following data:

- Register Value Name — Name of the register specified by the [add_register_value](#) command in the pattern generation dofile.
- Value string — Binary value loaded into the register, if known. The register is loaded when the [write_patterns](#) command is executed. Before [write_patterns](#) is executed, this column contain Xs for registers with dynamic contents. For register values with a width greater than 200, only the first 200 bits of the value are displayed.
- Width — Number of bits in the register.
- Dynamic/Static — Shows the DRC impact.
 - Dynamic: The contents of the register is not known/not used during DRC and can be changed.
 - Static: The contents of the register is known and used during DRC and cannot be changed.
- Source — The source of the register contents: user-defined or tool-determined.
- LSB/MSB First — Whether the register is applied from MSB > LSB or LSB > MSB.
- Pin Inversion — Indicates whether any inversions are present. Contains two values that refer to [input_pin_inversion](#) and [output_pin_inversion](#): F = false and T = true.

See “[Serial Register Load and Unload for LogicBIST and ATPG](#)” in the *Tessent Shell User’s Manual* for complete information.

Arguments

- $> file_pathname$

An optional redirection operator and pathname pair for creating or replacing the contents of *file_pathname*.

- *>> file.pathname*

An optional redirection operator and pathname pair for appending to the contents of *file.pathname*.

Examples

The following example reports the values of LPCT configuration data fields before and after the write_patterns command is executed. In this example, if you issue “[set_lpct_controller -max_shift 1000](#)”, the lpct_config_shift_length register has the width of 10, as shown below.

report_register_value

Report output before the write_patterns command is executed:

Register value name	Value string	Width	Dynamic/ Static	Source	LSB/ MSB First	Pin inversion
lpct_config_capture_depth	xx	2	dynamic	capture width	LSB first	FF
lpct_config_chain_pattern_load_count	XXXX XXXX XX	10	dynamic	chain patterns load/unload count	LSB first	FF
lpct_config_edt_bypass	0	1	static	user specified	MSB first	FF
lpct_config_reset_control	0	1	static	user specified	MSB first	FF
lpct_config_scan_en_control	0	1	static	user specified	MSB first	FF
lpct_config_scan_pattern_load_count	XXXX XXXX XXXX XXXX XXxx	20	dynamic	scan patterns load/unload count	LSB first	FF
lpct_config_shift_length	XXXX XXXX XX	10	dynamic	shift length	LSB first	FF

Report output after the write_patterns command is executed:

Register value name	Value string	Width	Dynamic / Static	Source	LSB/MSB First	Pin inversion
lpct_config_capture_depth	10	2	dynamic	capture width	LSB first	FF
lpct_config_chain_pattern_load_count	000001 0110	10	dynamic	chain patterns load/unload count	LSB first	FF
lpct_config_edt_bypass	0	1	static	user specified	MSB first	FF
lpct_config_reset_control	0	1	static	user specified	MSB first	FF
lpct_config_scan_en_control	0	1	static	user specified	MSB first	FF
lpct_config_scan_pattern_load_count	000000 000001 011111 11	20	dynamic	scan patterns load/unload count	LSB first	FF

Related Topics

- [add_register_value](#)
- [delete_register_value](#)
- [set_register_value](#)

[report_resources](#)

Context: unspecified, all contexts

Mode: all modes

Displays the machine resources used by the active tool session.

Usage

`report_resources`

Description

Displays the machine resources used by the active tool session.

The `report_resources` command displays the cumulative processing time and the process memory usage for the machine on which the tool is running.

The tool also reports CPU time that is the cumulative CPU time of the master process since you invoked the run.

Arguments

None

Examples

The following example reports on machine resources:

```
report_resources
// Machine Name: bongo
// User Name: smith
// User CPU Time: 27.8 seconds
// System CPU Time: 1.6 seconds
// Memory Used: 141.739 MB
```

[set_pattern_buffer](#)

[report_processors](#)

report rtl_to_gates_mapping

Context: all contexts

Mode: all modes

Reports the name-mapping rules for RTL to post-synthesis/post-layout name mapping.

Usage

```
report rtl_to_gates_mapping
```

Description

Reports the name-mapping rules for RTL to post-synthesis/post-layout name mapping specified that exists by default or was added using the [add rtl_to_gates_mapping](#) command.

See the [add rtl_to_gates_mapping](#) command description to know what those mappings are for, and how to customize them.

Arguments

None.

Examples

The following example calls the report_rtl_to_gates_mapping before any RTL to gates mappings were added using the [add rtl_to_gates_mapping](#) command. In this case, the report shows the built-in default mappings. The [add rtl_to_gates_mapping](#) command is used to add an instance name mapping. The second report_rtl_to_gates_mapping invocation shows the added mapping.

report rtl_to_gates_mapping

```
// Index Register name map
// -----
// 1   '\% (name)_reg '

report_run_synthesis_options

Context: unspecified, dft, patterns

Mode: setup, analysis, insertion

Reports the values for all options set with the [set_run_synthesis_options](#) command.

Usage

```
report_run_synthesis_options
```

Description

Reports the values for all options set with the [set_run_synthesis_options](#) command.

Arguments

None.

Examples

The following example demonstrates using of this command:

```
SETUP> set_run_synthesis_options dc_shell -startup_file .synopsys_dc.setup
SETUP> report_run_synthesis_options

// Synthesis options
// -----
// Option           Value
// -----
// default_synthesis_tool    dc_shell
// synthesis_output_directory .synthesis_outdir
// compilation_options      {}
// pre_compilation_commands {set_scan_configuration -style multiplexed_flip_flop}
// post_compilation_commands {change_names -rules verilog -hier}
// startup_file          .synopsys_dc.setup
// command_name          dc_shell
//
```

report_scan_cells

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: analysis, insertion (dft -scan context only)

Displays a report on the scan cells that reside in the specified scan chains.

Usage

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

```
report_scan_cells [-All | {chain_name [{-Range cell_id1 cell_id2} | cell_id...]}...]  
[-VERilog] [-Power_domain] [{> | >>} file_pathname]
```

Context: dft -scan

```
report_scan_cells [-All | chain_name...] [-SHift_register_flops]  
[-Power_domain] [-SCan_mode scan_mode] [-Filename filename [-Replace]]  
[{> | >>} file_pathname]
```

Context: dft -test_points -no_rtl

```
report_scan_cells [-All | chain_name...] [-SHift_register_flops]  
[-Power_domain] [-Filename filename [-Replace]] [{> | >>} file_pathname]
```

Description

Displays a report on the scan cells that reside in the specified scan chains.

The report_scan_cells command provides a report on the scan cells within specific scan chains. The report provides the following information for each scan cell:

- Chain cell index number (cell ID), where 0 is the scan cell closest to the scan-out pin.
- Scan chain in which the scan cell resides.
- Scan group in which the scan cell resides. (The scan group data will be hidden if the design has only scan group.)
- Sequential element type, primitive type, and latch triggering type during shifting. The latch triggering type can be one of the following: LE, TE, AH, AL.
- Inversion data for each sequential element.
- Gate index number for each sequential element.
- Shift clock name and inversion status at the clock input of each sequential element. (“dft -edt” and “patterns -scan” only)
- Top-level library model cell name of each sequential element.
- Instance name of each sequential element.
- Library instance name, if one is defined.

- Cell input and output pins.

For more information, see “[Scan Terminology](#)” in the *Tessent Scan and ATPG User’s Manual*.

If you issue the command without specifying any arguments, then the tool displays a report on the scan cells for all scan chains.

Tip

 If you are saving a log of the tool session, reporting all scan cells will fill the logfile with information for every scan cell—a lot of information if the design is large! To reduce the impact on the logfile in this case, consider reporting on only one scan chain.

Note

 Although scan cells are listed in the order of nearest-to-output first, the sequential elements inside one cell are not listed in that order (the master is always listed first).

Be aware that when reading hierarchical names into its internal database, the tool hides backslashes (\), converts periods (.) to slashes (/), and ignores spaces. For example, the tool reads the cell name, “FFH\E\MY_SCAN_FF .SCAN_FF5” in a WGL pattern, as “FFH/E/MY_SCAN_FF/SCAN_FF5”, storing the latter in its internal database. To report on this cell, you must reference it by the name that is stored internally.

Note

 The difference between the internal hierarchical name and the name in the WGL file of the preceding example does not alter the correctness of the tool. That is, the output pattern file remains consistent with the original netlist.

dft -scan only: If you issue the command with the -Filename switch, then the tool writes the scan cells to a file in the format that can be read by the [insert_test_logic](#) command. The format of the written file is different than the format of the viewed report. You can optionally edit the scan cell order in the file before reading the file with the [insert_test_logic](#) command.

Arguments

- -All

An optional switch that displays information for all the scan cells in all the scan chains. This is the default.

- chain_name

An optional, repeatable string that specifies a scan chain whose scan cell data you want to display. When you use this argument without accompanying cell IDs, the tool displays information for all the scan cells in the scan chain. If you follow the chain_name argument with the -Range switch (and beginning and ending cell IDs for the range), the tool displays information for every cell in the range. If you provide one or more cell IDs without the -Range switch, the tool displays information for just those cells in that chain.

- -Range *cell_id1* *cell_id2*
An optional switch and pair of integers that specify the beginning and ending cell IDs of a range of scan cells in *chain_name* whose data you want to display.
- *cell_id*
An optional repeatable integer that specifies the index number (cell ID) of a scan cell and, together with the *chain_name* argument, identifies a specific scan cell whose data you want to display.
- -VERilog
An optional switch that outputs the cell instance and pin pathnames in Verilog syntax, rather than using the default netlist independent format.
- -SHift_register_flops (dft -scan only)
An optional switch that specifies to print only the shift register flip-flops that are stitched into scan chains.
- -Filename *filename* [-Replace] (dft -scan only)
An optional switch and string that specifies that the tool writes the list of scan cells to a file. The format of the written file is different than the format of the viewed report; see the [insert_test_logic](#) filename argument for detailed information on the file format. The *-Replace* switch specifies that the file should be overwritten if it already exists.
- -Power_domain
An optional switch that creates a “Power Domain” column in the report when applicable.
- -Scan_mode *scan_mode*
An optional switch and string pair that specifies the scan mode for which you want to tool to report scan cell information.
- >*file_pathname*
An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.
- >>*file_pathname*
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

Example 1

This example displays a list of the scan cells for scan chain0. The design only has one scan group; therefore, the scan group column is not shown.

```
report_scan_cells chain0
```

cell#	chain	memory_type	inv	gate#	shift_clock	inv	cell_name	instance_name	(ext.pin names)
0	chain0	MASTER (LA-AH)	FFTT	24848	/clk	F	DFF3	/Q_I4	" "
1	chain0	MASTER (LA-AH)	FFFF	25040	/clk	F	DFF1	/H_I4	" "
		SLAVE (FF-TE)	FFFF	24849	/clk	T	DFF2	/Q_I4	" "
2	chain0	MASTER (LA-AH)	FFFF	24546	/clk	F	DFF1	/R_I1	" "
		SLAVE (FF-TE)	FFFF	25041	/clk	T	DFF2	/Q_I4	" "
3	chain0	MASTER (LA-AH)	FFFF	24542	/clk	F	DFF1	/R_I1	" "
		SLAVE (FF-TE)	FFFF	24547	/clk	T	DFF2	/Q_I4	" "
4	chain0	MASTER (LA-AH)	FFFF	24914	/clk	F	DFF1	/S_I1	" "
		SLAVE (FF-TE)	FFFF	24543	/clk	T	DFF2	/Q_I4	" "
5	chain0	MASTER (LA-AH)	FFFF	24544	/clk	F	DFF1	/Z_I4	" "
		SLAVE (FF-TE)	FFFF	24915	/clk	T	DFF2	/Q_I4	" "
6	chain0	MASTER (LA-AH)	FFFF	24540	/clk	F	DFF2	/N_I3	" "
		SLAVE (FF-TE)	FFFF	24545	/clk	T	DFF2	/Q_I4	" "

The first column in the report displays the chain cell index number, where 0 is the scan cell closest to the scan-out pin.

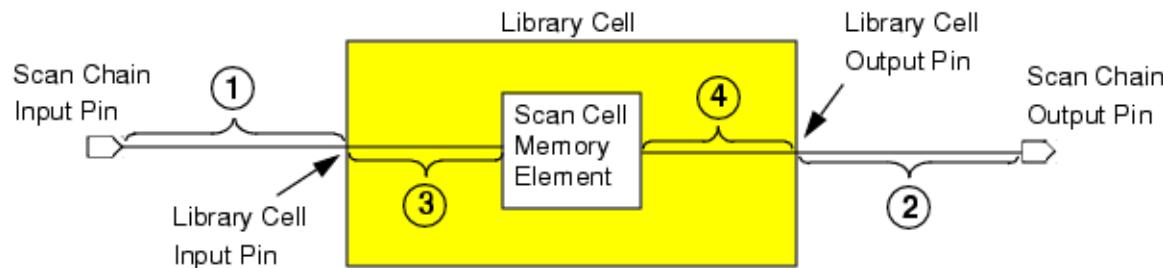

The second column displays the name of the scan chain the scan cell is in.

The third column displays the scan cell's sequential element type(s), primitive type, and latch triggering type during shifting. The latch triggering type can be any of the following: LE, TE, AH, AL.

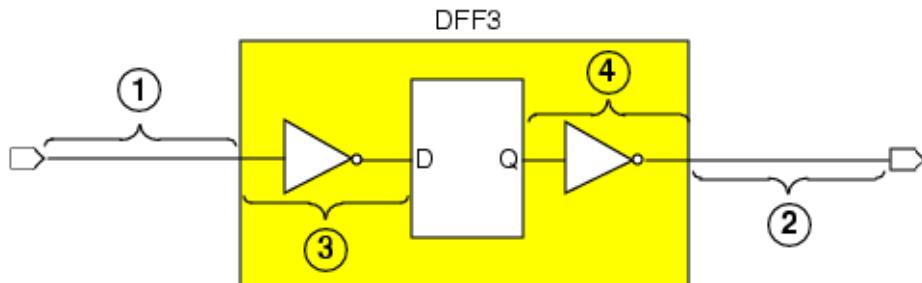

The fourth column (inv) contains inversion data using F (false) to indicate no inversion difference and T (true) to indicate inversion difference. The inversion data has four parts for each scan cell memory element. The report presents these details (left-to-right) as follows:

- Inversion of the signal between the scan chain input pin and the library cell input pin.
- Inversion of the signal between the library cell output pin and the scan chain output pin.
- Inversion of the signal between the library cell input pin and the scan cell memory element (primitive).
- Inversion of the signal between the scan cell memory element (primitive) and the library cell output pin.

The following diagram illustrates the four parts of the “inv” column:

For example, scan cell 0 in the previous scan cell report for chain0 shows inversion data FFTT. This indicates that library cell DFF3 contains an inverter on the input data path as well as one on the output path as shown here:

The inversion data is useful when comparing scan cell data reported in the tool (“set_gate_report -pattern_index n”) to values stored in the pattern file. Since different pattern formats handle inversions differently, the scan cell inversion data can also be useful in understanding differences between pattern formats.

The fifth column displays the gate index number.

The sixth column displays the name of the shift clock for the scan cell.

Note

 In the rare case where a single scan cell’s clock port is driven by multiple shift clocks at the same time, the tool reports the data for only one of the clocks. An example would be two different shift clocks with identical waveforms ANDed together to drive the scan cell’s clock port (not recommended due to the potential for clock skew).

The seventh column shows whether the shift clock’s defined inactive state corresponds to the cell’s clock input value that for level-sensitive devices results in the cell becoming inactive, or for edge-triggered devices is the initial value of a capturing transition. If they correspond (no inversion), an F is listed. If they do not correspond (inversion), a T is listed. For more information on the meaning of “inactive” as it applies to scan clocks, refer to the [add_clocks](#) command description.

Note

 If the scan cell is a hierarchical model, inversion is indicated with respect to the clock ports of sequential element primitives instantiated within the model, not with respect to the clock input(s) at the top level of the model.

The eighth column displays the cell name of the sequential element.

The ninth column displays the instance name of the sequential element.

The tenth column displays the library instance name. If there is no library instance name, the report shows two double-quotes in the library instance name field.

Note

To see the name of the library model corresponding to a particular scan cell, open the Design Browser window of DFTVisualizer with the [open_visualizer](#) command. The Design Browser will open by default, and with the Instance tab active in the Design Browser, find the instance name of the scan cell. The library model is listed to the right of the instance name.

The last column displays the library cell input and output pins of the scan cell. If the scan cell input or output pin does not directly connect to the library cell boundary pin, the report shows a dash (-) in the corresponding pin field.

Example 2

The following example displays a list of all scan cells in the analysis system mode:

```
add_scan_groups group1 scanfile
add_scan_chains chain1 group1 indata2 outdata4
set_system_mode analysis
report_scan_cells
```

CellNo	Chain Name	Group Name	Pathname	CellName	ScanOut	Clock	Clock Polarity
0	chain1	group1	/MQ_I400	sffr	Q	clk2	(+)
1	chain1	group1	/FH_I400	sffr	QB	clk2	(+)
2	chain1	group1	/FQ_I10	sffr	QB	clk2	(+)
-	chain1	group1	/lckup1	latch	Q	clk1	(-)
3	chain1	group1	/RP_I10	sffr	Q	clk1	(+)
4	chain1	group1	/IS_I10	sffr	Q	clk1	(+)
5	chain1	group1	/CZ_I400	sffr	QB	clk1	(+)

- The first column displays the chain cell index number, where 0-0 is the scan cell closest to the scan-out pin.
- The second column displays the chain name where the scan cell resides.
- The third column displays the group name where the scan cell resides.
- The fourth column displays the hierarchical path of the scan cell.
- The fifth column displays the library model name for the scan cell.
- The sixth column displays the scan out port of the scan cell.
- The seventh column displays the clock for the scan cell.
- The eighth column displays the polarity of the clock of the scan cell.

Example 3

The following dft -scan example adds the new column ShiftRegID/CellNo to the report when it identifies a shift register in the netlist. This column contains a tool-assigned number for the shift register ID and a cell number that indicates the order in which the flip-flops are originally connected in the shift register structures. The column contains “-/-” for those cells that are not part of a shift register.

report_scan_cells

CellNo	Name	Polarity	Chain	Group	ShiftReg		Clock	
			Name	Pathname	ID/CellNo	CellName		
0	chain1	dummy	/ud5	-/-	sff	Q	clk	(+)
1	chain1	dummy	/ud6	-/-	sff	Q	clk	(+)
2	chain1	dummy	/ud4	1/4	dff	Q	clk	(+)
3	chain1	dummy	/ud3	1/3	dff	Q	clk	(+)
4	chain1	dummy	/ud2	1/2	dff	Q	clk	(+)
5	chain1	dummy	/ud1	1/1	sff	QB	clk	(+)

Example 4

The following dft -scan example uses the -Shift_register_flops switch to print only the shift register flops in the report:

report_scan_cells -shift_register_flops

CellNo	Name	Polarity	Chain	Group	ShiftReg		Clock	
			Name	Pathname	ID/CellNo	CellName		
2	chain1	dummy	/ud4	1/4	dff	Q	clk	(+)
3	chain1	dummy	/ud3	1/3	dff	Q	clk	(+)
4	chain1	dummy	/ud2	1/2	dff	Q	clk	(+)
5	chain1	dummy	/ud1	1/1	sff	QB	clk	(+)

Example 5

The following example shows use of the -Power_domain switch to report on power domains.

report_scan_cells -power_domain

CellNo	ChainName	GroupName	Pathname	CellName	ScanOut	Clock	ClockPolarity	PowerDomain
0	chain1	dummy	/I2/df_0001_1	sff	QB	clk	(+)	PD2
1	chain1	dummy	/I2/df_0002_1	sff	QB	clk	(+)	PD2
2	chain1	dummy	/I2/df_0003_1	sff	QB	clk	(+)	PD2
0	chain2	dummy	/I10/df_0003_1	sff	Q	clk	(+)	PD3
1	chain2	dummy	/I10/df_0001_1	sff	QB	clk	(+)	PD3
2	chain2	dummy	/I10/df_0002	sff	QB	clk	(+)	PD3
0	chain3	dummy	/I6	sff	QB	clk	(+)	PD1

Example 6

The following dft -scan example shows the additional output that is reported when sub-chains are encountered. Specifically, the starting and ending cell in a sub-chain are listed as a range value in the CellNo column, the clock for the first and last cell in the sub-chain are listed in the Clock column, and the polarity of each clock is listed in the Clock Polarity column.

CellNo	Chain	Group				Clock	
CellNo	Name	Name	Pathname	CellName	ScanOut	Clock	Polarity
0	chain1	grp1	/usf2	SCIFTD11S10	SO	sysCLK	(+)
1	chain1	grp1	/usf1	SCIFTD11S10	SO	sysCLK	(+)
0-3	chain2	grp1	/um1	&subchain1	SO	sysCLK,sysCLK	(+,+)
4-7	chain2	grp1	/uB1/um1	&subchain1	SO	sysCLK,sysCLK	(+,+)
8-9	chain2	grp1	/uC1	&subchain2	so	sysCLK,sysCLK	(+,+)
10	chain2	grp1	/uff2	SCIFTD11S10	SO	sysCLK	(+)
11	chain2	grp1	/uB1/uff2	SCIFTD11S10	SO	sysCLK	(+)
0-3	chain3	grp1	/um2	&subchain1	SO	MYTCLK,MYTCLK	(+,+)
4-7	chain3	grp1	/uB2/um2	&subchain1	SO	MYTCLK,MYTCLK	(+,+)
8-11	chain3	grp1	/uB2/um1	&subchain1	SO	MYTCLK,MYTCLK	(+,+)
12-15	chain3	grp1	/uB1/um2	subchain1	SO	MYTCLK,MYTCLK	(+,+)
16-17	chain3	grp1	/uC2	&subchain2	so	MYTCLK,MYTCLK	(+,+)
18	chain3	grp1	/uff1	SCIFTD11S10	SO	MYTCLK	(+)
19	chain3	grp1	/uB1/uff1	SCIFTD11S10	SO	MYTCLK	(+)
20	chain3	grp1	/uB2/uff1	SCIFTD11S10	SO	MYTCLK	(+)
21	chain3	grp1	/uB2/uff2	SCIFTD11S10	SO	MYTCLK	(+)

Related Topics

[add_scan_chains](#)

[add_scan_groups](#)

report_scan_chains

Context: dft -scan, dft -test_points -no_rtl, dft (with no sub-context)

Mode: all

Displays a report on all the current scan chains.

Usage

patterns -scan Usage

```
report_scan_chains [-All_blocks] [-SUBchains [-Verbose]] [-Inversion]  
[-INVALID_scan_pins] [{> | >>} file_pathname]
```

dft -scan Usage

```
report_scan_chains [{> | >>} file_pathname]
```

Description

Displays a report on all the current scan chains.

The report shows the following information for each scan chain:

- Name of the scan chain
- Name of the scan chain group
- Scan chain input and output pins
- Length of the scan chain
- Name of the scan clock(s) (but only after you enable the E8 DRC in setup mode)

If the DRC E8 handling is set to anything other than Ignore when leaving Setup system mode, the command additionally lists the clocks specified to be pulsed in the shift procedure in the test procedure file. This enhanced report is only available in non-Setup modes. The clocks reported are likely a superset of the clocks that are actually used to clock the scan cells. For a precise report of the shift clocks, use the [report_scan_cells](#) command.

Arguments

- `-All_blocks`

Note

This switch is only for the top-level Pattern Generation Phase of modular Tessent TestKompress, where the netlist read in includes multiple EDT blocks.

An optional switch that displays information for all scan chains in every modular EDT block. Without this switch, only information defined for the current EDT block displays. If a current EDT block is not defined, the information for all EDT blocks displays. Use the current EDT block using either the [add_edt_blocks](#) or [set_current_edt_block](#) command. “EDT block” is the term used for a decompressor/compactor pair and the scan chains it

controls/observes. For more information, refer to the “[Modular Compressed ATPG](#)” chapter of the *Tessent TestKompress User’s Manual*.

When using the TCD-based automated flow, the tools adds all EDT blocks and does not set the current block. To report the scan chains in this case, you must use the `-all_blocks` switch or use `set_current_edt_block` to identify the blocks.

- **-SUBchains**

An optional switch that displays information about the subchains of the scan chains, including the number of required serial shifts and the number of scan cells in each subchain. Only the scan chains with a subchain display.

- **-Verbose**

An optional switch that displays detailed information about the scan cells in each subchain.

- **-Inversion**

An optional switch that displays information about whether there is any net inversion across the entire length of the scan chain, between the scan input pin and scan output pin. For EDT only, this switch also displays whether there is any inversion between the decompressor output and the input of the scan chain and whether there is any inversion between the scan chain output and the compactor output. This switch can be used in all modes except Setup mode.

- **-INVALID_scan_pins**

An optional switch that displays only scan chains that have invalid scan pin definitions (input pin and/or output pin). When using this option, in addition to filtering the chains, the tools also adds “(invalid)” next to every non-existent pin. See “[Example 6](#)” on page 1749.

In some cases when EDT Finder is on, you may only end up with invalid pins because the tool relaxes the pin checks when a chain is added. Having any invalid pins means EDT Finder cannot be turned off; this switch allows you to find invalid pins that prevent EDT Finder from being disabled.

- **> file_pathname**

An optional redirection operator and pathname pair for creating or replacing the contents of `file_pathname`.

- **>> file_pathname**

An optional redirection operator and pathname pair for appending to the contents of `file_pathname`.

Examples

Example 1

The following example displays a report of all the scan chains and their scan clocks. Note that because the tool ignores the E8 DRC by default, the command does not display scan clock information.

ATPG> report_scan_chains

```
chain = chain1 group = grp1 input = /scan_in1 output = /scan_out1 length = 27
chain = chain2 group = grp1 input = /scan_in2 output = /scan_out2 length = 28
chain = chain3 group = grp1 input = /scan_in3 output = /scan_out3 length = 28
```

However, when you enable the E8 DRC in setup mode, the tool stores and reports scan clock information:

```
SETUP> set_drc_handling e8 note
SETUP> set_syststem_mode atpg
ANALYSIS> report_scan_chains
chain = chain1 group = grp1 input = /scan_in1 output = /scan_out1 length = 27
master_clock(s) = /SCK1
chain = chain2 group = grp1 input = /scan_in2 output = /scan_out2 length = 28
master_clock(s) = /SCK2
chain = chain3 group = grp1 input = /scan_in3 output = /scan_out3 length = 28
master_clock(s) = /SCK3
```

Example 2

The following example displays a report of all the subchains.

```
report_scan_chains -subchains
chain = c1 group = g1 input = /SI0 output = /SO0 length = 11
  subchain-1 from chain "c1" cell 0 to cell 4, length = 5
    1 sub-chain in chain "c1", maximum subchain length within the chain is 5
chain = c3 group = g1 input = /SI2 output = /SO2 length = 7
  subchain-1 from chain "c3" cell 1 to cell 5, length = 5
    1 sub-chain in chain "c3", maximum subchain length within the chain is 5

The following 2 library models include sub-chains:
library_name max_subchain_length
----- -----
macro_sff1           5
reg5                 5

Total 2 sub-chains in 2 library models, which cause 4 extra parallel
shifts.
```

Example 3

The following example indicates there is net inversion across the entire length of the scan chain, there is no inversion between the decompressor output and the input of the scan chain, and there is inversion between the scan chain output and the compactor output.

```
report_scan_chains -inversion
chain = chain1 group = grp1 input = /cpu_i/scan_in1 output =
/cpu_i/scan_out1 length = 152 inversion = Yes decompressor_inversion = No
compactor_inversion = Yes
```

Example 4

The following example shows reporting when power domains are present in the design:

report_scan_chains

```
Power domain 'PD2' chains:  
-----  
chain = chain1 group = dummy input = /scan_in1 output = /scan_out1  
length = 3 scan_enable = /scan_en clock = /clk  
  
Power domain 'PD3' chains:  
-----  
chain = chain2 group = dummy input = /scan_in2 output = /so2 length = 3  
scan_enable = /scan_en clock = /clk  
  
Power domain 'PD1' chains:  
-----  
chain = chain3 group = dummy input = /scan_in3 output = /scan_out2  
length = 1 scan_enable = /scan_en clock = /clk
```

Example 5

The following example displays a detailed report of the scan cells in the subchains.

report_scan_chains -sub -verbose

```
chain = c1 group = g1 input = /SI0 output = /SO0 length = 11  
    sub-chain-1 from chain "c1" cell 0 to cell 4, length = 5  
-----  
cell# chain memory_type gate# library_name instance_name (ext.pinnames)  
-----  
0    c1    MASTER (FF-LE) 147 macro_sff1 /macro1  ""  (-,Q)  
1    c1    MASTER (FF-LE) 148 macro_sff1 /macro1  ""  (-,-)  
2    c1    MASTER (FF-LE) 149 macro_sff1 /macro1  ""  (-,-)  
3    c1    MASTER (FF-LE) 150 macro_sff1 /macro1  ""  (-,-)  
4    c1    MASTER (FF-LE) 151 macro_sff1 /macro1  ""  (SI,-)  
1 sub-chain in chain "c1", maximum sub-chain length within the chain is 5  
chain = c3 group = g1 input = /SI2 output = /SO2 length = 7  
    sub-chain-1 from chain "c3" cell 1 to cell 5, length = 5  
-----  
cell# chain memory_type gate# library_name instance_name (ext.pinnames)  
-----  
1    c3    MASTER (FF-LE) 164 reg5      /macro5/reg0 s_5   (-,SO)  
2    c3    MASTER (FF-LE) 165 reg5      /macro5/reg0 s_4   (-,-)  
3    c3    MASTER (FF-LE) 166 reg5      /macro5/reg0 s_3   (-,-)  
4    c3    MASTER (FF-LE) 167 reg5      /macro5/reg0 s_2   (-,-)  
5    c3    MASTER (FF-LE) 168 reg5      /macro5/reg0 x_1   (SI,-)  
1 sub-chain in chain "c3", maximum sub-chain length within the chain is 5
```

The following 2 library models include sub-chains:

library_name	max_subchain_length
macro_sff1	5
reg5	5

Total 2 sub-chains in 2 library models, which cause 4 extra parallel shifts.

Example 6

In the following example, the -INValid_scan_pins switch is used to display scan chains that have invalid scan pin definitions:

```
SETUP> report_scan_chains -all_blocks -invalid_scan_pins

EDT block = 'm1_28x16' chain = m1_chain5 group = grp1 input =
  'invalid_scanin1' (invalid) output = 'invalid_scanout1' (invalid) length
  = unknownEDT block = 'm2_4x32' chain = m2_chain1 group = grp1
  input = 'invalid_scanin2' (invalid)
  output = '/core2_4x32/retimetest_i/edt_so1' length = unknownEDT
  block = 'm2_4x32' chain = m2_chain2 group = grp1
  input = 'invalid_scanin3' (invalid)
  output = '/core2_4x32/retimetest_i/edt_so2' length = unknown
```

report_scan_elements

Context: dft -scan, dft -test_points -no_rtl, dft (with no sub-context)

Mode: all modes

Reports the scan elements that are created by the tool for scan insertion purposes.

Usage

```
report_scan_elements [object_spec] [-columns column_names]  
[-add_columns column_names]
```

Description

Use this command to report the scan elements that are created by the tool for scan insertion purposes.

The report is printed in a table format where each column represents an attribute specified by the attribute_name list. Only segment and leaf_cell type of scan_segments are reported unless specified by the object_spec argument. Use the -columns switch to specify which columns to show and the order in which they appear. The “name” column is mandatory and will always be shown. You can add additional columns after the default columns (or after the columns specified with the –columns switch) using the -add_columns switch.

Column names can be any of the following:

- Special Columns
 - si_so_clocks — the si,so clock domains. Each clock domain is preceded by +/- to indicate pos_edge/neg_edge accordingly.
- Scan Element Attribute Columns

All scan element built-in attributes listed in the “[Scan Element Object Type](#)” on page 3144“[Built in attributes on Scan Element \(SE\) Object Type](#)” on page 2.
- Module Attribute Columns

All module built-in attributes listed in “[Module](#)” on page 3058
- Instance Attribute Columns

All instance built-in attributes listed in “[Instance](#)” on page 3069

Arguments

- *object_spec*

An optional value that specifies a Tcl list of one or more object names or a collection of one or more scan element objects. Only existing scan_segment objects will be shown.

- **-columns *column_names***

An optional list of attributes or connector values to display for each scan element specified, including composite attributes such as “si_so_clocks”.

- **-add_columns *column_names***

An optional list of columns to append after the columns specified by the -columns switch (or after the default columns).

Examples

Example 1

The following example shows the default columns printed when the command is issued with no arguments.

```
report_scan_elements
```

name	type	length	si_so_clocks	state	is_non_scannable_reason
sch1/f5/SO1	segment	2	-clk1,-clk2	usable	--
sch2/f5/SO2	segment	2	+clk1,+clk3	usable	--
sch3/f6/so	segment	2	-clk2,+clk5	usable	--
/f	leaf_cell	1	+test_clk	ignored	inferred_from_drc
/f2	leaf_cell	1	+test_clk	ignored	user_specified
/f3	leaf_cell	2	-clk1	usable	--

Example 2

The following example includes user-specified columns.

```
report_scan_elements [get_scan_elements -state unusable] -columns {type id state is_valid}
```

name	type	id	state	is_valid
shift_register#/f4	shift_register	10	unusable	true
chain0	chain	12	unusable	true
inferred#bucket_0_1	inferred	13	unusable	true

Example 3

The following example adds additional columns to the default output using the -add_columns switch.

```
report_scan_elements -add_columns {type id used}
```

```
=====
name      type     length  si_so_clocks state   is_non_scannable_reason  id    used
-----  -----  -----  -----  -----  -----
sch1/f5/SO1 segment  2      -clk1,-clk2  usable   --                15   true
sch2/f5/SO2 segment  2      +clk1,+clk3  usable   --                16   true
sch3/f6/so  segment  2      -clk2,+clk5  usable   --                17   true
/f        leaf_cell 1      +test_clk   ignored  inferred_from_drc  19   false
/f2       leaf_cell 1      +test_clk   ignored  user_specified    20   false
/f3       leaf_cell 2      -clk1     usable   --                21   false
```

Example 4

The following example illustrates how you can define the columns of the report using a Tcl variable.

```
set cord { type state is_non_scannable_reason name}
report_scan_elements -column $cord [get_scan_element -state ignored]

=====
type      state   is_non_scannable_reason  name
-----  -----  -----  -----
leaf_cell  ignored  missing_scan_model    /tessent_persistent_cell_shift_capture_clock
leaf_cell  ignored  missing_scan_model    /tessent_persistent_cell_edt_clock
leaf_cell  ignored  imported_from_icl    /chip_top_gate_tessent_tap_main_inst/
leaf_cell  ignored  imported_from_icl    /chip_top_gate_tessent_tap_main_inst/instr_reg_2_
leaf_cell  ignored  imported_from_icl    /chip_top_gate_tessent_tap_main_inst/instr_reg_1_
```

report_scan_enable

Context: dft -scan, dft -test_points

Mode: analysis, insertion

Reports on scan_enable signals and associated scan chains.

Usage

```
report_scan_enable [-scan_mode scan_mode] [<> | >>] file_pathname
```

Description

Reports on scan_enable signals and associated scan chains.

The following details are reported for each scan enable signal:

- Primary input port (top-level scan enable port)
- Internal connection node (internal instance pin designated as the scan enable signal driver)
- Associated scan chain(s)

Arguments

- **-scan_mode *scan_mode***

An optional switch and string pair that specifies the scan mode for which you want to tool to report information.

- **> *file_pathname***

An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.

- **>> *file_pathname***

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

Example 1

The following example reports the scan_enable details for all modes.

```
report_scan_enable
```

```
Scan mode 'int_mode' scan enables:  
-----  
Primary Input      Internal Connection Node  Scan Chain  
-----  
/spi_top/scan_en_out --                      int_mode_chain0  
                                         int_mode_chain1  
                                         int_mode_chain2  
                                         int_mode_chain3  
                                         int_mode_chain4  
  
Scan mode 'ext_mode' scan enables:  
-----  
Primary Input      Internal Connection Node  Scan Chain  
-----  
/spi_top/scan_en_out --                      ext_mode_chain0
```

Example 2

The following example reports the scan_enable details for int_mode only:

```
report_scan_enable -scan_mode int_mode  
Scan mode 'int_mode' scan enables:  
-----  
Primary Input      Internal Connection Node  Scan Chain  
-----  
/spi_top/scan_en_out --                      int_mode_chain0  
                                         int_mode_chain1  
                                         int_mode_chain2  
                                         int_mode_chain3  
                                         int_mode_chain4
```

[set_scan_enable](#)

report_scan_groups

Context: dft -edt, dft -scan, dft -test_points, patterns -scan,
patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup, analysis

Displays a report on all the current scan chain groups.

Usage

`report_scan_groups [{> | >>} file_pathname]`

Description

Displays a report on all the current scan chain groups.

The `report_scan_groups` command provides the following information in a report for each scan chain group:

- Name of the scan chain group
- Number of scan chains within the scan chain group
- Number of shifts
- Name of the test procedure file, which contains the information for controlling the scan chains in the reported scan chain group

Arguments

- `>file_pathname`

An optional redirection operator and pathname pair for creating or replacing the contents of `file_pathname`.

- `>>file_pathname`

An optional redirection operator and pathname pair for appending to the contents of `file_pathname`.

Examples

The following example displays a report of all the scan groups:

```
add_scan_groups group1 scanfile
add_scan_groups group2 scanfile1
report_scan_groups
```

Related Topics

[add_scan_groups](#)

[delete_scan_groups](#)

report_scan_models

Context: dft -scan

Mode: setup, analysis

Displays the sequential scan models currently in the scan model list.

Usage

```
report_scan_models
```

Description

Displays the sequential scan models currently in the scan model list.

The report_scan_models command displays sequential models which you previously added to the scan model list by using the [add_scan_instances](#) command.

Arguments

None

Examples

The following example displays all the sequential scan models from the scan model list:

```
add_scan_instances -modules d_flip_flop1 d_flip_flop2  
report_scan_models
```

report_scan_modes

Context: dft -edt, dft -logic_bist, patterns -scan, patterns -scan_diagnosis

Mode: setup

Reports all available scan modes after they are inserted by Tesson Scan.

Usage

```
report_scan_modes [-core core_name]
```

Description

Reports all available scan modes after they are inserted by Tesson Scan.

Arguments

- `-core core_name`

An optional switch that specify the core name for which the scan mode should be reported.

Examples

Example 1

The following example displays the scan modes before a scan mode was imported.

report_scan_modes

```
// command: report_scan_modes
//           Mode Name  Mode Type  EDT Instruments  OCC Instruments
//           -----  -----  -----  -----
//           int_edt_mode    internal      1          10
//           ext_mode        external      2
//           int_single_mode internal     10
```

Example 2

The following example displays the scan modes after a scan mode was imported.

report_scan_modes

```
//           Mode Name  Mode Type  EDT Instruments  OCC Instruments
//           -----  -----  -----  -----
//           int_edt_mode    internal      1          10
//           * ext_mode        external      2
//           int_single_mode internal     10
//           * = last imported scan mode
```

[import_scan_mode](#)

report_scan_polygons

Context: patterns -scan_diagnosis

Mode: setup, analysis

Traces scan chains and reports the cell and output net polygons for inter-scan cell logic located along the traces.

Usage

```
report_scan_polygons [-chain chain_name ...] [-start cell_number] [-stop cell_number]  
[-layout_marker marker_file] [-all_core_instances]
```

Description

The report_scan_polygons command traces from scan chain output to scan chain input for the specified chains and cell range. It reports the inter-scan cell logic found along the traces and the logics' bounding boxes. The report includes the logics' layers, critical areas, and polygons.

Scan cell numbering starts at 0 for the scan cell closest to the scan output and advances through the cells to the scan input. You can filter the report to include only specified chains and specified cells.

Refer to “[Inter-Scan Cell Polygon Reporting for Chain Diagnosis](#)” in the *Tessent Diagnosis User’s Manual* for more information.

Arguments

- **-chain *chain_name* ...**
An optional switch with strings that specifies a list of scan chain names as reported by the chain diagnosis report. By default, the tool reports all chains in the design.
- **-start *cell_number***
An optional switch and string pair that specifies to begin tracing inter-scan cell logic at the specified scan cell number. The default, 0, represents the scan cell closest to the scan output pin.
- **-stop *cell_number***
An optional switch and string pair that specifies to stop tracing inter-scan cell logic at the specified scan cell number. The default, -1, represents the scan cell closest to the scan input pin.
- **-layout_marker *marker_file***
An option switch and string pair that specifies to write a report in layout marker format supported by Calibre DESIGNrev.
- **-all_core_instances**
An optional switch that specifies to generate an inter-scan cell logic report with scanned net pathnames at the chip level. By default, the tool reports the scanned net pathnames at the

core level. This switch pertains to hierarchical designs and has no effect on non-hierarchical designs. Specifically, the tool generates the scanned net pathnames for each instance of a given core reported at the chip level. Refer to “[Inter-Scan Cell Polygon Reporting for Chain Diagnosis](#)” in the *Tessent Diagnosis User’s Manual*.

Examples

The following example reports the inter-scan cell logic for suspect 16 in the chain diagnosis report, which is suspect scan cell 333 on scan chain 78:

```
16      65  STUCK(IN+CELL+OUT) 1 /top_dut/io/data_out/SO FFTX1 \
top_dut/io/n18 333 chain78 /
```

Specifically, the following command specifies to trace and report the inter-scan cell logic between scan cell 333 and scan cell 334. The report shows that there is a buffer along the trace from scan cell 333 to scan cell 334.

```
report_scan_polygons -chain chain78 -start 333 -stop 334
```

For the scan cells and inter-scan cell logic, the report’s header lines list the identifier name, its gate type, library model name, and pin instance for each scan cell and connecting logic gate. For each listed cell and cell logic, it then reports the layer name (for nets) or “cell” (where “cell” is the bounding box of the cell listed in the header line), the critical area (for nets only), and the layout defect bounding box coordinates for the cell and output net.

[get_layout_core_instance](#)

set_layout_core_instance

report_scan_segments

Context: dft -scan, dft -test_points -no_rtl, dft (with no sub-context)

Mode: all modes

Reports the scan segment declarations that are defined either via add_scan_segments command or tcd_scan files.

Usage

```
report_scan_elements [object_spec] [-columns column_names]  
[-add_columns column_names]
```

Description

Use this command to report the scan segment declarations that are defined either via add_scan_segments command or tcd_scan files.

The report is printed in a table format where columns represent the scan segment specifications, such as length, traceability, pin names on the segment container and so forth. The inversion information of the pins is represented with a ‘~’ in front of the pin names in the table.

Note

 Pin columns will show the full pin path in the event that the pin path is different than the name path or “.” to indicate the path is the same as the path of the scan element as indicated in the name field.

Column names can be any of the following:

- Special Columns
 - from_tcd — the from_tcd scan segment property.
 - reset_pins — the active_high_reset pin(s) (preceded by “~” if polarity is inverted).
 - scan_en_pins — the scan_enable pin(s) (preceded by “~” if polarity is inverted).
 - set_pins — the active_high_set pin(s) (preceded by “~” if polarity is inverted).
 - si_pin — the scan_in pin(s) (preceded by “~” if polarity is inverted).
 - si_so_clock_pins — the clock_in,clock_out pins (each clock is preceded by “~” if polarity is inverted).
 - si_so_clocks — the si,so clock domains. Each clock domain is preceded by +/- to indicate pos_edge/neg_edge accordingly.
 - ste_pins — the test_enable pin(s) (preceded by “~” if polarity is inverted).
 - so_pin — the scan_out pin(s) (preceded by “~” if polarity is inverted)
- Scan Element Attribute Columns

All scan element built-in attributes listed in the “[Scan Element Object Type](#)” on page 3144“Built in attributes on Scan Element (SE) Object Type” on page 2.

- Module Attribute Columns
All module built-in attributes listed in “[Module](#)” on page 3058
- Instance Attribute Columns
All instance built-in attributes listed in “[Instance](#)” on page 3069

Arguments

- *object_spec*
An optional value that specifies a Tcl list of one or more object names or a collection of one or more scan element objects. Only existing scan_segment objects will be shown.
- **-columns** *column_names*
An optional list of attributes or connector values to display for each scan element, including composite attributes such as “si_so_clocks”.
- **-add_columns** *column_names*
An optional list of columns to append after the columns specified by the -columns switch (or after the default columns).

Examples

The following example shows the default columns printed when the command is issued with no arguments.

report_scan_segments

Name	length	traceable	si_pin	so_pin	si_so_clocks	si_so_clock_pins	scan_en_pins	set_pins	reset_pins	ste_pins
s1_ch1/s1/so1 5	yes		./si1	./so1	—	./clk1,./clk1	./se	—	—	—
s2_ch2/s1/so2 5	no		./si2	./so2	—	./clk3n,./clk3n	./clk3n,./clk3n	./se	—	—

report_scan_volume

Context: dft -edt, patterns -scan

Mode: analysis

Displays the volume of scan data used by the pattern set.

Usage

```
report_scan_volume [-External] [<> | >>] file_pathname]
```

Description

Displays the volume of scan data used by the pattern set.

The report_scan_volume command displays the volume of scan data used by the pattern set, including chain test patterns. The report format depends on the design and type of patterns, as illustrated in the examples. Because the pattern count is not a good measure of EDT compression for different scan configurations, this command gives you a metric that is equally good for EDT and regular ATPG, making it easier to compare their results.

Arguments

- `-External`

An optional switch that displays the volume of scan data used by the external pattern set. Prior to using this switch, you must specify an external pattern set using the [read_patterns](#) command.

- `>file_pathname`

An optional redirection operator and pathname pair for creating *or* replacing the contents of *file_pathname*.

- `>>file_pathname`

An optional redirection operator and pathname pair for appending to the contents of *file_pathname*.

Examples

Example 1

This basic EDT design example and the examples that follow show the volume display for various types of designs and patterns.

$$\text{Scan Volume} = (\# \text{ Scan Channels}) \times (\# \text{ Shift Cycles}) \times (\# \text{ Scan Loads})$$

```
// -----
// Scan volume report.
// -----
//   channels : 1
//   shift cycles : 371+32
// -----
//   pattern   # test   # scan           volume
//   type     patterns   loads (cell loads or unloads)
// -----
// chain test      6       6             2418
```

Example 2

The following example is a basic EDT design where Ram_sequential or multiple-load patterns trigger an expanded format because of a difference in input and output volume:

$$\text{Input Volume} = (\# \text{ Scan Channels}) \times (\# \text{ Shift Cycles}) \times (\# \text{ Scan Loads})$$

$$\text{Output Volume} = (\# \text{ Scan Channels}) \times (\# \text{ Shift Cycles}) \times (\# \text{ Test Patterns})$$

```
// -----
// Scan volume report.
// -----
//   channels : 1
//   shift cycles : 371+32
// -----
//   pattern   # test   # scan   input volume   output volume   average volume
//   type     patterns   loads   (cell loads)   (cell unloads)
// -----
// chain test      6       6         2418          2418          2418
// basic          34      34        13702         13702         13702
// clock_po       2        2         806            806            806
// ram_seq        57      223       89869         22971         56420
// clock_seq      304     304       122512        122512        122512
// multi_load    12       24        9672          4836          7254
// -----
// total          415     593       238979        167245        203112
```

Example 3

The following example is an EDT design where the number of input channels differs from the number of output channels:

$$\text{Input Volume} = (\# \text{ Input Channels}) \times (\# \text{ Shift Cycles}) \times (\# \text{ Scan Loads})$$

$$\text{Output Volume} = (\# \text{ Output Channels}) \times (\# \text{ Shift Cycles}) \times (\# \text{ Test Patterns})$$

```
// -----
// Scan volume report.
// -----
//      input channels : 8
//      output channels : 9
//      shift cycles   : 30
// -----
//      pattern    # test  # scan  input volume  output volume  average volume
//      type       patterns loads   (cell loads) (cell unloads)
// -----
//      chain test     4      4        960          1080         1020
//      basic        80     80      19200         21600        20400
//      ram_seq       31     118      28320         8370         18345
//      clock_seq     85     85      20400         22950        21675
//      multi_load    10     30       7200          2700         4950
// -----
//      total         210    317      76080         56700        66390
```

Example 4

The following example is a Tessent FastScan or Tessent TestKompress (EDT Off) design; no Ram_sequential or multiple-load patterns:

$$\text{Scan Volume} = (\# \text{ Scan Chains}) \times (\# \text{ Shift Cycles}) \times (\# \text{ Scan Loads})$$

```
// -----
// Scan volume report.
// -----
//      scan chains : 10
//      shift cycles : 31
// -----
//      pattern    # test  # scan           volume
//      type       patterns loads   (cell loads or unloads)
// -----
//      chain_test     1      1            310
```

Example 5

The following example is a Tessent FastScan or Tessent TestKompress (EDT Off) design with Ram_sequential or multiple-load patterns:

$$\text{Input Volume} = (\# \text{ Scan Chains}) \times (\# \text{ Shift Cycles}) \times (\# \text{ Scan Loads})$$

$$\text{Output Volume} = (\# \text{ Scan Chains}) \times (\# \text{ Shift Cycles}) \times (\# \text{ Test Patterns})$$

```
// -----
// Scan volume report.
// -----
//      scan chains : 10
//      shift cycles : 31
// -----
//      pattern    # test   # scan   input volume   output volume   average volume
//      type      patterns   loads   (cell loads)   (cell unloads)
// -----
//      chain test      1       1           310           310           310
//      basic          42      42        13020        13020        13020
//      clock_po       1       1           310           310           310
//      ram_seq        6       18          5580          1860          3720
//      clock_seq      53      53        16430        16430        16430
//      multi_load     3       6           1860          930          1395
// -----
//      total         106     121        37510        32860        35185
```

report_seq_transparent_procedures

Context: dft -edt, patterns -scan

Mode: analysis

Displays a list of seq_transparent test procedures along with the associated data that you specify.

Usage

```
report_seq_transparent_procedures [-All | procedure_name...] [-CElls] [-Load_disturbs]
[-CAapture_disturbs] [{> | >>} file_pathname]
```

Description

Displays a list of seq_transparent test procedures along with the associated data that you specify.

The report_seq_transparent_procedures command displays a list of the specified seq_transparent test procedures. You can optionally display data associated with each seq_transparent test procedure by specifying the appropriate switches.

If you do not specify any of the data switches, the command does not provide any details about the procedures.

Arguments

- **-All**
An optional switch that displays the associated data for all seq_transparent procedures. If you do not specify any other argument with the -All switch, the command simply lists the names of all the currently defined seq_transparent procedures. This is the default.
- **procedure_name**
An optional repeatable string that specifies the names of the seq_transparent procedures whose data you want to display.
- **-CElls**
An optional switch that displays the seq_transparent cells associated with the specified procedures. By default, the tools do not display these cells.
- **-Load_disturbs**
An optional switch that displays the scan cells with load disturbs associated with the specified procedures. By default, the tools do not display these cells.
- **-CAapture_disturbs**
An optional switch that displays the scan cells, primary outputs, seq_transparent cells, and RAMs which had capture disturbs. By default, the tools do not display these items.

- **>file.pathname**

An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file.pathname*.

- **>>file.pathname**

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file.pathname*.

Examples

The following example displays all the seq_transparent test procedures, along with the associated scan cells that had load disturbs:

```
add_scan_groups g1 seqproc.g1
add_scan_chains c1 g1 si so
add_clocks 0 clk
set_system_mode analysis
report_seq_transparent_procedures -all -load_disturbs
```

[report_gates](#)

report_sequential_fault_depth

Context: dft -edt, patterns -scan

Mode: analysis

Displays estimates of maximum test coverage possible with different sequential depth settings.

Usage

```
report_sequential_fault_depth [<> | >>] file_pathname]
```

Description

Displays estimates of maximum test coverage possible with different sequential depth settings.

The report_sequential_fault_depth command displays the maximum test coverage the tool estimates is possible if all relevant collapsed faults are detectable. Use this command to quickly assess the upper limits of coverage possible under optimal test conditions for various sequential depths.

The data is displayed in three columns as follows:

- Depth numbers for fifteen successive sequential depths, starting with the current depth setting. The default sequential depth upon invocation of the tool is zero, but you can change it using the -Sequential switch with the [set_pattern_type](#) command.
- Number of targeted faults for each depth
- Estimated maximum collapsed test coverage achievable under the assumption that all relevant collapsed faults can be detected. This figure is an upper bound of the coverage you can expect.

Note

Relevant faults include those the tool declared ATPG_untestable (AU) in a previous ATPG run—because the tool will retarget these faults when you increase the depth. Accordingly, the tool includes these AU faults in the row corresponding to the current depth+1.

Arguments

- >*file_pathname*

An optional redirection operator and pathname pair for creating or replacing the contents of *file_pathname*.

- >>*file_pathname*

An optional redirection operator and pathname pair for appending to the contents of *file_pathname*.

Examples

The following example shows the output of the report_sequential_fault_depth command for a sequential depth of 4:

report_sequential_fault_depth

```
// Structural heuristic analysis of the sequential depth of faults
//
//   Set      Number      Max.
// Depth    of target    possible
//          to        faults    TC[%]
//          this      (coll.)  (coll.)
//          4         1450     89.37
//          5         7002     93.59
//          6         7852     94.42
//
//          ...
//          15        11897    98.34
//          16        12033    98.47
//          17        12099    98.53
//          18        12159    98.59
```

report_shift_registers

Context: dft -scan, dft - test_points

Mode: setup, analysis

Reports the identified shift registers in the design after switching to analysis mode.

Usage

```
report_shift_registers [-Verbose | -Summary]
```

Description

Reports the identified shift registers in the design after switching to analysis mode.

The tool tries to preserve the original connections inside the identified shift registers during stitching. Therefore, this command may report the shift registers in the design differently, before and after the execution of the insert_test_logic command.

For each identified shift register, this command reports the following information:

- ID, assigned by the tool
- Length
- First and last flip-flop properties (instance pathname, clock edge and name, library model name) unless the -verbose switch is specified in which case the properties of all flip-flops in the shift registers are reported

Arguments

- **-Verbose**
An optional switch that reports all of the flip-flops identified in the shift registers.
- **-Summary**
An optional switch that reports a summary text without printing the flip-flops identified in the shift registers.

Examples

Example 1

The following example shows the output when neither switch is specified:

report_shift_registers

Id	Length	SequentialCell	Clock	Library
		Instance PathName	Edge & Name	ModelName
[1]	4	/ud1 /ud4	+ clk + clk	dff dff
[2]	2	/uA/uf9 /uA/uf10	- clk - clk	dff dff
// Number of sequential elements in design: 10 // Number of shift register flops recorded for scan insertion: 6 // => 60% of all sequential elements in design // Number of shift registers recorded for scan insertion: 2 // Longest shift register has 4 flops. // Shortest shift register has 2 flops. // Potential number of nonscan flops to be converted to scan cells: 2 // Potential number of scan cells to be converted to nonscan flops: 0				

Example 2

The following example shows the output when the -verbose switch is specified:

report_shift_registers -verbose

Id	Length	SequentialCell	Clock	Library
		InstancePathName	Edge & Name	ModelName
[1]	4	/ud1 /ud2 /ud3 /ud4	+ clk + clk + clk + clk	dff dff dff dff
[2]	2	/uA/uf9 /uA/uf10	- clk - clk	dff dff
// Number of sequential elements in design: 10 // Number of shift register flops recorded for scan insertion: 6 // => 60% of all sequential elements in design // Number of shift registers recorded for scan insertion: 2 // Longest shift register has 4 flops. // Shortest shift register has 2 flops. // Potential number of nonscan flops to be converted to scan cells: 2 // Potential number of scan cells to be converted to nonscan flops: 0				

Example 3

The following example shows the output when the -summary switch is specified:

report_shift_registers -summary

```
// Number of sequential elements in design: 6
// Number of shift register flops recorded for scan insertion: 4
// => 66.67% of all sequential elements in design
// Number of shift registers recorded for scan insertion: 1
// Longest shift register has 4 flops.
// Shortest shift register has 4 flops.
// Potential number of nonscan flops to be converted to scan cells: 1
// Potential number of scan cells to be converted to nonscan flops: 0
```

report_silicon_insight_result

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Reports the summary diagnosis results for failing flops and pseudo failing flops for ATPG.

Usage

```
report_silicon_insight_result -atpg_datalog {scan_cells | patterns | full}
```

Arguments

- **-atpg_datalog {scan_cells | patterns | full}**

A required switch and string choice that specifies the type of summary information to return:

scan_cells—Reports a list of failing cells and pattern counts for the failing cells. This type of report is useful for determining how often each cell fails in all failing patterns.

patterns—Reports a list of all failing patterns and their failing flop/cell count per failing pattern.

full—Reports a list of all failing patterns, their failure counts, and a description of each failing cell in the pattern.

Examples

Example 1

The following example displays the format for the scan_cells summary diagnosis results. For failing flops, the report displays the cell name, channel ID, and cell index. For failing_pseudo_flops, the report displays the channel ID and cell index.

```
// Cells summary: Summary report for failing patterns count per cell:  
// -----  
// | CellName | ChannelId | CellIndex | PatternCount |  
// -----  
// | PIN | SFRWE_c2_2 | 0 | 80 |  
// | my_glue/cpu_i/uPORT/ix1734 | edt_channel13 | 15 | 1 |  
// | my_glue/cpu_i/uPORT/ix687 | edt_channel13 | 17 | 1 |  
// | my_glue/cpu_i/uPORT/ix1754 | edt_channel13 | 18 | 1 |  
// | my_glue/cpu_i/uPORT/ix1794 | edt_channel13 | 1 | 1 |  
// | my_glue/cpu_i/uPORT/ix1814 | edt_channel13 | 2 | 1 |  
// | my_glue/cpu_i/uPORT/ix1834 | edt_channel13 | 3 | 1 |  
// | my_glue/cpu_i/uPORT/ix1854 | edt_channel13 | 4 | 1 |  
// | my_glue/cpu_i/uPORT/ix701 | edt_channel13 | 10 | 1 |  
// | my_glue/cpu_i/uPORT/ix729 | edt_channel13 | 12 | 1 |
```

Example 2

The following example displays the format for the patterns summary diagnosis results.

```
// Patterns summary: Summary report for failing flop frequency per pattern:  
// -----  
// | Pattern# | FlopCount |  
// -----  
// | 0 | 1 |  
// | 1 | 4 |  
// | 2 | 5 |  
// | 3 | 6 |  
// | 4 | 1 |
```

Example 3

The following example displays the format for the full summary diagnosis results. For failing flops, the report displays the cell name, channel ID, and cell index. For failing_pseudo_flops, the report displays the channel ID and cell index.

```
// Full report: Full report for failing patterns:  
// -----  
// | Pattern# | CellName | ChannelId | CellIndex | Chain | CellId |  
// -----  
// | 0 | PIN | SFRWE_c2_2 | 0 | | |  
// | 1 | PIN | SFRWE_c2_2 | 0 | | |  
// | 1 | my_glue/cpu_i/uPORT/ix1734 | edt_channel3 | 15 | chain18 | 15 |  
// | 1 | my_glue/cpu_i/uPORT/ix687 | edt_channel3 | 17 | chain18 | 17 |  
// | 1 | my_glue/cpu_i/uPORT/ix1754 | edt_channel3 | 18 | chain18 | 18 |  
// | 2 | PIN | SFRWE_c2_2 | 0 | | |  
// | 2 | my_glue/cpu_i/uPORT/ix1794 | edt_channel3 | 1 | chain19 | 1 |  
// | 2 | my_glue/cpu_i/uPORT/ix1814 | edt_channel3 | 2 | chain19 | 2 |  
// | 2 | my_glue/cpu_i/uPORT/ix1834 | edt_channel3 | 3 | chain19 | 3 |  
// | 2 | my_glue/cpu_i/uPORT/ix1854 | edt_channel3 | 4 | chain19 | 4 |
```

report_simdut_faults

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Reports the SimDUT faults.

Usage

report_simdut_faults

Arguments

None

Examples

The following example reports a list of active stuck-at faults stored in the simulator:

```
report_simdut_faults

// Net name | fault type
// -----
// /SIMDUT_TB/DUT_inst/block1/ram1/\MEM_reg[32][1] /Q | 1
// /SIMDUT_TB/DUT_inst/block1/ram1/\MEM_reg[32][2] /Q | 0
// /SIMDUT_TB/DUT_inst/block1/ram1/\MEM_reg[32][4] /Q | 1
```

report_simulation_contexts

Context: all contexts

Mode: setup, analysis

Prerequisite: The flat model must already exist

Lists the available simulation contexts and indicates the current simulation context.

Usage

```
report_simulation_contexts [-predefined | -user_defined]
```

Description

Lists the available simulation contexts and indicates the current simulation context.

The report_simulation_contexts command lists all simulation contexts. Note that the command reports available simulation contexts, some of which are only available after the tool reads a procedure file.

If you issue the command without arguments, the command reports all simulation contexts as follows:

```
Simulation Context Report

Name           Class      Populated
-----
empty_context   User-defined yes
stable_after_setup Predefined no
stable_capture   Predefined no
* stable_load_unload Predefined no
stable_shift     Predefined no
tie_value        Predefined yes

* = current simulation context
```

The Populated column reports with a “yes” only those contexts that have correct simulation values. The simulation values are created in the DRCs.

Arguments

- **-predefined**

An optional switch that reports predefined simulation contexts, which are listed in [Table 6-7](#) on page 2023.

- **-user_defined**

An optional switch that reports user-defined simulation contexts.

report_simulation_forces

Context: all contexts

Mode: setup, analysis

Prerequisite: The flat model must already exist

Lists the active forces on the specified gate_pin objects.

Usage

report_simulation_forces [*obj_spec*]

Description

Lists the active forces on the specified gate_pin objects.

The report_simulation_forces command lists the simulation forces on the specified gate_pin object(s). When you issue this command without arguments, the tool lists all simulation forces of the current simulation context.

Arguments

- *obj_spec*

An optional value that specifies one or more gate_pin objects.

Examples

The following example shows the output of the report_simulation_forces command:

```
ANALYSIS> add_simulation_forces [get_gate_pins I1] -value 0
ANALYSIS> add_simulation_forces [get_gate_pins I2] -value Z
ANALYSIS> add_simulation_forces [get_gate_pins reg12/Q] -value 1
ANALYSIS> report_simulation_forces
```

Gate Pin	Gate Pin ID	Value
'Din1[0]'	7.0	0
'Din1[1]'	6.0	Z
'Din1[2]'	5.0	1

report_simulation_library_sources

Context: unspecified, all contexts

Mode: all modes

Reports the values specified with the set_simulation_library_sources command.

Usage

```
report_simulation_library_sources
```

Description

Reports the values specified with the [set_simulation_library_sources](#) command.

Arguments

None.

Examples

The following example uses the [set_simulation_library_sources](#) to define search paths, and to map a pre-compiled library name to its physical directory. The report_simulation_library_sources command is then used to report them.

```
set_simulation_library_sources \
  -y ..//verilog ..//data/customPads \
  -v ..//data/extralib.v \
  -extensions .v \
  -logical_library_map_list {mylib ..//data}
report_simulation_library_sources

// Simulation Library Source Paths
// =====
// type    path                      file extensions
// -----  -----
// dir     '../verilog'              'v v.gz'
// dir     '../..//data/customPads'   '.v.gz'
// file   '../data/extralib.v'
//
// Simulation Library Logical Library Map
// =====
// name    dir path
// -----  -----
// mylib   ..//data
```

Related Topics

[set_simulation_library_sources](#)

report_static_dft_signal_settings

Context: dft patterns

Mode: setup, analysis, insertion

Prerequisites: ICL is elaborated

Reports the setting specified or implied with the [set_static_dft_signal_values](#) command.

Usage

```
report_static_dft_signal_settings  
[-all | -current_design | -icl_instances icl_instances | -instances instances]
```

Description

Reports the settings specified or implied with the [set_static_dft_signal_values](#) command. All static DFT signals implemented with IJTAG can be set using the [set_static_dft_signal_values](#) command. See the [add_dft_signals](#) command for information on how to add the DFT signals. The DFT signals are grouped by each module in which you added the signals and ran the [process_dft_specification](#) command. These modules have the `tessent_design_level` attribute equal to “chip”, “physical_block”, and “sub_block” in their extracted ICL module view.

When setting a static DFT signal within an instance, the other DFT signals without an explicit setting are assigned an implicit value following the logic described in the [set_static_dft_signal_values](#) command description section.

Arguments

- **-all**

An optional switch that reports the settings that exist on DFT signals found within all ICL instances that have the `tessent_design_level` attribute set to “chip”, “physical_block”, and “sub_block” within their ICL module definition. The DFT signals found within the top module are also reported.

The `-all`, `-current_design`, `-icl_instances`, and `-instances` switches are mutually exclusive. If unspecified, the `-current_design` switch is the default.

- **-current_design**

An optional switch that reports the settings that exist on DFT signals found within the top module. The top-level module must have the `tessent_design_level` attribute set to “chip”, “physical_block”, and “sub_block” within the ICL module definition.

The `-all`, `-current_design`, `-icl_instances`, and `-instances` switches are mutually exclusive. If unspecified, the `-current_design` switch is the default.

- **-icl_instances *icl_instances***

An optional switch that reports the settings that exist on DFT signals found within the specified ICL instances. These ICL instances must have the `tessent_design_level` attribute set to “chip”, “physical_block”, and “sub_block” within their ICL module definition.

The -all, -current_design, -icl_instances, and -instances switches are mutually exclusive. If unspecified, the -current_design switch is the default.

- -instances *instances*

An optional switch that reports the settings that exist on DFT signals found within the specified design instances. These design instances must match the value of the “hierarchical_design_instance” attribute found on an ICL instance with the tesson_design_level attribute set to “chip”, “physical_block”, and “sub_block” within their ICL module definition.

The -all, -current_design, -icl_instances, and -instances switches are mutually exclusive. If unspecified, the -current_design switch is the default.

Examples

The following example shows the report generated for a block where the [set_static_dft_signal_values](#) was explicitly called for the ltest_en DFT signal. The report shows the inferred values on the other signals.

```
// ICL Module      : sub_block_13

// -----  -----
// DFT Signal Name Usage          Set value Set source
// -----  -----
// all_test        global_dft_control 1       Inferred
// ext_ltest_en    logic_test_control -       -
// int_ltest_en    logic_test_control -       -
// ltest_en        logic_test_control 1       Explicit
// ext_multi       scan_mode(external) -       -
// int_edt         scan_mode(internal) -       -
```

      [-LESsthan percentage]
      [-LEVel integer]
      [-DETections integer]
      [-INDent integer | [-USe_full_instance_path]
      [-CSV]]]
   [-DISplay]
   [(> | >>) file_pathname]
```

Description

Displays a detailed statistics report to the screen.

The tool also reports CPU time that is the cumulative CPU time of the master process since you invoked the run.

When you use the -Instance switch, the tool's statistics report lists the following three groups of information:

- The current number of collapsed or total faults, depending on the current fault mode, in each class. By default, the fault mode is full. The report does not display fault classes with no members.
- The percentage of test coverage, fault coverage, fault coverage loss, and ATPG effectiveness for collapsed or total faults. By default, the fault mode is full, however the tool can report either the collapsed number or full number depending on the current fault mode.
- The total numbers for the following:
 - Total patterns simulated in the preceding fault simulation process. This subgroup may additionally contain total numbers for the following internal patterns sets:
 - Basic scan patterns
 - Clock_po patterns

- Ram_sequential patterns
- Clock_sequential patterns
- Total patterns currently in the test pattern set
- Total CPU time

If a pattern type has no patterns, the report does not display the count for that type. If all patterns are basic patterns, it will not display any count. And it counts clock_sequential patterns that are also clock_po only as clock_sequential patterns.

When you use the -Hierarchy switch, the statistics report lists the following two groups of information for each reported hierarchical instance:

- Instance leaf name (add -USe_full_instance_path switch to report entire instance path)
- A customizable list of statistics that, by default, consists of the following:
 - Module name
 - Total number of faults
 - Number of unobserved (UO) faults
 - Number of ATPG untestable (AU) faults
 - Test coverage

When you issue the “set_atpg_timing On” command prior to create_patterns, the statistics report also includes delay test coverage. For more information about how the tool calculates delay test coverage, refer to the *Tessent Scan and ATPG User’s Manual*.

Arguments

- -DEtailed_analysis [DI] [-Threshold *threshold_number*]An optional switch that, by default, reports detailed information for the following fault sub-classes:
 - AU.CC (CELL_CONSTRAINTS)
 - AU.PC (PIN_CONSTRAINTS)
 - AU.TC (TIED_CELLS)
 - UD.AAB (ATPG_ABORT)
 - UD.EAB (EDT_ABORT)
 - UD.UNS (UNSUCCESS)

For information about any of these fault sub-classes, refer to the discussion about “[Fault Sub-classes](#)” in the *Tessent Scan and ATPG User’s Manual*.

For an example of reporting detailed statistics for AU or DI sub-classes, refer to “[Example 2](#)” on page 1793.

DI

An optional literal that enables the tool to report the DI fault sub-classes without performing the detailed analysis for AU faults, which can be time consuming. All of the DI sub-classes are listed under “[Fault Sub-classes](#)” in the *Tessent Scan and ATPG User’s Manual*. Note that the tool always performs analysis for all DI fault sub-classes, with the exception of DI.EDT, which you control using the [set_fault_subclass_analysis](#) command. For more information about DI.EDT analysis, refer to that command description.

-Threshold *threshold_number*

An optional switch and numerical pair that limits the list of untestable faults displayed. The *threshold_number* is the minimum coverage loss percentage to display. The default threshold is 0.1%. Faults having a coverage loss less than the threshold are summarized at the end of the list (see “[Example 2](#)” on page 1793).

- -Instance *instance_pathname*

An optional switch and string pair that reports fault statistics for a specific instance. The *instance_pathname* is the name of a circuit block whose statistics you want to report. Only fault statistics are affected by this option; pattern count statistics apply to the entire design.

- -Model ALL | *model_name*

An optional switch and string pair that specifies reporting statistics for all models or a single named model in a Tessent Cell library. When specifying a single model, *model_name* must match a cell model in the Tessent Cell library. This switch is only available for Tessent FastScan and Tessent TestKompress when invoked in model mode (-model). If you use this switch in other than model mode, the tool issues the following error:

Error: -model reporting only available for -model tool invocations.

- -CLOCK_domains SUMMARY | ALL | *clock_pathname...*

An optional switch and literal or repeatable string pair that you use for the following:

- Reporting the summary of clock domain test coverage; or
- Specifying a list of clocks to report the coverage(s) for the specified clock domain(s).

Choose from the following options:

SUMMARY — A literal that reports a summary of clock domain coverage and produces a Clock Domain Summary section. For each clock domain, the tool reports the percentage of faults in the clock domain with respect to the total fault population, and reports the relevant test coverage numbers for each clock domain.

ALL — A literal that reports the detailed coverage information for all clock domains.

clock_pathnames... — A repeatable string specifying a clock domain or clock domains. The tool reports the detailed coverage information for the specified clock domains.

- **-Hierarchy**

An optional switch that allows fault statistics to be reported for each hierarchical instance in the design. The tool uses columns for all fields reported. For each reported instance, the tool displays the instance name and flags the instance if it is a gray box (GB) or black box (BB). If an instance is a gray box, the tool adds rows reporting statistics of faults for “Instances in netlist” and “Instances not in netlist”. By default, the tool lists the following statistics for each reported instance:

- Module name
- Total number of faults
- Number of unobserved (UO) faults
- Number of ATPG untestable (AU) faults
- Test coverage
- Test coverage loss

-FORmat “format_code...”

An optional switch and a string of one or more format codes that, together with the **-Hierarchy** switch, specifies which data to display and the order in which to display it. Use this switch to tailor the content and arrangement of displayed data in hierarchical reports. By default, only the instance column is displayed when using the **-format** switch. [Table 5-17](#) lists the format code literals this switch recognizes and the information displayed for each.

Table 5-17. Format Codes

Tessent FastScan Information (uncollapsed)	Format Code	Report Label
Fault coverage	%fc	Fault Coverage
Test coverage	%tc	Test Coverage
Test coverage loss	%tcl	TC Loss
Relevant test coverage	%rtc	Relevant TC
ATPG effectiveness	%ae	ATPG Eff.
Module name	mo	Module
Number of faults	#f	# faults
Fault category	<category>[.<subclass>]	<CAT>[.<SUB>]

The **-format** option reports statistics for fault subclasses specified using format codes with this format:

<fault category>[.<subclass>]

For example:

```
report_statistics -hierarchy -format "%tc %rtc AU AU.BB" -level 1
Hierarchical Statistics Report
Stuck-at Faults
-----
Instance          Test Coverage Relevant TC   AU    AU.BB
-----
-top-            59.12%      59.12%    14465    116
CHIPJ_MGsg_INT_CD_FLOP_DECODER_INST 79.41%      79.41%      7      0
DEF              89.85%      89.85%    166      0
LVISION_JTAP_INST        0.00%      0.00%      0      0
LVISION_LOGICTEST_INST       0.00%      0.00%      0      0
LV_BURST_CLK_CTRL_I1        0.00%      0.00%      0      0
LV_BURST_CLK_CTRL_I2        0.00%      0.00%      0      0
LV_SE_CTRL_BL5_P_I1        77.34%      77.34%    29      0
LV_SE_CTRL_BL5_P_I2        6.83%       76.83%    19      0
LV_SHIFT_CLK_CTRL_INST      0.00%      0.00%      0      0
TLB_inst           57.69%      57.69%    4100    116
```

All format codes, including the fault codes, are case insensitive. For example:

```
report_statistics -hierarchy -format "%fc au Au.UNC Di.sCAn, DI.UNC"
```

When duplicated format codes exist in the format code list, only one appears in the reported statistics.

Information displays in the same order as the format codes in the command. The default for this switch is:

```
-format "mo #f uo au %tc"
```

The results display as shown in the following example:

```
Hierarchical Statistics Report
Stuck-at Faults
-----
Instance     Module     #faults   UO      AU    Test Coverage
-----
-top-       my_core    46250    2316    768    93.16%
u10        m3s018bo   6240     1038    99     81.36%
u11        m3s015bo   4526     122     60     95.97%
u12        m3s016bo_3  590      7       8      97.46%
u1         m3s020bo   2146     87     33     94.40%
```

Note

 You must include a space between each format code you specify, and begin and end the sequence of format codes with a double quotation mark ("").

-Sort *format code* [-Ascending | -Descending]

An optional switch and literal pair that allows the tool to sort the results by the column indicated by *format code*. Sorting begins with level 1 instances, proceeds

with each level 1 instance's child (level 2), and continues hierarchically until complete. If -sort is not used, the report is sorted by the instance names in ascending alphabetical order.

-Ascending

An optional switch to sort in ascending order.

-Descending

An optional switch to sort in descending order. This is the default sort order.

The -sort option parser supports fault <category>[.<subclass>] format codes, case insensitive format codes, and will ignore duplicated format column codes.

-EXClude_unlisted_faults

An optional switch that excludes unlisted faults from the report and calculations. It also omits the "Instances in netlist" and "Instances not in netlist" lines from the report.

-Grayboxes_only

An optional switch that together with the -Hierarchy switch, limits the report to graybox instances, not including the top instance. This option automatically enables the "-use_full_instance_path" option.

When you use this switch, the header of the statistics report includes the text "(Grayboxes Only)".

-LESsthan *percentage*

An optional switch and real number pair that, together with the -hierarchy switch, specifies to report only module instances with test coverage less than or equal to the specified percentage. The default percentage is 100.0 and causes all module instances to be reported.

Specifying "-lessthan 90.0", as shown in this example, the tool reports statistics only for module instance u10 because u10 is the only instance with test coverage less than or equal to 90%:

```
report_statistics -hierarchy -lessthan 90.0
```

```
Hierarchical Statistics Report
Stuck-at Faults
-----
Instance      Module      #faults    UO      AU  Test Coverage
-----        -----       -----      --   ---   -----
u10          m3s018bo    6240       1038     9    81.36%
```

-LEVel *integer*

An optional switch and integer pair that, together with the -Hierarchy switch, controls the hierarchy reporting depth. The tool reports all hierarchical levels down to and including the level you specify, counting from the top level, which is 0. If you specify "-level 1", for example, the tool will display data for the top level and the instances one level of hierarchy beneath the top level. By using this switch to restrict reporting

to the upper levels of a design's hierarchy, you can reduce the command's processing time on very large designs with deep hierarchy. The maximum allowed value is 1000.

-DETectors *integer*

An optional switch and integer pair used with the -Hierarchy switch to represent the number of multiple detections. When specified, the DS fault count, test coverage, relevant coverage, fault coverage, test coverage loss, and ATPG efficiency metrics adjust to reflect the values with detections greater than or equal to the detection number specified.

By default, the tool runs as though you had specified “-detections 1”.

-INDent *integer*

An optional switch and integer pair that, together with the -hierarchy switch, specifies the number of additional spaces to indent the information for each subsequent level of reported hierarchy. The default indentation is two spaces. Specifying “-indent 0” removes all indentation. The maximum allowed value is 10.

-USe_full_instance_path

An optional switch used to display the complete instance path. Without it, the report displays the leaf instance name and the instantiation level is shown by indentation.

-CSV

An optional switch that uses a comma as a delimiter between the columns in the report, making the data readily usable within spreadsheet programs. This option automatically enables the “-use_full_instance_path” option.

When you use this switch, the statistics report has no header.

- -Display

An optional switch that specifies to display the following columns in the DFTVisualizer Instance Browser: Test Coverage, Test Coverage Loss, Total Faults, AU, and Relevant Test Coverage.

- > *file_pathname*

An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.

- >> *file_pathname*

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

Example 1

The following example displays a statistics report for the top level instance in a design after performing an ATPG run:

```
set_system_mode analysis  
create_patterns  
report_statistics
```

```
Statistics Report  
Transition Faults  
-----  
Fault Classes  
-----  
Fault Classes #faults #faults  
              (total) (total relevant)  
-----

  /u2 (36) TX          14 ( 9.72%)
  /u4/u5/u3 (41) TX    14 ( 9.72%)
  /u7 (37) TX          10 ( 6.94%)
  /u4/u3 (39) TX       10 ( 6.94%)
  (Combined tied cells) 17 (11.81%)
  Unclassified         4 ( 2.78%)
-----
Coverage
-----
test_coverage        0.00%
fault_coverage       0.00%
atpg_effectiveness  100.00%
-----
#test_patterns        0
#simulated_patterns   0
CPU_time (secs)      1.8
-----
```

Use the -Threshold switch if you want to limit the detailed list of untested faults. Use the following command to show the detailed breakout of the DI fault sub-classes in addition to the AU and UD sub-classes:

```
report_statistics -detailed_analysis DI
```

```
Statistics Report
Stuck-at Faults
-----
...
-----
Fault Sub-classes
-----
DI (det_implication)          30 ( 0.06%)
EDT (edt_logic)              600 ( 1.20%)
SCAN (scan_path)              2146 ( 4.30%)
SEN (scan_enable)             180 ( 0.36%)
CLK (clock)                   300 ( 0.60%)
SR (set_reset)                30 ( 0.06%)
MEM (memory)                  30 ( 0.06%)
DIN (data_in)                 30 ( 0.06%)
...
```

Example 3

The following example shows the statistics report for relevant coverage. A second column is added to the report to compare statistics. The excluded fault sub-classes are marked as “deleted”.

```
set_relevant_coverage -exclude fp
report_statistics
```

Statistics Report Stuck-at Faults		
Fault Classes	#faults (total)	#faults (total relevant)

/in_hcm[1]	0.96%	21.75%
/in_hcm[0]	0.43%	21.80%
/bidi[15]	0.45%	21.29%
/bidi[14]	0.04%	2.00%

Example 5

The following example performs timing-aware ATPG using SDF timing data. Note that the statistics report includes delay test coverage:

```
set_system_mode analysis
read_sdf my_design.sdf
set_atpg_timing on -clock_waveform DEFAULT 3 1 1
create_patterns
report_statistics
```

Statistics Report		
Transition Faults		
Fault Classes	#faults (coll.)	#faults (total)
FU (full)	3370612	4741152
UC (uncontrolled)	846	1339
UO (unobserved)	41993	63027
DS (det_simulation)	2518486	3799766

#test_patterns		3508
#clock_sequential_patterns		3508
#simulated_patterns		3616
CPU_time (secs)		17372.7

Example 6

The following example shows the multiple detection test coverage report at the end of the normal report_statistics output when some unlisted faults are loaded using the “read_faults -graybox” command and AU.PC faults are excluded from the relevant test coverage.

```
read_faults top_faults.txt -retain
read_faults core1_faults.txt -graybox -retain
set_relevant_coverage -exclude au.pc
report_statistics
```

The following shows the left side of the command output:

```
Statistics Report
Stuck-at Faults

Example 7

The following example shows the statistical fault report when gray or black boxes are present:

report_statistics -Hierarchy -LEVel 2

Hierarchical Statistics Report Stuck-at Faults						
Instance	Module	#faults	UO	AU	Test	Coverage
-top-	tde_top_bscan	1602	2316	768	93.16%	
bsr_il	bsr_instance_1	0	0	0	0%	
coria	tde_top	1466	36	95	90.97%	
u1(GB)	td_edt	20	0	10	0.00%	
u2	t_des	1466	36	95	90.79%	
pad_il	pad_inst1	10	0	10	0.00%	
tdbuf (BB)	tri_en_hi	10	0	10	0.00%	
tap_i	tap	0	0	0	0.00%	

Example 8

The following example shows that the rows for “Instances Not in netlist” and “Instances in netlist” display, because the command is set to the level of the gray box. In such a case, the report also shows the next lower level instances for the gray box:

report_statistics -hierarchy -LEVel 3

Hierarchical Statistics Report Stuck-at Faults						
Instance	Module	#faults	UO	AU	Test	Coverage
-top-	tde_top_bscan	1602	2316	768	93.16%	
bsr_il	bsr_instance_1	0	0	0	0%	
coria	tde_top	1466	36	95	90.97%	
u1(GB)	td_edt	20	0	10	0.00%	
Instances Not in netlist		15	0	5	0.00%	
Instances in netlist		5	0	5	0.00%	
inst1	xxxx	3	2	1	0.00%	
inst2	yyyy	2	0	10	0.00%	
u2	t_des	1466	36	95	90.79%	
pad_il	pad_inst1	10	0	10	0.00%	
tdbuf (BB)	tri_en_hi	10	0	10	0.00%	
tap_i	tap	0	0	0	0.00%	

Example 9

The following example shows the hierarchical statistics report using the **-grayboxes_only** switch:

report_statistics -hierarchy -grayboxes_only

Hierarchical Statistics Report (Grayboxes Only) Stuck-at Faults						
Instance	Module	#faults	UO	AU	Test	Coverage
/elt_inst (GB)	elt	18198	8	242	98.44%	
Instances not in netlist	elt	15176	8	88	99.30%	
Instances in netlist	elt	3022	0	154	93.51%	

Example 10

The following example shows the hierarchical statistics report using the -EXClude_unlisted_faults switch:

```
report_statistics -Hierarchy -Level 3 -EXClude_unlisted_faults
```

Hierarchical Statistics Report Stuck-at Faults						
Instance	Module	#faults	UO	AU	Test	Coverage
-top-	tde_top_bscan	1602	2316	768	93.16%	
bsr_il	bsr_instance_1	0	0	0	0	0%
coria	tde_top	1466	36	95	90.97%	
u1 (GB)	td_edt	20	0	10	0.00%	
inst1	xxxx	3	2	1	0.00%	
inst2	YYYY	2	0	10	0.00%	
u2	t_des	1466	36	95	90.79%	
pad_il	pad_inst1	10	0	10	0.00%	
tdbuf (BB)	tri_en_hi	10	0	10	0.00%	
tap_i	tap	0	0	0	0.00%	

Example 11

This is an example of the hierarchical statistics report using -detection option to adjust the report to reflect the values with detections greater than or equal to two.

```
report_statistics -hierarchy -detections 2 -level 1 -exclude_unlisted_faults -format "DS %tc  
%rtc %fc %ae"
```

Hierarchical Statistics Report Stuck-at Faults (Detections >= 2)						
Instance	DS	Test Coverage	TC Loss	Relevant TC	Fault Coverage	ATPG Eff.
-top-	13324	59.76%	40.24%	56.76%	47.44%	99.28%

report_synchronous_clock_groups

Context: dft, patterns

Mode: setup, analysis

Displays a list of all user-defined synchronous clock groups.

Usage

`report_synchronous_clock_groups`

Note

 Synchronous clock groups have no impact on scan chain analysis, test point identification, and EDT IP insertion (in the dft -scan, dft -test_points and dft -edt sub-contexts).

Description

Displays a list of all user-defined synchronous clock groups.

The `report_synchronous_clock_groups` command displays a list of all clock groups that you defined with the `add_synchronous_clock_group` command. For more information about synchronous clock groups, refer to the [add_synchronous_clock_group](#) command description.

Arguments

None.

Examples

The following example creates two clock groups and lists them out.

```
SETUP> add_synchronous_clock_group {I1 I2}
SETUP> report_synchronous_clock_groups
```

```
User-defined Synchronous Clock Group
=====
// No.  Clocks (Labels)
//   --- -----
//     1    I1
//       I2
```

```
SETUP> add_synchronous_clock_group {I3 I4}
SETUP> report_synchronous_clock_groups
```

```
User-defined Synchronous Clock Groups
=====
// No.  Clocks (Labels)
//   --- -----
//     1    I1
//       I2
//     2    I3
//       I4
```

report_tcd_ldb_validation

Context: patterns -scan_diagnosis

Mode: setup

Verifies that the core instance pathnames and hierarchy in the TCD matches the core instance pathnames and hierarchy in the LDB.

Usage

```
report_tcd_ldb_validation -tcd tcdfile ... -ldb ldb_dir ...
```

Arguments

- **-tcd tcdfile ...**
Required switch and string pair that specifies one or more TCD files.
- **-ldb ldb_dir ...**
Required switch and string pair that specifies one or more LDB directories.

Description

The command extracts and compares the set of chip designs and core instance paths from the TCD files and the LDBs. The report lists the coverage of each instance path in the TCD files and the LDBs. The tool issues an error when the names do not match.

The typical flow runs ATPG, LDB creation, and diagnosis in separate phases. Run report_tcd_ldb_validation after ATPG and LDB creation to ensure that the correct data will available at diagnosis. Refer to “[Diagnosis for Hierarchical Design](#)” in the *Tessent Diagnosis User’s Manual* for details.

Examples

The following example validates the chip.tcd against the core data within the core.lbd and chip.lbd directories.

```
report_tcd_ldb_validation -tcd chip.tcd -ldblist core.lbd
```

Core validation report:

TCD Files:

Index	Filename	Design
1>	chip.tcd	chip_top_edt

LDB Directories:

Index	Directory	Design
1>	core.ldb	uUARTs_i

Instance Coverage:

Instance	TCDs	LDBs
cpu/core_1	1	1

The following example shows the output when you have multiple TCDs and cores. In the transcript, the third and fourth TCD files refer to the same chip with different pattern sets. Each chip has embedded cores and a chip level LDB. The first LDB refers to core “core_D,” which is not found in the LDB directories. The second LDB contains a top-level chip, which is not found in any TCD file leading to the chip’s instance not being found.

```
set tcd { chip_1.tcd chip_2.tcd chip_3.tcd }
set ldb { core_A.ldb core_B.ldb core_C.ldb chip_1.ldb chip_2.ldb chip_3.ldb chip_4.ldb }
report_tcd_ldb_validation -tcd $tcclist -ldb $ldblist
```

Core validation report:

TCD files:

Index	Filename	Design
1	chip_1.tcd	chip_1_edt_top
2	chip_2.tcd	chip_2_edt_top
3	chip_3.tcd	chip_3_edt_top
4	chip_4.tcd	chip_3_edt_top

Index	Directory	Design
1	core_A.ldb	core_A
2	core_B.ldb	core_B
3	core_C.ldb	core_C

Instance	TCDs	LDBs
cpu/core_A_1	1	1
cpu/core_A_2	1	1
cpu/core_B_1	1	2
cpu/core_D_1	1	[Not Found]
cpu/core_B_1	2	2
cpu/core_C_1	2	3
cpu/core_C_1	3 4	3
chip_4/core_B_1	[Not Found]	2

report_tcl_shell_options

Context: all contexts

Mode: setup

Lists the currently specified Tcl shell options.

Usage

`report_tcl_shell_options`

Description

Lists the currently specified Tcl shell options as specified with the [set_tcl_shell_options](#) command.

Arguments

None

Related Topics

[get_tcl_shell_option](#)

[set_tcl_shell_options](#)

report_test_end_icall

Context: dft, patterns -scan, patterns -scan_diagnosis, patterns -scan_retargeting

Mode: setup

Reports a single view of all existing iCalls specified with the [set_test_end_icall](#) command.

Usage

`report_test_end_icall`

Description

Reports a single view of all existing iCalls that were specified with the [set_test_setup_icall](#) command.

Arguments

None.

Related Topics

[report_test_setup_icall](#)

[set_test_setup_icall](#)

report_test_logic

Context: dft -scan, dft -test_points

Mode: insertion

Prerequisites: Test logic or test points must be added with the [insert_test_logic](#) command.

Displays the test logic that the tool added during the scan insertion process.

Usage

```
report_test_logic [-Instance | -Module | -Summary] [<> | >>] file_pathname
```

Description

Displays the test logic that the tool added during the scan insertion process.

The report_test_logic command displays information about the additional library cells instantiated in the design during the scan insertion process.

Arguments

- -Instance

An optional switch that displays the list of instance pathnames and the corresponding DFT library models inserted by the tool. This option also includes a summary of the number of each instance-based DFT library model that the tool inserted. This is the default.

- -Module

An optional switch that displays the list of module names, the list of instance pathnames, and the corresponding DFT library models that the tool inserted as test logic and test points. This option also includes a summary of the number of each module-based DFT library model that the tool inserted.

- -Summary

An optional switch that displays a summary that contains the number of each module and instance-based DFT library model that the tool inserted.

- > file_pathname

An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.

- >> file_pathname

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Related Topics

[insert_test_logic](#)

[report_test_points](#)

report_test_points

Context: dft -test_points

Mode: all modes

Displays test points that are inserted with the [insert_test_logic](#) command.

Usage

```
report_test_points [object_spec] [-columns column_names]  
[-add_columns column_names]
```

Description

Use this command to report the test points that are inserted with the [insert_test_logic](#) command.

The report is printed in a table format where each column represents the test point attributes, such as name, location, type, or internal_clock_domain, for each test_point. Use the -columns switch to specify which columns to show and the order in which they appear. By default, report_test_points will print the following test_point attributes:

```
name, type, control_point_type, enable_connection_name, clock_domain,  
flop_location.
```

You can add additional columns after the default columns (or after the columns specified with the –columns switch) using the -add_columns switch.

The following table summarize what is new or changed in the report_test_points command and provides a mapping between the old and new command options.

Previous command option	New command option
-internal_clock_paths	-add_columns clock_connection_name
-sharing id	-add_columns shared_id
Summary	(No longer supported)
-control/-observe	report_test_points [get_test_points –type control/ observe]
-tool_generated_only	report_test_points [get_test_points –origin design_analysis]

Arguments

- *object_spec*

An optional value that specifies a Tcl list of one or more object names or a collection of one or more test_point objects.

- **-columns *column_names***

An optional value that specifies a Tcl list of one or more object names that are the attributes of a test_point object. See “[Test Point Data Model](#)” for the list of Test point attributes that are valid column names.

- **-add_columns *column_names***

An optional list of columns to append after the columns specified by the -columns switch (or after the default columns). See “[Test Point Data Model](#)” for the list of Test point attributes that are valid column names.

Examples

Example 1

The following example shows the default columns printed when the command is issued with no arguments:

```
report_test_points
```

```
=====
name          type   control_point_type enable_connection_name  clock_domain
flop_location
-----

report_test_point_statistics

Context: dft -test_points

Mode: analysis (after analyze_test_points is run), insertion

Use this command to report statistics regarding the location of test points inside the design.

Usage

```
report_test_point_statistics [object_spec] [-top lines] [-columns column_names]  
[-sort {column ...}] [-add_columns column_names]
```

Description

The report_test_point_statistics command provides statistical information in a tabular format regarding the dispersion of test points throughout the design. This can help identify parts of the design that can be modified for greater controllability and/or observability and to reduce the number of test points needed.

By default, when no arguments or switches are specified, the output includes a row for each instance in the design that includes at least one test point. Each row will contain the module name (if the name is not unique it will include an asterisk followed by a unique index), columns that include the number of test points, control points and observe points in the specified instance (including test points in submodules below the module), and the full path to the instance.

The lines will be sorted in descending order according to the number of test points.

Note

 The command is only available after test point analysis and insertion of test points.

Arguments

- *object_spec*
An optional value that specifies a Tcl list of one or more modules or instances in the design, that controls which instances will be reported.
- *-top lines*
An optional switch and integer pair that specifies the number of the top rows of the report to be printed, not including the header.
- *-columns {*columns* ... }*
An optional switch that specifies to organize the output format according to a specified list of columns. The allowed columns are:
 - module
 - test_points
 - control_points

- observe_points
- instance

This switch also allows you to change the order of the columns and/or hide default columns.

- -sort *column*
An optional switch and column name that sorts the output rows according to the value of the specified column in descending order. Default is to sort according to the test_points column.
- -add_columns *column_names*
An optional list of columns to append after the columns specified by the -columns switch (or after the default columns).

Examples

Example 1

The following example prints the top two rows of the default report.

```
report_test_point_statistics -top 2
```

```
// command: report_test_point_statistics -top 2
=====
module          test_points  control_points  observe_points  instance
-----
MT_GET (top)    21 (100.0%)   14 (100.0%)    7 (100.0%)    /
MT_SET_DATA_WIDTH32 19 (90.5%)   14 (100.0%)    5 (71.4%)    /MT_BLK
```

Example 2

The following example reports the test point statistics for the specified instances.

```
report_test_point_statistics {MT_SET_DATA_WIDTH32 LCG_DATA_WIDTH32_1}
```

```
// command: report_test_point_statistics {MT_SET_DATA_WIDTH32 LCG_DATA_WIDTH32_1}
=====
module          test_points  control_points  observe_points  instance
-----
MT_GET (top)    21 (100.0%)   14 (100.0%)    7 (100.0%)    /
MT_SET_DATA_WIDTH32 19 (90.5%)   14 (100.0%)    5 (71.4%)    /MT_BLK
LCG_DATA_WIDTH32_1 3 (14.3%)    3 (21.4%)     0 (0.0%)     /MT_BLK/LCG2
```

report_test_setup_icall

Context: dft, patterns -scan, patterns -scan_diagnosis, patterns -scan_retargeting

Mode: setup

Reports a single view of all existing iCalls specified with the set_test_setup_icall command.

Usage

```
report_test_setup_icall
```

Description

Reports a single view of all existing iCalls specified with the set_test_setup_icall command.

Each iCall is reported as follows:

```
iCall iproc_name [arguments ...]
```

When multiple iCalls are merged, the command reports these iCalls within the “iMerge –begin” and “iMerge –end” as follows:

```
iMerge -begin  
  iCall iproc_name [arguments ...]  
  ...  
iMerge -end
```

Arguments

None.

report_test_stimulus

Context: dft -edt, patterns -scan

Mode: analysis

Displays the stimulus necessary to satisfy the specified set, write, or read conditions.

Usage

```
report_test_stimulus
  -Set {{id# | pin_path_name} {0 | 1 | Z}}...
  |-Cycle_set {[F]Irst_events | [L]Eading_edge_events | [LAst_events]
    {{id# | pin_path_name} {0 | 1 | Z} cycle#}...}...
  |-Write {{id# | instance_name} address_values [data_values]}...
  |-Read {{id# | instance_name} address_values}...
  |-RWx {{id# | instance_name} address_values}...
  |-SENsitize {{id# | instance_name | pin_path_name}
    [-Observe_at {id# | instance_name | pin_path_name} [-Expect {0 | 1 | X | Z}]]}
  |-Port port_number
  [-Verb[ose] | -Noverbose] [-PRevious] [-STore] [> | >>] file_pathname]
```

Description

Displays the stimulus necessary to satisfy the specified set, write, or read conditions.

This command identifies how to sensitize scan chain blockage points. For example, if you first delete all scan groups and then go to the ATPG system mode, you can issue the report_test_stimulus command for possible conditions to satisfy sensitization. That is, if the blockage was at an AND gate, you can try to set an input of the gate to 1.

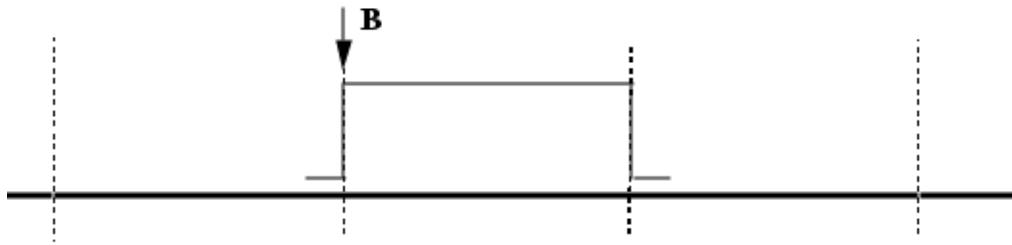

If test generation is successful, the stimulus necessary to satisfy the specified conditions is displayed. The stimulus for scan cells is identified by the gate index number, instance name, and cell ID number of the scan chain.

You can access the simulated values for internal gates by using the set_gate_report command with a parallel_pattern of 0.

You can also use the “report_test_stimulus -Cycle_set” command to specify the conditions at different event times or test cycles for analysis (for example, sequential controllability analysis and transition fault analysis). Each test cycle consists of at most three sets of events (clock-off, leading edge, and trailing edge) simulated in a single cycle. The following is a description of what determines the set of events within which the justified/simulated event occurs:

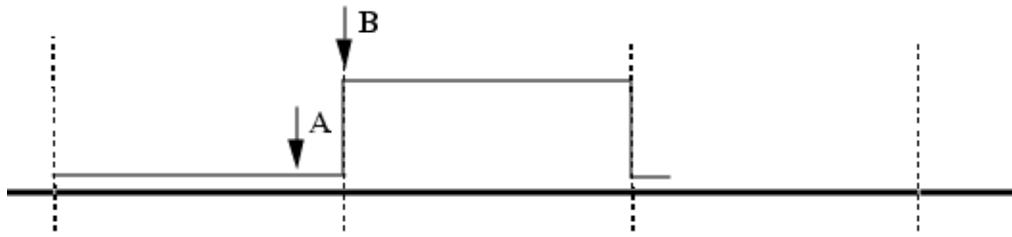

- When both “clock-off simulation” and “split capture” are turned off (the default unless the “set_clock_off_simulation On” and “set_split_capture_cycle On” commands are issued or set by ATPG Expert), a cycle includes one set of simulation events; that is, there are no clock-off events and the leading edge and the trailing edge are handled in one time frame. The simulation occurs at point B as shown in [Figure 5-11](#).

Figure 5-11. set_clock_off_simulation Off and set_split_capture_cycle Off

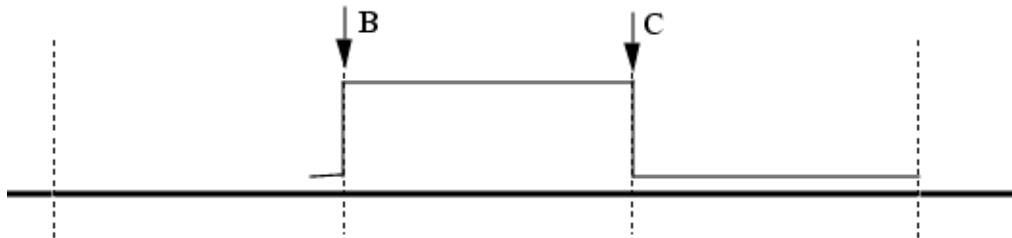

- When “clock-off simulation” is turned on and “split capture” is turned off, a cycle includes two sets of simulation events: clock-off events, and the events handling both the leading edge and the trailing edge events. The two simulation points for this case are at points A for clock-off events and B for leading and trailing edge events with “split capture” off as shown in [Figure 5-12](#).

Figure 5-12. set_clock_off_simulation On and set_split_capture_cycle Off

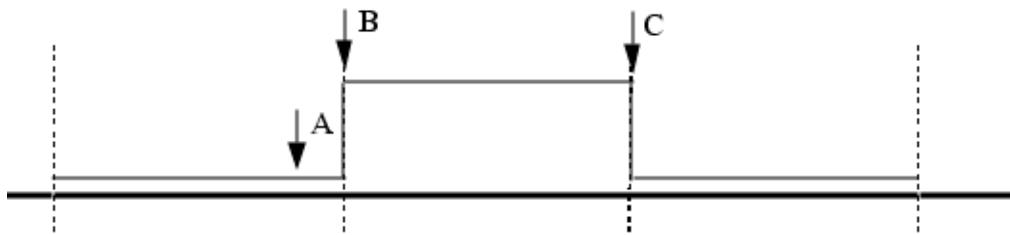

- When “clock-off simulation” is turned off and “split capture” is turned on, a cycle includes two sets of simulation events: the leading edge and trailing edge events. For this case (as shown in [Figure 5-13](#)), the simulation points are point B for the leading edge events and point C for the trailing edge events. Turning on “split capture” is necessary if a leading edge flip-flop feeds a trailing edge flip-flop in the functional path.

Figure 5-13. set_clock_off_simulation Off and set_split_capture_cycle On

- When both “clock-off simulation and” “split capture” are turned on, a cycle includes three sets of events: clock-off, the leading edge, and the trailing edge. [Figure 5-14](#) includes the three simulation points: A for clock-off, B for leading edge, and C for trailing edge events.

Figure 5-14. set_clock_off_simulation On and Set Split Capture On

Arguments

- **-Set *id# | pin_path_name* 0 | 1 | Z**

A switch with a repeatable argument and literal pair that specifies the pin and its value for which you want to generate the appropriate stimulus. You may specify multiple argument pairs with a single -Set switch.

id# — An integer that specifies the identification number of the gate for which you want to set the output pin. The gate cannot be a RAM or ROM gate.

pin_path_name — A string that specifies the pathname of the pin you want to set.

0 — A literal that sets the *id#* or *pin_path_name* to 0.

1 — A literal that sets the *id#* or *pin_path_name* to 1.

Z — A literal that sets the *id#* or *pin_path_name* to Z.

- **-Cycle_set {[-FIrst_events | -LEading_edge_events | -LAst_events] { {*id# | pin_path_name*} {0 | 1 | Z} *cycle#*} ...}**

A switch and repeatable argument, literal, and number set that specifies the pin, its value, and the cycle to set the value at the pin for which you want to generate the appropriate stimulus.

The events switches determine when the value is justified/simulated in the cycle. The events switches hold for all triples (pin, value, cycle) specified thereafter until another events switch is specified in the same command. For example, you can specify “report_test_stimulus -first <triple> <triple> -last <triple>” rather than “report_test_stimulus -first <triple> -first <triple> -last <triple>”.

-FIrst_events — A switch that sets the value of all pin triplets following this switch when the first events are simulated. If the “set_clock_off_simulation On” command has been issued or set by ATPG Expert, this event is the clock-off simulation; otherwise, it is always the present leading edge event simulation.

-LEading_edge_events — A switch that sets the value of all pin triplets following this switch at the leading edge event simulation. ATPG always has one set of events, called the “leading edge,” that it simulates by default in all cycles. Leading edge always refers to that one possibility.

-LAst_events — A switch that sets the value of all pin triplets following this switch in the last set of simulation events that occur in every cycle. This is the default. If the “set_split_capture_cycle On” command was issued or set by ATPG expert, this event

is the trailing edge events simulation. By default, the value of all pins is set at the trailing edge event in the cycle if an events switch is not specified in the -Cycle_set switch. Also, when there are several -Cycle_set switches specified in the same command line, each -Cycle_set switch resets its default time frame to the trailing edge frame regardless of the time frame specified in the previous -Cycle_set switch.

id# — An integer that specifies the identification number of the gate for which you want to set the output pin. The gate *id#* cannot be a flattened RAM or ROM gate.

pin_path_name — A string that specifies the pathname of the pin you want to set.

0 — A literal that sets the *id#* or *pin_path_name* to 0.

1 — A literal that sets the *id#* or *pin_path_name* to 1.

Z — A literal that sets the *id#* or *pin_path_name* to Z.

cycle# — An integer that specifies the post-load capture cycle in which the event is to occur.

With named capture procedures, the first cycle after the first scan load is “1”, the second cycle after first scan load is “2”, and so on.

Without named capture procedures, “1” indicates the cycle may be anywhere in the window and can “slide” within the allocated depth. The *cycle#* earlier is always “0” if it exists, before that “-1” if it exists, and so on. The *cycle#* after “1” is always “2”, and so on. For example, if the depth is set to 1 by you or ATPG Expert, then there is only cycle “1”. If the depth is set to 2, the cycles could be numbered “0” then “1” or “1” then “2”. In this case, if you specified “0” and “1” for *cycle#*, the cycles are the first and second cycles and there is no cycle “2”. However, if you specified “1” and “2” for *cycle#*, the cycles are the first and second cycles, and there is no cycle “0”.

Note

 When used without named capture procedures, -Cycle_set is not constrained from satisfying control requirements in the observation cycle(s). Therefore, it is possible for it to succeed although ATPG (stuck-fault, transition fault, MacroTest read/observe pattern, etc.) would fail, because they typically will have reserved at least one observation cycle. Such false successes can be prevented by temporarily reducing depth to artificially reserve observation cycle(s), or by scheduling a clock pulse or some other event in each observation cycle. Each solves the false success problem by creating -cycle_set compatibility with the cycle requirements imposed upon ATPG for it to succeed. If -Cycle_set fails, ATPG should also.

- **-Write *id# | instance_name address_values data_values***

A switch with a repeatable argument that specifies the RAM to which you want to write and, optionally, its address and data values. You may specify multiple argument triplets with a single -Write switch. The switch arguments are:

id# — An integer that specifies the identification number of the RAM gate to which you want to write.

instance_name — A string that specifies the pathname of the RAM instance to which you want to write.

address_values — A required character string consisting of 0's and 1's that specifies the values you want to place on the RAM address lines. The least significant value must be the last character in the string. The number of characters in the string must not exceed the number of RAM address lines available.

data_values — An optional character string consisting of 0's, 1's, and X's that specifies the values you want to place on the RAM data lines. The least significant value must be the last character in the string. The number of characters in the string must not exceed the number of RAM data lines available.

If you do not specify the -Port switch, the command assumes the first port (port 0).

- **-Read *id# | instance_name address_values***

A switch with a repeatable argument that specifies the RAM from which you want to read and, optionally, its address value. You may specify multiple argument pairs with a single -Read switch.

id# — An integer that specifies the identification number of the RAM gate from which you want to read.

instance_name — A string that specifies the pathname of the RAM instance from which you want to read.

address_values — A required character string consisting of 0's and 1's that specifies the values you want to place on the RAM address lines. The least significant value must be the last character in the string. The number of characters in the string must not exceed the number of RAM address lines available.

If you do not specify the -Port switch, the command assumes the first port (port 0).

- **-RWx *id# | instance_name address_values***

A switch that allows a port read to be combined with a port write by combining -write and a -previous option in the commands after -rwx. Both the read and write enables of the RAM are then asserted together. The switch arguments are:

id# — An integer that specifies the identification number of the RAM gate from which you want to read.

instance_name — A string that specifies the pathname of the RAM instance from which you want to read.

address_values — A required character string consisting of 0's and 1's that specifies the values you want to place on the RAM address lines. The least significant value must be the last character in the string. The number of characters in the string must not exceed the number of RAM address lines available.

- **-SENSitize *id# | instance_name / pin_path_name***

A switch that allows any primitive pin or pins to be targeted for sensitization; RAM pin, RAM port, ROM pin, ROM port, MUX output pin, MUX input pin, and so on. The conditions necessary to observe the output pins (or pin) of that primitive are calculated and reported.

Note

 The -SENsitize argument, like [macrotest](#), uses a functional observation technique, unlike the basic ATPG algorithm for structural faults. Consequently, there must be a single sensitizable path from the site to be observed to some observation site (scan cell or observable PO). The sensitizable path must be through combinational gates (specifically, no sequential). If the tool can sensitize this path, then ATPG should succeed. If the tool cannot sensitize this path, then ATPG will fail. This failure, however, indicates nothing about why a fault site is untestable, and you cannot make any conclusions about why ATPG is failing.

By issuing successive -sensitize options with different pin path names while also including the -previous option, you can find (and store with -store) the conditions that would allow a test to observe multiple sites simultaneously, even though they are driven by the outputs of different primitives. In this way, you can specify more than one pin for simultaneous observation. If a single primitive has multiple outputs, such as a RAM, and only the RAM instance name is given, all of the outputs of the RAM will be observed simultaneously, or a report of failure to sensitize will be issued. The switch arguments are:

id# — An integer that specifies the identification number of the RAM gate from which you want to read.

instance_name — A string that specifies the pathname of the RAM instance from which you want to read.

pin_path_name — A string that specifies the pathname of the pin that you want to sensitize.

-Observe_at *id# | pin_path_name | instance_name*

Specifies where the sensitized primitive output should be observed (latched for comparison). The -observe_at switch only applies to the -Sensitize switch when a single pin is specified. It is possible to specify multiple -Sensitize/-Observe_at pairings by using the -Previous option. If non-interfering paths cannot be created between all simultaneously active -Sensitize/-Observe_at points, a message is issued, and the run terminated.

-Expect 0 | 1 | X | Z

The -expect modifier also only applies if a -sensitize option is given on the same command line. It is followed by the expected output value for the primitive to be sensitized (either 0, 1, or X). The X value can also be specified using lower case x, and means unspecified output value. For example, if a RAM is being sensitized, then one output value for each output bit of the RAM must be specified if output values are given using -expect. The bits should be specified in the same order as the RAM's outputs. If a RAM named mem1 is specified with outputs Dout<7>...Dout<0>, then if the expected outputs are included, there must be 8 expected values starting with the expected value for Dout<7> as the leftmost bit. For example, 1000000x after -expect could be used to specify that the RAM's outputs are expected to be 1 for Dout<7>, and 0 for all other bits except Dout<0>, the expected output of which is Unknown or Don't Care. If this RAM's outputs were sensitized to scan latches along an inverting

path, 0111111X would be stored as the expected latched results to be scanned out as the test results.

- **-Port *port_number***

An optional switch and integer pair that specifies the identification number of the port to use for reading or writing RAM. The port identification number is zero-based; that is, the first port is “port 0”. The default is 0.

- **-Verbose**

An optional switch that displays the pattern that the command creates to satisfy the specified settings. This is the default.

- **-Noverbose**

An optional switch that specifies to not display the pattern that the command creates to satisfy the specified settings.

- **-PPrevious**

An optional switch that retains the settings from the previous report_test_stimulus command and adds them to the current settings. When this switch is used, the command displays all of the retained settings. The default is to not retain the settings.

- **-STore (not available in Tesson TestKompress (EDT On))**

An optional switch that places the command-created pattern in the internal test pattern area. You can then write this pattern to a file, in any format, by using the write_patterns command. The default is to not place the pattern in the internal test pattern area.

- **> *file_pathname***

An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.

- **>> *file_pathname***

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

Example 1

The following example command line is used for determining what stimulus is needed to write 11011 to address location 01011 for a RAM gate (gate ID number is 67):

```
set_system_mode analysis
report_test_stimulus -write 67 01011 11011
```

The following is an example of the display from the previous command line:

```
// Time = 0
// Force 1 /W1 (1)
// Force 0 /A1[4] (2)
// Force 1 /A1[3] (3)
// Force 0 /A1[2] (4)
// Force 1 /A1[1] (5)
// Force 1 /A1[0] (6)
// Force 0 /OE (7)
// Force 1 /D1[0] (14)
// Force 1 /D1[1] (15)
// Force 0 /D1[2] (16)
// Force 1 /D1[3] (17)
// Force 1 /D1[4] (18)
```

Example 2

The following example command lines display the stimulus necessary to satisfy the specified conditions at different event times or test cycles. It is assumed that both “split capture” and “clock-off simulation” are turned on, and you want to determine if a slow-to-fall transition can be launched at the output pin of gate 245.

`report_test_stimulus -cycle_set 245 1 0 245 0 1`

In this example, logic 1 is set at the default/last event (trailing due to split capture) simulated in cycle 0, and logic 0 is set at the default/last event (trailing due to split capture) simulated in cycle 1.

`report_test_stimulus -cycle_set -leading_edge 245 1 0 245 0 1`

In this example, logic 1 is set at the leading edge event of cycle 0, and logic 0 is set at the leading edge event of cycle 1.

`report_test_stimulus -cycle_set -first_events 245 1 0 245 0 1`

In this example, logic 1 is set at the first event (clock-off) simulated in cycle 0, and logic 0 is set at the first event (clock-off in this example) of cycle 1.

`report_test_stimulus -cycle_set -first_events 245 1 0 -last_events 245 0 1`

In this example, logic 1 is set at the first (clock-off) event simulated in cycle 0, and logic 0 is set at the last event (trailing edge) simulated in cycle 1.

Example 3

In the following example command lines, it is assumed only split capture is turned on, and you want to determine if a slow-to-rise transition can be launched at the output pin of gate 245.

`report_test_stimulus -cycle_set 245 0 1 245 1 2`

In this example, logic 0 is set at the default/last (trailing due to split capture) event simulated in cycle 1, and logic 1 is set at the default/last (trailing due to split capture) event simulated in cycle 2.

report_test_stimulus -cycle_set -leading_edge 245 0 1 245 1 2

In this example, logic 0 is set at the leading edge event of cycle 1, and logic 1 is set at the leading edge event of cycle 2.

report_test_stimulus -cycle_set -first_events 245 0 1 245 1 2

In this example, logic 0 is set at the first (leading-edge) event simulated in cycle 1, and logic 1 is set at the first (leading-edge in this example) event of cycle 2.

report_test_stimulus -cycle_set -first_events 245 0 1 -last_events 245 1 2

In this example, logic 0 is set at the first (leading_edge) event simulated in cycle 1, and logic 1 is set at the last (trailing edge in this example) event simulated in cycle 2.

report_testbench_simulation_options

Context: unspecified, all contexts

Mode: all modes

Reports the default values for many options used in the [run_testbench_simulations](#) command.

Usage

```
report_testbench_simulation_options [-simulator {questa | vcs}]
```

Description

Reports the default values for many options used in the [run_testbench_simulations](#) command.

Arguments

- `-simulator questa | vcs`

A switch and literal that specifies the simulator you want to use for simulation. The default value is “questa” from Mentor Graphics. The other option is vcs from Synopsys.

Examples

The following example shows the result of the `report_testbench_simulation_options` command before any default value was changed and after the simulation output directory default value was changed.

```
SETUP> set_context patterns
SETUP> set_testbench_simulation_options -simulation_output_directory ./my_sim_outdir
SETUP> report_testbench_simulation_options

// Testbench simulation options
// =====
// -----
// Option           Value
// -----
// default_simulator      questa
// simulation_output_directory    ./my_sim_outdir
// keep_simulation_data      on_failure
// store_simulation_waveforms   off
// simulation_timeout        unlimited
// parallel_simulations       1
// simulator_options          {}
// waveform_configuration_commands {log -r /*; run -all; exit}
//
```

report_tied_signals

Context: all contexts

Mode: all modes

Displays a list of the tied floating signals and pins.

Usage

```
report_tied_signals [-Class {Full | User | System}] [{>} | >>] file_pathname]
```

Description

Displays a list of the tied floating signals and pins.

The report_tied_signals command displays either the user class, system class, or full classes of tied floating signals and pins. If you do not specify a class, the command displays all the tied floating signals and pins.

Arguments

- **-Class Full | User | System**

An optional switch and literal pair that specifies the source (or class) of the tied floating signals or pins which you want to display. The literal choices are as follows:

Full — A literal that displays all the tied floating signals or pins in the user and system class. This is the default.

User — A literal that displays only the tied floating signals or pins created using the add_tied_signals command.

System — A literal that displays only the netlist-described tied floating signals or pins.

- **>file_pathname**

An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.

- **>>file_pathname**

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

The following example displays the tied floating signals from the user class:

```
add_tied_signals 1 vcc vdd
report_tied_signals -class user
```

report_timeplate

Context: dft -edt, dft -scan, dft -test_points, patterns -ijtag, patterns -scan, patterns -scan_retargeting, patterns -failure_mapping

Mode: setup, analysis

Displays the specified timeplate.

Usage

```
report_timeplate {timeplate_name | -All} [-COre core_name [-MOde mode_name]] [{> | >>}  
file_pathname]
```

Description

Displays the specified timeplate.

The report_timeplate command displays all timeplates or the specified timeplate.

Arguments

- ***timeplate_name***

A string that specifies which timeplate to display.

- **-All**

A switch that specifies for the tool to display all timeplates. This is the default.

- **-COre *core_name***

An optional switch and string pair that specifies that the tool reports the timeplate for a given core. The core must exist, or an error will be issued.

- **-MOde *mode_name***

An optional switch and string pair that specifies that the tool reports the timeplate for the given mode of a core defined by the -core *core_name* switch. The tool reports an error if this switch is specified without the -core switch. This switch is not necessary when there is only one mode for a core. If a core has more than one mode, an error will be issued if the mode is not specified.

- **> *file_pathname***

An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.

- **>> *file_pathname***

An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

Example 1

The following example displays the timeplate named *tp1*.

report_timeplate tp1**Example 2**

The following example shows using the -EXpand_iprocs switch to work with the set of used ports and vector callbacks in:

ANALYSIS> report_timeplate test_setup --expand_iprocs

```
procedure test_setup =
    timeplate tp1 ;
    iReset;
    // Begin expanded iCall m8051_B1_edt_i.setup edt_low_power_shift_en on ;
    // cycle 1 start at time 40
    cycle =
        annotate "+ Targets: ..."
        ...
    end;
    // End expanded iCall
    // cycle 5 starts at time 200
    cycle =
        ...
    end;
end;
```

Example 3

This is an example of using report_timeplate with the -core switch:

report_timeplate -core piccpu_maxlen16_1

```
timeplate gen_tp1 =
    force_pi 0 ;
    measure_po 100 ;
    pulse core_1_clk 200 100;
    pulse core_1_edt_clock 200 100;
    pulse core_1_ramclk 200 100;
    period 400 ;
end;
```

report_udfm_statistics

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: analysis

Reports detailed fault coverage based on the UDFM defect models.

Usage

```
report_udfm_statistics [-INstance pathname...] [-Groups name ...]  
[-GROUPS_Only {On | Off}] [-Percent {On | Off}] [-SET_Baseline]  
[(> | >>) file_name]
```

Description

Reports detailed fault coverage based on the UDFM defect models. The report contains columns for DS, DI, PT, TI, BL, RE, AU, UC, UO, UU, PU faults.

The report contains the following information as well as any additional columns you specify.

If no group is defined as a result of executing the command, by default every defect model is reported in a single row. The column headings are as follows:

- Type — Lists the UDFM type name that belongs to the defect model. For groups that collect defect models from multiple UDFM types, “---” is reported.
- Block — Identifies the object the defect model is defined on: Module, Cell, or Instance. For groups that collect different defect models, “---” is reported.
- Name — Lists the defect specific module, cell or instance name. For groups, the specified string is reported.
- Instances — Lists the number of instances of the specified module, cell, or instance identified in the design. This number is always greater zero because defect models that cannot be matched to an instance of the circuit are not reported.
- Port-Insts — Lists the number of instances where only port faults are active (that is, these instances have no cell internal faults). The information allows you to see if specific defects other than traditional port faults are targeted. The numbers in this column mean the following:
 - Port-Insts=0 — The UDFM definition contains fault definitions for cell internal defects. This means that not just port faults are targeted.
 - Port-Insts=Instances — When these two columns list the same number, the UDFM definition contains fault definitions for port faults only. This can be the case when fault sites have been added by using the add_fault_sites command.
 - Port-Insts > 0 and < Instances — Even if the UDFM definition contains a fault definition for cell internal defects, the cell-internal defects may have been dropped from the count because the flip-flop isn't part of a scan chain.

- Faults — Lists the number of faults that exist due to the specified defect model or group.
- Add-DT — Lists the difference between the stored baseline and the current status for detected faults (DT). This column displays only if there was a previous call of this function to store the baseline.
- GN — Lists the coverage gain between the stored baseline and the current status with $GN=(Add-DT/(DS+DI+PT+AU+UC+UO+PU)*100)$. This column displays only if there was a previous call of this function to store the baseline.

Arguments

- -INstance *pathname* ...

An optional switch and repeatable string that limits the report of UDFM statistics to one or more specific instances. The pathname argument specifies the name of a circuit block.

- -Groups *name* ...

An optional switch and repeatable string that defines a group of UDFM defect models based on the specified *name* string(s). You can specify multiple name arguments to create multiple groups. Each *name* string creates one group. The *name* string may include any number of asterisk (*) and/or question mark (?) wildcard characters.

For example, the following string creates two groups: one with all defect models that contain an “AND” in their name and another with all defect models that contain an “OR” in their name.

```
-Groups *AND* *OR*
```

All matching models are collected regardless of whether they are a module, a cell, or an instance. Note that in the case of multiple group names, the command adds individual models to only one group, which is the first group name in the list that matches a particular model.

- -GROUPS_Only On | Off

An optional switch and literal pair that specify how UDFM defect models that do not match any of the defined groups are reported. By default, all UDFM defect models that do not match any of the defined groups are reported in a single row. If -GROUPS_Only is set to On, this row is not created.

- -Percent On | Off

An optional switch and literal pair that specify to report individual fault classes as an integer or as a percentage. By default, the values of the individual fault classes are reported as a percentage. When this switch is set to off, fault classes are reported as an absolute number.

- -SET_Baseline

An optional switch that specifies for the tool to store the current coverage information as a baseline so that subsequent report_udfm_statistics commands can add information about the coverage gain. Note that the baseline becomes invalid if the fault list is modified, for

example, by an [add_faults](#) or [delete_faults](#) command. The baseline also becomes invalid if you subsequently specify a different pathname with the -Instance switch.

Examples

Example 1

In this example, the command generates a detailed fault coverage report based on the UDFM defect models. The report contains columns for DS, DI, PT, TI, BL, RE, AU, UC, UO, UU, PU.

report_udfm_statistics

Note

 Please note that due to space some fault class columns in the report have been removed.

report_version_data

Context: unspecified, all contexts

Mode: all modes

Displays the current software version information.

Usage

```
report_version_data [{> | >>} file_pathname]
```

Description

Displays the current software version information.

The report_version_data command displays information relating to the software title, version, and date.

Arguments

- `>file_pathname`
An optional redirection operator and pathname pair for creating or replacing the contents of *file_pathname*.
- `>>file_pathname`
An optional redirection operator and pathname pair for appending to the contents of *file_pathname*.

Examples

The following is an example of the output this command:

```
report_version_data
```

```
Version data: Tesson Shell 2012.3   Wed Sep 05 21:31:33 GMT 2012
```

report_wrapper_cells

Tools Supported: DFTAdvisor

Scope: Dft

Context: dft -scan

Mode: analysis

Reports information about the identified wrapper cells for each I/O port subjected to wrapper cell identification.

Usage

```
report_wrapper_cells [-Summary | -Verbose]
```

Description

Reports information about the identified wrapper cells for each I/O port subjected to wrapper cell identification.

If you specify no arguments, the tool reports the following information for each I/O:

- Primary I/O port name and its direction (Input or Output).
- Total number of sequential cells identified for this I/O.
- Whether the IO's wrapper cell will be a dedicated wrapper cell or an existing (shared) cell.
- The reason the cell was promoted to being a shared wrapper cell, or if wrapper cell identification failed the reason for the failure. For a description of all possible failures see [Table 5](#)Table 1-1

If you specify -Verbose, in addition to the above information, the tool reports the following:

- Identified wrapper cell path names for each I/O that succeeded the identification or “new cell” for the I/Os that failed wrapper cell identification and are subject to I/O registration.
- Wrapper chain type indicates whether the corresponding identified wrapper cell is part of the Input or Output wrapper chain.
- Clocks controlling both the identified wrapper cells and wrapper cells to be added.

If you specify -Summary, the tool reports the following:

- Total number of primary inputs.
- Total number of primary outputs.
- Total number of identified wrapper cells.
- Total number of added wrapper cells.

Table 5-18. Reason for Failed Identification

Reason Failed Identification	Description
Max Logic Level	Exceeded the integer limit on the number of combinational logic levels between this PI/PO and the first level of sequential cells.
Max Fan In	Exceeded the integer limit on the total number of fanins at the instance.
Max Fan Out	Exceeded the integer limit on the total number of fanouts at the instance.
Combinational Feed-thru	Encountered no sequential cells or combinational logic other than buffers/inverters before reaching PO/PI: port_name.
Seq Feed-thru	Encountered no combinational logic and just one sequential cell before reaching PO/PI: port_name.
Combinational Logic Only	Encountered combinational logic only before reaching PO/PI: portname.
Black Box Instance	Encountered a blackboxed instance: instance_name.
Pre-Existing Scan Cell	Encountered a sequential cell belonging to a pre-existing scan chain: instance_name.
Non-Scan Sequential Cell	Encountered a non-scan sequential cell: instance_name
Input Wrapper Cell	Encountered a sequential cell that was already identified as an output or input wrapper cell: instance_name.
Max Identified Cells	Exceeded the integer limit on the number of sequential cells identified per PO/PI.
Max Combinational Gates	Exceeded the integer limit on the number of combinational logic gates traced per PO/PI.
No Cells Identified	Unconnected or floating PO/PI.
Scan-in Pin	Port is a scan-in pin. Port is in the I/O registration list and will be registered.
Scan-out Pin	Port is a scan out pin. Port is in the I/O registration list and will be registered.
Driving a Scan-in	Port is driving a scan-in pin pin_name. Port is in the I/O registration list and will be registered.
Driven by a Scan-out	Port is driven by a scan-out pin pin_name. Port is in the I/O registration list and will be registered.
Input Subchain	Encountered a sequential cell belonging to a subchain that was assigned to an Input wrapper chain: inst-name.

Table 5-18. Reason for Failed Identification (cont.)

Reason Failed Identification	Description
Output Subchain	Encountered a sequential cell belonging to a subchain that was assigned to an Output wrapper chain: inst-name.
Subchain or Multibit Cell	Encountered a subchain or multibit cell with scan cells inside it not reachable from PIs/POs.
Input Subchain or Multibit Cell	Encountered a subchain or multibit cell that was already identified as an output wrapper cell.
Output Subchain or Multibit Cell	Encountered a subchain or multibit cell that was already identified as an input wrapper cell.
Not Traced Subchain Cell	Encountered a sequential cell belonging to a subchain whose internal scan path is not known: inst-name.
Unidentified failure	The reason for failure cannot be identified.

Arguments

- **-Summary**
An optional switch. For information about this switch, refer to the above description.
- **-Verbose**
An optional switch. For information about this switch, refer to the above description.

Examples

Example 1

The following example shows the output generated when the report_wrapper_cells command is executed without the -verbose or -summary switch.

```
report_wrapper_cells
> report_wrapper_cells
-----
Primary I/O # Shared Wrapper Cells      Shared/      Reason
Port          (Direct/Internal-Feedback) Dedicated
              Identified [32/32]           Wrapper Cell
-----
'po' (O)     1                         shared       --
'pi' (I)     1/0                       shared       --
'cen4' (I)   1/0                       shared       clock_gater promoted
'cen5' (I)   1/0                       shared       clock_gater promoted
-----
```

Example 2

The following example shows the output generated when the report_wrapper_cells command is executed with the -summary switch.

```
report_wrapper_cells -summary
```

Command Dictionary (R) **report_wrapper_cells**

```
> report_wrapper_cells -summary
-----
Inputs   Outputs  Shared Wrapper Cells  Inferred Dedicated
(#[#)      (#[#)    Identified (#[#)        Wrapper Cells (#[#)
-----
17       5         3                   0
-----
```

Example 3

The following example shows a snippet of the output generated when the report_wrapper_cells command is executed with the -verbose switch.

report_wrapper_cells -verbose

```
> report_wrapper_cells -verbose
-----
Primary I/O # Shared Wrapper Cells      Wrapper  Wrapper  Clock     Shared/      Reason
Port          (Direct/Internal-Feedback) Cell     Cell      Type
Identified [32/32]           Name      Type
-----
'po' (O)    1           'ff1'    input    'gclk1'  shared    --
'pi' (I)    1/0        'ff1'    input    'gclk1'  shared    --
'cen4' (I)  1/0        'ff4'    output   'clk4'   shared
clock_gater promoted

clock_gater promoted
-----
The wrapper cells identification has failed for the following PIs and POs.
Dedicated wrapper cells will be added to these PIs and POs unless specifically excluded
by the user.
-----
'pi4'           input                           Encountered
combinational logic only before reaching PO: 'pol'
                                         No dedicated
wrapper cells will be added to this PI based on user specifications.
'pol'           output                          Encountered
combinational logic only before reaching PI: 'pi4'
                                         No dedicated
wrapper cells will be added to this PO based on user specifications.
-----
No dedicated wrapper cells will be added to these PIs and POs unless explicitly specified
by the user.
-----
'cen1'           input                           Constrained port
'clk1'           input                           Clock port
'pil'            input                           Unconnected or
blocked PI
'po2'           output                          Unconnected or
blocked PO
-----
```

report_write_controls

Context: dft -edt, dft -scan, dft -test_points, patterns -scan,
patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup, analysis

Displays the currently defined write control lines and their off-states.

Usage

`report_write_controls [> | >>] file_pathname]`

Description

Displays the currently defined write control lines and their off-states.

The report_write_controls command displays the write control lines, with corresponding off-states, added using the add_write_controls command.

Arguments

- `> file_pathname`
An optional redirection operator and pathname pair for creating *or* replacing the contents of *file_pathname*.
- `>> file_pathname`
An optional redirection operator and pathname pair for appending to the contents of *file_pathname*.

Examples

The following example adds four write control lines and then displays a list of the control line definitions:

```
add_write_controls 0 w1 w3
add_write_controls 1 w2 w4
report_write_controls
```

report_write_patterns_options

Context: patterns -ijtag, patterns -scan, patterns -scan_diagnosis, patterns -scan_retargeting

Mode: setup, analysis

Displays the current set of ports or current set of vector callbacks to use when writing patterns.

Usage

Usage for Port Lists

```
report_write_patterns_options [-existing_used_ports | -additional_port_list  
| -all_used_port_list]
```

Usage for Vector Callbacks

```
report_write_patterns_options [-vector_callbacks]
```

Description

This command displays the current set of ports or current set of vector callbacks to use when writing patterns.

Port List Specifics

This command and options are used to display the current set of ports to use when writing patterns. The `-existing_used_ports` option displays only the current subset of existing design ports. The option `-additional_ports` displays only the additional ports that were not part of the original design ports. The `all_used_ports` option reports the current subset of existing design ports and any extra ports added with `-additional_ports`. The report is a tabular format which lists the port names, port direction the port is an additional port, and if the port is a clock and what its offstate is if it is a clock. If no subset exists, a message stating that there is no subset is issued, but the full list of default ports is then listed. If the `report_write_pattern_options` command is issued without any options, all `write_pattern_options` settings are reported (the `all_used_ports` and the vector callbacks).

Vector Callback Specifics

This command reports the current vector callback procs listing each callback proc name followed by a textual representation of any activation trigger. If the `report_write_pattern_options` command is issued without any options, all `write_pattern_options` settings are reported (the used ports and the vector callbacks).

Arguments

- `-existing_used_ports`
An optional switch that reports only the current subset of the existing design ports.
- `-additional_port_list`
An optional switch that reports only the additional ports that were not part of the original design ports.

- **-all_used_port_list**
An optional switch that reports the current subset of existing design ports and any extra ports added with -additional_ports.
- **-vector_callbacks**
An optional switch that reports the current vector callback procs.

report_xbounding

Context: dft -scan, dft -test_points

Mode: analysis

Reports the X-sources and optionally the scan cells used in bounding. You must issue this command to report X-bounding.

Usage

```
report_xbounding {[ -verbose { all | non_mcp_bounding_points | mcp_bounding_points } ]}  
[ -ignored_x_sources { on | off } ] [> | >> file_pathname]
```

Description

Reports the X-sources and optionally the scan cells used in bounding. You must issue this command to report X-bounding.

By default, this command reports a summary that includes the number of identified X-sources and also the number of control points that are required to block these X-sources from reaching any scan cells (or potential scan cells). The command can also be used to report the location of the X-bounding logic (typically muxes) as well as the control signals for the bounding logic.

Arguments

- **-verbose all | non_mcp_bounding_points | mcp_bounding_points**
An optional switch and optional literal that reports the location of the scan cells used in the bounding.
Choose one from the following:
 - all** — Reports all scan cells used in the bounding including non-MCP and MCP bounding points. This is the default.
 - non_mcp_bounding_points** — Reports only non-MCP bounding points.
 - mcp_bounding_points** — Reports only MCP bounding points.
- **-ignored_x_sources { on | off }**
An optional switch and literal that specifies to report X-sources that do not need to be bounded, and the reasons why they will not be bounded. The default is off.
- **> *file_pathname***
An optional redirection operator and pathname pair, used at the end of the argument list, for creating or replacing the contents of *file_pathname*.
- **>> *file_pathname***
An optional redirection operator and pathname pair, used at the end of the argument list, for appending to the contents of *file_pathname*.

Examples

The following example shows the tool's verbose output:

```
report_xbounding -verbose
// Analyzed 52 static x-sources and 1 flop that captures false/
// multi-cycle paths.
// Added 53 control points for x-bounding.
//      52 control points bounding static x-sources.
//      1 control point bounding false or multi-cycle paths.
MUX gate at /NEA(3) bounding mux is driven by existing flop at : /u12/
L_MSIZ_reg_7_/Q (326)
MUX gate at /NESFR(4) bounding mux is driven by existing flop at : /u12/
u1/L_SP_reg_0_/Q (323)
```

reset_attribute_value

Context: unspecified, all contexts

Mode: all modes

Resets an attribute to its default value for the design objects specified in *obj_spec*.

Usage

```
reset_attribute_value { obj_spec | -object_types type_list} -name attribute_name [-silent]
```

Description

Resets an attribute to its default value for the specified design objects or design object types.

Resetting an attribute differs from setting it to its default value in the fact that the *reset_attribute_value* also makes the attribute unspecified so it does not show up when the *report_attributes* and *get_attribute_list* commands are executed using Usage 1. The attribute's default value is specified during registration of the attribute.

This command returns the default value set for the attribute as a string.

If the *attribute_name* does not exist, or if a design object or object type does not exist, an error message displays unless *-silent* is specified.

Arguments

- ***obj_spec***

A switch that specifies a Tcl list of one or more object names or a collection of one or more objects.

- **-object_types *type_list***

A switch that specifies a list of object types for which the given attribute name is to be reset. As an example, using “*reset_attribute_value -name XXX -object_type instance*” is equivalent to specifying “*reset_attribute_value -name XXX [get_instances]*” but is more efficient and requires less memory and time when the number of objects for the given object type is large.

- **-name *attribute_name***

A required switch and value pair that specify the name of the attribute.

- **-silent**

An optional switch that specifies to suppress error messages if the *attribute_name* does not exist, or if an object in *obj_spec* does not exist.

Examples

Example 1

The following example shows how the command resets the added_by values for all nets to its default (“John”):

```
reset_attribute_value {u1/net1 u1/net2 u2/net3 u2/net4} -name added_by  
get_attribute_value_list {u1/net1 u1/net2 u2/net3 u2/net4} -name added_by  
{John John John John}
```

Example 2

The following example resets the my_constraint attribute on all pins and nets.

```
reset_attribute_value -name my_constraint –object_types {pin net}
```

reset_au_faults

Context: dft -edt, patterns -scan

Mode: analysis

Reclassifies the faults in certain untestable categories.

Usage

```
reset_au_faults [-REClassify]
```

Description

Reclassifies the faults in certain untestable categories.

Table 5-19 shows these categories.

Table 5-19. Untestable Faults that are Reclassified by reset_au_faults

Untestable Fault	Fault Reclassification
Possibly detected untestable (PU)	Possibly detected testable (PT)
ATPG untestable (AU) except for AU.LBIST (not reclassified)	Uncontrolled (UC)

Deterministic fault simulators classify some untestable faults differently depending on the algorithm. You can use the reset_au_faults command to align those (potentially) misclassified faults.

When the command changes the fault classification, the tool then has the ability to analyze and further reclassify each previously-untestable fault. Allowing the tool the ability to analyze and reclassify those particular untestable faults increases the tool's efficiency.

Arguments

- **-REClassify**

An optional switch that analyzes the AU faults to identify those which cannot be tested with the current settings. After resetting all AU faults, the tool will reclassify faults that are still untestable in the current mode back to AU. This switch is useful when reading in faults from a previous ATPG run, which has different settings or a different design configuration.

Reclassifying the faults to AU prior to pattern generation will improve performance. If you omit this switch, the tool does not reclassify the faults and resets all AU faults. See Example 2.

Examples

Example 1

The following example sets up the tool to run the simulation with an external pattern file and resets the ATPG untestable faults so that the tool can determine their appropriate fault category:

```
read_patterns testpatterns
read_faults /user/design/fault_file -retain
reset_au_faults
simulate_patterns
```

Example 2

The following example incrementally runs ATPG in two different modes, combining the results of each session, to target additional undetected faults and increase coverage.

Dofile 1

```
// set up design to run ATPG in mode 1
add_scan_groups grp1 testproc
add_scan_chains chain1 grp1 scan_in1 x_out[0]
add_scan_chains chain2 grp1 scan_in2 scan_out1
add_scan_chains chain3 grp1 scan_in3 scan_out2
add_clocks 0 rst
add_clocks 0 clk
add_input_constraints /G -C1

// generate patterns from mode 1 and write out faults
set_system_mode analysis
create_patterns
write_faults mode1.fault -replace
```

Dofile 2

```
// set up design to run ATPG in mode 2
add_scan_groups grp1 testproc
add_scan_chains chain4 grp1 scan_in4 y_out[2]
add_scan_chains chain5 grp1 scan_in5 x_out[5]
add_clocks 0 rst
add_clocks 0 clk
add_input_constraints /G -C1

// generate patterns from mode 2 and write out faults
set_system_mode analysis
read_faults mode1.fault -retain
reset_au_faults -reclassify
create_patterns
read_faults mode1.fault -merge
report_statistics
write_faults modes_1_and_2.fault -replace
```

reset_bypass_chains

Context: dft -edt, patterns -scan (EDT On), patterns -scan_diagnosis

Mode: setup

Removes user-specified EDT bypass chain connections.

Usage

```
reset_bypass_chains
```

Description

Removes user-specified EDT bypass chain connections.

The `reset_bypass_chains` command removes all EDT bypass chain connections that you previously defined using the `set_bypass_chains` command, and reverts determination of these connections to the tool.

Arguments

None

Examples

The following example displays information on all user-defined EDT bypass chains in a design with eight scan chains and two scan channels. The example then removes the definitions, and confirms that configuration of any EDT bypass chains will now be done automatically by the tool.

```
report_bypass_chains
//      Reporting user-defined bypass chains:
//
//      Bypass#  EDT chains
//      -----  -----
//      1        chain1, chain5, chain6
//      2        chain2, chain3, chain4, chain7, chain8

reset_bypass_chains
report_bypass_chains
//  No user-defined bypass chains to report.
```

reset_compactor_connections

Context: dft -edt, patterns -scan (EDT On), patterns -scan_diagnosis

Mode: setup

Removes user-specified EDT compactor connections.

Usage

```
reset_compactor_connections
```

Description

Removes user-specified EDT compactor connections.

The `reset_compactor_connections` command removes all EDT compactor connections that you previously defined using the `set_compactor_connections` command, and reverts determination of these connections to the tool.

Arguments

None

Examples

The following example displays information on all user-defined compactor connections in a design with eight scan chains and two scan channels. The example then removes the user-specified definitions. Configuration of compactor connections will now be handled automatically by the tool.

```
report_compactor_connections
//      Reporting user-defined compactor connections:
//      Channel  Chains
//      -----  -----
//      1        chain1, chain2, chain6, chain7, chain8
//      2        chain3 - chain5
```

```
reset_compactor_connections
report_compactor_connections
//  No user-defined compactor connections to report.
```

reset_design

Context: all contexts

Mode: setup

Clears all design setup data but keeps the design and library in memory.

Usage

`reset_design`

Description

Clears all design setup data but keeps the design and library in memory.

The command also retains the setting from the most recent [set_current_design](#) command execution.

Arguments

None

Related Topics

[delete_design](#)

[set_current_design](#)

reset_di_faults

Context: dft -edt, patterns -scan

Mode: analysis

Reclassifies DI faults to the UC category.

Usage

```
reset_di_faults {-ALL | -END_of_chains | -CHains [chain_name...]} | pin_pathname... }  
[-Stuck_at {01 | 0 | 1}] [-Both | -Rise | -Fall] [ -CELL_Output_only ]
```

Description

Reclassifies DI faults to the UC category.

The reset_di_faults command reclassifies det_implication (DI) faults to the uncontrolled (UC) category. When the fault type is stuck-at or transition, this command by default resets both stuck-at-0 (or slow-to-rise for transition faults) and stuck-at-1 (or slow-to-fall for transition faults) faults at each DI fault site. The command does not reclassify DI faults identified by other Tessonnt plugins, such as DI.MBIST and DI.MBISR faults identified by Tessonnt MemoryBIST. You can use one of the optional switches to reset just one, rather than both, faults at each DI fault site.

Use this command when you want faults that were previously classified as DI (and thus no longer targeted for detection) retargeted in the next ATPG and/or fault simulation run. For example, the tools currently declare scan path faults DI because they are tested by the chain test. This is not optimal in some cases; the end of each scan chain (after the last scan cell) is often used as a system path and it is sometimes desirable to create an at-speed transition fault test to exercise this path. The DI fault category prevents ATPG from targeting or simulating such faults. When the fault classification is changed to UC, the tool then has the ability to target the faults during ATPG and fault simulation.

Arguments

- **-ALL**
A switch that specifies for the tool to reset DI faults to UC. This is the invocation default.
- **-END_of_chains**
A switch that specifies to reset, for each scan chain, the scan path DI faults from the output of the last scan cell in the chain to the scan output pin.
- **-CHains [chain_name...]**
A switch and optional repeating string pair that resets DI faults, including scan input and output pin faults. If you do not specify a chain_name, the tool resets faults along all scan chains. You can optionally restrict the switch operation to one or more chain_names.

- ***pin.pathname...***

A repeating string that resets the DI faults on one or more pins. The *pin.pathname* must be an instance/pin name that exists in the flat model. These are typically model boundary pins, PIs, and POs.

- **-Stuck_at 01 | 0 | 1**

An optional switch and literal pair that specifies which DI faults to reset to UC. You should use this switch only if the fault type is stuck, although the tool accepts the switch regardless of fault type (see [set_fault_type](#)).

01 — A literal specifying that for stuck-at faults the tool reset both the “stuck-at-0” and “stuck-at-1” faults; or for transition faults the tool reset both “slow-to-rise” and “slow-to-fall” faults. This is the default.

0 — A literal specifying that for stuck-at faults the tool reset only the “stuck-at-0” faults; or for transition faults the tool reset only “slow-to-rise” faults.

1 — A literal specifying that for stuck-at faults the tool reset only the “stuck-at-1” faults; or for transition faults the tool reset only “slow-to-fall” faults.

- **-Both | -Rise | -Fall**

Optional switches that specify which transition faults to reset to UC. These switches apply to transition faults only:

-Both - An optional switch that specifies to reset both slow-to-rise and slow-to-fall transition faults. This is the default.

-Rise - An optional switch that specifies to reset only the slow-to-rise transition faults.

-Fall - An optional switch that specifies to reset only the slow-to-fall transition faults.

- **-CELL_Output_only**

Optional switch that reclassifies DI faults only on the scan output ports of scan cells.

Examples

Example 1

The following example resets all stuck-at-0 and stuck-at-1 DI faults (including clock faults) to UC.

reset_di_faults

Example 2

The following example resets all stuck-at-0 faults declared DI anywhere in the netlist.

reset_di_faults -stuck_at 0

Example 3

The following example resets stuck-at-0 and stuck-at-1 DI faults at the output of the last cell of each chain.

reset_di_faults -end_of_chain

Example 4

The following example resets only the slow-to-rise transition fault at the output of the last cell of each chain.

`reset_di_faults -end_of_chain -rise`

Example 5

The following example resets any DI fault anywhere along chain1.

`reset_di_faults -chain chain1`

Example 6

The following example resets both DI faults at pin /top/mid/bottom/Q (any type fault).

`reset_di_faults /top/mid/bottom/Q -stuck_at 01`

Example 7

The following example is equivalent to the preceding example, except that it applies to transition faults only.

`reset_di_faults /top/mid/bottom/Q -both`

Example 8

The following example uses the defaults to reset_di_faults at the specified location (any fault type).

`reset_di_faults /top/mid/bottom/Q`

Example 9

The following example resets only the slow-to-rise transition fault at the specified location.

`reset_di_faults /top/mid/bottom/Q -rise`

Example 10

The following example resets only the stuck-at-1 fault (or slow-to-rise if transition fault) at the specified location.

`reset_di_faults /top/mid/bottom/Q -stuck_at 1`

reset_open_pattern_set

Context: patterns -ijtag

Mode: analysis

Clears the content of the currently open pattern set.

Usage

```
reset_open_pattern_set
```

Description

Clears the content of the currently open pattern set.

After this command executes, the pattern set remains opened. The state of the ICL network is restored to the state it was in at the beginning of the pattern set which is either the end state of the previously closed pattern set when the [open_pattern_set](#) -no_initial_ireset option is used or the reset state.

Arguments

None

Return Values

None

Examples

The following example clears the content of the currently open pattern set.

```
reset_open_pattern_set
```

reset_state

Context: dft -edt, dft -scan, patterns -scan, patterns -scan_diagnosis

Mode: analysis

Resets the circuit status.

Usage

```
reset_state
```

Description

Resets the circuit status.

Resets all faults, except AU, TI, BL, and RE faults, to be undetected in order to run a new simulation; and deletes the internal patterns.

dft -scan only:

Removes all instances from both the scan identification and test point identification lists that the tool identified.

Arguments

None

Examples

The following example first performs an ATPG run, then resets the circuit status, resets the faults to be undetected, deletes the internal patterns, and then performs a new ATPG run:

```
set_system_mode analysis
create_patterns
reset_state
create_patterns
```

reset_static_dft_signal_values

Context: dft patterns

Mode: setup, analysis

Resets the static DFT signal values that were previously set using the `set_static_dft_signal_values` command.

Usage

```
reset_static_dft_signal_values
  [-all | -current_design | -icl_instances icl_instances | -instances instances]
  [{dft_signal_name ...}]
```

Description

Resets the static DFT signals that were previously set using the [set_static_dft_signal_values](#) command. All static DFT signals implemented with IJTAG can be set using this command. See the [add_dft_signals](#) command for information on how to add the DFT signals. The DFT signals are grouped by each module in which you added DFT signals and ran the `process_dft_specification` command. These modules have the `tessent_design_level` attribute equal to “chip”, “physical_block”, and “sub_block” in their extracted ICL module view.

When setting a static DFT signal within an instance, the other DFT signals without an explicit setting are assigned an implicit value following the logic documented in the [set_static_dft_signal_values](#) command description. The `reset_static_dft_signal_values` command is used to remove an explicit setting. If applicable, the implied settings are also removed.

Arguments

- **-all**

An optional switch that removes the settings on the specified DFT signals found within all ICL instances that have the `tessent_design_level` attribute set to “chip”, “physical_block”, and “sub_block” within their ICL module definition. The DFT signals found within the top module are also reset.

The `-all`, `-current_design`, `-icl_instances`, and `-instances` switches are mutually exclusive. When unspecified, the `-current_design` switch is the default.

- **-current_design**

An optional switch that removes the settings on the specified DFT signals found within top module. The top-level module must have the `tessent_design_level` attribute set to “chip”, “physical_block”, and “sub_block” within its ICL module definition.

The `-all`, `-current_design`, `-icl_instances`, and `-instances` switches are mutually exclusive. When unspecified, the `-current_design` switch is the default.

- **-icl_instances *icl_instances***

An optional switch that removes the settings on the specified DFT signals found within the specified ICL instances. The specified ICL instances must have the `tessent_design_level` attribute set to “chip”, “physical_block”, and “sub_block” within their ICL module definition.

The `-all`, `-current_design`, `-icl_instances`, and `-instances` switches are mutually exclusive. When unspecified, the `-current_design` switch is the default.

- **-instances *instances***

An optional switch that removes the settings on the specified DFT signals found within the specified design instances. The specified design instances must match the value of the “`hierarchical_design_instance`” attribute found on an ICL instance with the `tessent_design_level` attribute set to “chip”, “physical_block”, and “sub_block” within their ICL module definition.

The `-all`, `-current_design`, `-icl_instances`, and `-instances` switches are mutually exclusive. When unspecified, the `-current_design` switch is the default.

- ***dft_signal_name***

A repeatable set of strings used to specify DFT signal names to reset. The string can also be a single well-formatted Tcl list containing DFT signal names. If you specify no `dft_signal_name`, then the tool resets all DFT signals.

Examples

The following example shows the use of the `report_static_dft_signal_settings` command after a signal was set using the `set_static_dft_signal_values` and after the same setting was reset using the `reset_static_dft_signal_values` command.

```
set_context patterns -ijtag
read_icl ./sub_block_l3.icl
set_current_design sub_block_l3

restore_design

Context: dft

Mode: insertion

Discards all edits performed in insertion mode and restores the design to its state prior to entering insertion mode.

Usage

`restore_design`

Description

Discards all edits performed in insertion mode and restores the design to its state prior to entering insertion mode.

Arguments

None

Examples

The following example creates a minor edit to the design, and then discards the edit:

```
SETUP> set_context dft -rtl
SETUP> read_verilog design1
SETUP> get_ports
{i1 i2}

SETUP> set_system_mode insertion
INSERTION> create_port i3
{i3}

INSERTION> get_ports
{i1 i2 i3}

INSERTION> restore_design
INSERTION> get_ports
{i1 i2}
```

Related Topics

[write_design](#)

run_synthesis

Mode: all contexts

Context: all modes

Invokes a synthesis manager to perform synthesis of the test logic RTL.

Usage

```
run_synthesis [-design_name design_name] [-design_id design_id] [-generate_scripts_only]  
[-synthesis_tool dc_shell] [-compilation_options option_list]  
[-pre_compilation_commands command_list]  
[-post_compilation_commands command_list]  
[-synthesis_output_directory directory] [-startup_file file_name]  
[-wait]
```

Description

Invokes a synthesis manager to perform synthesis on test logic RTL. The [check_synthesis](#) command monitors the synthesis results. Additionally, the [set_run_synthesis_options](#) command specifies the default values for options that can be set for run_synthesis command. The options that are defined with set_run_synthesis_options are overridden if they are explicitly defined with the run_synthesis command.

The run_synthesis command only synthesizes test logic RTL contained within the TSDB. When creating and inserting memory BIST, boundary scan or IJAG logic, the generated RTL is automatically written to the TSDB during process_dft_specification. With EDT logic RTL, the [write_edt_files](#) with the -tsdb option is required to create a TSDB that can be used with run_synthesis.

When the run_synthesis is used with a gate level design, a concatenated netlist of the design which contains the synthesized test logic and modified design modules will automatically be created and placed in the dft_inserted_designs directory of the TSDB.

This command is typically run with no arguments. It automatically uses the design name and design id from the previously processed DftSpecification(*design_name*, *design_id*) wrapper.

The command dispatches and connects to a synthesis manager using a socket. If a manager is already running, it simply connects to it. The synthesis manager is an unlicensed Tcl shell executable that uses the content found in the *design_name_design_id.synthesis_dc_shell* directory to synthesize the test logic for the given *design_name* and *design_id*.

[Figure 5-15](#) shows the subdirectories and files created with run_synthesis. Descriptions of their content and usage are also described. One synthesis manager is created per user/host combination. It remains alive even if Tesson Shell is terminated or suspended. The manager terminates itself when it has finished dispatching all of the simulations and Tesson Shell is not attached to it through a socket.

Figure 5-15. Typical Contents of the synthesis_outdir Directory

```

- *design_name_design_id.synthesis_dc_shell* — A directory that holds the synthesis data associated with a given *design_name* and *design_id*.
- *design_name_design_id.cells.instrument* — A directory that holds the synthesized rtl cells associated with a given *design_name* and *design_id*.
- *design_name_design_id_ijtag.instrument* — A directory that holds the synthesized IJTAG RTL instruments associated with a given *design_name* and *design_id*.
- *design_name_design_id_mbisr.instrument* — A directory that holds the synthesized BISR RTL instruments associated with a given *design_name* and *design_id*.
- *design_name_design_id_mbist.instrument* — A directory that holds the synthesized memory BIST RTL instruments associated with a given *design_name* and *design_id*.
- *command.log* — A file that contains a transcript of the commands executed by the synthesis tool.
- *synthesis_tool.synthesis_log* — A file that contains the complete transcript that is generated when running the *synthesis.script*. The synthesis manager simply redirects the output of the script into this file. The [check_synthesis](#) command parses this file and reports the status.
- *synthesis_tool.synthesis_tcl* — A file that contains the Tcl script that this used to perform the synthesis by the *synthesis_tool* invoked by the *synthesis.script*.
- *file_copy.script* — A file that contains the script to manually copy the synthesized modules back to the TSDB.
- *file_list* — A file that contains the list of files used by the *file_copy.script*.
- *synthesis.script* — A file that contains the commands to invoke *synthesis_tool* with the *synthesis_tool.synthesis_tcl* that synthesizes the test logic RTL.

Environment Variables

Synthesis Script Variables

For the run_synthesis command, a list of environment variables is exported to a side shell script that is used by the synthesis scripts when they are executed. This way, the execution should be consistent even when executed standalone, without the simulation/synthesis managers.

This is particularly important because the environment variables can be changed in Tesson Shell. When changed this way, the modified environment variables were automatically inherited when sub-invoking a shell command with the 'exec' or 'system' command. However, since those environment variable were not exported to the simulation/synthesis scripts, the behavior could be different than when sub-invoking the scripts directly with 'exec' or 'system' from Tesson Shell if some key environment variables were modified inside Tesson Shell.

By default, the following list of environment variables are exported:

- VCS_ARCH_OVERRIDE
- PATH
- LD_LIBRARY_PATH
- *_HOME
- *_VERSION
- *_LICENSE_FILE

In addition to the variables in that list, more environment variables can be exported by specifying a list of names ('*' accepted) in an environment variable.

For synthesis, environment variable 'TESSENT_SYNTH_ENVVAR_LIST' is used.

For example, in Tesson Shell, using:

```
setenv TESSENT_SYNTH_ENVVAR_LIST [list MY_VARS_* ANOTHER_VAR]
```

will pick-up and export any environment variable with names that start with 'MY_VARS_' and the variable name 'ANOTHER_VAR'. When a variable name in those lists is optionally prefixed by a '-' sign, it won't be exported. The optional '+' sign is accepted and also, it is the default behavior.

A side file is generated that includes the export of all the selected environment variables and that file is sources by the main synthesis scripts. The file is named *setup.script* and exported to the following location:

synthesis_outdir/design_name_design_id.synthesis_tool

VCS_ARCH_OVERRIDE Variable

The VCS_ARCH_OVERRIDE environment variable is automatically exported in the generated *synthesis.script* with the 'linux' value only when the variable is not set in the setup script and the operating system is detected as 'linux'.

In order to change this default behavior, issue the following command prior to the calling the *run_synthesis* command:

```
setenv VCS_ARCH_OVERRIDE ""
```

Synthesis Logfile Variable

When the environment variable TESSENT_SYNTH_MANAGER_ENABLE_LOG is set to the value 1, a log file is produced that contains the information exchanged between Tesson Shell and the synthesis manager. By default, the name of the file is './tesson_synth_manager.log' and the path and name of this file can be specified by the environment variable TESSENT_SYNTH_MANAGER_LOG_FILE_NAME.

By default, the file is overwritten for every Tesson Shell session. It is possible to append to an existing file by changing the file name and specifying the letter 'a' after the file name. The optional letter 'w' reproduces the default behavior.

For example, the following enables the log append to the specified file, if it already exists:

```
setenv TESSENT_SYNTH_MANAGER_ENABLE_LOG 1  
setenv TESSENT_SYNTH_MANAGER_LOG_FILE_NAME './my_tesson_synth_manager.log a'
```

Synthesis Instance Manager

The TESSENT_SYNTH_MANAGER_INSTANCES environment variable can be used to control the number of managers. By default, when this environment variable is not set, the tool creates one manager per user per host. This is the same as setting the value to 1. When you use a value greater than 1, one manager per user per host per Tesson Shell session is started with the manager name being the following:

```
tesson_synth_manager_pid
```

Using this name, it is possible to find the manager in the PID list reported by the OS using the command:

```
ps -F -C tclsh8.5.exe | cat
```

Synthesis Socket Manager

The TESSENT_SYNTH_MANAGER_SOCKET_SELECTION environment variable is used to manage sockets. The default value is "server" which causes the manager to use any socket channel returned by operating system.

The value "auto" means that the tool automatically selects a socket as returned by the operating system and requests that the started manager use it.

Specifying an integer value forces the started manager to use the specified socket, if available.

Synthesis Timeout Manager

The TESSENT_SYNTH_MANAGER_TIMEOUT_SECS environment variable controls how long the tool waits for the socket manager. By default, the run_synthesis command waits for the manager to start and open a socket for 300 sec (5 minutes). You can use this environment variable to change this value.

Synthesis Debug

As an alternative to the enable log environment variable, you can use the TESSENT_DEBUG_CONTROL environment variable to generate a logfile. You set the TESSENT_DEBUG_CONTROL environment variable to the following value:

```
+tessent_synth_manager/log_file
```

or use the following in Tesson Shell:

```
set_debug_control +tessent_synth_manager/log_file
```

It is possible to generate debug information while the managers are starting/running with the following debug controls:

```
+tessent_synth_manager/show_debug_info
```

This information can be of value to Mentor Graphics personnel in the case where a manager refuses to start or does not perform as expected.

Arguments

- **-design_name *design_name***

An optional switch and value pair that specifies the design name to which run_synthesis will be associated with. By default, the name of the current design is used when it is set. If you run the command immediately after running the process_dft_specification command, you do not need to specify this option.

- **-design_id *design_id***

An optional switch and value pair that specifies the design id to which run_synthesis will be associated with. By default, the name of the current design id is used when it is set. If you run the command immediately after running the process_dft_specification command, you do not need to specify this option.

- **-generate_scripts_only**

An optional switch that fully populates the synthesis output directory but does not run the synthesis tool. You can use this option to create the synthesis scripts, and then invoke synthesis using the generated scripts stand alone rather using the synthesis manager.

- **-synthesis_tool dc_shell**

An optional switch and value pair that specifies the synthesis tool you wish to use for synthesis. The default and currently only permitted option is “dc_shell”. Other synthesis tools may be supported in future releases.

- **-compilation_options *option_list***

An optional switch and option list that specifies additional options to be added to the synthesis compile command used in the <synthesis_tool>.synthesis_tcl. An example would be the -boundary_optimization option for dc_shell.

- **-pre_compilation_commands *command_list***

An optional switch and tcl command list that adds the provided commands to <synthesis_tool>.synthesis_tcl so that they are executed before the compilation command is executed by the synthesis tool. Each element of the list becomes a command line in the <synthesis_tool>.synthesis_tcl script.

- **-post_compilation_commands *command_list***

An optional switch and tcl command list that adds the provided commands to <synthesis_tool>.synthesis_tcl so that they are executed after the compilation command is executed by the synthesis tool. Each element of the list becomes a command line in the <synthesis_tool>.synthesis_tcl script.

- **-synthesis_output_directory *directory***

An optional switch and value pair that specifies the synthesis output directory. The default directory is synthesis_outdir and is located in the Tesson Shell invocation directory.

- **-startup_file *file_name***

An optional switch and file path that allows the user to explicitly specify the startup file that will be used by the synthesis tool. The file specified is copied into the actual synthesis directory.

Note

 If a startup file is not specified and a .synopsys_dc.setup file exists in the Tesson run directory, it will automatically be copied into the synthesis run directory. If relative paths are utilized within this setup file, it should be noted the synthesis run directory is two levels below where Tesson Shell is launched and these paths should account for this execution point.

- **-wait**

An optional switch that waits for synthesis task to be completed before returning with a completion message. When running in interactive mode, the command reports a status line

that is updated every second showing at what stage synthesis is current operating, which can be unscheduled, queued, running, pass, or fail, as shown below:

```
...
// Synthesis script creation for 'blockB_rtl' completed.
//
// Submitting
'./synthesis_outdir/blockB_rtl.synthesis_dc_shell/synthesis.script'
to synthesis manager
// Waiting for the synthesis to complete
unscheduled 0 queued 0 running 0 pass 1 fail 0
// The 17 synthesized files listed in
'./synthesis_outdir/blockB_rtl.synthesis_dc_shell/file_list' were
copied to the current tsdb output directory.
```

Examples

The following are examples of run_synthesis using various options.

Example 1

This example runs synthesis without any command options, after completing process_dft_specification:

SETUP> run_synthesis

```

// Synthesis script creation for 'blockB_rtl'
// Begin processing of instrument synthesis dictionaries
// Processing containers for instrument type 'rtl_cells'
// Synthesis dictionary
./tsdb_outdir/instruments/blockB_rtl_cells.instrument/
blockB_rtl_cells.synthesis_dictionary
// Processing containers for instrument type 'ijtag'
// Synthesis dictionary
./tsdb_outdir/instruments/blockB_rtl_ijtag.instrument/
blockB_rtl_ijtag.synthesis_dictionary
// Processing containers for instrument type 'mbisr'
// Synthesis dictionary
./tsdb_outdir/instruments/blockB_rtl_mbisr.instrument/
blockB_rtl_mbisr.synthesis_dictionary
// Processing containers for instrument type 'mbist'
// Synthesis dictionary
./tsdb_outdir/instruments/blockB_rtl_mbist.instrument/
blockB_rtl_mbist.synthesis_dictionary
// Done processing of instrument synthesis dictionaries
//
// Writing TCL synthesis script
'./synthesis_outdir/blockB_rtl.synthesis_dc_shell/dc_shell.synthesis_tcl'
// Writing the synthesis shell script
'./synthesis_outdir/blockB_rtl.synthesis_dc_shell/synthesis.script'
// Writing the file copy shell script
'./synthesis_outdir/blockB_rtl.synthesis_dc_shell/file_copy.script'
// Writing the synthesized file list
'./synthesis_outdir/blockB_rtl.synthesis_dc_shell/file_list'
// Synthesis script creation for 'blockB_rtl' completed.
//
// Submitting
'./synthesis_outdir/blockB_rtl.synthesis_dc_shell/synthesis.script' to
synthesis manager

```

Example 2

This example runs synthesis with `-generate_scripts_only` options so that you may run synthesis outside Tesson Shell:

SETUP> `run_synthesis -generate_scripts_only`

```
// Synthesis script creation for 'blockB_rtl'  
// Begin processing of instrument synthesis dictionaries  
// Processing containers for instrument type 'rtl_cells'  
// Synthesis dictionary  
.tsdb_outdir/instruments/blockB_rtl_cells.instrument/  
blockB_rtl_cells.synthesis_dictionary  
// Processing containers for instrument type 'ijtag'  
// Synthesis dictionary  
.tsdb_outdir/instruments/blockB_rtl_ijtag.instrument/  
blockB_rtl_ijtag.synthesis_dictionary  
// Processing containers for instrument type 'mbisr'  
// Synthesis dictionary  
.tsdb_outdir/instruments/blockB_rtl_mbisr.instrument/  
blockB_rtl_mbisr.synthesis_dictionary  
// Processing containers for instrument type 'mbist'  
// Synthesis dictionary  
.tsdb_outdir/instruments/blockB_rtl_mbist.instrument/  
blockB_rtl_mbist.synthesis_dictionary  
// Done processing of instrument synthesis dictionaries  
//  
// Writing TCL synthesis script  
'.synthesis_outdir/blockB_rtl.synthesis_dc_shell/dc_shell.synthesis_tcl'  
// Writing the synthesis shell script  
'.synthesis_outdir/blockB_rtl.synthesis_dc_shell/synthesis.script'  
// Writing the file copy shell script  
'.synthesis_outdir/blockB_rtl.synthesis_dc_shell/file_copy.script'  

```

  [-compilation_options option_list]
  [-simulator_options option_list]
  [-extra_verilog_files list_of_files]
  [-extra_top_modules module_name_list]
  [-simulation_output_directory simulation_output_directory]
  [-simdut_output_directory simdut_output_directory]
  [-simdut_server] [-generate_simdut_files_only]
  [-no_wait]
```

Description

Invokes a simulation manager to run a set of simulation test benches. The [check_testbench_simulations](#) command monitors the simulation results.

This command is typically run with no arguments at all. It automatically uses the design name, design id, and pattern id found in the previously processed [PatternsSpecification\(design_name, design_id, pattern_id\)](#) wrapper.

The information on how to load the design view into the simulator is contained in the *<design_name>.design_source_dictionary* files found inside the [dft_inserted_designs](#)

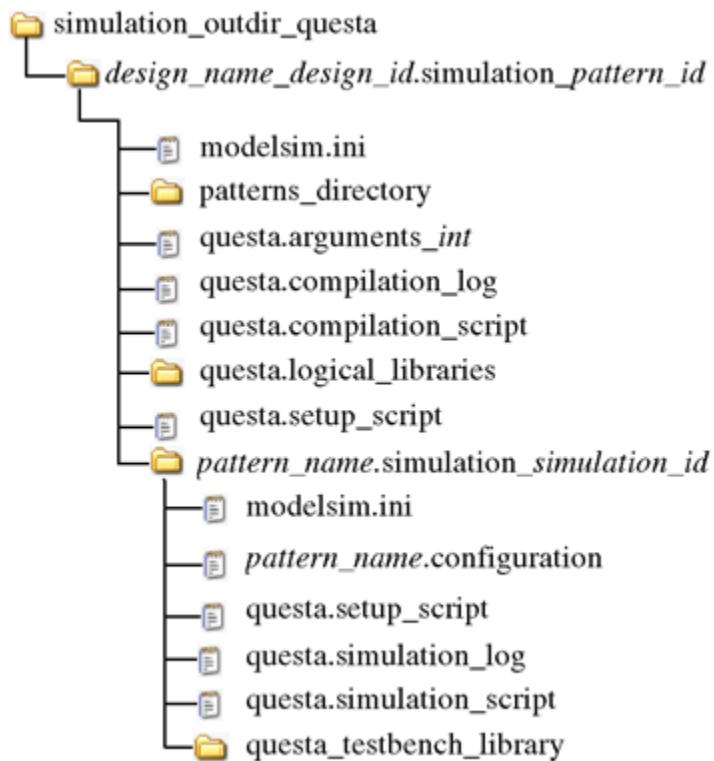

directories. The only missing information is where to find the simulation library models because those are not loaded inside Tesson Shell. You specify the location of the simulation library models using the [set_simulation_library_sources](#) command.

Refer to the “[check_testbench_simulations -report_status](#)” switch for details on obtaining status for a given simulation run.

The command dispatches and connects to a simulation manager using a socket. If a manager is already running, it simply connects to it. The simulation manager is an unlicensed Tcl shell executable that uses the content found in the simulation.data_dictionary file inside the *design_name_design_id.patterns_pattern_id* directory to compile the design and the test benches into the specified -simulation_output_directory, and to simulate them using the specified simulator. The simulations are run in series or in parallel based on the specified -parallel_simulations value. [Figure 5-16](#) shows the subdirectories and files created below the specified -simulation_output_directory. Descriptions of their content and usage are described next.

One simulation manager is created per user/host combination. It remains alive even if Tesson Shell is terminated. The manager terminates itself when it has finished dispatching all of the simulations and Tesson Shell is not attached to it through a socket.

Figure 5-16. Example Output Directory Structure (Questa)

- *design_name_design_id.simulation_pattern_id*

A directory that holds the simulation data associated with a given *design_name*, *design_id*, and *pattern_id* combination.

- *patterns_directory*

A soft link that points back to the directory in which the Verilog test bench files exists. The *simulator.simulation_script* file uses that link to access the test bench file.

- *simulator.arguments_int*

A file created for all each unique set of “-y ... -v ... +libext+...” in the compilation/simulation shell scripts generated. This file is added to the Verilog compilation command as “-f *simulator.arguments_int*”.

- *simulator.compilation_script*

A file that contains simulator-specific commands to map logical libraries to physical directories and compile the complete design into the various logical libraries. An extra logical library called “tsdb_interface” is created and the *design_name.format_interface* files of the first level of physical block modules are compiled into it. The *pattern_name.configuration_files* use this library to bind the interface view for different instances of physical blocks based on what was specified in the LowerPhysicalBlockInstances wrapper inside the [SimulationOptions](#) wrapper.

- *simulator.logical_libraries*

A directory that contains one subdirectory per logical library, and in which the compilation data is stored.

- *simulator.compilation_log*

A file that contains the complete transcript generated when running the *simulator.compilation_script*. The simulation manager simply redirects the output of the script into this file.

- *pattern_name.simulation[_simulation_id]*

A directory that is created to simulate each pattern. The *_simulation_id* extension suffix is only present when the “run_testbench_simulations [-simulation_id string](#)” option is used.

- *simulator_testbench_library*

A directory used to store the compilation data for the test bench and the configuration file. The use of a unique directory per pattern enables the deletion of it once the simulation is done based on the “run_testbench_simulations [-keep_simulation_data on | off | on_failure](#)” option value.

- *simulator.simulation_script*

A file that contains simulator-specific commands to map logical libraries to physical directories, compile the test bench as well as the configuration file, and run the simulation.

- *patterns.configuration*

A file that contains a Verilog configuration that is used to control whether a *physical_block* instance uses the full view or the interface view when simulating the given patterns test bench.

- *simulator.simulation_log*

A file that contains the complete transcript that is generated when running the *simulator.simulation_script*. The simulation manager simply redirects the output of the script into this file. The [check_testbench_simulations](#) command parses those files to look for miscompares.

- *simulator.simulation_log_reference*

A file that contains a copy of a previously-generated *simulator.simulation_log* file. This file is manually created by copying the *simulator.simulation_log* file when you are doing simulations with fault insertion.

This file instructs the [check_testbench_simulations](#) command to expect those exact failures in the newly generated *simulator.simulation_log* file. You can also use the -expected_miscompare_count option but this method does not check on which object and in which test step the miscompares actually happened. For example, if you are doing fault insertion to test the memory repair solution, you want to make sure the miscompares are in the memory BIST step prior to repair and not in the one after repair.

The use of the *simulator.simulation_log_reference* file enables you to precisely specify the location of the miscompares. Those files are typically stored in *pattern_name.simulation[_simulation_id]* directories where the *simulation_id* is not null so as not to lose the fault-free simulation directories.

Figure 5-17. Outdir Directory Structure for VCS

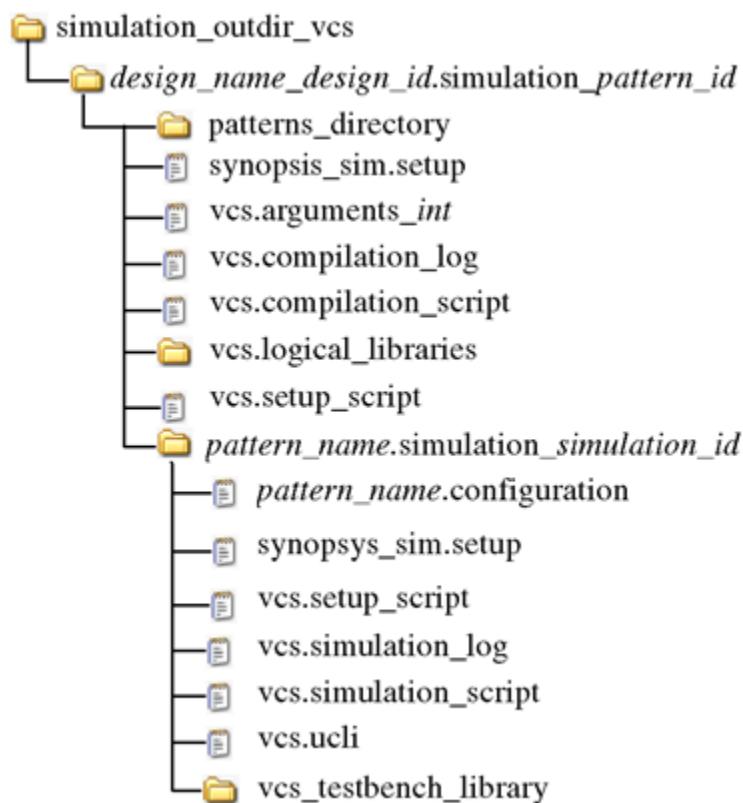

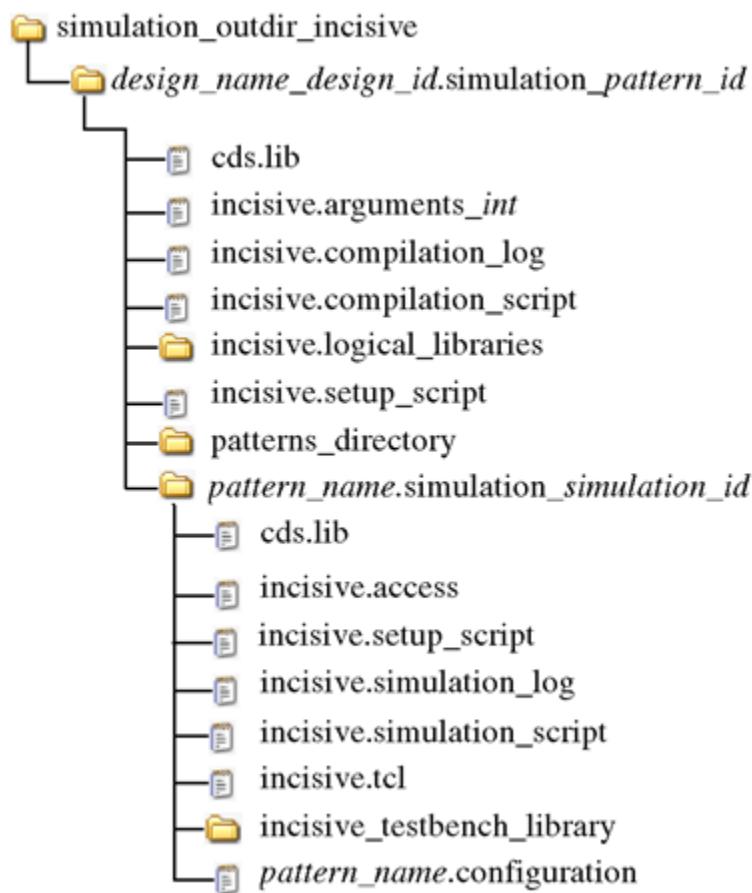

Figure 5-18. Output Directory Structure for Incisive

Environment Variables

Simulation Script Variables

For the `run_testbench_simulations` command, a list of environment variables is exported to a side shell script that is used by the synthesis scripts when they are executed. This way, the execution should be consistent even when executed standalone, without the simulation/synthesis managers.

This is particularly important because the environment variables can be changed in Tesson Shell. When changed this way, the modified environment variables were automatically inherited when sub-invoking a shell command with the '`exec`' or '`system`' command. However, since those environment variable were not exported to the simulation/synthesis scripts, the behavior could be different than when sub-invoking the scripts directly with '`exec`' or '`system`' from Tesson Shell if some key environment variables were modified inside Tesson Shell.

By default, the following list of environment variables are exported:

- PATH
- LD_LIBRARY_PATH

- * _HOME
- * _VERSION
- * _LICENSE_FILE
- MTI* (set to “64” when the MTI_VCO_MODE variable is *not* set)

In addition to the variables in that list, more environment variables can be exported by specifying a list of names ('*' accepted) in an environment variable.

For simulations, the 'TESSENT_SIM_ENVVAR_LIST' environment variable is used.

For example, in Tesson Shell, using:

```
setenv TESSENT_SIM_ENVVAR_LIST [list MY_VARS_* ANOTHER_VAR]
```

will pick-up and export any environment variable with names that start with 'MY_VARS_' and the variable name 'ANOTHER_VAR'. When a variable name in those lists is optionally prefixed by a '-' sign, it won't be exported. The optional '+' sign is accepted and also, it's the default behavior.

A side file is generated that includes the export of all the selected environment variables and that file is sourced by the main simulation scripts. The file is named *simulator.setup_script* and is exported to the following locations:

```
simulation_outdir/design_name_design_id.simulation_simulation_id
```

```
simulation_outdir/design_name_design_id.simulation_simulation_id/
pattern_name.simulation[_pattern_id]
```

Simulator HOME Environment Variables

When setting the following simulator HOME environment variables to the simulator software's *install_home*:

- QUESTA_HOME
- VCS_HOME
- INCISIVE_HOME

the *run_testbench_simulations* command automatically looks in the following locations:

- *install_path/bin*
- *install_path/tools/bin*

to find the required commands. When found, the generated *simulator.setup_script* will have the PATH environment variable automatically appended with the path to the *bin* directory. Setting this environment variable is not required if the PATH environment variable in Tesson Shell already includes the path to the *bin* directory of the required commands.

Simulation Logfile Variable

When the environment variable TESSENT_SIM_MANAGER_ENABLE_LOG is set to the value 1, a log file is produced that contains the information exchanged between Tesson Shell and the simulation manager. By default, the name of the file is './tesson_sim_manager.log' and the path and name of this file can be specified by the environment variable TESSENT_SIM_MANAGER_LOG_FILE_NAME.

By default, the file is overwritten for every Tesson Shell session. It is possible to append to an existing file by changing the file name and specifying the letter 'a' after the file name. The optional letter 'w' reproduces the default behavior.

For example, the following enables the log append to the specified file, if it already exists:

```
setenv TESSENT_SIM_MANAGER_ENABLE_LOG 1  
setenv TESSENT_SIM_MANAGER_LOG_FILE_NAME './my_tesson_sim_manager.log a'
```

Simulation Instance Manager

The TESSENT_SIM_MANAGER_INSTANCES environment variable can be used to control the number of managers. By default, when this environment variable is not set, the tool creates one manager per user per host. This is the same as setting the value to 1.

When you use a value greater than 1, one manager per user per host per Tesson Shell session is started with the manager name being the following:

```
tesson_sim_manager_pid
```

Using this name, it is possible to find the manager in the PID list reported by the OS using the command:

```
ps -F -C tclsh8.5.exe | cat
```

Simulation Socket Manager

The TESSENT_SIM_MANAGER_SOCKET_SELECTION environment variable is used to manage sockets. The default value is "server" which causes the manager to use any socket channel returned by operating system.

The value "auto" means that the tool automatically selects a socket as returned by the operating system and requests that the started manager use it.

Specifying an integer value forces the started manager to use the specified socket, if available.

Simulation Timeout Manager

The TESSENT_SIM_MANAGER_TIMEOUT_SECS environment variable controls how long the tool waits for the socket manager. By default, the command waits for the manager to start and open a socket for 300 sec (5 minutes). You can use this environment variable to change this value.

Simulation Debug

As an alternative to the enable log environment variable, you can use the TESSENT_DEBUG_CONTROL environment variable to generate a logfile.

You set the TESSENT_DEBUG_CONTROL environment variable to the following value:

```
+tessent_sim_manager/log_file
```

or use the following in Tesson Shell:

```
set_debug_control +tessent_sim_manager/log_file
```

It is possible to generate debug information while the managers are starting/running with the following debug controls:

```
+tessent_sim_manager/show_debug_info
```

This information can be of value to Mentor Graphics personnel in the case where a manager refuses to start or does not perform as expected.

Clock Monitoring During Simulation

By default clock monitoring is enabled during simulation.

Note

- ❑ The clock monitoring relies on the design hierarchy being present. If the design has been ungrouped then it may be necessary to turn off the monitoring using the [monitor_internal_clock_pins](#) property in the [SimulationOptions](#) wrapper or use one of the macros shown in the example below when running the simulation.
-

The this monitoring is done by a Verilog side file generated in the same directory as the simulation test benches as follows:

```
tsdb_outdir/patterns/design_name_design_id.patterns_pattern_id/
patterns_name_CLOCK_MONITOR.v
```

The same file can be found with the *patterns_directory* softlink created by the [run_testbench_simulation](#) command under the following:

```
<simulation_outdir>/<design_name>_<design_id>.patterns_<pattern_id>/patterns_directory/
```

For example, for a Patterns(MemoryBist_P1) entry in the [PatternsSpecification](#), the clock monitoring side-file contains the following:

```
//  
=====  
// File : MemoryBist_P1_CLOCK_MONITOR.v  
// Description : Clock Monitor module for pattern MemoryBist_P1  
//  
//  
=====  
// By default the clock monitoring is enabled.  
// To disable clock monitoring define one of the following macros:  
// MGC_DISABLE_CLOCK_MONITOR  
// MGC_DISABLE_CLOCK_MONITOR_MemoryBist_P1  
//  
`define MGC_ENABLE_CLOCK_MONITOR  
`ifdef MGC_DISABLE_CLOCK_MONITOR  
    `undef MGC_ENABLE_CLOCK_MONITOR  
`endif  
`ifndef MGC_DISABLE_CLOCK_MONITOR_MemoryBist_P1  
    `undef MGC_ENABLE_CLOCK_MONITOR  
`endif  
`ifndef MGC_ENABLE_CLOCK_MONITOR  
    `timescale 100fs/10fs  
`endif  
  
To disable all clock monitoring, use:  
-simulation_macro_definitions MGC_DISABLE_CLOCK_MONITOR  
  
To disable clock monitoring only for the Patterns(MemoryBist_P1), use:  
-simulation_macro_definitions MGC_DISABLE_CLOCK_MONITOR_MemoryBist_P1
```

Arguments

- **-design_name *design_name***
An optional switch and value pair that specifies the design name to which the patterns to simulate are associated with. By default, the name of the *current_design* is used when it is set. If you run the command immediately after running the [process_patterns_specification](#) command, you do not need to specify this option.
- **-design_id *design_id***
An optional switch and value pair that specifies the *design_id* to which the patterns to simulate are associated to. By default, the *pattern_id* used by the previously run [process_patterns_specification](#) command is reused automatically; otherwise, the *design_id* value set using the [set_context](#) command is used. If you run the command immediately after running the [process_patterns_specification](#) command, you do not need to specify this option.
- **-pattern_id *pattern_id***
An optional switch and value pair that specifies the pattern id to which the patterns to simulate are associated to. By default, the *pattern_id* used by the previously run

process_patterns_specification command is reused automatically. If you run the command immediately after running the process_patterns_specification command, you do not need to specify this option.

- -report_list

An optional switch that tells the command to simply echo the list of patterns available in the *design_name_design_id.patterns_pattern_id/simulation.data_dictionary* file after it has been filtered using the -select or -exclude switch values.

- -select *pattern_name_glob_list*

An optional switch and value pair that specifies a list of pattern names or pattern name glob patterns to include in the simulation run. The full list of pattern names can be reported using the -report_list option, and is stored in the simulation.data_dictionary file found inside the *design_name_design_id.patterns_pattern_id* directory.

- -exclude *pattern_name_glob_list*

An optional switch and value pair that specifies a list of pattern names or pattern name glob patterns to exclude from the simulation run. The full list of pattern names can be reported using the -report_list option that is stored in the simulation.data_dictionary file found inside the *design_name_design_id.patterns_pattern_id* directory.

- -generate_scripts_only

An optional switch and value pair that tells the command to fully populate the simulation output directory as described in [Figure 5-16](#), but not actually run the compilation and simulation scripts. You can use this option to create the simulation scripts, and then invoke them yourself instead of letting them be managed by the simulation manager.

- -parallel_simulations {1 | 2...MAX_INT | maxcpu}

An optional switch and value pair that specifies to the manager the number of simulations that are allowed to run in parallel. By default, only one simulation is launched at a time. MAX_INT is the maximum integer value that the host machine allows. The maxcpu literal specifies using all available CPUs on the host machine. You can increase the parallelism based on the number of simulator licenses you have and the number of CPUs and memory available on your machine.

- -expected_miscompare_count *int*

An optional switch and value pair that specifies that the set of patterns selected by the -select option have an expected mismatch count. This option is typically used in combination with the -simulation_id and the -simulation_macro_definition switches when doing fault insertion simulations. The fault insertion logic is triggered by the specified “define” macros. They can also be done with explicit forces inside a side module which you load and compile using the -extra_verilog_files option. Using the -simulation_id option allows you to keep a fault free simulation directory while generating new ones for the fault insertion variations.

A more precise mechanism to document expected failures is to copy the *simulator.simulation_log* file to *simulator.simulation_log_reference* once you have inspected and verified it contains the right mismatches. You can also create a directory

beside the specified *simulation_outdir* having the same name with an extra *.reference* extension.

You copy the *simulator.simulation_log* file in the same subdirectory relative to *simulation_outdir.reference* as it exist in the *simulation_outdir* directory. If the *simulator.simulation_log_reference* is not found beside the log file but *simulator.simulation_log* exists inside *simulation_outdir.reference/same_sub_path*, then this file will be used as the reference. The [check_testbench_simulations](#) command will not only verify that the right number of mismatches exists, but that they actually exist on the right objects and in the right test step. For future reruns of the flow, simply pre-populate the *simulator.simulation_log_reference* files inside the directories in which you are doing fault insertion and the [check_testbench_simulations](#) command will automatically use them.

- **-simulation_id string**
An optional switch and value pair that specifies a simulation id string to name the *pattern_name.simulation[_simulation_id]* directory. This is typically used in conjunction with the -simulation_macro_definitions and/or the -extra_verilog_files options to trigger failures in the simulations. For more information, see the -expected_miscompare_count switch description.
- **-simulator questa | vcs | incisive**
An optional switch and value pair that specifies the simulator you want to use for simulation. The default value is “questa” from Mentor Graphics.
- **-simulation_timeout time | unlimited**
An optional switch and value pair that specifies the time out value you want to use when waiting for a simulation to complete. The default value is “unlimited” which means the simulation will be allowed to run for as long as it takes.
- **-keep_simulation_data on | off | on_failure**
An optional switch and value pair that specifies the conditions under which to keep the simulation data after the simulation has completed. The deletion of the *simulator.logical_libraries* directory and the debug output generated when using the -store_simulation_waveforms option is controlled by this option. The default value is “on_failure”.
- **-store_simulation_waveforms on | off**
An optional switch and value pair that specifies to store simulation waveform data so that they can be reviewed if the simulation failed. The deletion of this data is controlled by the -keep_simulation_data option. The default value is “off”.
- **-simulation_run_commands *simulator_commands***
An optional switch and value pair that specifies the commands to use when the -store_simulation_waveform switch is off. If the -store_simulation_waveforms is set to on, then the content from the -waveform_configuration_commands switch is pre-pended to the -simulation_run_commands switch.

- **-waveform_configuration_commands** *simulator_command_list*

An optional switch and value pair that specifies a list of simulator-specific commands to control the resolution of the stored waveform data. When you specify “store_simulation_waveforms on” without the -waveform_configuration_commands option, all waveforms are stored which may dramatically slow down the simulation on a large design.

- **-compilation_macro_definitions** {*macro[=value]* ...}

An optional switch and value pair that specifies a list of macro definitions to pass to the Verilog compilation command inside the *simulator.compilation_script* file which is where your design is compiled. This is typically used to configure your simulation library.

- **-simulation_macro_definitions** {*macro[=value]* ...}

An optional switch and value pair that specifies a list of macro definitions to pass to the Verilog compilation command inside the *simulator.simulation_script* file which is where your test bench and side modules are compiled. You can use this option to trigger special fault insertion code inside your side modules to perform fault insertion simulation. See the -expected_miscompare_count switch description.

- **-compilation_options** *option_list*

An optional switch and value pair that specifies a list of compilation options (for example, +initreg) that modify the compilation script during runtime. The *option_list* uses the following syntax:

```
-compilation_options {[global_options] [verilog verilog_options] [vhdl vhdl_options]}

○ The verilog options are passed only to the command that compiles Verilog source files.

○ The vhdl options are be passed only to the command that compiles the VHDL source files.

○ The global_options can also be expressed as “global {global_options}”.
```

The braces are mandatory in order to identify the options preceded by the language or “global”.

See [Example 4](#).

- **-simulator_options** *option_list*

An optional switch and value pair that specifies a list of options to pass to the simulation command. These are simulator-specific commands and must be consistently specified with the -simulator option.

If you are using ModelSim as your simulator, this switch can be used to pass in the -debugDB option to the tool so the *vsim.dbg* file is created and can be accessed using the

schematic viewer when debugging your waveforms. You must specify this option in conjunction with the -store_simulation_waveform switch as follows:

```
run_testbench_simulation -store_simulation_waveforms on \
-simulator_options "-debugDB"
```

- **-extra_verilog_files** *list_of_files*

An optional switch and value pair that specifies a list of individual Verilog files to compile in parallel to the test bench file. The *list_of_files* are *actual* Verilog files in contrast to a file containing references to Verilog source files. For example:

```
# A single Verilog file:
run_testbench_simulations -extra_verilog_files a.v

# Multiple Verilog files:
run_testbench_simulations -extra_verilog_files { a.v b.v c.v }
```

The files are typically used to contain codes that perform monitoring or fault insertion in the design. You must list the module names compiled within those files that you want to be active in parallel with the test bench using the -extra_top_modules option.

- **-extra_top_modules** *module_name_list*

An optional switch and value pair that specifies a list of modules to run in parallel with the test bench module. These modules are typically used to contain codes that perform monitoring or fault insertion in the design. You must load these modules in files specified with the -extra_verilog_files option.

- **-simulation_output_directory** *simulation_output_directory*

An optional switch and value pair that specifies the name and path of a directory in which to place the simulation directories. See [Figure 5-16](#) for more information about this directory.

- **-simdut_output_directory** *simdut_output_directory*

An optional switch and value pair that is specified with the -simdut_server option to reference the path to the directory that contains the SimDUT setup files that are required for simulation. Refer to “[Simulating Diagnosis of ATPG Patterns \(Non-TSDB Flow\)](#)” in the *Tessent SiliconInsight User’s Manual for Tessent Shell*.

- **-simdut_server**

An optional argument that specifies to run the test benches in Tessent SiliconInsight SimDUT mode. Refer to “[Simulating Desktop, ATE, and ATPG Behavior](#)” in the *Tessent SiliconInsight User’s Manual for Tessent Shell*.

- **-generate_simdut_files_only**

An optional argument that is specified with the -simdut_server option to indicate that Tessent SiliconInsight should generate the SimDUT setup files. By default, this directory is named SIMDUT.simulation and is located in the simdut_outdir directory. Refer to “[Generating the Setup Specification for ATPG \(Non-TSDB Flow\) Desktop Mode](#)” in the *Tessent SiliconInsight User’s Manual for Tessent Shell*.

- **-no_wait**

By default, the `run_testbench_simulations` command automatically waits for the simulations to complete and periodically updating a status line giving the progress of the ongoing simulations.

The optional `-no_wait` switch instructs the command to dispatch the simulation to the manager and not wait for them to complete. It is then possible to follow the progress of the simulations by invoking the `check_testbench_simulations` command. In fact, calling the `run_testbench_simulations` command without the '`-no_wait`' option is equivalent to doing the following:

```
run_testbench_simulations -no_wait ...
check_testbench_simulations -wait
```

Examples

Example 1

The following example runs the `run_testbench_simulations` command twice—once with no options and once to select a few patterns for which fault insertion is performed. Notice the use of the `-simulation_id` in the second invocation which allows the fault-free and fault-injected simulations to co-exist even when the same pattern name is reused. The example assumes that the `simulator.simulation_log` files were copied to `simulator.simulation_log_reference` in the `MemoryBist_*.simulation_FI` directories using the result of a previous run.

```
run_testbench_simulations
run_testbench_simulations -select MemoryBist_* \
    -simulation_macro_definitions {mem32x56_hi_add=4 mem32x56_hi_bit=2} \
    -simulation_id FI
check_testbench_simulations
```

Example 2

The following example shows how to use the “`write_design -tsdb -softlink_netlist`” command and switches to create a TSDB `dft_inserted_designs` container for a netlist generated from synthesis or layout, and on which you want to use the `run_testbench_simulations` command to simulate the patterns described in your [PatternsSpecification](#).

As shown in [Example 3](#) of the `read_design` command, you read in the post-synthesis or post-layout netlist using `read_verilog`, and then you read the ICL and TCD description using the `read_design -no_hdl` command. You then write out a TSDB `dft_inserted_design` container using the “`write_design-tsdb -softlink_netlist`” command and switches. If you are using this command to create a TSDB `dft_inserted_design` container for the post-layout view, you would specify `-design_id` with a name other than “gate,” because “`-design_id gate`” was likely used for the post-synthesis view.

```
set_context dft -design_id gate -no_rtl
read_cell_library cell_library
read_verilog path/my_design.vg
read_design my_design -design_id rtl -no_hdl -verbose
set_current_design my_design
write_design -tsdb -softlink_netlist -verbose
```

Now that you have a dft_inserted_design container for your netlist, you can either create a new PatternsSpecification using [create_patterns_specification](#) or re-use a pre-existing PatternsSpecification that was potentially modified to signoff the pre-synthesis design view.

```
set_context dft -no_rtl -design_id gate
# This loads the ICL and the interface view of the verilog design to get the full port list of the
# design. No need to read the full netlist to run process_patterns_specification
read_design my_design -view interface
set_current_design my_design

# Option 1: Recreate a brand new PatternsSpecification
create_patterns_specification

# Option 2: re-use pre-existing PatternsSpecification
read_config_data \
    ./tsdb_outdir/patterns/my_design_rtl.patterns_spec_signoff
set_config_value PatternsSpecification(my_design,rtl,signoff) -id <1> gate
process_patterns_specification
run_testbench_simulations

process_patterns_specification
run_testbench_simulations
```

Example 3

The following example shows the tool command sequence to setup the libraries, run the simulation, and check the simulation:

```
set_simulation_library_sources -v adk.v -v ram.v
run_testbench_simulations
check_testbench_simulations
```

Example 4

The following example demonstrates using the -compilation_options switch:

```
run_testbench_simulations -generate_scripts_only -simulator vcs \
    -simulator_options {-kdb -lca -debug_all} \
    -compilation_options \
        { global { -kdb } vhdl { -skip_translate_body } verilog { -timescale=1ns/1ps } }
```

Command Dictionary (S - Z)

The Command Dictionary describes the application commands for Tessent Shell. For quick reference, the commands appear alphabetically with each beginning on a separate page.

The command usage line syntax conventions are common to all products documented in this manual.

Table 6-1. Conventions for Command Line Syntax

Convention	Example	Usage
UPPercase	-STatic	Required argument letters are in uppercase; in most cases, you may omit lowercase letters when entering literal arguments, and you need not enter in uppercase. Arguments are normally case insensitive.
Boldface	set_fault_mode <u>Uncollapsed</u> Collapsed	A boldface font indicates a required argument.
[]	exit [-force]	Square brackets enclose optional arguments. Do not enter the brackets.
<i>Italic</i>	dofile <i>filename</i>	An italic font indicates a user-supplied argument.
{ }	add_ambiguous_paths <u>{path_name</u> -All} [-Max_paths number]	Braces enclose arguments to show grouping. Do not enter the braces.
	add_ambiguous_paths <u>{path_name</u> -All} [-Max_paths number]	The vertical bar indicates an either/or choice between items. Do not include the bar in the command.
Underline	set_dofile_abort <u>ON</u> <u>OFF</u>	An underlined item indicates either the default argument or the default value of an argument.
...	add_clocks <i>off_state</i> <u>pin_list</u> ...	An ellipsis follows an argument that may appear more than once. Do not include the ellipsis when entering commands.

Command Descriptions

This section describes commands, alphabetically from S through Z, that available in Tessent Shell. The beginning of each command description shows the contexts and modes that support the command and provides the following information:

Context: Lists each context and sub-context that supports the command. “All contexts” means that the command is supported in all available contexts. “Unspecified” means that you do not have to set a context to use the command.

Mode: Lists each mode that supports the command. “All modes” means that the command is supported in all available modes. In some cases, a particular mode supports the command only within certain contexts, and this is noted in parentheses after the mode type.

Table 6-2. Commands S Through Z

Command	Description
select_display_instances	Selects the specified objects in the Flat Schematic and Hierarchical Schematic windows.
set_abort_limit	Specifies the abort limit for the test pattern generator.
set_atpg_fill	Specifies how the tool should fill unspecified bits in ATPG patterns.
set_atpg_limits	Specifies the ATPG process limits at which the tool terminates the ATPG process.
set_atpg_timing	Enables and defines parameters for timing-aware ATPG and fault simulation.
set_attribute_options	Modifies options of any registered user-defined attribute.
set_attribute_value	Sets an attribute's value for the objects specified in object_spec.
set_au_analysis	Specifies whether the ATPG uses the ATPG untestable information to place ATPG untestable faults directly in the AU fault class.
set_bidi_gating	Specifies how bidirectional (bidi) pins are controlled during scan chain shifting to prevent potential bus contention or to ensure an on/off state during testing.
set_bist_chain_test	Disables all capture clock activity for the specified number of patterns in the fault simulation during execution of the chain test.
set_bist_debug	Sets up a trace of LFSR(s) value during a pattern's shift cycles.

Table 6-2. Commands S Through Z (cont.)

Command	Description
<code>set_bist_trace</code>	Enables the tracing of PRPG and MISR values associated with each BIST pattern to facilitate signature mismatch debugging and other diagnostics.
<code>set_boundary_scan_port_options</code>	Sets options relative to boundary scan on ports of the design.
<code>set_bus_handling</code>	Specifies the bus contention results that you desire for the identified buses.
<code>set_bus_simulation</code>	Specifies whether the tool uses global or local bus simulation analysis.
<code>set_bypass_chains</code>	Specifies a list of scan chains to connect in series to form a particular EDT bypass chain.
<code>set_capture_clock</code>	Specifies the capture clock for random pattern simulation or, optionally, for all ATPG pattern simulation.
<code>set_capture_handling</code>	Specifies how the tool globally handles the data capture of state elements that have C3 and C4 rule violations.
<code>set_capture_procedures</code>	Enables or disables the tool's use of a specified subset of named capture procedures when generating test patterns.
<code>set_cell_library_options</code>	Sets the specified options for library parsing and design elaboration.
<code>set_cell_model_mapping</code>	Overrides the non-scan to scan model mapping defined by the tool.
<code>set_chain_test</code>	Specifies binary sequences for chain test.
<code>set_checkpointing_options</code>	Enables checkpointing and specifies the associated options.
<code>set_clock_controller_pins</code>	Specifies the connection information for the clock controller pins.
<code>set_clock_controls</code>	Enables and disables the clock control definitions in the test procedure file.
<code>set_clock_gating</code>	Specifies clock gating cells whose unconnected test-enable ports need to be connected to either the scan enable signal or a specified signal (pin).
<code>set_clock_gating_enable</code>	Associates clocks that control clock gating devices with enable signal drivers.
<code>set_clock_off_simulation</code>	Enables or disables the simulation where all clock primary inputs are at their "off" value, other primary inputs have been forced to values, and state elements are at the values scanned in or resulting from capture in the previous cycle.

Table 6-2. Commands S Through Z (cont.)

Command	Description
<code>set_clock_options</code>	Allows you to specify multiple options for a single clock.
<code>set_clock_restriction</code>	Specifies whether ATPG can create patterns with more than one active capture clock.
<code>set_compactor_connections</code>	Specifies the scan chains for the tool to connect to a particular scan channel output.
<code>set_config_value</code>	Sets the value of an element in the configuration data.
<code>set_contention_check</code>	Specifies whether or not contention checking is on and the conditions under which checks are performed. Contention checking is set to On when the tool is invoked.
<code>set_context</code>	Specifies the current usage context of Tesson Shell.
<code>set_core_instance_parameters</code>	Changes the parameters of instruments previously added with the <code>add_core_instances</code> command.
<code>set_current_design</code>	Specifies the top level of the design for all subsequent commands until reset by another execution of this command.
<code>set_current_edt_block</code>	Directs the tool to apply certain subsequent commands to a particular EDT block only.
<code>set_current_edt_configuration</code>	Sets a particular compression configuration for the tool to use within the current design block.
<code>set_current_mode</code>	Specifies the current test mode in pattern retargeting and core mapping flows.
<code>set_current_silicon_insight_setup</code>	Sets the currently selected setup in the Tesson SiliconInsight Setup Specification.
<code>set_current_simulation_context</code>	Sets the current simulation context.
<code>set_decision_order</code>	Specifies how the ATPG selects gate input or output nodes for evaluation during ATPG.
<code>set_dedicated_wrapper_cell_options</code>	This command controls the inferring of the dedicated wrapper cells on all or the specified primary IOs.
<code>set_defaults_value</code>	Sets the default value of a property in one of the DefaultsSpecification (policy) wrappers.
<code>set_design_include_directories</code>	Specifies one or more directory paths that contain `include files for use by subsequent <code>read_verilog</code> commands.
<code>set_design_level</code>	Specifies the level of the current design.
<code>set_design_macros</code>	Specifies one or more defined macros for use by subsequent commands.

Table 6-2. Commands S Through Z (cont.)

Command	Description
<code>set_design_sources</code>	Specifies where the tool should look for the definition of undefined modules in the list of files specified by the <code>read_verilog</code> command.
<code>set_dft_enable_options</code>	Enables or disables the control or observe points.
<code>set_dft_specification_requirements</code>	Specifies the requirements to be checked when the <code>check_design_rules</code> command runs, and those to be included into the DftSpecification when the <code>create_dft_specification</code> command is run.
<code>set_diagnosis_options</code>	Specifies the type of diagnosis performed by the <code>diagnose_failures</code> command.
<code>set_display</code>	Sets the DISPLAY environment variable from the tool's command line.
<code>set_dofile_abort</code>	Specifies whether the tool aborts or continues dofile execution if it detects an error condition.
<code>set_drc_handling</code>	Specifies how the tool handles design rule violations.
<code>set_driver_restriction</code>	Specifies whether the tool allows multiple drivers on buses and multiple active ports on gates.
<code>set_edt_abort_analysis_options</code>	Specifies the number of EDT Aborted (EAB) test cubes on which to perform EAB fault analysis.
<code>set_edt_finder</code>	Controls whether the tool automatically identifies EDT logic and updates scan chain pins during test pattern generation.
<code>set_edt_instances</code>	Specifies the location in which the tool places the EDT logic.
<code>set_edt_mapping</code>	Enables or disables automatic mapping of block-level dofile commands so block-level dofiles can be reused without modification for top-level pattern creation.
<code>set_edt_options</code>	Determines whether compression is on and specifies parameters for the EDT logic, including scan channels, bypass circuitry, lockup cells, pipeline stages, and compactor type.
<code>set_edt_pins</code>	By default, all EDT pins are created as dedicated pins with default names and no inversions. The same <code>set_edt_pins</code> command must be used for both the pattern generation phase and the EDT logic creation phase to generate patterns correctly for modified pins.
<code>set_edt_power_controller</code>	Generates and inserts a power controller in the compression logic to enable low-power shift.

Table 6-2. Commands S Through Z (cont.)

Command	Description
<code>set_external_capture_options</code>	Specifies the number of tester cycles to be used in the capture window of all patterns.
<code>set_external_simulator</code>	Specifies the shell command to use to invoke an external simulator for verifying tool-produced patterns.
<code>set_fails_report</code>	Specifies whether the design rules checker displays clock rule failures.
<code>set_failure_mapping_options</code>	Specifies filters you can apply when performing reverse mapping of top-level failures to the core in hierarchical designs flows.
<code>set_fault_mode</code>	Specifies whether the fault mode is collapsed or uncollapsed.
<code>set_fault_sampling</code>	Specifies the fault sampling percentage used for circuit evaluation or scan identification.
<code>set_fault_subclass_analyses</code>	Turns on or off the analysis for the specified fault class(es).
<code>set_fault_type</code>	Specifies the fault model type for ATPG.
<code>set_flattener_rule_handling</code>	Specifies how the tool globally handles flattening violations.
<code>set_gate_level</code>	Specifies the hierarchical level of gate reporting and displaying.
<code>set_gate_report</code>	Specifies the information displayed by the <code>report_gates</code> command and in the DFTVisualizer windows.
<code>set_gzip_options</code>	Specifies GNU gzip options to use with the GNU gzip command.
<code>set_icl_extraction_options</code>	Customizes the behavior of ICL extraction.
<code>set_icl_scan_interface_ports</code>	Sets the names of the ports in the specified scan interface previously added by <code>add_icl_scan_interfaces</code> that ICL extraction will create in the new ICL top module.
<code>set_iddq_checks</code>	Specifies the restrictions and conditions to use when creating or selecting patterns for detecting IDDQ faults.
<code>set_ijtag_instance_options</code>	Sets options on instances for which there is a matched ICL module.
<code>set_ijtag_retargeting_options</code>	Enables you to configure different aspects of ijtag retargeting.
<code>set_insertion_options</code>	Specifies the values for the insertion options. The option settings affect the behavior of the insertion commands.

Table 6-2. Commands S Through Z (cont.)

Command	Description
<code>set_insert_test_logic_options</code>	Sets new prefix/infix values that will be used when logic is created by the <code>insert_test_logic</code> command.
<code>set_internal_fault</code>	Specifies whether the tool allows faults within or only on the boundary of library models.
<code>set_internal_name</code>	Specifies whether to delete or keep pin names of library internal pins containing no-fault attributes.
<code>set_io_mask</code>	Modifies the behavior of bidirectional pins so that their expected values will always be X during test cycles in which the primary input portion of the bidirectional pin is being forced.
<code>set_latch_handling</code>	Specifies whether the tool considers non-transparent latches for scan insertion while test logic is turned on.
<code>set_layout_core_instance</code>	Sets the current layout core instance for inter-scan cell logic reporting with the <code>report_scan_polygons</code> command.
<code>set_lbist_controller_options</code>	Specifies global options to configure the LogicBIST controller.
<code>set_lbist_instances</code>	Specifies the instance in which the LogicBIST controller or single chain mode logic is placed.
<code>set_lbist_pins</code>	Specifies the connection information for LogicBIST controller pins and enables renaming LogicBIST pins.
<code>set_lbist_power_controller_options</code>	Specifies creation of the low-power shift controller for LogicBIST.
<code>set_learn_report</code>	Specifies whether the <code>report_gates</code> command can display the learned behavior for a specific gate.
<code>set_lfsr_seed</code>	Sets the initial value of a PRPG or a MISR.
<code>set_lfsrs</code>	Changes the <code>shift_type</code> and <code>tap_type</code> default setting for the <code>add_lfsrs</code> and <code>add_lfsr_taps</code> commands.
<code>set_license_queue_timeout</code>	Specifies the amount of time that the tool queues for one or more required licenses when not immediately available.
<code>set_list_file</code>	Specifies the name of the list file into which the tool places the pins' logic values during simulation.
<code>set_logfile_handling</code>	Specifies for the tool to direct the transcript information to a file.
<code>set_logical_design_libraries</code>	Defines the set of available logical libraries that can be used by the <code>read_verilog</code> and <code>read_vhdl -in_library</code> option.
<code>set_loop_handling</code>	Specifies how the tool handles feedback networks.

Table 6-2. Commands S Through Z (cont.)

Command	Description
set_lpct_condition_bits	Specifies the condition scan cells (condition bits) in the design core to connect to the Type 3 low pin count test (LPCT) controller.
set_lpct_controller	Enables the creation of and specifies the configurations for a low pin count test (LPCT) controller for use with EDT logic.
set_lpct_instances	Inserts the low pin count test (LPCT) controller and clock gater in a specified hierarchical instance within the design core.
set_lpct_pins	Specifies control pins and connections between the low pin count test (LPCT) controller and the core design.
set_macrotest_options	Prepares a black box macro to allow MacroTest conversion of patterns at the boundaries of that instance.
set_memory_identification_options	Sets options and pattern expressions to validate memory TCD are associated with memory modules to be tested by MemoryBIST.
set_memory_instance_options	Set options on or for memory instances to be used by the check_design_rules and create_dft_specification commands.
set_misr_connections	Describes the connections between the scan chain outputs and the MISR.
set_module_matching_options	Defines the acceptable prefixes and suffixes or regular expressions to use when matching an ICL module to a design module within ICL extraction.
set_multiple_detection	Enables the multiple detection of faults.
set_multiprocessing_options	Sets the values of several variables that affect multiprocessing commands for ATPG or simulation.
set_net_dominance	Specifies the fault effect of bus contention on tri-state nets.
set_net_resolution	Specifies the behavior of multi-driver nets.
set_number_shifts	Sets the number of shifts for loading or unloading the scan chains.
set_observation_point	Specifies the observation point for random pattern fault simulation.
set_output_masks	Ignores any fault effects that propagate to the primary output pins you select.
set_parallel_load_subchains	Specifies whether the internal parallel access functionality is enabled or disabled.

Table 6-2. Commands S Through Z (cont.)

Command	Description
<code>set_pathdelay_holdpi</code>	Specifies whether the ATPG keeps non-clock primary inputs at a constant state after the first force.
<code>set_pattern_buffer</code>	Stores run-time pattern data in temporary files in the directory specified.
<code>set_pattern_classification</code>	Specifies the order in which to store test patterns.
<code>set_pattern_filtering</code>	Creates a temporary set of sampled scan patterns.
<code>set_pattern_source</code>	Specifies the source of the test patterns.
<code>set_pattern_type</code>	Specifies the type of pattern(s) used by ATPG simulation.
<code>set_physical_translation</code>	Translates special Verilog characters to SPICE-readable characters that Calibre applications can read.
<code>set_possible_credit</code>	Specifies the percentage of credit that the tool assigns possible-detected faults.
<code>set_power_control</code>	Enables low-power ATPG and sets up a switching and/or capture threshold.
<code>set_power_metrics</code>	Calculates shift and capture power during test pattern generation and simulation.
<code>set_procedure_cycle_checking</code>	Enables test procedure cycle timing checking to be done immediately following scan chain tracing during design rules checking.
<code>set_procedure_retargeting_options</code>	Controls the behavior of the automatic merging and mapping (retargeting) of core-level load_unload and shift procedures to top-level test procedures and mapping of core-level test_setup and test_end IJTAG procedures.
<code>set_procfile_name</code>	Specifies a new procedure file for the tool to process at a later time.
<code>set_quick_synthesis_options</code>	This command sets options for quick synthesis.
<code>set_ram_initialization</code>	Specifies whether to initialize RAM and ROM gates that do not have initialization files.
<code>set_random_atpg</code>	Specifies whether the tool uses random patterns during ATPG.
<code>set_random_clocks</code>	Specifies whether Tessent FastScan uses combinational or clock_sequential patterns for random pattern simulation.
<code>set_random_patterns</code>	Specifies the number of random patterns that the tool simulates.

Table 6-2. Commands S Through Z (cont.)

Command	Description
set_read_verilog_options	Sets certain options globally for subsequent read_verilog commands.
set_register_value	Allows you to specify the register value variable outside of Setup mode.
set_relevant_coverage	Determines which sub-class(es) of untestable faults are included in or excluded from the relevant coverage reported by the tool.
set_run_synthesis_options	Specifies the default values for options that can be set for the run_synthesis command.
set_scan_chain_options	Specifies options for managing scan chains within the hybrid TK/LBIST flow.
set_scan_enable	Assigns scan_enable signals to specific scan chains.
set_scan_insertion_options	Specifies the high-level options for the scan insertion process.
set_scan_signals	Specifies the input control signals' drivers used by the insert_test_logic command.
set_screen_display	Specifies whether the tool writes the transcript to the session window.
set_shadow_check	Specifies whether the tool identifies sequential elements as "shadow" elements during scan chain tracing.
set_shift_register_identification	Enables/disables shift register identification. The default is ON.
set_silicon_insight_option	Specifies optional settings for running Tesson SiliconInsight.
set_simulation_library_sources	Defines the directories and files in which to search for the simulation Verilog library cells that are to be used by the run_testbench_simulations command.
set_simulation_options	The set_simulation_options command controls the behavior of the tool during pattern generation and simulation.
set_skewed_load	Specifies whether the tool includes a skewed load in the patterns.
set_split_capture_cycle	Controls whether the tool updates simulation data between clock edges.
set_stability_check	Specifies whether the tool checks the effect of applying the main shift procedure on non-scan cells.

Table 6-2. Commands S Through Z (cont.)

Command	Description
set_static_dft_signal_values	Sets the static DFT signal that exists in the design such that the signal can be used as part of a test_setup.
set_static_learning	Specifies whether the tool performs the learning analysis to make the ATPG process more efficient.
set_system_mode	Specifies the operational state you want the tool to enter.
set_tcl_shell_options	Specifies options for the Tcl shell.
set_test_end_icall	Adds an iCall to the start of the test_end procedure.
set_test_logic	Inserts test logic to control the set, reset, clock, enable, or write control signals to make them scannable when scan chains are inserted.
set_test_point_analysis_options	Sets the maximum number of test points, the breakdown in control and observe points, the target fault coverage and the number of pseudo random patterns to be applied and some other parameters that are taken into account during test point analysis.
set_test_point_insertion_options	Sets parameters related to test point insertion.
set_test_point_types	Specifies the type of test points to insert in the design.
set_test_setup_icall	Adds an iCall to the end of the test_setup procedure.
set_testbench_simulation_options	Specifies the default values for a set of options that exist in the run_testbench_simulations command.
set_tied_signals	Changes the default value for floating pins and floating nets which do not have assigned values.
set_timing_exceptions_handling	Changes the default handling of timing exception paths (false paths and multicycle paths) read by the read_sdc command.
set_tla_loop_handling	Specifies how to simulate feedback loops that contain transparent latches (TLAs).
set_tool_options	Sets certain options for Tesson Shell.
set_trace_flat_model_options	Modifies the default behavior of the trace_flat_model command.
set_trace_report	Specifies whether the tool displays gates in the scan chain trace.
set_transcript_style	Specifies the style in which the tool transcripts commands.
set_transient_detection	Specifies whether the tool detects all zero width events on the clock lines of state elements.

Table 6-2. Commands S Through Z (cont.)

Command	Description
set_transition_holdpi	Specifies for the tool to freeze all primary input values other than clocks and RAM controls during multiple cycles of pattern generation.
set_tristate_gating	Specifies how tri-state devices are controlled during scan chain shifting.
set_tsdb_output_directory	Sets the TSDB output directory used by the process_dft_specification command.
set_visualizer_logging	Writes the commands entered into the Transcript window to the file specified by the <i>enhanced_dofile</i> argument.
set_visualizer_preferences	Controls a subset of DFTVisualizer preferences for the Flat Schematic and Hierarchical Schematic windows.
set_wrapper_analysis_options	This command sets up parameters for the wrapper cells analysis.
set_write_patterns_options	Creates the subset of ports or vector callbacks to use with the write_patterns command.
set_xbounding_options	Sets up the parameters for X bounding insertion. The analysis is triggered by the analyze_xbounding command.
set_xclock_handling	Specifies whether the sequential element model outputs X when any of its clock inputs become X.
set_z_handling	Specifies the simulation handling for high impedance signals on internal and external tri-state nets.
set_zhold_behavior	Specifies whether ZHOLD gates retain their state values.
setenv	Sets a shell environment variable within the tool environment.
shutdown_sid_tester	Terminates the currently active SID tester process that was created by executing the launch_sid_tester command.
simulate_clock_pulses	Pulses one or more clocks within the current simulation context.
simulate_forces	Simulates the queued forces in the current simulation context.
simulate_patterns	Performs simulation by applying the specified pattern source.
sizeof_collection	Returns the number of objects in a collection.
sort_collection	Sorts a collection based on the value of one or more attributes, resulting in a new sorted collection.

Table 6-2. Commands S Through Z (cont.)

Command	Description
start_silicon_insight	Starts Tessent SiliconInsight and initializes the data structures.
stop_silicon_insight	Stops Tessent SiliconInsight.
system	Passes the specified command to the operating system for execution.
trace_flat_model	Traces the flat model taking into account the current simulation context.
uncompress_layout	Uncompresses a Layout Database.
uniquify_instances	Uniquifies the module definition of the specified instance objects found in obj_spec.
unmark_display_instances	Returns the specified marked instances to their original color. Color marking occurs with the mark_display_instances command.
unregister_attribute	Unregisters a user-defined attribute that was registered using the register_attribute command.
unregister_static_dft_signal_names	Unregisters previously registered static DFT signal names.
unregister_tcl_command	Unregisters a command that was previously registered using the register_tcl_command.
unselect_display_instances	Unselects the specified objects in the Flat and Hierarchical Schematic window(s).
unsetenv	Unsets a shell environment variable within the tool environment.
update_implication_detections	Performs an analysis on the undetected and possibly detected faults to determine if any of those faults can be classified as detected-by-implication.
verify_patterns	Performs pattern verification for diagnosis, and creates, updates, or loads the Diagnosis Startup Cache for use with the diagnosis tool.
write_atpg_setup	Writes a test procedure file and a dofile that describes the chains that were created during scan insertion. In addition, for multi-mode scan insertion, the tool also generates a dofile that can be used to verify all of the defined scan modes.
write_cell_library	Writes out a single library file of all library files loaded by the read_cell_library command.

Table 6-2. Commands S Through Z (cont.)

Command	Description
<code>write_config_data</code>	Writes the configuration data presently in memory into a file. When using the -wrappers option, the data written to the file can be limited to some specific wrappers.
<code>write_core_description</code>	Writes out the core description corresponding to the current chip level.
<code>write_core_timing_constraints</code>	Creates timing (SDC) files that provide the constraints related to the scan path and ATPG settings in the core design.
<code>write_design</code>	Writes the current design in Verilog netlist format to the specified file.
<code>write_design_import_script</code>	Generates a script that can be processed by a synthesis tool to synthesize an RTL design that has been DFT inserted.
<code>write_design_source_dictionary</code>	Writes a design-source dictionary into a file. This file contains the file and directory paths relative to the output file location.
<code>write_diagnosis</code>	Writes diagnosis reports in text, comma separated values (CSV), and layout (physical) marker location formats.
<code>write_edt_files</code>	Creates the files that implement the EDT logic.
<code>write_failing_paths</code>	Reports, for each diagnosed symptom from a failure log, the scan pattern number, suspect(s) and paths.
<code>write_failures</code>	Injects faults and/or writes failing pattern results to a file.
<code>write_fault_sites</code>	Writes path definitions or bridge entries from the internal list to a file.
<code>write_faults</code>	Writes fault information from the current fault list to a file.
<code>write_flat_model</code>	Saves the flattened circuit model, the scan trace, and all DRC-related information to a specific binary file.
<code>write_icl</code>	Writes out ICL modules created and/or read in with the <code>read_icl</code> command to the specified file.
<code>write_loops</code>	Writes a list of all the current feedback loops to a file.
<code>write_memory_repair_dictionary</code>	Writes the CompressBisrChain configuration file.
<code>write_modelfile</code>	Writes all internal states for a RAM or ROM gate into the file that you specify.
<code>write_patterns</code>	Saves the current test pattern set to a file in a specified format.
<code>write_primary_inputs</code>	Writes primary inputs to the specified file.

Table 6-2. Commands S Through Z (cont.)

Command	Description
write_primary_outputs	Writes primary outputs to the specified file.
write_procedure_testbench	Writes a test bench for verifying correct operation of internal signals used in procedures.
write_procfile	Writes existing procedure and timing data to the named test procedure file.
write_scan_order	Writes the scan chains into the SCANCHAINS section of the ScanDEF file, where each statement describes a single scan chain. ScanDEF is a subset of the DEF language.
write_scan_setup	Writes out a dofile containing all necessary steps for scan insertion.
write_test_point_dofile	Writes out a dofile containing the test points.
write_tsdb_data	Populates the contents of the Tesson Shell Data Base (TSDB).
write_visualizer_dofile	Writes a dofile containing the commands needed to recreate the current instance and data sets displayed in the DFTVisualizer windows.
write_visualizer_preferences	Writes the current DFTVisualizer preference settings to the specified file.
write_window_contents	Saves the current content of the specified DFTVisualizer window to the specified file.

select_display_instances

Context: all contexts

Mode: setup, analysis

Selects the specified objects in the Flat Schematic and Hierarchical Schematic windows.

Usage

```
select_display_instances {{gate_id# | instance_name | pin_pathname} ... [-ADD] | -ALI}  
[-Display {FLAt_schematic |  
HIErarchical_schematic}]
```

Description

Selects the specified objects in the Flat Schematic and Hierarchical Schematic window(s).

By default, the command first unselects any previously selected gates. To keep previously selected gates selected, include the -Add switch.

Arguments

- ***gate_id#***

A repeatable integer that specifies the gate identification number of a gate to select. The value of the *gate_id#* argument is the unique identification number that the tool automatically assigns to every gate within the design during the model flattening process.

- ***instance_name***

A repeatable string that specifies the name of an instance to select.

- ***pin_pathname***

A repeatable string that specifies the name of a pin associated with a gate you want to select.

- **-ADD**

An optional switch that selects specified objects without first unselecting previously-selected objects.

- **-ALI**

A switch that selects all currently displayed gates.

- **-Display {FLAt_schematic | HIErarchical_schematic}**

An optional switch and literal pair that specifies the window in which this command selects objects. The following literals can be used with the -Display switch:

FLAt_schematic — Selects the specified objects in the Flat Schematic window. This is the default behavior.

HIErarchical_schematic — Selects the specified objects in the Hierarchical Schematic window.

Examples

The following example first selects one object in the Flat Schematic window, then selects two more without unselecting the first:

```
select_display_instances /i$144/q  
select_display_instances /i$142/q /i$141/q -add
```

Related Topics

set_abort_limit

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies the abort limit for the test pattern generator.

Usage

```
set_abort_limit comb_abort_limit [seq_abort_limit]
```

Description

Specifies the abort limit for the test pattern generator.

The set_abort_limit command performs slightly differently depending on which tool you are using. Use this command when there are some remaining undetected faults and the test coverage is still too low. By increasing the abort limit, you can allow the tool to detect those remaining undetected faults, and thereby raise the coverage. The following paragraphs describe how the command operates for each tool.

Tip

 If you use the [create_patterns](#) command, you do not need to issue this command. This is because create_patterns automatically determines an appropriate abort limit.

The set_abort_limit command specifies, for combinational and/or clock sequential test generation, the maximum number of attempts the test pattern generator allows before aborting a fault. If the limit is too low, the test pattern generator may abort too many faults and fault coverage could be too low. However, if the limit is too high, it may take too much time to complete the test generation process. The default combinational abort limit value is 30.

During the test generation process for a given fault, the test pattern generator attempts combinational or ram sequential test generation first. If this fails to create a test or prove redundancy, and you specified a non-zero sequential depth by using the [set_pattern_type](#) command, the test pattern generator performs clock sequential test generation. The default abort limit for clock sequential test generation is the same as that for the combinational test generation (30).

Arguments

- ***comb_abort_limit***

A required integer that specifies the maximum number of conflicts for each target fault that the test pattern generator allows during the combinational test generation process. The default is 30.

If you set the combinational abort limit to 0 and the test pattern generator can perform clock sequential test generation, the generator does not perform combinational test generation.

- ***seq_abort_limit***

An optional integer that specifies the maximum number of conflicts for each target fault that the test pattern generator allows during the clock sequential test generation process. The default is the current *comb_abort_limit* default.

If you set the sequential abort limit to 0, the test pattern generator does not perform clock sequential test generation.

Examples

The following example performs an ATPG run, then continues the run with a higher abort limit for the maximum number of allowed conflicts:

```
set_system_mode analysis
create_patterns
set_abort_limit 100
create_patterns
```

set_atpg_fill

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies how the tool should fill unspecified bits in ATPG patterns.

Usage

`set_atpg_fill {Random | X | 0 | 1}`

Description

Specifies how the tool should fill unspecified bits in ATPG patterns.

Every pattern generated by ATPG has deterministic bits and unspecified bits. This command allows you to specify that the tool fills those unspecified bits with random values (the default) or X's, 0's, or 1's. This command is useful for getting the test cube that the ATPG generated to test a given fault by setting the fill to X.

Note, this command is only valid in Tessent TestKompress when EDT is set to off with the “[set_edt_options -off](#)” command.

Arguments

- Random | X | 0 | 1

A required literal that instructs the tool how to fill unspecified bits in ATPG patterns.

Examples

The following example fills unspecified bits in ATPG patterns with X's:

`set_atpg_fill X`

[set_atpg_limits](#)

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies the ATPG process limits at which the tool terminates the ATPG process.

Usage

```
set_atpg_limits {OFF|{[-Cpu_seconds [OFF|integer]] [-Pattern_count [OFF|integer]] [-Test_coverage [OFF|real | {real integer} ...]]}}
```

Description

Specifies the ATPG process limits at which the tool terminates the ATPG process.

The `set_atpg_limits` command determines the limitations under which the ATPG process operates. Upon invocation of the tool, all the command option limitations are off. If you set any of the limitations, and during an ATPG run the tool reaches one of those limits, the tool terminates the ATPG process. You can use any combination of the three arguments (limitation types). When you specify more than one limitation types, the tool terminates the ATPG process when any of the specified limitation types reaches its limit.

You can check the current settings of the `set_atpg_limits` command by using the [report_environment](#) command.

Arguments

- OFF
An optional literal that turns off *all* ATPG process limits previously set with this command.
- -Cpu_seconds OFF | *integer*
An optional switch and argument pair that specifies the maximum number of CPU seconds that any future ATPG process can consume before the tool terminates the process. The argument choices are as follows:

OFF—A literal specifying that there is no limit to the amount of CPU time the ATPG process consumes during an ATPG process. This is the invocation default.

integer—A positive integer that specifies the maximum number of CPU seconds that the tool can consume during an ATPG process. When the tool reaches the maximum, it terminates the ATPG process.

- -Pattern_count [OFF | *integer*]
An optional switch and argument pair that specifies the maximum number of test patterns that any future ATPG process can generate before the tool terminates the process. The argument choices are as follows:

OFF—A literal specifying that there is no limit to the number of test patterns the ATPG process generates during an ATPG process. This is the invocation default.

integer — A positive integer that specifies the maximum number of test patterns that the tool can generate during an ATPG process. When the tool reaches the maximum, it terminates the ATPG process.

- -Test_coverage [OFF | *real* | {*real integer*} ...]

An optional switch and argument pair that specifies the maximum percentage of test coverage that any future ATPG process need reach before the tool terminates the process. The argument choices are as follows:

OFF — A literal specifying the 100 percent test coverage limit during an ATPG process.

The tool terminates the ATPG process when either 100 percent coverage is attained or when the ATPG process has completed. This is the invocation default.

real — A positive real number that specifies the maximum percentage of test coverage that the tool should achieve during an ATPG process (value range is 0 to 100.0).

When the tool reaches the maximum, it terminates the ATPG process.

{*real integer*} — One or more pairs of real and integer numbers that specifies the multiple detect coverage. For example, “-test_coverage 90.5 2” specifies the multiple detect test coverage as 90.5 for multiple detection of 2.

When you specify multiple list pairs, such as “-test_coverage 95 1 85 5,” ATPG stops at 95% coverage in the first pass targeting one detect. Then in the second pass, ATPG stops at 95% or if it completes before 95%. This continues for passes 3 and 4. Pass 5 (targeting 5-detect) stops when ATPG reaches 85% or if it completes before 85%. When you specify multiple list pairs, you cannot associate a higher detect number with a higher test coverage limit. When you specify multiple test coverage limits, the tool terminates the ATPG process only when all limits are met.

Examples

Example 1

The following example sets two of the three limits on the ATPG process and then shows the relevant setup data from the report_environment command:

```
set_atpg_limits -cpu_sec 500 -test_coverage 99.5 -pattern_count 100000
report_environment

...
atpg limits =      500.00 sec 95.50% coverage 100000 patterns
...
```

If the ATPG process reaches either of these two limits, the process terminates. Notice that the information from the report_environment command only shows the settings that are different from the invocation defaults of Off.

Example 2

The following example shows ATPG to target 5-detect with 99% test coverage as first detect limit and 95% multiple detect test coverage limit for the 2-detect to 5-detect:

```
set_multiple_detection -guaranteed_atpg_detections 5
set_atpg_limits -test_coverage 99 1 95 2
report_environment
create_patterns
```

[report_environment](#)

set_atpg_timing

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Enables and defines parameters for timing-aware ATPG and fault simulation.

Usage

```
set_atpg_timing
  [OFF | ON]
  [[-Clock_waveform {DEFAULT | clock_pin_pathname | clock_gate_id}
    {clock_waveform}...]
   [-DELEte_clock_waveform {ALL | clock_pin_pathname | clock_gate_id}...]
   [-SLack_margin_for_fault_dropping {OFF | slack_margin | slack_margin_percentage%}]
   [-TIMING_CRITICAL timing_margin%]]
```

Description

Enables and defines parameters for timing-aware ATPG and fault simulation.

For complete information, see “[Timing-Aware ATPG](#)” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- OFF | ON
An optional literal that disables or enables timing-aware ATPG.
- -Clock_waveform
An optional switch that defines a clock waveform for evaluating slack and test metrics.

With the exception of SDQL, timing-aware ATPG uses the test clock frequency for the clock waveform you specify with this switch. The test clock frequency is the ATE testing clock frequency, which may not be the same as the normal operation frequency (System Clock).

When you issue the [report_atpg_timing](#) command, the tool reports both the test clock and system clock.

Note

 The timing information from the test procedure file is not used. You must define the clock information for all clocks in the design, even for those not used for ATPG (not used in a named capture procedure).

There are two parameters associated with the -Clock_waveform switch:

DEFAULT | *clock_pin_pathname* | *clock_gate_id*

A string that identifies the clock pin either by pin pathname or gate id. Use the DEFAULT keyword to define a waveform for all clocks that are not explicitly

defined. If you define multiple waveforms for a pin or gate id, the last specified waveform is used.

clock_waveform

Defines the waveform of the clock. The clock waveform will be used for the test clock domain.

The *clock_waveform* includes three floating numbers in the following order, separated by commas:

clock_period, offset, pulse_width

The units are the same as what is specified in the SDF file, which defaults to 1 ns.

- **-DELEte_clock_waveform {ALL | *clock_pin_pathname* | *clock_gate_id*}**

An optional switch and string or literal pair that deletes a clock waveform that was previously defined by the -clock_waveform switch. Use the ALL keyword to delete all explicitly defined clock waveforms. The DEFAULT clock waveform is not deleted by the ALL keyword.

- **-SLack_margin_for_fault_dropping [OFF | *slack_margin* / *slack_margin_percentage%*]**

An optional switch and literal or numerical pair that specifies the fault dropping criteria in addition to the fault detection.

The default setting for this switch is 50%. This means that for faults detected by fault simulation, if the testable minimum slack (Tms) is more than 50% of the actual test slack (Ta), then the fault is dropped. (When ATPG targets a fault, that fault is effectively dropped no matter what fault dropping criteria is in effect.)

OFF

Disables the additional dropping criteria, so the detection by the fault simulation is the same as the regular transition faults.

slack_margin

When a real number “r” is specified without a percentage sign (%), it is treated as the slack margin for the fault dropping condition. A fault is dropped from the target list when the fault is detected and the following condition holds:

$$(Ta-Tms) < r$$

Where Ta is the slack used by ATPG, and Tms is the testable minimum slack with respect to the test clock.

slack_margin_percentage%

If a real number “r”, ranged in [0, 100.0], is followed by a percentage sign (%), it is treated as the slack margin percentage for the fault dropping condition. A fault is dropped from the target list when the fault is detected and the following condition holds:

$$(Ta-Tms)*100/ Ta < r$$

Where Ta is the slack used by ATPG, and Tms is the testable minimum slack with respect to the test clock.

If set to 100%, faults are dropped regardless of slack.

- **-TIMING_CRITICAL timing_margin%**

An optional switch and numerical pair that selects timing-critical faults. Before running ATPG, the static longest delay path is calculated for each fault. The *timing_margin* is calculated using the following equation:

$$\text{Timing_margin\%} = (\text{static_longest_delay_path}) / (\text{static_longest_delay_path} + \text{slack}) * 100\%$$

If the *timing_margin* for a fault is greater than the specified value, the fault will be selected. For example, assume there are two faults (F1 and F2) with static longest delay paths of 8.5 ns and 9.5 ns, respectively. The clock period is 10 ns, which creates a *timing_margin* of 85% for F1 and 95% for F2. If you specify “-timing_critical 90%”, F2 is selected and F1 is not.

ATPG still runs with the complete fault list, but the *slack_margin_for_fault_dropping* is applied only to the selected timing-critical faults. Selecting a large *timing_margin* (90%) is recommended to speed up ATPG. If you want to target only selected timing-critical faults, follow the command sequence described in “[Run Time Reduction for Timing-Aware ATPG](#)” in the *Tessent Scan and ATPG User’s Manual*.

Examples

The following example enables timing-aware ATPG and defines the clock information:

```
set_atpg_timing -clock test_clk 16000 8000 8000
set_atpg_timing -clock default 36000 18000 18000
set_atpg_timing on
```

[report_atpg_timing](#)
[report_statistics](#)

set_attribute_options

Context: unspecified, all contexts

Mode: all modes

Modifies options of any registered user-defined attribute.

Usage

```
set_attribute_options -name attribute_name_list [-object_types type_list]
    [-export_during_write {auto | off | on}]
    [-preserve_boundary_in_flat_model {off | on}]
    [-applies_to_child_instances {off | on}]
    [-display_in_gui {off | on}]
    [-gui_marking_index marking_index] [-silent]
```

Description

Modifies options of any registered user-defined attribute.

Specifically, this command modifies the `-applies_to_child_instances`, `-preserve_boundary_in_flat_model`, `-display_in_gui`, and `-gui_marking_index` options of any registered user-defined attribute.

Arguments

- **-name attribute_name_list**

A required switch and value pair that specifies an attribute name or a Tcl list of attribute names whose options are to be modified.

- **-object_types type_list**

An optional switch and value pair that specifies the object type or a Tcl list of design object types whose attribute configuration settings are to be modified. The attributes of object types not included in this list remain unaffected. If this argument is omitted, by default, the attribute options of all design object types for which the attributes are registered on are modified.

- **-export_during_write auto | off | on**

An optional switch and literal pair that specifies which module and port ICL attributes are written into the ICL output when a module is written out using the [write_icl](#) command. Any attribute that does not have this value set is written out in the same form as it was read in; any attribute value set with the [set_attribute_value](#) command since being read in is ignored.

You should use this default behavior when you want to write out the attribute as it was read in. You can modify the default behavior using the following literals:

auto — Use *auto* when you want to update the value of an attribute that was read in with the ICL source. In this case, the value read in from ICL is written out unless an alternative value has been set using the [set_attribute_value](#) command, which will be written out instead. If the ICL source did not have an attribute definition, the value set

using the `set_attribute_value` command is ignored and not written out when the ICL is written.

on — Use *on* when you want to update an attribute that was read in with the ICL source, or to cause a new ICL attribute definition to be created for that attribute when the ICL is written. The attribute value set using the `set_attribute_value` command is written out when the ICL is written out. However, the attribute definitions that were not read in from the ICL source are also written out.

off — Use *off* when you want an attribute to be ignored and omitted as the ICL is being written out. The value read in from ICL and any subsequent attribute value set using the `set_attribute_value` is ignored when the ICL is written out. The output ICL file will not have an attribute definition for this attribute.

- `-preserve_boundary_in_flat_model off` **on**

An optional switch that specifies whether to preserve certain hierarchical pins or nets and their attributes during design flattening based on an attribute of a module, instance, port, pin, or net. The `-preserve_boundary_in_flat_model` only works with hierarchical design objects: modules, instances, ports, pins, and nets. If you attempt to use this option with objects other than hierarchical design objects, then the tool issues a warning and ignores the option.

For module attributes, this option preserves all pins of all instances of the module, if the attribute is set to a non-default value. For instance attributes, this option preserves all pins of the instance, if the attribute is set to a non-default value. For port attributes, this option preserves only the corresponding pin on each instance of the port's module, if the attribute is set to a non-default value. These preserved hierarchical pins become buffers in the flat model and are no-faulted. By default, hierarchical pins are not preserved. For net attributes, this option preserves the net boundary with a buffer in the flat model which drives the original fanout of the net and provides a [Gate_pin](#) having the name of the net.

If you set an attribute on a pin of a design model, instance, port, pin, or net by enabling this option, the flat model will need to be reconstructed. The attribute is not lost during flattening.

Note that by default, only the boundaries of library cells are preserved in the flat model. (Those are the locations where faults are added for ATPG, for example.) So the boundaries of higher-level modules in the design are not preserved in the flat model by default. When you use the “`-preserve_boundary_in_flat_model on`” switch, each hierarchical pin or net and boundary of an instance is preserved in the flat model with place-holder buffers corresponding to each pin or net. A `gate_pin` object then exists in the flat model to match the hierarchical pin or net. The instance names of the pin or net and `gate_pin` are the same.

- `-applies_to_child_instances off` **on**

An optional switch that defines if the attribute is also visible on the instances below the instances or the instances of the modules on which the attribute is defined. This option can only be set to true on attributes defined for objects of type instance or module.

- **-display_in_gui {off|on}**

An optional switch and literal pair that specifies whether the attribute(s) specified by the name argument is visible in the Debug and DesignFlat and Hierarchical Schematic windows of DFTVisualizer.

off — The attribute is not visible in the Debug and DesignFlat and Hierarchical Schematic windows.

on — The attribute is visible in the Debug and DesignFlat and Hierarchical Schematic windows.

- **-gui_marking_index *marking_index***

An optional switch and value pair that specifies the marking index that DFTVisualizer uses when displaying the attribute(s). The marking index is an integer (1-10) that maps to one of ten colors. DFTVisualizer uses the specified color as a background when it displays the attribute. The default is 1 which maps to light blue.

- **-silent**

An optional switch that suppresses error messages if one or more attributes in *attribute_name_list* do not exist.

Examples

Example 1

The following example shows how to configure the attribute named power_domain in order for it to be visible in all child instances of the instance for which it is defined:

```
set_attribute_options -name power_domain -object_types instance
                     -applies_to_child_instances on
```

Example 2

This example demonstrates how an attribute value is written or not written into the ICL module representation based on the value of the set_attribute_options -export_during_write setting. This example assumes that the following ICL module has been read in:

```
Module block {
    DataInPort din;
    DataOutPort dout;
    Attribute speed = "100";
}
```

Executing the following commands in Tessent Shell, using the default set_attribute_options settings, produces the module definition that follows:

```
register_attribute -name speed -object_type icl_module -value_type string
set_attribute_value [get_icl_modules block] -name speed -value "200"
register_attribute -name added_by -object_type icl_module -value_type string
set_attribute_value [get_icl_modules block] -name added_by -value "John"

# report the ICL module with the default attribute export_during_write setting
report_icl_module block
```

```
Module block {
    DataInPort din;
    DataOutPort dout;
    Attribute speed = "100";
}
```

Executing the following additional commands in Tessent Shell, using the `set_attribute_options auto` setting, produces the module definition that follows:

```
# set the attribute to auto export
set_attribute_options -name speed -export_during_write auto
set_attribute_options -name added_by -export_during_write auto
report_icl_module block

Module block {
    DataInPort din;
    DataOutPort dout;
    Attribute speed = "200";
}
```

Executing the following additional commands in Tessent Shell, using the `set_attribute_options on` setting, produces the module definition that follows:

```
# set the attribute to always export
set_attribute_options -name speed -export_during_write on
set_attribute_options -name added_by -export_during_write on
report_icl_module block

Module block {
    DataInPort din;
    DataOutPort dout;
    Attribute speed = "200";
    Attribute added_by = "John";
}
```

Executing the following additional commands in Tessent Shell, using the `set_attribute_options off` setting, produces the module definition that follows:

```
# set the attribute to always export
set_attribute_options -name speed -export_during_write off
set_attribute_options -name added_by -export_during_write off
report_icl_module block

Module block {
    DataInPort din;
    DataOutPort dout;
}
```

set_attribute_value

Context: unspecified, all contexts

Mode: all modes

Sets an attribute's value for the objects specified in *object_spec*.

Usage

```
set_attribute_value object_spec -name attribute_name -value attribute_value [-silent]
```

Description

Sets an attribute's value for the objects specified in *object_spec*. This command returns a collection of objects on which the attribute value has been set.

If the command fails setting the attribute on any element, an error message is given to the user and the command returns TCL_ERROR. This can be suppressed by using -silent (No error messages and no TCL_ERROR).

[Table 6-3](#) lists some of the attributes that you can specify with the `set_attribute_value` command.

Table 6-3. User-Specifiable Attributes

Name	Definition	Object	Values
default_fault_classification_0	<p>String that provides an initial fault classification for the gate_pin on which it is set. This attribute corresponds to stuck-at-0 or slow-to-rise. You use the “set_attribute_value” command to set the desired default fault classification. During the flow, when the “add_faults” and “load_faults” commands are called, or when the tool internally adds faults for scan-based test pattern generation, the fault sites marked with this attribute will be initialized with the specified default fault classification, instead of UC. This attribute only applies to the stuck fault model and transition fault model. It also applies to the UDFM fault model with no condition (for example, port faults) so that UDFM continues to work as a superset of stuck/transition. If this is set on a pin that is no-faulted or a non-fault site, it will be ignored.</p> <p>This attribute is useful to identify gate_pins which are AU during scan-based test generation, but tested by some other test mode. You identify those faults using DI.<label>, where label identifies the test mode in which those faults are covered. For example, Tessent memory BIST uses the DI.mbisr value to identify the fault in the BISR register which are not testable by scan-based test generation, but covered in the memory BIST test.</p> <p>See Example 4 below for a typical use model</p>	pin or gate_pin	Any pre-defined fault class and subclass(if fault class is AU or DI). Default value is UC.

Table 6-3. User-Specifiable Attributes (cont.)

Name	Definition	Object	Values
default_fault_classification_1	<p>String that provides an initial fault classification for the gate_pin on which it is set. This attribute corresponds to stuck-at-1 or slow-to-fall. You use the “set_attribute_value” command to set the desired default fault classification. During the flow, when the “add_faults” and “load_faults” commands are called, or when the tool internally adds faults for scan-based test generation, the fault sites marked with this attribute will be initialized with the specified default fault classification, instead of UC. This attribute only applies to the stuck fault model and transition fault model. It also applies to the UDFM fault model with no condition (for example, port faults) so that UDFM continues to work as a superset of stuck/transition. If this is set on a pin that is no-faulted or a non-fault site, it will be ignored.</p> <p>This attribute is useful to identify gate_pins which are AU during scan-based test generation, but tested by some other test mode. You identify those faults using DI.<label>, where label identifies the test mode in which those faults are covered. For example, Tessent memory BIST uses the DI.mbrisr value to identify the fault in the BISR register which are not testable by scan-based test generation, but covered in the memory BIST test.</p> <p>See Example 4 below for a typical use model</p>	pin or gate_pin	Any pre-defined fault class and subclass(if fault class is AU or DI). Default value is UC.
ignore_for_graybox	Specifies a primary output/bidi pin to exclude from graybox analysis. By default, this attribute is set to false for all primary output/bidi pins, hence they are considered by the graybox analysis as backtracing origins. Setting this attribute on an output/bidi pin of a sub-module or an input pin of any module has no effect on graybox analysis. You need to exclude the scan output pins of core chains (or channel output pins if it is a design containing EDT hardware) from graybox analysis using this attribute because the tool cannot automatically determine which output/bidi pins are for core chains. For more information about this attribute, refer to the analyze_graybox command description.	pin	true, false (default)
in_graybox	Specifies instances to include or exclude from graybox netlist. For more information about this attribute, refer to the analyze_graybox command description.	instance, net	true, false (default)

Table 6-3. User-Specifiable Attributes (cont.)

Name	Definition	Object	Values
is_hard_module	When true, prevents a module from having any changes to its internal logic during test logic insertion, meaning that the module is written to the scanDEF file unexpanded (the scanDEF file references the hard macro's module instance rather than any flip-flops inside).	module	true, false (default)

Arguments

- ***object_spec***
A required value that specifies a Tcl list of one or more object names, or a collection of one or more objects.
- **-name *attribute_name***
A required switch and value pair that specifies the name of the attribute to set.
When an initial fault classification for a pin is specified with the default_fault_classification_0 or default_fault_classification_1 attributes (for example, DI.USER), the fault will first be analyzed through DI/UU/TI/BL fault analysis and will only be added by its specified name (DI.USER) if it is not classified as a DI/UU/TI/BL fault.
- **-value *attribute_value***
A required switch and value pair that specifies the value to which to set the attribute.
- **-silent**
An optional switch that suppresses error messages.

Examples

Example 1

The following example sets the is_hard_module attribute to true for all modules whose names starts with mem_.

```
set_attribute_value [get_modules mem_*] -name is_hard_module
{mem_a mem_b mem_c}
```

Example 2

This example sets the user-defined attribute clock_domain to clka on pin u1/u2/ck.

```
set_attribute_value u1/u2/ck -name clock_domain -value clka
{u1/u2/ck}
```

Example 3

The following example excludes clk1 and clk2 from X-constraining during core-level retargetable pattern generation of the CPU core.

```

SETUP> set_context patterns -scan
SETUP> set_current_mode -type internal
SETUP> read_verilog CPU.v
SETUP> read_cell_library atpglib
SETUP> set_current_design
SETUP> set_attribute_value {clk1 clk2} -name \
    is_excluded_from_isolation_constraints
SETUP> set_system_mode analysis
ANALYSIS> write_core_description CPU.tcd -replace
ANALYSIS> create_patterns
ANALYSIS> write_patterns CPU_stuck.retpat.qz -replace
ANALYSIS> write_faults CPU_stuck.faults.qz -replace
...

```

Example 4

This example uses the trace_flat_model command to find all the fault sites in the combinational fanout of a port and initialize them as “DI.my_test_mode”. This port is not testable by scan-based test generation, but it is covered by another test mode called “my_test_mode”. Instead of ending up as AU, the fault sites are marked as DI.my_test_mode.

```

SETUP> set_context patterns
SETUP> read_cell_library atpgff.atpg_lib
SETUP> read_verilog design.v
SETUP> set_current_design
SETUP> create_flat_model
SETUP> set gate_pins [trace_flat_model \
    -from my_test_port \
    -direction forward \
    -controllability connected \
    -tag_condition "fault_site"]
SETUP> set_attribute_value $gate_pins -name default_fault_classification_0 -value
DI.my_test_mode
SETUP> set_attribute_value $gate_pins -name default_fault_classification_1 -value
DI.my_test_mode

```

[set_au_analysis](#)

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies whether the ATPG uses the ATPG untestable information to place ATPG untestable faults directly in the AU fault class.

Usage

`set_au_analysis {ON | OFF}`

Description

Specifies whether the ATPG uses the ATPG untestable information to place ATPG untestable faults directly in the AU fault class.

The `set_au_analysis` command specifies whether the ATPG process can use the ATPG untestable information. Upon invocation of the tool, the AU analysis is set to On; therefore, the ATPG process uses the ATPG untestable information. Once the tool places a fault in the AU fault class, it removes the fault from the active fault list and does not simulate it. This prevents the ATPG process from identifying the faults as possibly-detected during an ATPG run. However, you may use a switch on the `compress_patterns` command to identify possible detections of AU faults.

Arguments

- **ON**

A literal that specifies for the tool to use the ATPG untestable information to place ATPG untestable faults directly in the AU fault class during any future ATPG processes. This is the invocation default.

- **OFF**

A literal that specifies for the tool not to use the ATPG untestable information to place ATPG untestable faults directly in the AU fault class during any future ATPG processes.

Examples

The following example specifies not to use ATPG untestable information during the ATPG run:

```
set_system_mode analysis
set_au_analysis off
create_patterns
```

set_bidi_gating

Context: dft -scan, dft -test_points

Mode: setup

Specifies how bidirectional (bidi) pins are controlled during scan chain shifting to prevent potential bus contention or to ensure an on/off state during testing.

Usage

```
set_bidi_gating [Off | ON | Scan] [-Control {SEn | TEn}] [-Direction Input | Output]
[-Top {All | primary_bidi_pin...}] [-Force_gating]
```

Description

Specifies how bidirectional (bidi) pins are controlled during scan chain shifting to prevent potential bus contention or to ensure an on/off state during testing.

When enabled, test logic is inserted for bidi pins as necessary to control the enable signal and/or the input/output direction as specified.

By default, when the enable signal of a bidi pin is directly controlled by a primary input, by TIE0, or by TIE1, no gating is necessary and a force statement for the primary input is added to the load_unload procedure in the new procedure file. This behavior can be overridden by using the -Force_gating switch.

You can also specify which enable signal (TEN or SEN) enables bidi pins.

Arguments

- **Off | ON | Scan**

Required literal that specifies whether to insert test logic to control the enable lines of bidi pins during scan chain shifting. For more information on scan chain shifting, see “[Test Logic Insertion](#)” in the *Tessent Scan and ATPG User’s Manual*. Literal options include:

Off — no test logic is inserted to control bidi pins. Default setting.

ON — test logic is inserted as necessary to control bidi pins.

Scan — inserts test logic on the scan I/O bidi pins to control the direction of the bidi pin for scan shifting and ensure the success of scan chain tracing. Scan output bidi pins are gated to be in output mode while all other bidi pins are gated to be in input mode (Z state on the tester).

- **-Control SEn | TEn**

An optional switch and literal pair that specifies the enable signal used to control bidi pins. Options include:

SEn — scan_enable signal. Default setting.

TEn — test_enable signal.

- **-Direction Input | Output**

An optional switch and literal pair that specifies the direction of the bidi pins specified by the **-Top** switch. Options include:

Input — bidi pins are gated so they are in input mode. Default setting.

Output — bidi pins are gated so they are in output mode.

- **-Top All | *primary_bidi_pin*...**

An optional switch and literal or repeatable string pair that specifies which bidi pins are controlled with the specified enable signal. Options include:

All — all bidi pins. Default setting.

primary_bidi_pin — a specified primary bidi pin. Test logic is inserted to ensure that these bidi pins are controlled as specified.

- **-Force_gating**

An optional switch that adds test logic to the enable lines of bidirectional pins that are directly controlled by primary inputs, by TIE1, or by TIE0. When the enable line is directly controlled by a primary input, the tool adds the force statement for this primary input to the load_unload procedure in the procedure file.

Examples

Example 1

The following example uses the **set_bidi_gating** command to insert test logic to control all bidi pins used for scan I/O via the SEN signal, and reports the gated bidi pin.

```
add_clocks 0 clk
set_tristate_gating on
set_bidi_gating scan
set_system_mode analysis
add_scan_mode unwrapped -si_connections c1 bidi_in1/X \
    -so_connections blkB1/blkA/utri2/A
analyze_scan_chains
```

Example 2

The following example uses the **force_gating** switch to insert gating logic controlled by the TEN control signal on the enable line of /ui01 and reports the gated tri-state devices. /ui01 is a bidirectional device driving primary inout port dinout[1]; its enable signal is directly controlled by the primary input /io_control1.

```
set_bidi_gating on -control ten -direction input -top dinout[1] -force_gating
```

set_bist_chain_test

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Disables all capture clock activity for the specified number of patterns in the fault simulation during execution of the chain test.

Usage

`set_bist_chain_test [None | number_of_patterns]`

Description

Disables all capture clock activity for the specified number of patterns in the fault simulation during execution of the chain test.

By default, the tool runs a 32 pattern chain test and disables all capture clock activity for those 32 patterns, which means that the unload values will exactly match the load values during those patterns.

Hybrid TK/LBIST Flow

The tool automatically includes this command and literal in the generated logicBIST fault simulation dofile—refer to the *Hybrid TK/LBIST Flow User's Manual* for complete information.

Arguments

- None
An optional literal that specifies that the tool should not disable the capture clock activity since there is no chain test being ran.
- *number_of_patterns*
An optional integer that specifies for the tool to disable all capture clock activity for the number of chain test patterns that are to be driven through the scan chains, which is 32 by default.

[read_patterns](#)

[set_random_patterns](#)

set_bist_debug

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Sets up a trace of LFSR(s) value during a pattern's shift cycles.

Usage

```
set_bist_debug -None | [LFSR_name... {pattern_number | All}]
```

Hybrid TK/LBIST Flow Usage

```
set_bist_debug -None | [LFSR_name... {pattern_number | All}] |  
[-decompressor [block_name] {pattern_number | All}]
```

Description

Sets up a trace of LFSR(s) value during a pattern's shift cycles.

To facilitate signature mismatch debugging and other diagnostics, the set_bist_debug command enables the tracing of all specified MISR and PRPG values associated with a given pattern, or all BIST patterns. If low-power hardware is enabled in the hybrid TK/LBIST flow, the low-power hold register value is traced along with its corresponding PRPG.

Arguments

- **-None**

A switch that clears the list of PRPGs and MISRs the tool is currently monitoring.

- ***LFSR_name***

A repeatable string that specifies the name of the MISRs and PRPGs whose values the tool will trace. To list all MISRs and PRPGs in the design, use the report_lfsrs command.

Of the next two arguments, you must choose one.

- ***pattern_number***

An integer that specifies the pattern number for which the MISR or decompressor values will be traced.

- **All**

A literal that specifies to write out the value of the specified MISRs and PRPGs only at the end of the pattern, for every pattern.

Hybrid TK/LBIST Flow Arguments

- **-decompressor**

A required switch that takes an optional *block_name* to specify that decompressor values for this block should be reported. (The decompressor is acting as a PRPG during logicBIST.) When using a single EDT module, the *block_name* is optional but is required in the modular

EDT flow. If you do not specify *block_name*, the tool reports decompressor values for all blocks.

- *block_name*

An optional string that specifies the name of the EDT block containing the decompressor to evaluate. The *block_name* must be one you defined previously using the [add_edt_blocks](#) command.

Examples

Example 1

The following example initiates a trace on the values of both the MISR and the PRPG for the pattern, 61, and shows the resulting transcript:

```
// command: set_bist_debug misr prpg 61
// command: simulate_patterns
// -----
// Simulation performed for #gates = 5732 #faults = 418
// system mode = fault simulation      pattern source = 63 BIST patterns
// -----
// #patterns test      #faults #faults    # eff.    # test      process
// simulated coverage in list detected   patterns patterns  CPU time
// begin bist patterns: capture clock = /clk, observe point = MASTER
begin debug data for PRPGs pattern = 61
    PRPG      prpg    0  100000111111010
    PRPG      prpg    1  010000011111101
    PRPG      prpg    2  100101001111110
    PRPG      prpg    3  010010100111111
    .

[set_bist_trace](#)
[add_lfsrs](#)
[report_lfsrs](#)

set_bist_trace

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Enables the tracing of PRPG and MISR values associated with each BIST pattern to facilitate signature mismatch debugging and other diagnostics.

Usage

```
set_bist_trace [-Nolfsr | {-Lfsr filename [-Replace] [-Interval interval] [-Offset offset]})]
```

Hybrid TK/LBIST Flow Usage

```
set_bist_trace [-prpg_data_file filename -misr_data_file filename]
  {[-prpg_pload_file filename -misr_pload_file filename] [-range beg_int end_int]}
  [-low_power] [-replace]
```

Description

Enables the tracing of PRPG and MISR values associated with each BIST pattern to facilitate signature mismatch debugging and other diagnostics.

The traced values are logged in *filename* in the following format:

```

0 PRPG prpg 1111111111111111
0 MISR misr 1111111111111111
1 PRPG prpg 1001010001011000
2 PRPG prpg 0101111001100101
...
32 PRPG prpg 1100100000000110
1 MISR misr 11100111011000010110
2 MISR misr 11001110011100001110
3 MISR misr 01011001100111011001
...
32 MISR misr 01011001100111011001
32 PRPG prpg 1100100000000110
...

```

The first element on each line is the pattern number, followed by the simulated element type (MISR or PRPG). The third element is the name of the simulated element. The names shown in the previous example are the default names assigned by the add_lfsrs commands included in the BIST-Controller-phase-generated fault simulation driver. You can edit the driver file to rename the elements.

Note

 Do not modify or delete any header information in *filename*. Microcoded test bench instructions are generated based on information in this header.

The sequence of activities that occur within the simulation of the BIST controller determines the order of the lines in *filename*.

If you issue multiple `set_bist_trace` commands before the [simulate_patterns](#) command, only the last one issued is executed.

To reduce the volume of data written to *filename*, use the `-Interval` and `-Offset` switches. See the [Example 1](#) section for this command.

Arguments

- **`-Nolfsr`**
An optional switch that disables LFSR value tracing. This is the default.
- **`-Lfsr filename`**
An optional switch and string pair that enables tracing of PRPG and MISR values during a BIST run and writes those values to the *filename* file.
- **`-Replace`**
An optional switch that replaces the contents of *filename* if that file already exists.
- **`-Interval interval`**
An optional switch and integer pair that writes the PRPG and MISR values to *filename* for the patterns beginning at 0 and separated by the *interval* given by the *interval* integer. The values for the first and last patterns are always written.
- **`-Offset offset`**
An optional switch and integer pair that writes the PRPG and MISR values to *filename* beginning at the pattern number given by the *offset* integer. The values for the first and last patterns are always written.

Hybrid TK/LBIST Flow Arguments

- **`-prpg_data_file filename -misr_data_file filename`**
Two optional switches and string pairs that enable tracing of the PRPG and MISR values for all patterns during a BIST run and write those values to the respective *filename* file. The files are written in a format compatible with the LV Flow.
- **`-prpg_pload_file filename -misr_pload_file filename`**
Two optional switches and string pairs that enable tracing for a few important clock cycles of the PRPG and MISR values during a BIST run and write those values to the respective *filename* file. The files are written in a format compatible with the LV Flow and are used for parallel load simulations.
- **`-range beg_int end_int`**
An optional switch and integer pair that defines a range of patterns to be written out to the PRPG/MISR files when using the `-prpg_pload_file` and `-misr_pload_file` options. By default, the full pattern range for a BIST run is written out.

- **-low_power**

An optional switch that defines whether the hybrid TK/LBIST flow should have the low-power values written out to the PRPG file when using the **-prpg_data_file** and **-prpg_pload_file** options.

- **-replace**

An optional switch that replaces the contents of *filename* if that file already exists.

Examples

Example 1

The following example writes traced values to the *lfsr.trace* file, but only writes the values for every 256th pattern to conserve disk space.

```
set_bist_trace -lfsr lfsr.trace -replace -interval 256
```

In the preceding example, if you discover a problem begins after pattern 1530, you might narrow the search by using the following command:

```
set_bist_trace -lfsr lfsr.trace -replace -offset 1530 -interval 16
```

and then finish by using the following command:

```
set_bist_trace -lfsr lfsr.trace -replace -offset 1594
```

Example 2 (Hybrid TK/LBIST Flow)

The following example writes out PRPG and MISR data files, with low-power values:

```
set_bist_trace -prpg_data_file LV_WORKDIR/TOP.prpg_data_lbist \
-misr_data_file LV_WORKDIR/TOP.misr_data_lbist \
-low_power \
-replace
```

Example 3 (Hybrid TK/LBIST Flow)

The following example writes out the PRPG and MISR parallel load data files, with low-power values, for the first 256 patterns:

```
set_bist_trace -prpg_pload_file LV_WORKDIR/TOP.prpg_pload_lbist \
-misr_pload_file LV_WORKDIR/TOP.misr_pload_lbist \
-low_power \
-range 0 255 \
-replace
```

Related Topics

[set_bist_debug](#)

set_boundary_scan_port_options

Context: dft

Mode: setup

Sets options relative to boundary scan on ports of the design.

Usage

```
set_boundary_scan_port_options {port_spec -cell_options cell_options} |  
    -pin_order_file file_name | -pad_io_ports pad_io_ports
```

Description

Sets options relative to boundary scan on ports of the design.

The -pin_order_file and -pad_io_ports options apply to all ports.

When the [set_dft_specification_requirements](#) -boundary_scan option is set to on, the options defined with this command are considered by the [check_design_rules](#) and [create_dft_specification](#) commands.

Arguments

- *port_spec*

An optional string that specifies a Tcl list of names of one or more ports, or a collection containing one or more ports of the current design.

- -cell_options *cell_options*

An optional literal pair that defines the options to associate to the specified ports. The allowed values are:

```
normal | no_bscan_cell | dont_touch | no_connect | analog |  
compliance_enable0 | compliance_enable1 |  
{output_only no_capture_core_signal} | {input_only {clock |  
sample_only}} | add_dot6_from_pad_cell
```

See [Table 10-4](#) for a description of these values.

- -pin_order_file *file_name*

An optional value pair that is used to reference an existing [pin_order_file : file_name](#). When this option is used, the specified pin_order_file will be validated during the [check_design_rules](#) command instead of being created. If you create this file from a different tool or you re-order the one that was created from a previous run of Tessent Shell, you must point to your file using this option to have it used. You can avoid having to manually reorder this file by reading in a DEF file using the [read_def](#) command.

- -pad_io_ports *pad_io_ports*

An optional value pair used to specify the ports on the current design that are to be equipped with boundary scan cells. This option is only used when the design level is physical_block

or sub_block as specified using the [set_design_level](#) command. The pad_io_ports string is a Tcl list of names of one or more ports, or a collection containing one or more ports of the current design.

Examples

The following example use the -cell_options option to set the sample_only option on a set of ports. Notice that if you have power and ground ports in your design and the design level is top, as specified by the [set_design_level](#) command, you must set the function attribute on them to power and ground as shown here.

```
> set_boundary_scan_port_options [get_ports HIO*] \
    -cell_options sample_only
> set_attribute_value [get_ports vdd*] -name function -value power
> set_attribute_value [get_ports vss*] -name function -value ground
```

[report_boundary_scan_port_options](#)

[set_bus_handling](#)

Context: dft -edt, patterns -scan

Mode: analysis

Specifies the bus contention results that you desire for the identified buses.

Usage

```
set_bus_handling {Pass | Fail | Abort} {-All | -Pass | -Fail | -Bidi | -ABort | [-Instances  
instance_name...] | bus_gate_id#... | net_pathname...}
```

Description

Specifies the bus contention results that you desire for the identified buses.

The set_bus_handling command preassigns the contention check handling result that you desire during simulation for the buses that you specify. Upon invocation, the tool automatically calculates the bus contention handling as documented under the [set_contention_check](#) command description. The tool rejects (from the internal test pattern set) ATPG-generated patterns that can cause bus contention. The set_bus_handling command lets you override the automatic contention calculations, thereby changing whether or not the tool performs a simulator-based check using such a pattern.

The tool resets the bus contention handling back to the automatically calculated value whenever you make a change to the modeling that requires the tool to perform a complete re-analysis of the contention mutual exclusivity (such as changing the net resolution or the pin constraints).

Caution

 Overriding the automatically calculated contention check handling results can cause trouble downstream if there is a problem with the design that required modification due to the bus contention.

Arguments

- **Pass**

A literal that specifies for the tool to not perform bus contention evaluations on the buses that you identify and to treat them as if they had passed. This allows the tool to retain patterns that it would otherwise reject due to a contention check failure.

- **Fail**

A literal that specifies for the tool to treat the buses that you identify as if they had failed the bus contention evaluations. This causes the tool to reject patterns that it would otherwise retain due to passing the contention check.

- **Abort**

A literal that specifies the bus aborted the bus contention evaluations before determining whether the bus passed or failed. This can be used with the `analyze_bus -Drc_check` command to verify ATPG constraints which you have added to correct bus failures.

- **-All**

A switch that specifies for the tool to change all buses to a specified state reset.

- **-Pass**

A switch that specifies for the tool to change to specified state for the buses that have previously passed the [E10](#) DRC rule.

- **-Fail**

A switch that specifies for the tool to change to specified state for the buses that have previously failed the [E10](#) DRC rule.

- **-Bidi**

A switch that specifies for the tool to change to specified state for bidi buses identified by the [E10](#) DRC rule.

- **-ABort**

A switch that specifies for the tool to change to specified state for the buses that have previously aborted the [E10](#) DRC rule.

- **-Instances *instance_name***

An optional switch and repeatable string that specifies the instances where the included buses are to be changed to the specified state.

- ***bus_gate_id#***

A repeatable integer that specifies the gate identification numbers of the buses whose contention handling you want to override. If a bus is cascading, you must specify the dominant bus.

- ***net_pathname***

A repeatable string that specifies a net name of the buses to be changed to a specified state.

Examples

The following example turns the bus contention checking off, allowing the bus to pass the evaluations. However, this action can cause trouble in the future if there is a problem with the design that required modification due to the bus contention.

report_bus_data 321

```
/FA1/ha1/XOR1/OUT/ (321) handling=fail type=strong #Drivers=4
  Learn Data:poss_X=yes, poss_Z=yes, poss_mult_drivers_on=yes
  BUS Drivers: 156(SW) 252(SW) 307(SW) 308(SW)
```

set_bus_handling pass 321
report_bus_data 321

```
/FA1/Ha1/Xor1/OUT/ (321) handling=pass type=strong #Drivers=4
Learn Data:poss_X=yes, poss_Z=yes, poss_mult_drivers_on=yes
BUS Drivers: 156(SW) 252SW) 307(SW) 308(SW)
```

[set_contention_check](#)

set_bus_simulation

Context: dft -edt, patterns -scan

Mode: analysis

Specifies whether the tool uses global or local bus simulation analysis.

Usage

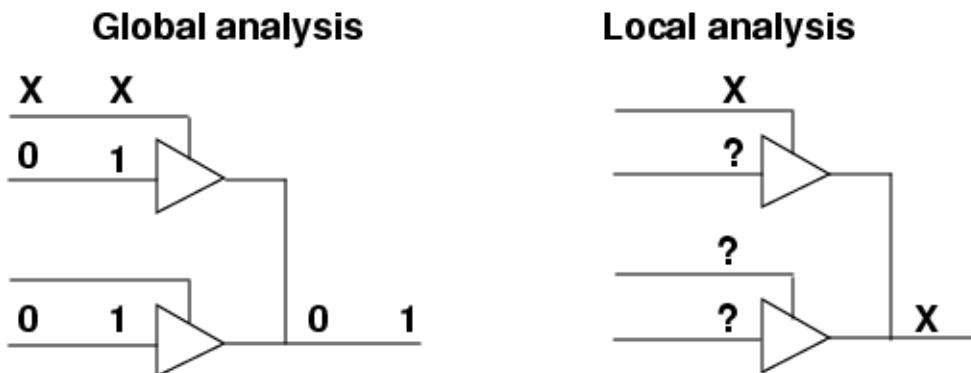

set_bus_simulation [Global | Local]

Description

Specifies whether the tool uses global or local bus simulation analysis.

This command simplifies typical back end verification flows by providing the option to turn off global analysis and use only the values that can be determined by inspecting the immediate input gates (tri-state devices or TSDs) driving a bus. [Figure 6-1](#) shows an example of how the setting of this command effects pattern creation.

Figure 6-1. Global versus Local Bus Simulation Analysis Example

Global analysis assumes a consensus value (0 or 1) is driven onto the bus when one or more of the tri-state enables is X and all inputs to the tri-states are the same (either all 0 or all 1). This most closely matches real hardware behavior. Local analysis assumes an X is driven onto the bus if any of the tri-state enables is X, regardless of the values on the inputs to the tri-states. It is more pessimistic, but more closely matches typical Verilog UDP behavior.

This command is provided to resolve compatibility issues with tools that do not perform global analysis. For example, if your design includes instances of TSDs for gating signals onto a bus, and their behavior in a timing-based simulator is as shown on the right in the preceding figure, using global analysis for pattern creation can result in simulation mismatches when you perform timing-based verification of the test patterns. You can avoid these mismatches by using this command to specify local bus simulation analysis for pattern creation.

Tip The [report_environment](#) command will display the analysis type currently in effect.

Arguments

- Global
Specifies for the tool to perform global bus simulation analysis. This is the default.
- Local
Specifies for the tool to perform local bus simulation analysis.

[report_environment](#)

set_bypass_chains

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup

Specifies a list of scan chains to connect in series to form a particular EDT bypass chain.

Usage

```
set_bypass_chains {-Bypass_chain_number chain_number}  
[-Edt_chains {chain_name...} [-Pins bypass_input bypass_output]]
```

Description

Specifies a list of scan chains to connect in series to form a particular EDT bypass chain.

This command allows you to customize the configuration of the bypass chains; for example, to meet unique routing requirements.

If you use this command to customize the bypass chains, you must specify all the EDT bypass chains.

Arguments

- **-Bypass_chain_number *chain_number***

A required switch and positive integer pair that identifies the EDT channel to connect to the specified scan chains to form an EDT bypass chain.

Note

 When you specify the number of channels using the set_edt_options command -Channels switch, the channels are numbered consecutively starting at 1.

- **-Edt_chains {*chain_name...*}**

An optional switch and repeatable string pair that specifies the internal scan chains to connect in series to form the specified bypass chain. The chains are connected from channel input to channel output in the order specified.

- **-Pins *bypass_input bypass_output***

An optional switch and double string that specifies the input and output pins for bypass chains that exist in the design netlist before EDT logic is generated.

Note

 Scan chains and bypass chains must use the same input and output pins.

Examples

Example 1

The following example sets up the EDT logic for a design with eight scan chains named *chain1* through *chain8*. The design is setup with two EDT channels and chains 1, 5 and 6 are connected

in series to channel 1 to form bypass chain 1 and the results display. Any number in the Bypass# column with *no connections* next to it represents an undefined bypass chain.

```
set_edt_options -channels 2
set_bypass_chains -bypass_chain 1 -edt_chains chain1 chain5 chain6
report_bypass_chains

//      Reporting user-defined bypass chains:
//
//      Bypass#  EDT chains
//      -----  -----
//      1        chain1, chain5, chain6
//      2        no connections
//
```

The following commands define the remaining bypass chain and displays the completed user-defined bypass configuration.

```
set_bypass_chains -bypass_chain 2 -edt_chains chain2 chain3 chain4 chain7 chain8
report_bypass_chains

//      Reporting user-defined bypass chains:
//
//      Bypass#  EDT chains
//      -----  -----
//      1        chain1, chain5, chain6
//      2        chain2, chain3, chain4, chain7, chain8
//
```

Example 2

The following example shows a dofile segment that sets up the scan chains and bypass chains for EDT logic and then shows the resulting EDT logic file.

```
// Internal scan chains
add_scan_chains chain1 grp1 scan_in1 scan_out1
add_scan_chains chain2 grp1 scan_in2 scan_out2
add_scan_chains chain3 grp1 scan_in3 scan_out3
add_scan_chains chain4 grp1 scan_in4 scan_out4
//
// Bypass scan chains
set_edt_options -channels 2 -bypass use_existing_bypass_chains
set_bypass_chains -bypass_chain 1 -pins scan_in1 scan_out1 -edt_chains \
chain1 chain2
set_bypass_chains -bypass_chain 2 -pins scan_in2 scan_out2 -edt_chains \
chain3 chain4
```

Muxes are added for only the internal scan pins that are also bypass chain pins as shown in the following EDT logic file.

```

module TOP_edt_bypass_logic (edt_bypass, edt_channels_in, edt_channels_out,
                           edt_scan_in, edt_scan_out, edt_bypass_in, edt_bypass_out);
  input      edt_bypass;
  input [1:0] edt_channels_in;
  output [1:0] edt_channels_out;
  output [3:0] edt_scan_in;
  input [3:0] edt_scan_out;
  input [3:0] edt_bypass_in;
  input [1:0] edt_bypass_out;

  assign edt_scan_in[0] = edt_bypass ? edt_channels_in[0] : edt_bypass_in[0];
  assign edt_scan_in[1] = edt_bypass ? edt_channels_in[1] : edt_bypass_in[1];
  assign edt_scan_in[2] = edt_bypass_in[2];
  assign edt_scan_in[3] = edt_bypass_in[3];

  assign edt_channels_out[0] = edt_bypass ? edt_scan_out[0] : edt_bypass_out[0];
  assign edt_channels_out[1] = edt_bypass ? edt_scan_out[1] : edt_bypass_out[1];
endmodule

```

set_capture_clock

Context: dft -edt, dft -scan, dft -test_points, patterns -scan,
patterns -scan_diagnosis

Mode: setup, analysis

Specifies the capture clock for random pattern simulation or, optionally, for all ATPG pattern simulation.

Usage

```
set_capture_clock [primary_input_pin] [-Atpg [-Allow_multiple_cycles]] | ANY
```

Description

Specifies the capture clock for random pattern simulation or, optionally, for all ATPG pattern simulation.

This command affects the capture clock that is used during DRC simulation and may be useful for designs with certain types of test logic that must be initialized properly to pass scan chain tracing.

The set_capture_clock command specifies the name of the capture clock the tool uses during random pattern simulation. You can specify the name of either a specific pin or a clock procedure in a test procedure file that identifies the pin. In either case, the pin must be a currently defined clock pin. Also, the capture clock that you specify cannot have a pin constraint.

If you do not specify a capture clock with this command, the tool sets the capture clock to none. If there is no specified capture clock and there is only one clock in the circuit that is not a set or reset line, the tool sets that clock as the capture clock during rules checking and displays a warning message that identifies the capture clock.

When you add a capture clock, the tool checks for pulse-always or pulse-in-capture clocks. If any exist, the tool does not create the capture clock and issues an error. For example:

```
add_clocks 0 CLK1 -pulse_in_capture
add_clocks 0 CLK2
set_capture_clock CLK2 -atpg
// Error: Clock CLK2 cannot be defined as capture clock in the presence
of pulse-in-capture clock CLK1.
```

When you add a pulse-always or pulse-in-capture clock, the tool checks for a user-defined capture clock, a warning message is issued, and the user-defined capture clock is reset to none. For example:

```
add_clocks 0 CLK2
set_capture_clock CLK2 -atpg
add_clocks 0 CLK1 -pulse_always
```

```
// Warning: set_capture_clock is reset as consequence of adding a pulse-
in-capture clock.
```

The `set_clock_options` command's `-pulse_always` and `-pulse_in_capture` switches behave the same way as `add_clocks`. The warning or error will be reported and the capture clock resets when a user-defined capture clock exists.

These two checks only report when you define synchronous pulse-always or pulse-in-capture clocks with a capture clock specified. You can define an asynchronous free running clock in the presence of a capture clock.

You can use the [report_environment](#) command to list the capture clock and the [report_clocks](#) command to identify the current list of clocks.

Note

 This command applies only to random pattern generation unless you include the `-Atpg` switch; then it applies to all scan patterns created during the ATPG process.

The `set_capture_clock` command specifies a particular clock as the capture clock during random pattern generation or, optionally, ATPG. For random pattern generation alone, the command takes effect only if you previously issued a “[simulate_patterns](#) `-source random`” command.

When you have specified a capture clock with this command, the tool may pulse other defined clocks, but it does not use them for capture. You can specify the capture clock by providing the name of a specific pin in a test procedure file that identifies a currently defined clock pin. The capture clock that you specify cannot have a pin constraint.

You can undo a previously specified capture clock choice by issuing this command without any arguments. This will make all clocks available for clocking and capture.

Note

 During ATPG, the capture clock specified with this command is ignored if one or more named capture procedures are available and their use is enabled with “`set_capture_procedure on`” (the default).

Arguments

- *primary_input_pin*

An optional string that specifies the name of the primary input pin you want to assign as the capture clock.

- `-Atpg`

An optional switch that directs the tool to use the specified capture clock as the only capture clock for all patterns created during the ATPG process, not just random patterns. This option also forces the tool to pulse the capture clock only once per capture cycle per pattern, unless you also use the `-allow_multiple_cycles` switch, causing the tool to generate combinational

and clock sequential patterns (no RAM sequential or chain test patterns). If specified in Setup mode, this switch turns on some additional design rule checks (DRCs).

When using this switch in Setup mode, all named capture procedures (NCPs) are disabled by default when entering a non-Setup mode. In addition, the `create_patterns` command can then create only patterns with the specified capture clock. After entering a non-Setup mode, you can manually enable NCPs by using the “`set_capture_procedure On`” command. The tool then checks to ensure that each of the NCPs pulse the capture clock once and only once. The tool does not enable those NCPs that do not satisfy this clock sequence.

Note

 When using Tessent TestKompress (EDT On), you must specify this switch to enable the command to work properly with EDT.

- **-Allow_multiple_cycles**

An optional switch that allows the tool to create patterns with multiple pulses of the capture clock. Using this switch disables the DRC stability check that uses the capture clock, thus allowing ATPG to create patterns with multiple clock pulses of the specified capture clock. This switch is available only when you also use the `-atpg` switch.

- **ANY**(Tessent FastScan and Tessent TestKompress only)

An optional string that specifies any clock can be a capture clock. This is the default if `primary_input_pin` is not specified.

Examples

The following example specifies a capture clock:

```
add_clocks 1 clock1
set_capture_clock clock1
set_system_mode analysis
set_random_patterns 612
```

set_capture_handling

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies how the tool globally handles the data capture of state elements that have C3 and C4 rule violations.

Usage

```
set_capture_handling {-Ls {Old | New | X} -Te {Old | New | X}}
```

Description

Tip

 This command should rarely be used. For most designs, other than those that require mixed capture handling, you should not use this command but rather use split capture handling. Split capture handling is automatically set if needed when you use the [create_patterns](#) command. Alternatively, you can directly set split capture handling using the [set_split_capture_cycle](#) command.

Specifies how the tool globally handles the data capture of state elements that have C3 and C4 rule violations.

The set_capture_handling command gives you some ability to globally change how the tool simulates data capture in the presence of C3 and C4 clock rules violations. C3 and C4 clock rules checks ensure that a clock line cannot capture data affected by the clock, and that any data the clock does capture does not affect the clock line itself. The tool does not normally allow C3 or C4 data capturing violations during simulation.

For information on the C3 and C4 rules, refer to the “[Clock Rules \(C Rules\)](#)” section.

You can use this command to set the global data capture behavior for level sensitive (-Ls) or trailing edge (-Te) devices. For each device type, you can specify for the tool to simulate old, new, or X data at the source points. You can override the global data capture handling for individual state elements by using the [add_capture_handling](#) command.

Arguments

- **-Ls {Old | New | X}**

A switch and literal pair that specifies how you want the tool to handle the data capturing of level-sensitive state elements. The literal choices are as follows:

Old — A literal that specifies for the tool to determine the output value of a level-sensitive source state element by using the data that existed prior to the current clock cycle. The tool then passes this value to the state element’s sink state elements. This is the default behavior of the tool upon invocation.

New — A literal that specifies for the tool to determine the output value of a level sensitive source state element by using the data from the current clock cycle. The tool then passes this value to the state element's sink state elements. The tool limits the scope of this capture handling effect to the circuitry between the source and sink points. The tool will not propagate the newly-captured effect past the sink point.

X — A literal that specifies for the tool to determine the output value of a level-sensitive source state element by using the data from the current clock cycle unless the previous values are different from the current values. If the values differ, the tool passes an unknown (X) value to the state element's sink state elements.

- **-Te {Old | New | X}**

A switch and literal pair that specifies how you want the tool to handle the data capturing of trailing edge sensitive state elements. The literal choices are as follows:

Old — A literal that specifies for the tool to determine the output value of a trailing edge sensitive source state element by using the data that existed prior to the current clock cycle. The tool then passes this value to the state element's sink state elements. This is the default behavior of the tool upon invocation.

New — A literal that specifies for the tool to determine the output value of a trailing edge sensitive source state element by using the data from the current clock cycle. The tool then passes this value to the state element's sink state elements. The tool limits the scope of this capture handling effect to the circuitry between the source and sink points. The tool will not propagate the newly-captured effect past the sink point.

X — A literal that specifies for the tool to determine the output value of a trailing edge sensitive source state element by using the data from the current clock cycle unless the previous values are different from the current values. If the values differ, the tool passes an unknown (X) value to the state element's sink state elements.

Examples

The following example changes the data capture handling for all trailing edge state elements that have C3 and C4 rule violations:

```
set_capture_handling -te new
```

[delete_capture_handling](#)
[report_capture_handling](#)

set_capture_procedures

Context: dft -edt, patterns -scan

Mode: analysis

Enables or disables the tool’s use of a specified subset of named capture procedures when generating test patterns.

Usage

```
set_capture_procedures {ON | OFF} {-All | -Created_capture_procedure |  
-Loaded_capture_procedure | [procedure_name...]}
```

Description

Enables or disables the tool’s use of a specified subset of named capture procedures when generating test patterns.

By default, the tool uses all named capture procedures defined in the test procedure file, except any that fail to pass DRC. The tool never uses capture procedures that fail DRC.

This command is useful when you want to use a subset of the defined capture procedures for certain types of faults, because the remaining capture procedures may be unable to detect the faults.

Note

 The set_capture_procedures command applies to test generation only, not to fault simulation. If you generate test patterns using “set_capture_procedure off”, for example, fault simulation will still simulate those test patterns even if you issue a “set_capture_procedure on” command prior to fault simulation.

Arguments

- ON

A literal that enables use of the specified named capture procedures during test generation. This is the default. If one or more named capture procedures is enabled with this option, the tool does not use the default capture procedure; it uses the named capture procedure(s) exclusively. In this case, if the conditions to test a fault require a particular sequence of clocks or cycles that is not defined in one of the named capture procedures, the fault will be untestable.

Note

 As shown in the examples, use of the “on” option to specify a subset of the defined capture procedures must be preceded by “set_capture_procedure off -all”.

- **OFF**

A literal that disables use of the specified named capture procedures during test generation. If you use this option with “-all” to disable all named capture procedures, ATPG uses the default capture procedure, if present. Otherwise, it runs as if there are no capture procedures defined in the test procedure file.

Note

Use of the “on” option to specify a subset of the defined capture procedures must be preceded by “set_capture_procedure off -all”.

- **-All**

A switch that enables or disables use of all capture procedures defined in the test procedure file. This is the default.

- **-Created_capture_procedure**

A switch that enables or disables use of only the named capture procedures internally created from the [create_capture_procedures](#) command.

- **-Loaded_capture_procedure**

A switch that enables or disables use of only the named capture procedures loaded from the [read_procfile](#) command or the procedure file associated with the scan group definition.

- **procedure_name...**

A repeatable string that enables or disables use of only the named capture procedures with the user-specified name.

Examples

Example 1

The following example loads a fault list, disables use of all capture procedures, enables just the capture procedure named c1_capture, then creates patterns:

```
read_faults clock1_fault_list
set_capture_procedures off -all
set_capture_procedures on c1_capture
create_patterns
```

Example 2

The following example creates named capture procedures from generated patterns, then disables use of loaded capture procedures:

```
create_patterns
create_capture_procedures -pattern internal
set_capture_procedures off -loaded_capture_procedure
```

[report_capture_procedures](#)

[set_drc_handling](#)

set_cell_library_options

Context: unspecified, all contexts

Mode: setup

Sets the specified options for library parsing and design elaboration.

Usage

```
set_cell_library_options [-prefer_cell_library {on | off}] [-force] ]
    [-report_duplicate_models {off | on}]
    [-report_floating_nets {off | on}]
    [-report_errors_only {off | on}]
    [-augment_dft_cell_selections {single_selection_only | on | off}]
    [-default_dft_cell_selection_name default_dft_cell_sel_name]
    [-create_default_dft_cell_selection {on | off}]
    [-liberty_ignore_dont_use {on | off}]
```

Description

Sets the specified options for library parsing and design elaboration.

When you issue the command without arguments, the command reports the current library options settings.

Arguments

- **-prefer_cell_library {on | off}**

An optional switch and literal pair that controls the tool's behavior when reading in a design that has both a Verilog module and a cell library model with the same name. By default the tool chooses the cell library model.

If your design has been elaborated, you cannot change the **-prefer_cell_library** option without losing setup data. If you want to change this option after elaboration, you must use the **-force** switch to explicitly indicate that it is alright for the tool to discard previously defined setup information.

When you specify “off” before issuing the [set_current_design](#) command, the tool chooses the Verilog module.

- **-force (available only in contexts that operate in no_rtl mode)**

An optional switch that specifies to suppress the error message that normally prevents the accidental deletion of previously defined setup information. If you execute the “**set_cell_library_options -prefer_cell_library option**” command after your design has been elaborated, the tool will normally display an error message indicating that if it executes the command, the setup information you have already specified will be discarded. You use this switch to suppress this error message and indicate that it is acceptable for the tool to delete the previously defined setup data.

- **-report_duplicate_models {off|on}**

An optional switch that specifies to issue a separate note for each duplicate model parsed by `read_cell_library`. Otherwise a summary of the total number of duplicate models is issued by default.

- **-report_floating_nets {off|on}**

An optional switch that specifies to issue a separate note for each floating net in each model parsed by `read_cell_library`. Otherwise a summary of the total number of models with floating nets and the total number of floating nets is issued by default.

- **-report_errors_only {off|on}**

An optional switch and literal pair that specifies to suppress warnings and notes and report error messages only. The default is off.

- **-augment_dft_cell_selections {single_selection_only|on|off}**

An optional switch and literal pair that specifies whether to augment parsed `dft_cell_selection` information by adding any legal function not specified within that `dft_cell_selection`.

For example, if a `dft_cell_selection` has nand cell but no xor cell, but a parsed model performs the xor function, then the model will be added as an xor cell in the `dft_cell_selection` and can be used for test insertion and execution of the `get_dft_cell` command.

By default, augmentation occurs only if a single `dft_cell_selection` is parsed in all `read_cell_library` files. When augmentation occurs augmented entries will not be written out by the `write_cell_library` command, and the resulting `dft_cell_selections` will be exactly as parsed. For more information, see the [write_cell_library](#) command.

- **-default_dft_cell_selection_name *default_dft_cell_sel_name***

An optional switch and string that sets the default `dft_cell_selection` to use for test insertion and the execution of the `get_dft_cell` command. Without this command, when two or more `dft_cell_selections` are parsed, test insertion uses the last parsed `dft_cell_selection`, and `get_dft_cell` will error unless a `dft_cell_selection_name` is specified with the `get_dft_cell` command. This option sets the default `dft_cell_selection` to use for both test insertion and the execution of the `get_dft_cell` command.

The `default_cell_sel_name` must be the same as one of the names from the “`dft_cell_selection (dft_cell_selection_name) ()`” statements parsed when the `read_cell_library` command is executed. If `default_cell_sel_name` is “” then the behavior reverts to the behavior before any execution of the “`set_cell_library_options -default_dft_cell_selection_name`” command.

- **-create_default_dft_cell_selection {on|off}**

An optional switch and literal pair that determines whether a default `dft_cell_selection` is created when no `dft_cell_selection` is parsed.

- **-liberty_ignore_dont_use { on | off }**

An optional switch and literal pair that determines whether “cell_type = prohibited;” is placed inside the corresponding Tesson model representing a Liberty cell containing “dont_use” inside the Liberty cell group for that cell. In Liberty, “dont_use” indicates that a synthesis tool should not insert that cell into a netlist when optimizing, and the default of -liberty_ignore_dont_use is “off”, which causes “cell_type = prohibited;” to be placed inside the model so that Tesson test tools will not insert such a cell to create test logic needed for testing. To prevent the inclusion of “cell_type = prohibited” inside the corresponding (same name) Tesson model for a Liberty cell containing “dont_use”, you must issue this command and set this switch to off before the read_liberty command containing the cells, to have any impact on the resultant Tesson cell library models.

Examples

In the following example, no Liberty Cell inside liberty_source_file, or any Liberty Cell of a subsequent “read_liberty” command, will have “cell_type = prohibited;” placed inside the corresponding Tesson read_cell_library model due to a “dont_use” in the Liberty syntax.

```
set_cell_library_options -liberty_ignore_dont_use on
read_liberty liberty_source_file
read_cell_library corresponding_tesson_models_filename
write_cell_library final_tesson_cell_library_with_liberty_info_merged_filename
```

In Liberty source given to read_liberty :

```
cell("AN2") {
    dont_use : true ;
```

Tesson write_cell_library for Liberty cell default model output :

```
model AN2 .
...
    cell_type = prohibited;
    simulation_function = and;
...
```

Tesson write_cell_library for Liberty cell after specifying
“set_cell_library_options -liberty_ignore_dont_use on”:

```
model AN2 .
...
    cell_type = and;
    simulation_function = and;
...
```

Context: dft -scan

Mode: setup, analysis

Prerequisites: You can only override the mapping for scan models of the same scan type. For example, a mux-DFF scan model can only be replaced by another mux-DFF scan model.

Overrides the non-scan to scan model mapping defined by the tool.

Usage

```
set_cell_model_mapping -New_model scan_model_name
    [-MODULE module_name... | -Instance {pathname... | instance_expression...} |
     -File filename] [-MODEL model_name...] [-Output scan_output_pin_name]
```

Description

Overrides the non-scan to scan model mapping defined by the tool.

You can change the scan model for an individual instance, all instances under a hierarchical instance, all instances in all occurrences of a module in the design, or all occurrences of the model in the entire design. Additionally, you can change the scan output pin of the scan model in the same manner.

Note

 Use this command for changing the existing non-scan to scan model mapping, as defined in the library, and *not* to define the mapping.

Refer to “[Scan Cell and Scan Output Mapping](#)” in the *Tessent Scan and ATPG User’s Manual* for conceptual information on this topic.

Arguments

• -New_model *scan_model_name*

A required switch and string that specify a new library model for the specified design instances.

• -MODULE *module_name*... | -Instance {*pathname*... | *instance_expression*...} | -File *filename*]

An optional switch and string or repeatable string that specify the design instances whose models should be mapped to the library model specified by the -New_model switch. If this switch is omitted, all instances of the model are specified with the -Model option.

-Module — Assigns the library model specified by -New_model to either all compatible design instances within the module *module_name* or to just the design instances of the model specified with the -Model option.

-Instance — Specifies the pathname(s) of either a hierarchical or library instance(s).

For a hierarchical instance, assigns the library model specified by *-New_model* to either all compatible design instances within this hierarchical instance or to just the design instances of the model specified with the *-Model model_name* option.

For a library instance, maps either all compatible instances to the specified *-New_model* library model or to just the instances of the model specified with the *-Model model_name* option. The repeatable string can be in the form of an absolute instance pathname or a pathname in regular expression form.

-File — Specifies the name of the file containing pathname(s) of instances that should be mapped to the *-New_model* model, if compatible.

- **-MODEL *model_name***

An optional switch and string that specify the name of an existing model whose design instances are to be mapped to the model specified by *-New_model*. The specified model can be either a non-scan or a scan model. However, the following assumptions are made:

Non-scan models — The new scan model is appropriate for the non-scan model.

Scan model — The old and new scan models are appropriate for at least one common non-scan model.

- **-Output *scan_output_pin_name***

An optional switch and string pair that specify the name of the scan output pin to use in place of the tool-defined scan output pin. The pin/port must have been declared as a scan-out port in the *scan_definition* section of *-New_model*.

set_chain_test

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies binary sequences for chain test.

Usage

Available when EDT is Off

```
set_chain_test [-SUPpress_capture_cycle {OFF|ON}]  
[{-SEQUENCE {bit_string | OFF} ... [-APPend | -REplace]}]
```

Available when EDT is On

```
set_chain_test [-SUPpress_capture_cycle {OFF|ON}]  
[{-SEQUENCE {bit_string | OFF} ... [-APPend | -REplace]}]  
[-Type {All | Nomask [with_1hot] | Mask [XOr_only | 1Hot_only]}]  
[-NOMASK_First {ON | OFF}]
```

Description

Specifies binary sequences for chain test.

Use this command to add one or more custom sequences to the current chain test or replace the current chain test sequences with all new sequences.

Arguments

- **-SUPpress_capture_cycle {OFF|ON}**

An optional switch and literal pair that suppresses the capture cycle from the chain test patterns. In the capture cycles, constrained pins are forced to their constrained values and cell constraints are justified.

By default, chain test patterns contain a capture cycle when there is no C1 violation. In case DRC detects C1 violations on the level-sensitive ports or set/reset ports, the tool automatically suppresses the capture cycle for the chain test patterns in order to avoid those C1-violated cells to be disturbed and prevent simulation mismatches. You can manually change the default setting (`set_chain_test -Suppress_capture_cycle Off`) to force the chain test patterns to include the capture cycle. Under this situation, the tool masks out the scan cells with a C1 violation on either synchronous port or set/reset ports to prevent mismatches because the C1-violated cells on a synchronous or set/reset port may cause the loading value to be disturbed in the capture cycle. Note that this masking effect could impact the diagnosability of the chain test failure but should not impact the overall test quality.

This switch also suppresses the capture cycle of the first pattern (`edt_setup`) before chain and scan test patterns when the low-power EDT decompressor or input channel pipelining is in use. For more information, see “[Low-Power Test](#)” in the *Tessent TestKompress User’s Manual*.

- **-SEQUENCE** *bit_string* | OFF

An optional, repeatable literal and string pair that specifies a binary sequence to shift into the scan chains, starting with the most significant bit.

When EDT is OFF, if the length of a specified bit string sequence is shorter than a scan chain, the specified sequence is repeated to fill the rest of the scan chain. If the specified sequence is longer than the scan chain, the extra less significant bits are truncated.

When EDT is ON, the tool attempts to get the sequence to occur once in one-hot patterns. This is not a repeating sequence.

Specifying OFF disables custom sequences. This allows you to revert back to using the default chain test.

- **-APPEND** (Available when EDT is Off)

An optional switch that specifies to add the specified sequences to the tool's current chain test sequences.

- **-REPLACE** (Available when EDT is Off)

An optional switch that specifies to replace the tool's current chain test sequences with the specified bit sequences. This is the default.

- **-TYPE** All | Nomask [with_1hot] | Mask [XOr_only | 1Hot_only] (Available when EDT is On)

An optional switch and literal that specifies the type of EDT chain test patterns that should be saved to minimize effort during simulation run time. The chain test patterns are saved when the [write_patterns](#) command is issued. The possible literal values for **-Type** are:

All — Saves chain test patterns with all types of masking. This option includes all non-masking and masking patterns as well as patterns to test all unused decoder values when all chain patterns are selected. As a result, the total number of patterns returned by this option may be greater than the sum of all non-masking and masking patterns. For more information on unused patterns, see “[EDT Logic and Chain Testing](#)” in the *Tessent TestKompress User’s Manual*.

Nomask — Only saves the non-masking chain test patterns.

with_1hot — Saves the 1-hot chain patterns along with the no-masked chain patterns.

Caution

 You must *not* use the Nomask option when saving your *production* test patterns. If you save the production pattern set using the “set_chain_test -type nomask” option, it is *very* difficult to identify which chain failed and automatic chain diagnosis is not possible.

If you are *not* using the low-power decompressor and you are constrained by the number of patterns you can simulate, you can run one non-masking pattern to achieve minimum coverage, as shown here:

```
set_chain_test -type nomask  
write_patterns pattern_filename -pattern_sets chain -serial -end 0
```

If you *are* using the low-power decompressor, it is safest to run all non-masking patterns so that every chain is tested, as shown here:

```
set_chain_test -type nomask  
write_patterns pattern_filename -pattern_sets chain -serial
```

Mask — Only saves the masking chain pattern.

XOr_only — For the Xpress compactor, saves only flexible masking chain patterns.

Note: This does not apply to the basic compactor.

1Hot_only — Saves only 1-hot masking chain patterns and two nomask patterns.

If you do not save 1-hot patterns (*Nomask* or *Mask [XOr_only]* options), Tesson Diagnosis may not have enough information to run chain diagnosis successfully. Without 1-hot patterns, chains in a compactor are scanned out together and the tool cannot identify the specific chain that contains the error. If you do not want to save 1-hot patterns but still want to run chain diagnosis, you must communicate to Tesson Diagnosis the failing chains using the following commands:

```
read_patterns scan_patterns  
diagnose_failures <failure_file> -faulty_chain <faulty_chain_name>\<faulty_chain_type>
```

This approach assumes internal failing chain information was reported through another method. For more information, see the [read_patterns](#) and [diagnose_failures](#) commands.

For more information on masking patterns, see “[Understanding Scan Chain Masking in the Compactor](#)” in the *Tesson TeskKompress User’s Manual*.

- **-NOMASK_First {ON | OFF}** (Available when EDT is On)

An optional switch that specifies whether to place EDT non-masking chain patterns first. The default is OFF which means that 1-Hot masking chain patterns are ordered first. The -Nomask_First ON option is only valid with -Type All—the option is ignored if used with -Type Mask.

Examples

Example 1

Assume a design contains two scan chains: chain1 is ten scan cells long and chain2 is eight cells long.

The following example saves the tool’s standard chain test patterns to the file my_chain_test.ascii. The sequences (minus X-padding) that you would see in the file are shown after the example commands.

```
set_system_mode analysis
write_patterns my_chain_test.ascii -pattern_sets chain -replace
```

Pattern 0

chain1: 0011001100

chain2: 00110011

Example 2

The following example replaces the current chain test sequences with three new sequences and saves the resultant chain test patterns:

```
set_system_mode analysis
set_chain_test -sequence 01 -sequence 1
set_chain_test -sequence 1001 -append
write_patterns my_chain_test.ascii -pattern_sets chain -replace
```

Now, in the my_chain_test.ascii file, you would see the following three chain test sequences (minus X-padding):

Pattern 0

chain1: 0101010101

chain2: 01010101

pattern 1

chain1: 1111111111

chain2: 11111111

pattern 2

chain1: 1001100110

chain2: 10011001

set_checkpointing_options

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Enables checkpointing and specifies the associated options.

Usage

```
set_checkpointing_options [OFF | ON {[-PATTERN_FIle filename]
[-PATTERN_FOrmat {Ascii | Binary}] [-Faultlist_file filename] [-Replace]
[-Period period]})]
```

Description

Enables checkpointing and specifies the associated options.

Checkpointing is when the tool automatically saves test patterns at regular periods, referred to as checkpoints, throughout the pattern creation process. This is useful when ATPG takes a long time and there is a possibility it could be interrupted accidentally.

The set_checkpointing_options command specifies the filename and time period in which the tool writes test patterns during test pattern generation.

You can use the -Faultlist_file option to save the fault list. In the case of an interruption, if you have saved the generated patterns, you can use this fault list to avoid the resimulation step. When you specify the -Faultlist_file option, the tool saves the checkpointed fault list, including the fault class and sub-class of each fault, to the specified file. Aborted faults are also written to the file.

You can use the set_checkpointing_options command multiple times within a session and each time modify only the options you want to change. The tool retains your unmodified settings from the previous commands.

Note

 Although you can issue the set_checkpointing_options command in any mode, the tool only writes out a checkpoint file in analysis mode with the set_checkpointing_options command set to On.

For additional information on checkpointing, refer to “[Checkpointing Setup](#)” in the Tessent Scan and ATPG User’s Manual.

Arguments

- OFF

A literal that specifies for the tool not to use the checkpointing functionality during test pattern generation. Patterns are not written to any file. This is the invocation default.

- **ON**
A literal that specifies for the tool to use the checkpointing functionality. The tool writes test patterns that it generates to the file that you specified with the `set_checkpointing_options` command.
- **-PATTERN_FILE *filename***
An optional switch and string pair that specifies the name of the file into which you want to write the test patterns during test pattern generation.
- **-PATTERN_FORMAT {Ascii | Binary}**
An optional switch and literal pair that allows the pattern files to be saved in binary or ASCII format. Binary is the default format.
- **-Faultlist_file *filename***
An optional switch and string pair that allows the fault list to be saved.
- **-Replace**
An optional switch that forces the tool to overwrite the file if it already exists. If you use the `-Replace` option and the tool does not create any new test patterns, the tool does not update the file.
- **-Period *period***
An optional switch and integer pair that specifies the number of minutes between each write of the test patterns. The default is 100 minutes.

Examples

The following example stores the generated test patterns every 120 minutes in a file called `my_checkpoint_file`. After each 120-minute interval, the tool creates a new file until the ATPG process ends.

```
set_system_mode analysis
set_checkpointing_options on -pattern_file my_checkpoint_file -period 120
create_patterns
```

[write_patterns](#)
[create_patterns](#)
[write_faults](#)

[set_clock_controller_pins](#)

Context: dft -logic_bist

Mode: setup

Specifies the connection information for the clock controller pins.

Usage

```
set_clock_controller_pins
  {shift_clock | shift_clock_en | shift_capture_clock | scan_en |
  | capture_en | lbist_en |
  capture_procedure_index | diag_clock_en }
  {internal_pin_name... | -no_connection} [-append]
```

Description

Specifies the connection information for the clock controller pins.

This command is used with the Hybrid TK/LBIST flow. Refer to the [Hybrid TK/LBIST Flow User's Manual](#) for complete information.

If you issue this command multiple times with the same pin type, then the last specified pin name(s) are used. To specify multiple pin names corresponding to a pin type, specify all the names in the same command, or use the -append switch to add to the list of already specified pins.

The pins you specify with this command are connected to the single top-level LogicBIST controller. This command is global in context and not specific to the current EDT block.

Manual specification of the clock controller pins is not required when Tessent OCC core instances have been added. In this case, only the capture_procedure_index connection is required.

Alternatively, you can specify the -no_connection switch instead of internal_pin_name in an RTL IP-creation flow (skeleton flow), where the clock controller is not yet available in the dummy design.

Note

 The internal_pin_name string and **-no_connection** switch are mutually exclusive.

Arguments

- **shift_clock internal_pin_name**

An optional literal and repeatable string that specifies the clock controller shift clock input. This pin is to be driven by the LogicBIST shift clock output from the controller in LogicBIST mode.

- **shift_clock_en *internal_pin_name***

An optional literal and repeatable string that specifies the clock controller shift clock enable input. This pin is to be driven by the LogicBIST shift clock enable output from the controller in LogicBIST mode.

- **shift_capture_clock *internal_pin_name***

An optional literal and repeatable string that specifies an input on the clock controller that needs to receive a clock that pulses during shift and capture, unlike the shift_clock that only pulses during the shift mode operation. This pin is driven by the LogicBIST shift capture clock output from the controller in LogicBIST mode. If this pin is not specified, then the output port will not be created. This option is mutually exclusive with shift_clock.

Specifying shift_capture_clock will clear any previously specified shift_clock connections.

- **scan_en *internal_pin_name***

An optional literal and repeatable string that specifies the clock controller scan enable input. This pin is to be driven by inverted LogicBIST capture enable output from the controller in LogicBIST mode.

- **capture_en *internal_pin_name***

An optional literal and string that specifies the capture enable trigger LBIST clock enable input. This is typically connected to LBIST capture enable output.

- **lbist_en *internal_pin_name***

An optional literal that specifies the LogicBIST enable pins.

- **capture_procedure_index *internal_pin_name***

An optional literal that specifies the connections to the signal that identifies the NCP used for the current pattern. Then internal_pin_name string identifies the pins in the clock controller for the NCP index specified from MSB to LSB.

A capture_procedure_index pin type has to be specified once per clock controller to add the list of NCP index pins for that clock controller. It is not possible to group the connections for the capture_procedure_index pin type for all clock controllers in a single command. The -append switch must be used to add to the pin specification for prior controllers.

- **diag_clock_en *internal_pin_name***

An optional literal and repeatable string that specifies the clock controller diagnosis clock enable input. The LogicBIST controller diag_clock_en output drives this pin. If you are using the shift_clock_en clock controller pin, you need a diag_clock_en connection to perform LogicBIST diagnosis. The diag_clock_en signal is only allowed when using “set_edt_options -single_bypass on.” When using shift_clock, the tool injects TCK during diagnosis through the shift_clock pin; if you want to inject TCK, you should use this pin.

- **-no_connection**

An optional switch used instead of internal_pin_name.

When the `-no_connection` switch is used, the design clock controller pin names need not be specified and no connections will be made. The pins are available at the LogicBIST IP boundary. This switch can be used in an RTL IP-creation flow, where the clock controller is not yet available in the dummy design.

- `-append`

An optional switch used to append to a previous list of pin names, instead of replacing. Without the `-append` switch, repeat usage of the `set_clock_controller_pins` command overwrites the previous list of pins for the specified pin type.

Examples

Example 1

The following example specifies using `controller/scan_en` as the scan enable input pin on the clock-controller interface:

```
set_clock_controller_pins scan_en controller/scan_en
```

Example 2

In this example, assume that the clock controller is not available in the design. The following example specifies the clock controller's shift clock but does not make any connection to the clock-controller interface:

```
set_clock_controller_pins shift_clock -no_connection
```

Example 3

This example connects the `lbist_en` output of the LogicBIST controller to the LogicBIST enable pin on multiple clock controllers. Note that the arguments should be specified in a list surrounded by braces.

```
set_clock_controller_pins lbist_en \
    {cc_clk1/lbist_mode cc_clk2/lbist_mode cc_clk3/lbist_mode}
```

Example 4

This example shows how to connect the NCP index pins of multiple clock controllers using the `-append` switch.

Note

 You must specify a connection for each clock controller separately as the `capture_procedure_index` pin type requires a list of pin names be declared for each clock controller.

```
set_clock_controller_pins capture_procedure_index \
    [get_pins cc_clk1/ncp*]
set_clock_controller_pins capture_procedure_index \
    [get_pins cc_clk2/ncp*] -append
set_clock_controller_pins capture_procedure_index \
    [get_pins cc_clk3/ncp*] -append
```

Issuing a report_clock_controller_pins command will show the following:

```
//  command: report_clock_controller_pins
//
//  PinType          Connection
//  -----
//  LBIST enable    cc_clk1/lbist_mode cc_clk2/lbist_mode
//                  cc_clk3/lbist_mode
//  Capture procedure index  cc_clk1/ncp_index[1] cc_clk1/ncp_index[0]
//                          cc_clk2/ncp_index[1] cc_clk2/ncp_index[0]
//                          cc_clk3/ncp_index[1] cc_clk3/ncp_index[0]
//
```

Related Topics

[report_clock_controller_pins](#)

[set_lbist_controller_options](#)

[set_clock_controls](#)

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Enables and disables the clock control definitions in the test procedure file.

Usage

```
set_clock_controls {ON | OFF}  
[-ENFORCE_off_conditions_outside_capture_if_pulse_in_capture_source {ON | OFF}]
```

Description

Enables and disables the clock control definitions in the test procedure file.

When enabled, the clock definitions are used for ATPG. Clock control definitions cannot be used simultaneously with Named Capture Procedures (NCPs).

For more information, see “[Support for Internal Clock Control](#)” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- **ON**

Required literal that enables clock control definitions. This is the default setting unless Named Capture Procedures (NCPs) are enabled in the test procedure file. When NCPs are enabled, the internal clocks are automatically disabled.

- **OFF**

Required literal that disables clock control definitions. Unless the internal clocks are controlled by NCPs, turning clock control off leads the tool to treat the internal clocks as directly controllable and ignore the constraints and condition bits imposed on ATPG by the clock control definitions. Any generated patterns are invalid since the clock controller requirements modeled using the clock control definitions are completely ignored by ATPG and simulation. The ability to turn off clock controls is provided only for debug purposes, and is typically used to determine if a fault is untestable because of the clock control constraints (and if the fault is testable if those constraints are not present).

- **-ENFORCE_off_conditions_outside_capture_if_pulse_in_capture_source {ON | OFF}**

An optional switch and keyword pair that enables turning off the following default behavior: when the source clock of a clock control is an pulse-in-capture clock, the tool uses condition bits to ensure that the internal clock is off in cycles beyond those generated by ATPG even if the source clock is pulsed beyond that point. This prevents disturbing the captured values.

When generating patterns in the presence of internal clocks controlled by using clock control definitions, the tool must either decide whether to use condition bits to suppress additional internal clock pulses beyond the sequential depth of the generated pattern or assume that disabling the source clock will suppress further internal clock pulses. For

example, consider that the clock control definition for a given internal clock specifies three condition bits: B1 to control the clock pulsing in the first cycle, B2 to control it pulsing in the second cycle, and B3 to control it pulsing in the third cycle. If ATPG generates a one-cycle pattern that pulses this clock, the tool encodes B1=1. The tool then has the option of encoding B2=0 and B3=0, or leaving them unspecified to be random-filled.

If the clock control definition has no source clock defined or has an asynchronous free-running clock, then the tool must encode those two additional condition bits to ensure that any pulses the OCC receives beyond the first pulse are suppressed and the internal clock only pulses once. On the other hand, if the clock control definition has a source clock that can be controlled by the tester and is now defined as pulse-in-capture or pulse-always, this source clock will be pulsed only once, and there is no need to waste encoding capacity to encode 00 into those two bits because the internal clock pulses only once regardless of the values loaded into B2 and B3.

The tool decides whether to use condition bits to suppress further internal clock pulses as follows:

If a clock control definition has no source clock, or its source clock(s) are asynchronous free-running, the tool applies the condition bits needed to suppress additional internal clock pulses beyond the sequential depth of the generated pattern. You have no way to change this.

If generating retargetable patterns (“set_current_mode -type internal”), the tool applies the condition bits to suppress additional internal clock pulses. You cannot change this because the clocks at the core boundary typically do receive additional clock pulses when retargeted and merged with patterns for other cores.

If the source clock(s) defined in a clock control block are pulse-in-capture, the tool applies the condition bits to suppress additional internal clock pulses. You can override this behavior by using “set_clock_controls on -enforce_off_conditions_outside_capture_if_pulse_in_capture_source off.” This reduces the number of specified bits and may improve EDT compression. However, if you use this option, you must be sure that the source clock will not be pulsed additional times than ATPG has pulsed it. Do not use the “set_external_capture_options -fixed_cycles” or “set_external_capture_options -minimum_cycles” commands when writing your patterns, since those options pulse the pulse-in-capture clocks when adding the padding cycles. Note that capture cycle padding is used for the type-3 LPCT controller, and as such, you should not use “set_clock_control on -enforce_off_conditions_outside_capture_if_pulse_in_capture_source off” in that case either.

If none of the previous conditions are satisfied and the source clock(s) are defined and completely under ATPG control with no constraints, then ATPG does not apply the condition bits to suppress additional internal clock pulses beyond the sequential depth of the generated pattern.

Examples

The following example is a debugging flow that disables all clock control definitions in the test procedure file and generates test patterns:

```
set_clock_controls off  
create_patterns
```

Related Topics

[report_clock_controls](#)

set_clock_gating

Context: dft -scan, dft -test_points

Mode: setup

Specifies clock gating cells whose unconnected test-enable ports need to be connected to either the scan enable signal or a specified signal (pin).

Usage

```
set_clock_gating {ON | OFF} [object_spec]
    [-Port_to_connect port_name [-INVert]]
    [-clock_port clock_port_name]
    [-clock_out_port clock_out_port_name]
```

Description

Specifies clock gating cells whose unconnected test-enable ports need to be connected to either the scan enable signal or a specified signal (pin).

Note

 When wrapper analysis is used, and the clock gater drives wrapper cells, then the port will be connected to a composite signal that consists of scan_enable or'ed with the appropriate mode enable (for example, ext_mode_enable). Alternatively, when multiple scan enables are used, the appropriate scan enable signal will be selected based on the type of scan cells each clock gater is driving.

The tool considers an unconnected port to be a port that is not connected to any net or is tied low (TIE0), tied high (TIE1), tied unknown (TIEX), or tied high impedance (TIEZ).

The tool does one of the following:

- Automatically checks if the test-enable port of each recognized clock gating instance or module is unconnected and, if unconnected, connects it to the scan enable signal.
- Automatically checks if the specified port of each specified instance is unconnected and, if unconnected, connects it to the scan enable signal.

Note

 This command is cumulative. Every “set_clock_gating on” command invocation adds to the list of clock gaters that will be connected, and every “set_clock_gating off” command invocation removes clock gaters from the list.

Arguments

- **ON**
A literal that specifies to connect the unconnected test-enable port of the provided instances or modules. If no *object_spec* is provided, it applies to all identified clock gaters. This is the default.
- **OFF**
A literal that specifies to not allow connecting the unconnected test-enable port of the provided instances or modules. If no *object_spec* is provided, it applies to all identified clock gaters.
- ***object_spec***
A Tcl list of one or more instances or modules or a collection of instances or modules.
- **-Port_to_connect *port_name*[-INVert]**
An optional switch and string pair that specifies the unconnected port of the clock gating cell to be connected to either the scan enable signal or to the specified signal.
-INVert — By default, the expected input value for the unconnected port is set to 1 during the shift cycle. This switch specifies that the expected input value is set to 0 during the shift cycle.

The -Port_to_connect option is required when you issue the command with the on switch and provide *object_spec*. For the command to succeed, the port names specified with this option must exist on all the modules/instances defined with *object_spec*. To add modules that have different names for their test-enable or clock pins, issue the command multiple times.

The default tool behavior is equivalent to “set_clock_gating on”, meaning that all identified clock gaters will be connected. The clock gaters are initially identified either through auto-identification or are inferred from the cell library.

The tool marks the unconnected clock gaters and identifies their test-enable pins according to the following priority:

- First, each clock gater explicitly provided with the “set_clock_gating on” command will be marked, and the port specified by the -port_to_connect switch will be identified as its test_enable pin.
- Next, every instance whose module’s cell_type equals clock_gating_and or clock_gating_or will be marked, and the port with the test_enable or test_enable_inv attribute will be identified as test-enable. If the clock gater is not driven by any synchronous clock it will not be marked.
- Finally, all auto-identified clock gater instances will be marked with one of their unconnected inputs identified as test-enable.

- **-clock_port *clock_port_name***

An optional switch and string pair that specifies the clock port of the clock gating cell. Use this option when the clock gating device is to be connected to an enable signal associated with the clock domain.

- **-clock_out_port *clock_out_port_name***

An optional switch and string pair that specifies the clock out port of the clock gating cell. Use this option when the clock gating device has multiple outputs.

Examples

The following example demonstrates the use of the set_clock_gating command:

```
set_clock_gating on /inst1/cgc1 -port_to_connect te  
set_clock_gating off /inst1/cgc2
```

The first set_clock_gating command connects the /inst1/cgc1/te pin to the relevant scan enable signal, marks all clock gaters whose cell module has cell_type clock_gating_and or clock_gating_or and identifies test-enable signal based on test_enable or test_enable_inv pin attribute. The second set_clock_gating command specifies that the /inst1/cgc2 instance will not be connected. All remaining auto-identified clock gaters will be marked and one of their unconnected enable pins will get connected to the appropriate scan enable.

Related Topics

[report_clock_gating](#)

set_clock_gating_enable

Context: dft -scan, dft -test_points

Mode: setup

Associates clocks that control clock gating devices with enable signal drivers.

Usage

```
set_clock_gating_enable enable_signal_driver_pathname [primary_input]
    [-Active {High | Low}]
    [-Clock_domain clock_signal_driver_pathname...]
```

Description

Associates clocks that control clock gating devices with enable signal drivers.

This command assumes that the clocks controlling the clock gating devices (whose enable ports are to be automatically connected) were added to the design with the [add_clocks](#) command.

The tool connects the unconnected enable ports of clock gating devices to the enable signal associated with the controlling clocks of these clock gating devices. The clock gating devices, the enable ports of the clock gating devices, and their clock ports must be specified with the [set_clock_gating](#) command.

Arguments

- ***enable_signal_driver_pathname***

A required string, single-element Tcl list or a collection that specifies either a new top-level port, an existing top-level enable port or an existing internal output pin to be connected to the unconnected enable port of a clock gating device.

The *enable_signal_driver_pathname* argument can be either a top-level enable port or an internal instance pin. If an internal instance pin is specified, the tool attempts to locate its primary input driver by tracing back to a primary input via a simple path; that is, through only inverters or buffers. If automatic identification of the primary input driver fails, the value of the *primary_input* option is used, if provided. Identification of the primary input is needed to generate the ATPG dofile and test procedure files.

- ***primary_input***

An optional Tcl list or a collection that specifies a top-level enable port for an internal instance pin provided by the *enable_signal_driver_pathname* argument. The specified top-level port is used when generating the ATPG dofile and test procedure files.

- **-Active {High | Low}**

An optional switch and literal pair that specify whether the enable signal is active low or active high. The default setting is high.

- **-Clock_domain** *clock_signal_driver_pathname...*

An optional switch and a repeatable string that specifies the defined clock(s) controlling clock gating devices whose unconnected enable ports are to be connected to the specified enable signal's driver.

Examples

The following example specifies the default clock gating enable signal to be used when the tool does not find an enable signal associated with the specified clock domain.

```
set_clock_gating_enable x  
set_clock_gating_enable y -clock_domain a
```

In this example, the signal x will be used to enable all clock gaters except for those in clock domain a, which will use signal y.

set_clock_off_simulation

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Enables or disables the simulation where all clock primary inputs are at their “off” value, other primary inputs have been forced to values, and state elements are at the values scanned in or resulting from capture in the previous cycle.

Usage

`set_clock_off_simulation ON | OFF`

Description

Enables or disables the simulation where all clock primary inputs are at their “off” value, other primary inputs have been forced to values, and state elements are at the values scanned in or resulting from capture in the previous cycle.

When simulating this event, the capture data for inputs is provided to leading edge triggered flip-flops.

Tip If you use ATPG Expert (create_patterns), you do not need to issue this command for better handling of DRC violations. ATPG Expert automatically enables it when needed. You may get better results by letting ATPG Expert decide when to use this command except in the case of transparent latch handling.

Note that the set_clock_off_simulation command affects ATPG (subsequent `create_patterns` commands) but not logic simulation (subsequent `simulate_patterns` commands).

Arguments

- **ON**
A literal that performs ATPG for all clock primary inputs at their “off” values.
- **OFF**
A literal that performs ATPG for all clock primary inputs at their active values. This is the default.

Examples

The following example enables clock_off simulation prior to creating patterns:

```
set_system_mode analysis
set_clock_off_simulation on
create_patterns
```

Related Topics

[set_split_capture_cycle](#)

[set_clock_options](#)

Context: dft, patterns

Mode: setup

Allows you to specify multiple options for a single clock.

Usage

```
set_clock_options object_spec [-label]  
  [[-period period {s | ms | us | ns | ps | fs}]  
   | [-reference ref_obj_spec [-reference_inv ref_inv_obj_spec]  
   | [-freq_multiplier freq_multiplier] [-freq_divider freq_divider]]]  
   [-pulse_always {ON | OFF} | -pulse_in_capture {ON | OFF}] [-off_state {0 | 1}]  
   [-dft_inject_node dft_inject_node] [-no_dft_connections]
```

Description

Allows you to specify multiple options for a single clock.

The `set_clock_options` command allows you to edit options for an existing clock without having to delete the clock and create a new clock with the [add_clocks](#) command.

Arguments

- ***object_spec***
A required string that specifies an existing clock using the name of a port, pin, pseudo_port, label, or a collection of one port, or one pin, one pseudo_port, or one label object. The *object_spec* cannot be a branch.
- **-label *label***
An optional switch and string pair that specifies an arbitrary alias name for the clock.
- **-period *period***
An optional switch and real number pair that specifies the base clock period. Setting the clock period changes the clock type from synchronous source to asynchronous source. Setting the clock period to a null string changes the clock type from asynchronous source to synchronous source.
- **[s | ms | us | ns | ps | fs]**
An optional literal that specifies a time unit if you use the -period switch. If you don't use this switch, the default is "ns."
- **-reference *ref_obj_spec* ("patterns -ijtag" only)**
An optional switch and string pair that specifies the source primary input port that is connected to the internal clock pin you specified with the *object_spec* argument. You use this switch only for an existing source clock on a pseudo_port, not for a port. Setting the *ref_obj_spec* to a null string changes the clock type from generated to synchronous source.

- **-reference_inv *ref_inv_obj_spec* (“patterns -ijtag” only)**

An optional switch and string pair that specifies a second primary input port if the **-reference** pin is a differential pin. You can use this switch only if you also use the **-reference** switch or if the *object_spec* is already a generated clock.

- **-freq_multiplier *freq_multiplier* (“patterns -ijtag” only)**

An optional switch and string pair that defines the multiply factor of the clock frequency between the reference pin and the internal clock pin specified with the *object_spec* argument. You can use this switch only if you also use the **-reference** switch or if the *object_spec* is already a generated clock.

- **-freq_divider *freq_divider* (“patterns -ijtag” only)**

An optional switch and string pair that defines the division factor of the clock frequency between the reference pin and the internal clock pin specified with the *object_spec* argument. You can use this switch only if you also use the **-reference** switch or if the *object_spec* is already a generated clock.

- **-pulse_always {ON | OFF}**

An optional switch and literal pair that specifies the *object_spec* as a pulse-always clock. A pulse-always clock is pulsed in every cycle. The clock you specify also pulses with any other clock, ignoring the specified clock restriction setting. You can use this switch only when *object_spec* is an existing source clock. This switch has no default value.

- **-pulse_in_capture {ON | OFF}**

An optional switch and literal pair that specifies the *object_spec* as a pulse-in-capture clock. A pulse-in-capture clock is always pulsed during the capture window. You can use this switch only when *object_spec* is an existing source clock. This switch has no default value.

- **-off_state {0 | 1}**

An optional switch and literal pair that specifies the off state of the clock. You cannot use this switch if *object_spec* is an existing async source or if you use the **-period** switch. This switch has no default value.

- **-dft_inject_node *dft_inject_node* (“dft” only)**

An optional switch and string pair that specifies where the DFT object affecting the clock (for example, a TCK injection multiplier) should be inserted along the clock path. You can introspect the status of this switch with the “[get_clock_option -dft_inject_node](#)” command and switch.

- **-no_dft_connections**

A Boolean switch that instructs the tool to not infer DFT connections to this clock. When choosing the clock for a dedicated wrapper cell or a test_point in the [insert_test_logic](#) command, the clock used by the majority of the flip-flops in the fanin or fanout of the node is normally used. If that clock was added with the **-no_dft_connections** switch, it is not chosen and instead the next majority clock is used. If all clocks the fanin or fanout were

added with the `-no_dft_connections` switch, the largest clock domains in the design without this switch are selected.

Examples

The following example creates a synchronous clock with a label, then uses the `set_clock_options` command to change the clock to asynchronous and assign a different label name:

```
SETUP> add_clocks 0 I3 -pulse_always -label sync3
```

```
SETUP> report_clocks
```

```
User-defined Clocks (1) :  
Sync and Async Clocks  
=====
```

Name	Label	Off State	Constraints	Internal
'I3'	sync3	0	Pulse always	No

```
SETUP> set_clock_options I3 -label async3 -period 100
```

```
SETUP> report_clocks
```

```
User-defined Clocks (1) :  
Sync and Async Clocks  
=====
```

Name	Label	Off State	Constraints	Internal	Period
'I3'	async3	-	Asynchronous	No	100.00ns

set_clock_restriction

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies whether ATPG can create patterns with more than one active capture clock.

Usage

```
set_clock_restriction {Clock_po | ON | OFF | Domain_clock [-Edge_interaction  
| -Any_interaction] | [-PULSE_interacting_clocks {OFF | ON}]  
[-MAX_SKew {Half_cycle |  
One_cycle | Multiple_cycles}]  
[-SAME_clocks_between_loads {OFF | ON}]  
[-COMPAtible_clocks_between_loads {OFF | ON}]  
[-IGNORE_unobservable_cells {ON | OFF}]
```

Description

Specifies whether ATPG can create patterns with more than one active capture clock.

The set_clock_restriction command changes the default behavior of ATPG regarding the creation of test patterns that have more than one active clock line.

Note

 Pulse-always clocks are excluded from clock restriction checking when you choose Clock_po or ON. For example, if you choose ON, and two pulse-always clocks are defined, then only one clock is allowed in addition to the pulse-always clocks.

If you choose Domain_clock, the tool forces pulse-always clocks to be compatible with other clocks.

Arguments

- **Clock_po**

A literal that specifies that multiple clocks are allowed to be active for clock_po patterns. For non-clock_po patterns, the option is equivalent to the ON option which only allows a single active clock per capture cycle.

For more information on clock_po patterns, see the “[Clock PO Patterns](#)” section in the *Tessent Scan and ATPG User’s Manual*.

- **ON**

A literal that specifies for the ATPG to create only patterns with, at most, a single active clock.

The ATPG treats equivalent clocks as a single clock, however, it treats multiple active clocks as a conflict condition and performs an exhaustive search for conditions necessary to detect the fault with no more than one active clock. Faults which the ATPG detects at

primary outputs (POs) that connect to clocks must also satisfy this condition. Faults detected at clock POs that require multiple active clocks for detection, require that you use the Clock_po option. You can accomplish this by setting the clock restriction to Clock_po and then re-running the ATPG.

During the bus contention prevention analysis portion of the ATPG, Tessent FastScan and Tessent TestKompress turn off any clock pins that the ATPG does not require for fault detection.

- **Off**

A literal that specifies for the ATPG process to create patterns with as many clocks on as it requires to detect faults. Using this option may cause race conditions due to multiple active clocks. Prevent these race conditions by specifying the On argument.

For Tessent FastScan and Tessent TestKompress — These tools concurrently apply any clocks they require for a given pattern. They display a message at the end of the ATPG run to indicate the number of patterns that had more than one active clock. When you change the clock restriction to off, these tools reset the ATPG untestable faults to undetected-uncontrolled.

- **Domain_clock**

A literal that specifies for ATPG to create patterns with compatible clocks on. This enables the tool to generate patterns that pulse compatible scan chain capture or system clocks at the same time. Normally, only one scan chain capture or system clock is pulsed in a cycle. The tool treats two clocks as compatible if their domains are completely independent of each other; that is, they can be in their “on” state at the same time without causing clock skew problems or race conditions.

The tool automatically analyzes circuit data from DRC to determine the compatible clocks. Therefore, if you use this option prior to DRC, the tool defers execution until DRC.

Note

 The tool’s analysis of clock domains only considers Tie-0 or Tie-1 gates that are Tie-0 or Tie-1 in both combinational and sequential ATPG.

- **-Edge_interaction**

An optional switch that, when the Domain_clock setting is in effect, specifies for the tool to determine if two clocks are compatible (C) or incompatible (I) based on their edge interactions, as summarized in [Table 6-4](#). The table covers the case where a source memory element is clocked by one clock, a sink memory element is clocked by a different clock, and the source and sink interact (the sink can capture data from the source).

Note

 Take care when interpreting what the “C” and “I” mean: “C” means only that the tool treats the result of the particular combination as being unaffected by clock skew. “I” means the tool treats the result of the particular combination as susceptible to skew.

You can issue the `set_clock_restriction` command with only this switch, and the tool will retain whatever clock restriction setting (`Clock_po`, `On`, `Off` or `Domain_clock`) is currently in effect. This switch has no effect on the analysis used for ATPG unless `Domain_clock` is in effect; however, it does affect the output of the [report_clock_domains](#) command.

This is the default upon invocation of these tools.

Table 6-4. Default Clock Compatibility Summary at a Clock Domain Boundary

		Sink			
		LE¹	TE²	AH(TE)³	AL(LE)⁴
S	LE⁵	I	C	C	I
O	TE⁶	C	I	I	C
U	AH(LE)⁷	I	C	C	I
R	AL(TE)⁸	C	I	I	C

1. LE = Edge sensitive element captures on PI clock's leading edge
2. TE = Edge sensitive element captures on PI clock's trailing edge
3. AH(TE) = Active high, level sensitive element captures on PI clock's trailing edge
4. AL(LE) = Active low, level sensitive element captures on PI clock's leading edge
5. LE = Edge sensitive element changes on PI clock's leading edge
6. TE = Edge sensitive element changes on PI clock's trailing edge
7. AH(LE) = Active high, level sensitive element changes on PI clock's leading edge
8. AL(TE) = Active low, level sensitive element changes on PI clock's trailing edge

ATPG Expert automatically sets the appropriate switch based upon the fault type. For stuck-at faults, ATPG Expert always sets “`set_clock_restriction domain_clock-edge_interaction`”.

- `-Any_interaction`

An optional switch that, when the `Domain_clock` setting is in effect, specifies for the tool to do a more conservative analysis of the clocking relationship between interacting source and sink memory elements in different clock domains. If the source is clocked by one clock, the sink is clocked by a different clock, and the two elements interact (the sink can capture data from the source), this switch causes the tool to treat the two clocks as incompatible. In other words, all the conditions shown in [Table 6-4](#) result in a determination of incompatibility.

You can issue the `set_clock_restriction` command with only this switch, and the tool will retain whatever clock restriction setting (`Clock_po`, `On`, `Off` or `Domain_clock`) is currently

in effect. This switch has no effect on the analysis used for ATPG unless Domain_clock is in effect; however, it does affect the output of the [report_clock_domains](#) command.

ATPG Expert automatically sets the appropriate switch based upon the fault type. For transition faults, ATPG Expert always sets “set_clock_restriction domain_clock -any_interaction -compatible_clocks_between_loads on”.

- **-PULSE_interacting_clocks {OFF|ON}**

An optional switch and literal pair that specifies whether the interacting clocks can be pulsed simultaneously during test. By default, the tool disables the pulsing of interacting clocks. The ON option allows pulsing pairs of interacting clocks during test generation. Note that this switch is effective only when you also specify the Domain_clock option.

When this switch is ON, the tool masks some state elements located at the inter-clock domain in order to avoid simulation mismatches. Therefore, you will notice more X values at the state elements than when this switch is OFF. The behavior of cross-domain path masking depends on the setting of the max clock skew, as described below for the -Max_skew switch.

Note

The tools treats user-defined compatible clocks (created with the [add_synchronous_clock_group](#) command) as compatible clock domains and does not mask out cross-clock domain paths between compatible clocks.

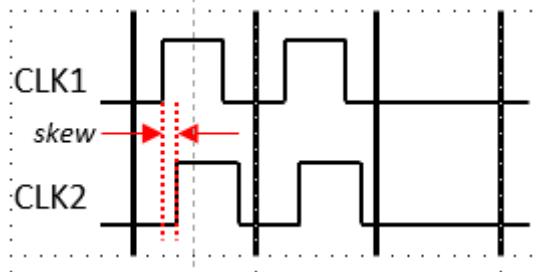

- **-MAX_SKW {Half_cycle | One_cycle | Multiple_cycles}**

An optional switch and literal pair that specifies the maximum skew between interacting clocks pulsed during capture. The maximum skew determines whether the observation state element should be masked or if fault simulation can give credit for detection. This option is effective only when the -Pulse_interacting_clocks option is enabled.

The maximum skew settings impact fault simulation as follows:

- Half_cycle — Only masks cross-clock domain paths of the same edge. [Figure 6-2](#) shows half-cycle skew:

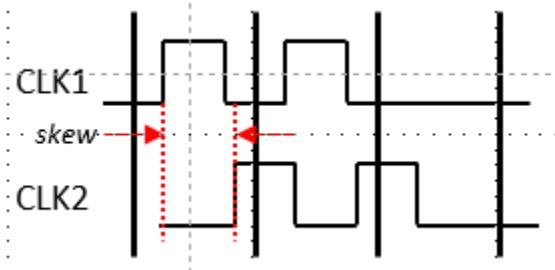

Figure 6-2. Half-cycle Skew

- One_cycle — Masks cross-clock paths of the same clock edge, leading edge to trailing edge of the same cycle, and trailing edge to the leading edge of the next cycle. It allows the transition to be tested by launching at the leading (trailing) edge of one clock and capturing at the next cycle leading (trailing) edge of another clock.

Figure 6-3 shows one-cycle skew:

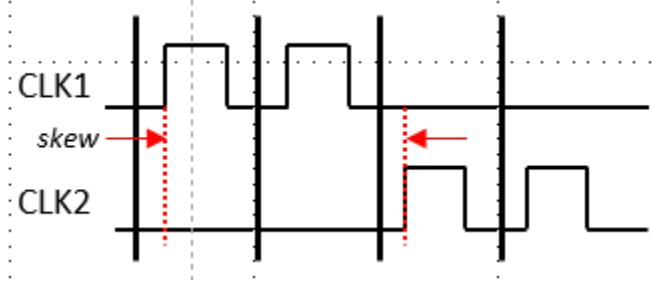

Figure 6-3. One-cycle Skew

- `Multiple_cycles` — Masks all cross-clock domain paths. Tool assumes multiple clock cycles between all cross-clock domain paths and simulates them as asynchronous.

Figure 6-4 shows multiple-cycle skew:

Figure 6-4. Multiple-cycle Skew

The default maximum skew settings are as follows:

- Static fault models (stuck-at and bridging) — Default setting is `Half_cycle`, although the default is `One_cycle` when you also use the `-Any_interaction` switch.
- At-speed fault models (transition and path delay) — When the `-same_clocks_between_loads` switch is disabled, interacting clocks may be pulsed in adjacent cycles. In this case, the default setting is `One_cycle`, which allows transition from one edge to the same edge in the next cycle. When the `-same_clocks_between_loads` switch is enabled, interacting clocks are pulsed in every cycle and all clock interactions should be considered invalid. To reduce the chance of simulation mismatches, the default setting is `Multiple_cycle`.

You can use the `-max_skew` switch to overwrite the default clock skew to either prevent simulation mismatch (by specifying more clock skew than the default) or obtain better test coverage (by specifying less clock skew than the default). However, when changing the max skew to be less than the default, it must match with the design clock timing; otherwise, there is the possibility of simulation mismatch.

- **-SAME_clocks_between_loads {OFF|ON}**

An optional switch and literal pair that specifies whether to use the same clocks in every cycle between load/unload operations (during capture cycles). This switch is useful for at-speed test generation when you want each pattern to test for delay faults in only one clock domain. When clocks are pulsed between loads, they will all be pulsed for every cycle between loads.

Generally, each test pattern created with this switch enabled will pulse the *same* clocks in every test cycle that pulses clocks. Multi-load patterns are an exception: for a multi-load pattern, the switch applies to each load/unload interval independently. Therefore, the clocks used in a particular interval might not be the clocks used in another interval in the same multi-load pattern.

When enabled, this switch has no effect on pattern simulation. However, the tool will transcript a warning message if a pattern violates the restriction. You can issue the `set_clock_restriction` command with only this argument, and the tool will retain whatever other clock restriction setting (`Clock_po`, `On`, `Off` or `Domain_clock`) is currently in effect.

OFF — A literal that disables the requirement to use the same clocks in every cycle within a load/unload interval during pattern creation. This is the invocation default.

ON — A literal that specifies to use the same clocks in every cycle within each load/unload interval during pattern creation.

- **-COMPAtible_clocks_between_loads {OFF|ON}**

An optional switch and literal pair that specifies that only compatible clocks are allowed to pulse between load/unload operations (during capture cycles). This switch is used with the `domain_clock` option.

OFF — A literal that turns off the compatible clock requirement. When set, incompatible clocks are not allowed to pulse in the same cycle, but they are allowed to pulse at different capture cycles.

ON — A literal that allows only compatible clocks to pulse within capture cycles. When set, incompatible clocks are never allowed to pulse between load/unload operations.

The “`-compatible_clocks_between_loads on`” switch and literal pair is not compatible with the `-edge_interaction` switch or `-pulse_interacting_clocks`. When you specify “`-compatible_clocks_between_loads on`” and `-edge_interaction`, the tool issues an error message. It also issues an error message when you specify “`-compatible_clocks_between_loads on`” and `-pulse_interacting_clocks`.

Tip

If you want to create patterns that test only intra-clock domain faults, and you want to allow multiple non-interacting clock domains to be tested simultaneously in order to reduce pattern count, issue the following command prior to creating patterns:

```
set_clock_restriction domain_clock -any_interaction  
-compatible_clocks_between_loads on
```

- **-IGNORE_unobservable_cells {ON | OFF}**

An optional switch and literal pair that bypasses checking any unobservable nonscan or scan cells for clock interaction purposes. You can issue the `set_clock_restriction` command with only this argument, and the tool will retain whatever other clock restriction setting (`Clock_po`, `On`, `Off`, or `Domain_clock`) is currently in effect.

ON — A literal that enables bypassing the check for unobservable nonscan or scan cells.

OFF — A literal that disables bypassing the check for unobservable nonscan or scan cells.

For example, if two clocks interact on a state element that is unobservable due to pin constraint or cell constraint, then the tool does not consider these two clocks incompatible for this statement when this switch is set to ON.

Examples

The following example checks the current clock restriction setting, adds the additional restriction that the tool use the same clocks in every cycle within each load/unload interval during pattern creation, then changes the basic setting from `clock_po` to “on”:

report_environment

```
...
clock restriction =      clock_po
...
```

set_clock_restriction -same_clocks_between_loads on
report_environment

```
...
clock restriction =      clock_po, same_clocks_between_loads
...
```

set_clock_restriction on
report_environment

```
clock restriction =      ON, same_clocks_between_loads
```

set_compactor_connections

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup

Specifies the scan chains for the tool to connect to a particular scan channel output.

Usage

```
set_compactor_connections {-CHANnel channel_number} {-CHAIns {chain_name...}}
```

Description

Specifies the scan chains for the tool to connect to a particular scan channel output.

The set_compactor_connections command specifies a list of scan chains whose outputs you want the tool to compact into the specified EDT scan channel output. The tool makes these connections using one or more stages of XOR gates in the compactor circuitry. If you use this command to specify the compactor connections for one scan channel and group of scan chains, you must use it for all the channels and chains in the design.

When generating the EDT IP, the tool uses the sequence of [add_scan_chains](#) commands to connect the EDT hardware to the scan chains. You can change the order of the add_scan_chains commands in your dofile to change how they are connected to the decompressor and compactor. However, this method changes both the decompressor and compactor connections for a particular chain.

Alternatively, you can use the set_compactor_connections command to override the tool's default connections and explicitly define the connections between scan chains and compactor. Using this command allows you to change the compactor connections without changing the default decompressor connections to those chains.

If you have dual configurations, you can still define the compactor connections using the set_compactor_connections command, but only for the configuration that uses all scan channels. The set_compactor_connections command is not tied to a specific configuration since you only need to define connections once for each channel.

Arguments

- **-CHANnel *channel_number***

A required switch and positive integer pair that identify the scan channel to connect to the specified group of scan chains.

When you specify the number of channels using the set_edt_options command *-Channels* switch, the tool numbers the channels consecutively starting at 1.

- **-CHAIns chain_name...**

A required switch and repeatable string pair that specify the internal scan chains whose outputs the tool should connect through the compactor circuitry to the specified scan channel output.

Examples

Example 1

For a design with eight scan chains named “chain1” through “chain8”, the following example sets up the EDT logic to have two scan channels. It then connects the outputs of chain1, chain5 and chain6 through the compactor to channel 1 and displays these connections. Any channel listed with “no connections” next to it still needs to be defined. The example goes on to define the remaining compactor connections and displays the completed configuration.

```
set_edt_options -channels 2
set_compactor_connections -channel 1 -chains chain1 chain5 chain6
report_compactor_connections

// Reporting user-defined compactor connections:
//
// Channel    Chains
// -----
//      1      chain1, chain5, chain6
//      2      no connections
//

set_compactor_connections -channel 2 -chains chain2 chain3 chain4 chain7 chain8
report_compactor_connections

// Reporting user-defined compactor connections:
//
// Channel    Chains
// -----
//      1      chain1, chain5, chain6
//      2      chain2, chain3, chain4, chain7, chain8
//
```

Example 2

In the following example, compactor connections are defined for a dual configuration. Note, the connections are only defined for the configuration that uses all scan channels.

```
set_current_edt_configuration config_high
set_edt_options -input 1 -output 1
set_current_edt_configuration config_low
set_edt_options -input 3 -output 3
set_compactor_connections -channel 1 -chains ...
set_compactor_connections -channel 2 -chains ...
set_compactor_connections -channel 3 -chains ...
```

Related Topics

[report_compactor_connections](#)
[reset_compactor_connections](#)

[**set_edt_options**](#)

set_config_value

Context: unspecified, all contexts

Mode: all modes

Sets the value of an element in the configuration data.

Usage

```
set_config_value config_spec
  [-in_wrapper wrapper_object_spec]
  [-id {position | id_name | all} | -value_id {position | value_name | all}]
  {values | -specify_default | -unspecify | -comment comment}
  [-partition partition]
```

Description

Sets the value of an element in the configuration data.

See the [get_attribute_value_list](#) command for strategies for introspection of object types.

Arguments

- ***config_spec***

A required value that specifies the name of a configuration element or a collection containing one configuration element. When ***config_spec*** is a collection, the **-in_wrapper** option cannot be used because the object contains all of the information about the configuration element. In order to use the **-in_wrapper** option, the ***config_spec*** value must be a name and the name must be relative to the specified wrapper element.

You can use a positional *id* for any level of hierarchy. You can also replace the *id* of a leaf name by the position. For example, the path “tmp(1)/<0>/wrp<1>” means “tmp(1)/wrp(abc)/wrp(def)” if “wrp(abc)” is the first element found inside “tmp(1)”, and “wrp(def)” is the second instance of a wrapper with a base name of “wrp” inside “tmp(1)/wrp(abc)”.

- **-in_wrapper *wrapper_object_spec***

An optional switch and value pair that specifies the parent wrapper in which the configuration element exists. The *wrapper_object_spec* value is the name of a wrapper or a collection containing a wrapper element. The name in ***config_spec*** is relative to the specified parent wrapper.

- **-id *position* | *id_name* | *all***

An optional switch and value pair that specifies that the data to set is the *id* of a wrapper or of a repeatable property. When using **-id all**, the command expects a well-formatted Tcl list unless the configuration element has metadata and there is only one non-repeatable **Id** declared for it. In this case, the value is supplied as a Tcl string which is the case for most wrappers and repeatable properties you will set.

When you have configuration elements with more than one *id*, you can set one *id* at a time using either its position or, if it has metadata, the *id* of the **Id** wrapper that declares the *id*. A

position is represented with an integer surrounded by <>. For example, <0> is the first id, <1> is the second, and so on.

- **-value_id** *position | value_name | all*

An optional switch and value pair that specifies that the data to set is the value of a property, repeatable property, or is a row inside a [DataWrapper](#) or a [CsvWrapper](#). If the -id or -value_id options are not specified, “-value_id all” is the default.

When using “-value_id all”, the tool expects a well-formatted Tcl list unless the configuration element has metadata and there is only one non-repeatable value declared for it. In this case, the value is expected to be a Tcl string which is the case for most properties you will set.

When you have configuration elements with more than one value, you can set one value at a time using either its position or, if it has metadata, the *id* of the [Value](#) wrapper that declares the value. A position is represented with an integer surrounded by <>. For example, <0> is the first value, <1> is the second, and so on.

- **values**

An string or Tcl list of strings that defines the value at which to set the [Ids](#) or [Values](#) of properties or wrappers. The tool also accepts collections where a value is expected and automatically extracts the name of the object, or list of object names.

You use a list only when using “-id all” or “-value_id all” unless the configuration element has metadata and there is only one non-repeatable id or value declared for it; otherwise, you use a string.

- **-specify_default**

An Boolean option that specifies that the property is to be set to its default value. This option is only allowed on properties.

- **-unspecify**

An Boolean option that specifies that the property is to be unspecified and thus return to its default value. This option is only allowed on properties.

- **-comment** *comment*

An switch and value pair that specifies the string comment for a configuration element.

- **-partition_name** *partition_name*

An optional Boolean option that specifies that the data requested is the name of the partition in which the configuration element exists. The example shows the returned value based on which partition the configuration element exists in.

An option and value pair that specifies the parent wrapper in which the configuration element exists. When the option is unspecified, the default partition is used which is where all specifications ([DftSpecification](#) and [DefaultsSpecification/DftSpecification](#)) are located. You can access the Core wrappers comprising the Tesson Core Description syntax in the tcd partition. Using the partition names meta: and meta:tcd allows you to access the

metadata configuration elements that define the default and tcd partitions.

[Table 6-5](#) summarizes the available partition names.

Table 6-5. Available Partition for Introspection

Partition name	Configuration data contained
(unspecified)	When the -partition option is unspecified, the Default partition is accessed which is where the DftSpecification and DefaultsSpecification/DftSpecification configuration data is located.
tcd	When the -partition option is specified with the tcd value, the Core wrappers comprising the Tesson Core Description syntax is accessed
meta	When the -partition option is specified with the meta value, the metadata configuration data defining the allowed syntax of the DftSpecification and DefaultsSpecification / DftSpecification is accessed.
meta:tcd	When the -partition option is specified with the meta:tcd value, the metadata configuration data defining the allowed syntax of the Core wrappers is accessed.

Examples

Example 1

The following example uses a foreach loop to set the properties inside a wrapper

```
> set int [get_config_el Interface \
- in /DftSpecification(corea,rtl)/IjtagNetwork/HostScanInterface(ijtag) ]
> foreach {prop val} {scan_in mySI scan_out mySO tck myTCK} {
    set_config_val $prop -in $int $val
}
> report_config_data $int
Interface {
    tck : myTCK;
    scan_in : mySI;
    scan_out : mySO;
}
```

Example 2

This example uses `set_config_value` to set a list of cell name in the [DftSpecification/force_creation_of_rtl_cells](#) property:

```
> set spec [create_dft_spec]
> set_config_value force_creation_of_rtl_cells -in $spec {and2 or2 inv}
> report_config_data $spec -l 1
DftSpecification(ctrl_core,rtl) {
    IjtagNetwork {
        // Not shown
    }
    force_creation_of_rtl_cells : And2, Or2, Inv;
    MemoryBist {
        // Not shown
    }
}
> get_config_value force_creation_of_rtl_cells -in $spec
And2 Or2 Inv
```

set_contention_check

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies whether or not contention checking is on and the conditions under which checks are performed. Contention checking is set to On when the tool is invoked.

Usage

```
set_contention_check {{ON | OFF} | CAPture_clock} [-Warning | -Error] [-Bus | -Port | -All] [-BIdi_retain | -BIDI_Mask] [-NO_Floating {BIdi_only | All_busses}] [-ATpg | -CATpg] [-NOVerbose | -Verbose | -VVerbose]}
```

Description

Specifies whether or not contention checking is on and the conditions under which checks are performed. Contention checking is set to On when the tool is invoked.

When a bused output of a tri-state driver (or switch) that is driving an X caused by an X on its enable is encountered, the contention is not reported if the data input to the driver is at the same level as other drivers on the bus. Also, the simulated value of the bus gate is resolved to a binary value if it can do so without tracing through additional bus gates.

Arguments

- **ON**

A literal that performs contention checking during simulation. The tool does not propagate captured data effects. This is the default.

If the set_split_capture_cycle command is on and there are multiple capture clocks in the design, the set_contention_check ON command performs a contention check not only before the capture but after the capture as well.

- **OFF**

A literal that specifies to not perform contention checking during simulation.

Tip

 If you create patterns using ATPG Expert (“create_patterns”), the tool automatically determines whether or not the -Atpg switch is necessary and will set it if simulation determines that too many patterns are being rejected due to contention; therefore, you do not need to specify “set_contention_check on -atpg”. This may, in some cases, be faster than setting it initially if a lot of fault coverage can be obtained using ATPG without it. If you are not sure if the switch is needed, it may be better to try running without it.

- **Capture_clock**

A literal that performs contention checking both with and without propagating captured data effects. If a clock, read control, or write control line connects to a bus, the tool also performs bus contention checking with all clocks off prior to the application of the capture clock. The

tool does not consider any contention patterns for fault simulation and does not place any of these patterns into the internal test pattern set.

Tip

i If you create patterns using ATPG Expert (“create_patterns”), the tool automatically determines if the -Catpg switch is necessary and use it only when it is needed; therefore all you need to specify is “set_contention_check capture_clock”. This may, in some cases, be faster than setting it initially if a lot of fault coverage can be obtained using ATPG without it. If you are not sure if the switch is needed, it may be better to try running without it.

- **-Warning**

An optional switch that displays a warning message, but continues simulation if bus contention occurs during simulation. The warning message indicates the number of patterns the tool rejected in the current simulation pass of 64 patterns and also identifies the bus gate on which the bus contention occurred.

- **-Error**

An optional switch that displays an error message and stops the simulation if bus contention occurs.

You can debug contention errors by using the -Error switch to stop simulation at the point of the first contention error.

Using this option, you can then view the simulated values of all gates in the first bus contention pattern by using the report_gates command.

The error message indicates the number of patterns the tool rejected in the current simulation pass of 64 patterns and also identifies the bus gate on which the bus contention occurred.

- **-Bus**

An optional switch that performs contention checking of tri-state driver buses. This is the default.

Tri-state logic allows several bus drivers to time-share a bus. However, if the circuit enables two bus drivers of opposite logic to drive the bus, physical damage can occur. This switch allows the tool to identify these conditions and notify you of their existence.

The tool identifies buses which have circuitry that prevents bus contention and does not check for bus contention problems. This eliminates false bus contention reporting when multiple inputs to a bus are at X. Bus contention that occurs on weak buses does not result in an E4 rules checking violation or pattern rejection during simulation. The tool continues to simulate them as an X state.

- **-Port**

An optional switch that performs contention checking for multiple-port flip-flops and latches. The tool identifies and rejects patterns during which any multiple-port latch or flip-flop has more than one clock, set, or reset input active (or at X).

- **-BIDI_Retain**

An optional switch that rejects patterns during contention checking that cause the direction of bidirectional pins to change following the capture clock.

- **-BIDI_Mask**

An optional switch that causes the fault simulator to modify the input values of bidi pins to avoid bus contention after the capture clock if a device pin changes from input mode to output mode as the clock is applied.

- **-NO_FLOATING {BIDI_only | ALL_busses}**

An optional switch and literal pair that checks for floating buses in addition to contention when bus contention checking is in effect. The BIDI_only option only checks for floating at buses associated with bidirectional pins. The ALL_busses option checks for floating at all buses. This switch enables the E11 DRC with handling set to warning if it was previously set to ignore. (If you have previously set E11 handling to note or error, your setting is retained).

The floating bus checks are always performed during pattern simulation when bus contention checking is in effect. If -Atpg or -Catpg is included, floating buses are avoided during test generation.

The following rules apply:

- Floating checks are performed for strong buses only, not weak buses.
- If a strong bus passes the E11 DRC, the switch does not apply to that bus.
- If a strong bus drives a pull bus, the strong bus is allowed to float if the weak input of the pull bus is set to a known binary value.
- This switch and the -BIDI_mask switch cannot be used together in the same command.
- This switch does not require that a bus have a known binary value to pass the floating check. The bus may be driven to an unknown binary value.
- If a bus is driven by a TIEX gate directly, the TIEX gate is treated as a source that can take on a Z value. As a result, it is impossible to avoid floating this bus and ATPG cannot generate any test patterns.

- **-ALL**

An optional switch that performs contention checking for both tri-state driver buses and multiple-port flip-flops and latches.

- **-ATPG**

An optional switch that forces all buses to a non-contention state, which ensures that test patterns are not created causing bus contention.

After completing normal test pattern generation for a fault, the tool forces all buses to a non-contention state. If the tool cannot satisfy this condition, given the conditions set by the

original pattern, the tool aborts the fault, excludes the pattern from the final test set, and displays a message indicating the number of these aborted faults for each simulation pass. No attempt is made to change the original pattern.

The -Atpg option results in additional effort by the test pattern generator and you should use it only when necessary.

Tip

 If you create patterns using ATPG Expert (“create_patterns”), you may get the best results by not explicitly specifying the -Atpg switch. ATPG Expert will automatically determine if the switch is necessary and utilize it only when it is needed.

- **-CATpg**

An optional switch that uses clock sequential ATPG effort in the capture cycle as well as all other cycles. If neither this switch nor the -Atpg switch is specified, the default will continue to be that there is no ATPG effort for bus contention in any cycle, and ATPG constraints are satisfied deterministically prior to the capture clock event only. Specifying the -Catpg switch without the Capture_clock option is equivalent to using just the -Atpg switch.

Tip

 If you create patterns using ATPG Expert (“create_patterns”), you may get the best results by not explicitly specifying the -Catpg switch. ATPG Expert will automatically determine if the switch is necessary and utilize it only when it is needed.

- **-Verbose**

An optional switch that reports the first reason for each pattern rejected (maximum of 64 messages per parallel pattern invocation).

- **-VVerbose**

An optional switch that reports every reason for each pattern rejected (there is no limit to the number of messages per parallel pattern invocation). The messages will be of the same type issued for the -Verbose switch.

Note

 For large designs, this option may produce thousands of lines of output for each pattern simulated.

- **-NOVerbose**

An optional switch that lets you turn off the -Verbose or -VVerbose effects that may have been set previously.

Examples

Example 1

The following example performs contention checking on multiple-port flip-flops and latches, stops the simulation if any bus contention occurs, and displays an error message. The message indicates the number of patterns rejected and the bus gate on which the bus contention occurred:

```
set_contention_check on -port -error
set_system_mode analysis
create_patterns
```

Example 2

The following example performs contention checking on both multiple-port sequential gates and tri-state buses, stops the simulation if any bus contention occurs, and displays an error message that will indicate the gate on which the contention occurred:

```
set_system_mode analysis
set_contention_check on -all
create_patterns
```

set_context

Context: unspecified, all contexts

Mode: all modes

Specifies the current usage context of Tesson Shell.

Usage

```
set_context dft [{-edt [-logic_bist]} | { -scan [-legacy]} | -test_points] [-rtl | -no_rtl]
[-license license_name] [-design_identifier string] [-force]

set_context patterns [-ijtag | -scan| -scan_retargeting | -scan_diagnosis | -failure_mapping]
[-silicon_insight] [-rtl | -no_rtl] [-license license_name]
[-design_identifier string] [-force]
```

Description

Specifies the current usage context of Tesson Shell. You must set the context before you can invoke most other commands in Tesson Shell.

If you attempt to change context and have generated patterns, the tool prompts you to save the patterns with an error message similar to the following:

```
// Error: Current test pattern set has not been saved. Save the
// patterns or use the -force switch.
```

Arguments

- **dft**

A required literal that sets the context to dft. In the basic dft context, you load your design in setup mode and then move to the insertion mode to execute design editing commands such as [create_connections](#), [create_instance](#), and [move_connections](#). When used with the -scan or -edt options, the dft context is used to insert scan chains or insert the EDT controller.

- **patterns**

A required literal that sets the context to patterns which provides functionality related to scan and IJTAG pattern generation, ICL extraction, and scan pattern diagnosis.

- **-scan**

An optional switch that is available in both patterns and dft contexts. This sub-context specifies ATPG and simulation functionality for standard ATPG, Tesson TestKompress, and LogicBIST patterns when specified with the patterns context, and for scan insertion when specified with the dft context.

- **-legacy**

An optional switch that is available in the dft context and must be specified in conjunction with the -scan switch. This sub-context specifies that Tesson Scan is invoked in the legacy mode without hierarchical scan insertion.

- **-edt**
An optional switch that is available in dft context. This sub-context specifies to create and insert EDT IP into the design. When you provide a scan-inserted netlist, the tool analyzes the scan chains and generates and inserts an appropriate EDT controller.
- **-logic_bist**
An optional switch that is available in the dft context and must be specified in conjunction with the -edt switch. This switch enables the hybrid TK/LBIST flow—refer to the *Hybrid TK/LBIST Flow User's Manual* for complete information.
- **-test_points**
An optional switch that is available in the dft context and specifies functionality for test point identification and insertion.
- **-ijtag**
An optional switch that is available only in patterns context. This sub-context specifies functionality related to the [IEEE 1687-2014](#) (IJKTAG) standard such as generating IJKTAG patterns by executing PDL commands such that they are retargeted to the current design boundary, and performing ICL extraction. When the [set_current_design](#) command is executed, the presence of an ICL module matching the specified current design name sets the context to ijtag retargeting. If there is no ICL module matching the specified current design name, the ICL extraction mode is enabled. Executing “[set_context](#) -extraction” returns 1 when in the extraction mode.
- **-scan_retargeting**
An optional switch that is available in the patterns context. This sub-context enables scan pattern retargeting functionality for retargeting core-level test patterns at the top level. For more information, see “[Scan Pattern Retargeting](#)” in the *Tessent Scan and ATPG User's Manual*.
- **-failure_mapping**
An optional switch that is available only in the patterns context. This sub-context specifies to reverse map top-level failure files for retargeted scan pattern results, which were generated from within the -scan_retargeting sub-context. Reverse mapping results in a set of core-level failure files that you can diagnose with Tessent Diagnosis. For more information, refer to the *Tessent Diagnosis User's Manual*.
- **-silicon_insight**
An optional switch that is available only in the patterns context. This sub-context enables the SiliconInsight capabilities. For more information, see the *Tessent SiliconInsight User's Manual for Tessent Shell*.
- **-rtl | -no_rtl**
In dft context, these switches specify whether you are performing netlist editing or RTL editing. You must use the -rtl option if you are editing RTL. You can use either option when

editing a netlist but be aware that the [write_design](#) usage model is different between these modes. If you want to write out your edited netlist into a single file, select the `-no_rtl` option.

Note

 By default, the tool enables the preserve escaping in RTL contexts and disables the escaping in non RTL contexts. Switching between `-rtl` and `-no_rtl` contexts in the same tool invocation enables and disables escaping automatically.

In the patterns `-ijtag` context, the `-rtl` switch is inferred if coming from the `dft` context and the `-rtl` option was used when setting the `dft` context. When entering the patterns `-ijtag` context from the unspecified context, `-no_rtl` is assumed. ICL Extraction makes use of quick synthesis to convert any RTL in the fanin or fanout of ICL modules. See the description of the [synthesize_before_analysis](#) and [exclude_from_synthesis](#) Module Built-in Attributes if you are using a `test_setup` procedure for ICL extraction.

In all other contexts, the `-rtl` switch is not allowed and the `-no_rtl` switch is optional because it is always inferred.

In patterns `-ijtag` context with RTL support, during ICL extraction the input cones in front of design ports with matched ICL attributes are synthesized and flattened in order to perform extraction of the paths and end points, which results in an extracted ICL top level description. Checking and debugging of trace issues, IJTAG-related checks and ICL semantic checks are also done at this stage. The same is true for output cones driven by design ports with matched ICL attributes.

- `-license license_name`

An optional switch and string pair that specifies a particular license to use. By default, Tessent Shell acquires the least expensive license available that provides the requested functionality. License names for MemoryBIST and BoundaryScan are accepted without the `-LV`, `-LVNS`, or `-TS` suffix and will default to the LV version of the license.

The `TESSENT_LICENSE_ORDER` environment variable modifies the priority and order of the available licenses. Any available licenses not explicitly listed in the value of the `TESSENT_LICENSE_ORDER` environment variable are appended to the list in their original order.

[Table 6-6](#) lists the supported license names for the available contexts and sub-contexts.

Table 6-6. Contexts Available by License

Context/Sub-Context	License Name(s)
dft -rtl; dft -no_rtl	DesignEditor BoundaryScan-LV BoundaryScan-LVNS BoundaryScan-TS ScanPro IJTAG PLLTest MemoryBIST-LV MemoryBIST-LVNS MemoryBIST-TS SerdessTest TestKompress LogicBIST MissionMode
dft -edt	TestKompress
dft -logic_bist -edt	LogicBIST
dft -scan	Scan ScanPro
dft -test_points	ScanPro LogicBIST

Table 6-6. Contexts Available by License (cont.)

Context/Sub-Context	License Name(s)
patterns -ijtag	IJTAG BoundaryScan-LV BoundaryScan-LVNS BoundaryScan-TS ScanPro PLLTest MemoryBIST-LV MemoryBIST-LVNS MemoryBIST-TS SerdessTest TestKompress LogicBIST MissionMode
patterns -scan	When EDT is used: TestKompress When EDT and LBIST are not used: TestKompress, FastScan When LBIST is used: LogicBIST
patterns -scan_retargeting	TestKompress
patterns -failure_mapping	Diagnosis
patterns -scan_diagnosis	Diagnosis
patterns -siliconinsight	SiliconInsight

If Tessent Shell is unable to acquire a license when setting the context, the tool returns an error message.

- **-design_identifier *design_id***

An option used to assign an identifier to the current design.

A *design_id* must only use a combination of the following characters:

- Alphabetic, both uppercase and lowercase. For example: “abc”, “ABC”, “AbC”, and so on.
- Numeric. For example: “123”.
- Underscore. For example: “A_1”.

For dft context, if this option is unspecified, the identifier defaults to “rtl” in the -rtl context, and to “gate” in the -no_rtl context. If you use the -design_identifier switch, then you must specify a *design_id* value. In the case of an empty string, the design identifier will fall back

to default value, which is gate or rtl in dft context or an empty string in the case of patterns context.

For patterns context, if this option is unspecified, the identifier defaults to either the value you previously set using `set_context` or to a null string if it was never set.

You only need to specify this option in the dft context when you are performing a second insertion pass on the same design. When you use the `process_dft_specification` command to insert all instruments in one insertion pass, the default value is adequate. In the dft context, the tool generates an error if module names matching `current_design_design_id_tessent_*` are found already instantiated into the design during transition to analysis mode or when running the `process_dft_specification` command; this indicates that you are performing a second insertion pass into that same design and that a new design identifier value needs to be specified.

- `-force`

An optional switch used to force Tessent Shell into the specified context.

Examples

Example 1

The following example demonstrates setting the context to dft. In this case, one of the dft licenses is checked out if one is not already checked out.

```
set_context dft -no_rtl
```

Example 2

The following example demonstrates setting the context to patterns -scan and requesting a TestKompress license. If the `-license` option is not specified, a FastScan license is first checked out if one is available. After that, a check is performed to determine whether LBIST or EDT modes are used; if they are, the Tessent FastScan feature is released and either the Tessent TestKompress or Tessent LBIST license is checked out, as appropriate.

```
set_context patterns -scan -license TestKompress
```

Related Topics

[report_context](#)

[get_context](#)

set_core_instance_parameters

Context: patterns -scan

Mode: setup

Changes the parameters of instruments previously added with the add_core_instances command.

Usage

```
set_core_instance_parameters {-instrument_type {edt | occ | lpct | lbist}  
| -cores core_names | -modules module_objects | -instances instance_objects }  
{-parameter_values parameter_list} [-silent]
```

Description

The instruments that the tool has extracted (that is, are a part of a core instance) have a limited set of parameters that can be overridden. This command is used to change these parameters.

Arguments

- **-instrument_type edt | occ | lpct | lbist**

A required switch and literal pair that changes all instances of a given type. Choose one from the following:

- edt
- occ
- lpct
- lbist

- **-cores core_names**

A required switch and string pair that changes the specified instrument parameters for the specified **core_names**, which is a Tcl list of one or more core names, or a collection of one or more core names.

- **-modules module_objects**

A required switch and string pair that changes the specified instrument parameters for the specified **module_objects**, which is a Tcl list of one or more object names (hierarchical names), or a collection of one or more objects.

- **-instances instance_objects**

A required switch and string pair that changes the specified instrument parameters for the specified **instance_objects**, which is a Tcl list of one or more object names (hierarchical names), or a collection of one or more objects.

- **-parameter_values *parameter_list***

A required switch and list that specify the instrument configuration parameter values to change. Refer to [Table 3-5](#) in the documentation for [add_core_instances](#) for a list of available instrument parameters.

- [-silent]

An optional switch that specifies to suppress warning messages.

Related Topics

[add_core_instances](#)

[import_scan_mode](#)

[report_core_instance_parameters](#)

[set_current_design](#)

Context: all contexts

Mode: setup, insertion

Specifies the top level of the design for all subsequent commands until reset by another execution of this command.

Usage

```
set_current_design [top_design [-icl_module icl_module]] [-verbose] [-in_library library]  
[-show_elaboration_warnings]
```

Description

Specifies the top level of the design for all subsequent commands until reset by another execution of this command.

When you issue this command without an argument, the tool automatically finds the top level of the design if only one exists. If the tool finds more than one top, the tool presents a list of the possible top levels; you must reissue the command and specify one of the top levels listed. Note, if you issue this command without an argument and a design is already elaborated, the same design is systematically re-elaborated.

Note that parameterized views of modules are only available to introspection if the parameterized module is instantiated below the current design. You can only set the current design to a module with default parameters, or to a non-parameterized module.

If you want to read additional designs or libraries after setting a top module, you must again issue the `set_current_design` command to re-elaborate the design before you can operate on the design.

If you have operated on the design or have read a flat model, you cannot read additional designs or libraries, or set a new top design without either deleting the current settings using the `delete_design` command or using the “`read_verilog -force`” or “`read_cell_library -force`” command.

When you use the command:

```
set_current_design [get_module M1 -in_library L1]
```

you are able to specify the logical library in which the module M1 exists. When using a `module_name` as the argument to the `set_current_design` command, the `-in_library` option is used to specify in which library to look for module name `module_name`. When the top level is an architecture instead of a module, the `get_module` command cannot be used to refer to it and you must refer to it only by name. In this case, you must use the `-in_library` switch if the architecture is not in the default logical library.

In the dft and “patterns -ijtag” context, the `set_current_design` command is used to set the current design even if the design only has an ICL view. When `set_current_design` executes in these contexts, if a loaded ICL module exists whose name matches the specified current design name, the tool sets the context to ijtag retargeting; if no loaded ICL module exists whose name matches the specified current design name, the tool enables the ICL extraction mode.

In the IJTAG retargeting context, if a design module is not already loaded, the tool creates a design module with the ports found in the ICL module. If a design module is already loaded, the tool verifies that the module contains all of the ports defined in the ICL module. If a file name `design_name.pdl` is found beside the file that contains the top level ICL module, the PDL file is automatically sourced as described in “[dft_inserted_designs](#)” on page 3768.

The tool writes out patterns that include the list of ports found within the design module as well as those in the ICL module. If you plan to use a `test_setup` procedure that interacts with ports that are in the design module but not described in the ICL module, you must load the design view and not allow it to be created from the ICL module.

Ports (and their attributes) are not deleted by the `set_current_design` command when their module is no longer in the elaboration tree. Instead, the tool stores this information, which becomes accessible when their module re-appears in the elaboration tree, for example, due to another issuance of the `set_current_design` command.

Elaborated Designs and Importing Generated Clocks

When in the DFT context with no sub-context, added clocks are rule checked when `set_dft_specification_requirements -memory_test` and/or `-logic_test` are set to on.

When `process_dft_specification` is called, the rule-checked clock definitions are stored into the TSDB in the following location within the `dft_inserted_designs` directory:

```
design_name_design_id.dft_inserted_design_design/design_name.tcd
```

In successive DFT insertion passes when the `set_current_design` command is called in the DFT context with no sub-context, the clocks are automatically restored. They are also automatically restored if the `set_current_design` command is called in the patterns -ijtag context. In contrast, the clocks are not automatically restored in the other contexts.

In the patterns -scan context, you use the `import_scan_mode` command followed by the `import_clocks` command to import the clocks. The `import_scan_mode` command only works if you used Tesson Scan for scan insertion, and the `import_clocks` command only works if you ran the DFT step described above that resulted in the clocks being stored in the TSDB.

Arguments

- *top_design*

An optional string that specifies the name of the top-level module in the design. When the module name is provided, the `set_current_design` command looks for the module in the

default library. If you want to make a module from a different library the current design, you can use the [get_modules](#) command to return the module and then pass the module object directly to set_current_design as follows:

```
set_current_design \
    [get_modules module_name -in_library library_name]
```

- **-icl_module *icl_module***

An optional switch and string pair that specifies the name of an already loaded ICL module to uniquify and associate with the current design being set. This switch must be used in the first insertion pass after synthesis when your RTL design is parameterized and multiple netlists are created for the design by your synthesis tool. It specifies the ICL module in the RTL view that maps to the top module of the netlist being elaborated.

As part of the first DFT insertion pass for a netlist generated by synthesis, the ICL must be uniquified in order to reconcile the naming of the netlist top module with that of the top ICL module. The set_current_design command invoked as “set_current_design *design_name* -icl_module *icl_module_name*” performs this uniquification. It updates the name of the ICL module to match the name of the top module of the netlist (*design_name*). All references to the pre-uniquified module are updated with the new name in the .icl, .tcd, and .tsdb_info files in the ./dft_inserted_designs/<block_name>.dft_inserted_design directory. In addition, the attribute tessent_original_module_name is added to the wrapper for the unqualified ICL module in the .icl file. The value of that attribute is the original name of the top module.

Further, when you perform the DFT insertion on the netlist at the parent block level, the ICL hierarchy in the .icl file in the

./dft_inserted_designs/<parent_block_name>.dft_inserted_design directory is updated to reflect the child block top modules in the gate view. The instance properties and the child ICL module names are all updated to reflect the child netlist names. The ChildBlockModules wrappers in the .tcd and .tsdb_info files are updated as well.

- **-in_library *library***

An optional switch and value pair that specifies to restrict the search to a specified library. The *library* value must be a single string corresponding to one of the logical library names defined with the [set_logical_design_libraries](#) command. When the -in_library option is not specified, the tool will only look for modules in the default library. Use this switch when the specified module or top level architecture name is not in the default library. This option is only allowed in the rtl context.

- **-verbose**

An optional switch that automatically reports each ICL file read by design module matching. For every ICL file read, the following messages are returned:

```
// Reading icl file filename
// Reading icl file filename
```

- **-show_elaboration_warnings**

An optional switch that displays details of netlist and library warnings.

Examples

Example 1

The following example sets the top design to block_1:

```
set_current_design block_1
// Note: Top design is 'block_1'.
```

Example 2

The following example finds the top level of the design (block_2) and sets it as the top. This use model only works in the no_rtl context and requires that all modules currently loaded are instantiated below a single module.

```
set_current_design
// Note: Top design is 'block_2'.
```

Example 3

The following example loads a mixed-language design in the DFT context in RTL mode.

```
SETUP> set_context dft -rtl
# Specify library1 and work as the two active libraries
SETUP> set_logical_design_libraries -logical_library_list {library1 work} \
-default_library work
SETUP> read_vhdl core*.vhdl -in_library library1 -format 93
# Set the current_design to core1 from library1
SETUP> set_current_design [get_modules core1 -in_library library1]
// Note: Top design is 'core1'.
```

Example 4

In the following example the parameterized design top_core_pv1 has two netlists after synthesis:

- top_core_pv1_1
- top_core_pv1_2

You load the design top_core_pv1_1 in preparation for the first gate_level insertion pass. When the design is elaborated using the set_current_design command, you need to specify the name of the top ICL module which existed in the RTL view as the value of the -icl_module option. The ICL module 'top_core_pv1' is renamed to 'top_core_pv1_1' and the original name is recorded in the attribute tesson_original_module_name.

```
SETUP> set_context dft -no_rtl -design_id gate1
SETUP> open_tsdb top_core_pv1.tsdb
SETUP> read_verilog ./synth/top_core_pv1/gates.top_core_pv1_1.v
SETUP> read_design top_core_pv1 -design_id rtl -no_hdl
SETUP> set_current_design top_core_pv1_1 -icl_module top_core_pv1
```

set_current_edt_block

Context: dft -edt, patterns -scan, patterns -scan_retargeting,
patterns -scan_diagnosis

Mode: setup, analysis

Directs the tool to apply certain subsequent commands to a particular EDT block only.

Usage

`set_current_edt_block block_name`

Description

Directs the tool to apply certain subsequent commands to a particular EDT block only.

The `set_current_edt_block` command restricts the applicability of certain subsequent commands to the EDT block having the specified *block_name*. This is referred to as setting or changing the EDT context and the EDT block on which context-sensitive commands currently operate is referred to as the current EDT block. The current EDT block remains the sole target of the context-sensitive commands until you delete its definition using the [delete_edt_blocks](#) command, or you change the context to a different EDT block using the [add_edt_blocks](#) command or another `set_current_edt_block` command.

Use this command when you want to define or redefine the attributes of a specific EDT block using context-sensitive commands. The `add_scan_chains` command, EDT-specific commands that define attributes for a given block, and some reporting commands are presently the only context-sensitive commands. All other commands (`set_system_mode`, `create_patterns` and `report_statistics` for example) apply to the entire netlist.

If multiple EDT blocks are defined and none of them is specified as the current EDT block, subsequent context-sensitive commands that define attributes for a given block (“[set_edt_options -channels](#)” for example) will return an error. This can happen if you add multiple EDT blocks, then delete the one that is the current EDT block.

For more information about EDT blocks or the modular Tessent TestKompress flow, refer to the “[Modular Compressed ATPG](#)” chapter of the *Tessent TestKompress User’s Manual*.

Arguments

- ***block_name***

A required string that specifies the name of the EDT block you wish to set as the current EDT block for subsequent context-sensitive commands. The *block_name* must be one you defined previously using the `add_edt_blocks` command. To view a list of the current defined block names, enter “`report_edt_blocks`”.

Examples

Example 1

The following example lists current user-defined block names, then changes the EDT context to the EDT block named “my_core1_block”:

```
report_edt_blocks
// my_core1_block
// my_core2_block
// my_core3_block
// my_core4_block      (current block)

set_current_edt_block my_core1_block
report_edt_blocks
// my_core1_block      (current block)
// my_core2_block
// my_core3_block
// my_core4_block
```

Example 2

The following example uses the `set_current_edt_block` command to force the context-sensitive `report_edt_configuration` command to report on specific EDT blocks:

```
set_current_edt_block my_core2_block
report_edt_configuration

//
// EDT block "my_core2_block"
// -----
// IP version:                  3
// External scan channels:    3
// Decompressor size:          10
// Clocking:                   edge-sensitive
//
// Note: Only current EDT block "my_core2_block" is reported. Use "report
//       edt configuration -all_blocks" to report the configurations of all
//       blocks.

set_current_edt_block my_core4_block
report_edt_configuration

//
// EDT block "my_core4_block"
// -----
// IP version:                  3
// External scan channels:    1
// Decompressor size:          8
// Clocking:                   edge-sensitive
//
// Note: Only current EDT block "my_core4_block" is reported. Use "report
//       edt configuration -all_blocks" to report the configurations of all
//       blocks.
```

Related Topics

[add_edt_blocks](#)

[delete_edt_blocks](#)

[report_edt_blocks](#)

set_current_edt_configuration

Context: dft -edt

Mode: setup

Prerequisites: One or more compression configurations must be defined with the [add_edt_configurations](#) command.

Sets a particular compression configuration for the tool to use within the current design block.

Usage

`set_current_edt_configuration config_name`

Description

Sets a particular compression configuration for the tool to use within the current design block.

This is necessary so that subsequent commands can be applied to define or redefine the attributes of the specific compression configuration.

For more information about compression configurations, see the “[Defining Dual Compression Configurations](#)” section of the *Tessent TestKompress User’s Manual*.

Arguments

- ***config_name***

A required string that specifies the name of a compression configuration. The *config_name* is the name specified when the compression configurations were defined. Use the `report_edt_configurations` command to display a list of the currently defined configuration names.

Examples

The following example sets the current EDT block, *my_core1_block*, and the compression configuration, *system_test*. Then, it redefines the input and output channels and reports the new configurations.

```
set_current_edt_block my_core1_block
report_edt_configuration

// my_core1_block
// IP version: 4
// Bypass logic: On
// Lockup cells: On
// Clocking: edge-sensitive
// Input channels: [manufacturing_test : 10] [system_test : 4]
// Output channels: [manufacturing_test : 5] [system_test : 2]
// Bypass chains: 5

set_current_edt_configuration system_test
set_edt_options -input_channels 3 -output_channels 3
report_edt_configuration
```

```
// my_core1_block
// IP version: 4
// Bypass logic: On
// Lockup cells: On
// Clocking: edge-sensitive
// Input channels: [manufacturing_test : 10] [system_test : 3]
// Output channels: [manufacturing_test : 5] [system_test : 3]
// Bypass chains: 5
```

set_current_mode

Context: patterns -scan, patterns -scan_diagnosis, patterns -scan_retargeting,
patterns -failure_mapping

Mode: setup

Specifies the current test mode in pattern retargeting and core mapping flows.

Usage

For -scan and -scan_diagnosis:

```
set_current_mode [mode_name] [-type mode_type]
```

For -scan_retargeting and -failure_mapping:

```
set_current_mode mode_name
```

Description

The set_current_mode command specifies the current test mode in pattern retargeting and core mapping flows. The different types of test modes (unwrapped, internal, external, and retargeting) imply different operating behaviors of the scan chains. The command specifies that the design's scan configuration is set up for a particular test mode, mainly for the purpose of generating retargetable patterns for a wrapped core, but you can also use the command in the “core mapping for ATPG” process. Depending on the mode type, the ATPG tool may apply certain constraints automatically (as described under “-type” below). For all mode types, the mode name and mode type are captured in the Tesson Core Description (TCD) file, which is used for pattern retargeting or core mapping.

In addition to the three test modes described under “-type” below, there is a fourth test mode called “retargeting,” which you cannot set with the -type switch and is the only test mode available in the “patterns -scan_retargeting” and “patterns -failure_mapping” contexts. The “retargeting” test mode provides access to lower-level cores for the purpose of retargeting patterns. Because “retargeting” is the only available test mode, it is not necessary to use the set_current_mode command in these contexts. The only situation in which you need to use the set_current_mode command is when you are in the “patterns -scan” or “patterns -scan_diagnosis” contexts and you want to do pattern retargeting.

If you have explicitly set the type and then use set_current_mode, without specifying -type, the tool will leave the type as it was set, rather than reset it to the context default.

For more information about the mapping process and TCD files, refer to “[Core Mapping for ATPG Process Overview](#)” in the *Tesson Scan and ATPG User’s Manual*. For more information about pattern retargeting, refer to “[Scan Pattern Retargeting](#)” in the *Tesson Scan and ATPG User’s Manual*.

Arguments

- *mode_name*

An optional or required literal that specifies a user-defined name for the mode. If you don't specify this argument, the *mode_name* argument defaults to the value of *mode_type*. The *mode_name* is optional for the *-scan* and *-scan_diagnosis* sub-contexts and is required for the *-scan_retargeting* and *-failure_mapping* sub-contexts.

- *-type mode_type (“patterns -scan” and “patterns -scan_diagnosis” only)*

An optional switch that specifies the test mode type for the tool when generating retargetable patterns. Valid options are:

unwrapped — Specifies the current default test mode in which ATPG runs in the “patterns -scan” context. This mode does not support core isolation or hierarchical test, so use this mode when generating patterns for designs that do not contain wrapper chains.

internal — Specifies the internal test mode of a wrapped core in which the tool generates patterns while the core is isolated from the rest of the design. Due to this isolation, those patterns are independent of circuitry outside of the core's wrapper chain and can therefore later be retargeted from the core level to a higher level of the design. When you specify this option, the tool automatically adds CX constraints to all primary inputs and masks all primary outputs during design rule checking and pattern generation. However, exceptions include primary inputs already constrained to 1 or 0, any clock, and scan chain or scan channel inputs/outputs. For more information, refer to “[Core-Level Pattern Generation](#)” in the *Tessent Scan and ATPG User's Manual*.

When you run ATPG in the internal type mode, primary inputs (PIs) and primary outputs (POs) are not valid fault sites when the core is embedded at the next level up, which creates inconsistencies between fault accounting at the core level and those at the top. The tool behavior is to not fault PIs and POs in this situation.

external— Specifies the external test mode of a core in which the tool generates patterns for the interconnect circuitry outside of the wrapper chain. You use the external mode after instantiating the core or a graybox representation in the design. For more information, refer to “[Generating Patterns in External Mode](#)” in the *Tessent Scan and ATPG User's Manual*. Note that using external mode does not change constraints or masking of the core pins (as with internal mode), so external mode is identical to unwrapped mode with regard to the tool's ATPG functionality; however, unlike unwrapped mode, external mode implies that you have instantiated wrapped cores.

Examples

This example sets the mode name and mode type to “internal”.

```
set_context patterns -scan
set_current_mode -type internal
```

set_current_silicon_insight_setup

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Sets the currently selected setup in the Tesson SiliconInsight Setup Specification.

Usage

`set_current_silicon_insight_setup setup_type`

Description

Each adaptor supports offline mode as indicated by the “_offline” suffix. Use this mode for testing that the patterns run well with the adaptor.

This command only affects the current session. If you want to save a change to the setup specification so that you can read it in using the `read_config_data` command in a subsequent session, you must use the `write_config_data` command.

Arguments

- *setup_type*

A required string that specifies one of the supported Tesson SiliconInsight setup specification types. Options are:

NoTester(batch_cdp)
Sid(jtagkey)
Sid(jtagkey_offline)
Sid(flyswatter2)
Sid(flyswatter2_offline)
Sid(olimex_arm_usb_ocd)

set_current_simulation_context

Context: all contexts

Mode: setup, analysis

Prerequisite: The flat model must already exist

Sets the current simulation context.

Usage

set_current_simulation_context *context_name*

Description

The set_current_simulation_context command sets the simulation context for later analysis and introspection. [Table 6-7](#) lists the predefined simulation contexts.

Table 6-7. Predefined Simulation Contexts

Simulation Context	Description
stable_after_setup	Specifies the values that are constant in the period following the end of the test_setup procedure and the beginning of the test_end procedure. For scan patterns, the value is constant throughout scan and capture cycles. For IJTAG patterns, the value is constant throughout any IJTAG operations.
stable_capture	Specifies the values that are constant throughout the capture procedures.
stable_load_unload	Specifies the values that are constant throughout the load_unload cycles.
stable_shift	Specifies the values that are constant throughout the shift cycles.
tie_value	Specifies the values that are constant due to tied nodes in the design. For example a net assigned to 1'b0 will have a tie value of 0. Primary inputs constrained with the “ add_input_constraints -ct0 or -ct1 ” switches as also considered tied and will be reported as constant in this simulation context.

Arguments

- *context_name*

A required literal that specifies the simulation context to make current. You can specify any of the simulation contexts listed in [Table 6-7](#) or any user-defined simulation contexts that have been added. By default, the simulation context is stable_after_setup.

Examples

The following example sets the current simulation context to stable_shift:

```
> set_current_simulation_context stable_shift
```

[report_simulation_contexts](#)

set_decision_order

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies how the ATPG selects gate input or output nodes for evaluation during ATPG.

Usage

`set_decision_order -NORandom | -Random`

Description

Specifies how the ATPG selects gate input or output nodes for evaluation during ATPG.

The `set_decision_order` command specifies whether ATPG chooses a gate input or output for evaluation randomly, or by its ease of evaluation. Ease of evaluation for a gate input depends on how easy it is for the tool to control the input. For a gate output, ease of evaluation is related to how easily the tool can observe the output. A nonrandom decision order causes the tool to evaluate the “easiest” gates first.

Arguments

- **-NORandom**

A required switch that causes the ATPG to choose the easiest evaluation when faced with a decision about which gate input or output to evaluate next. This is the default unless you are using the [create_patterns](#) command, which always uses a random decision order.

- **-Random**

A required switch that causes ATPG, when faced with a decision about which gate input or output to evaluate next, to make random decisions rather than choosing the easiest evaluation. This causes variation between patterns, tending to give a more compact vector set at the risk of creating more ATPG aborts.

Note

 In some cases, depending on circuit topology, changing the order in which the tool makes decisions during ATPG may improve performance. If large numbers of faults are being aborted, for example, you may eliminate or reduce aborted faults by setting the decision order to “random” without changing the abort limit.

Related Topics

[create_patterns](#)

set_dedicated_wrapper_cell_options

Context: dft -scan

Mode: setup

This command controls the inferring of the dedicated wrapper cells on all or the specified primary IOs.

Usage

```
set_dedicated_wrapper_cell_options [on | off | auto]
    [-ports port_spec]
    [-input_module_name module_spec]
    [-output_module_name module_spec]
    [-clock_source port_pin_spec]
```

Description

This command controls the inferring of the dedicated wrapper cells on all or the specified primary IOs, that is, it defines how each port of the current design is to be handled during wrapper analysis. It is an incremental command and can be used multiple times to generate a desired superset of options.

Note

 During wrapper analysis, the tool will check whether a PI is driving the Set/Reset ports of a flop encountered during the forward tracing, and if so, it will infer a dedicated wrapper cell on this PI.

Arguments

- **on | off | auto**

Ports that are excluded from wrapper analysis will not be affected by this command. If excluded ports are specified with the -ports switch or if the -ports switch is not specified and there are excluded ports in the design you will see the following warning:

```
// Warning: Ignoring excluded port(s) <port1>, <port2>, <port3> ...
//           To include these ports in wrapper analysis please use:
//           set_wrapper_analysis_options -clear_excluded_ports
```

An optional switch that specifies whether to auto infer the dedicated wrapper cells on all or the specified primary IOs, or to have the dedicated wrapper cells added to all or the specified primary IOs, or to have all or the specified primary IOs excluded from having the dedicated wrapper cells added to them:

Undriven outputs receive dedicated wrapper cells based on the configurations of “set_wrapper_analysis_options –register_undriven_output on|off” and will not be affected by global on|off|auto settings. However, specifying a specific undriven port (or group of undriven ports) with “-ports {...}” will override the –register_undriven_output settings for that/those specific port(s) as seen in Example 1 below.

- on — specifies to add a dedicated wrapper cell for the given ports. The “on” state is used to automatically register all primary IOs specified with the -ports switch (including undriven outputs), or to register all primary IOs (with the exception of undriven outputs) when the -ports specification is not provided.
- off — specifies to not allow inferring a dedicated wrapper cell for the given ports. The “off” state is used to exclude from the registration either the primary IOs specified with the -ports switch (including undriven output), or all primary IOs (with the exception of undriven output) when the -ports specification is not provided.

In addition, any previous mapping of clock source to wrapper cells will be cleared for the given ports (or for all ports if the -ports switch is not specified).

- auto — specifies that dedicated wrapper cells are inferred and determined by the tool during the wrapper cells analysis for the primary IOs specified with the -ports switch or all primary IOs when the -ports specification is not provided . This is the default.
- **-ports *port_spec***
An optional switch and string that specifies the ports for which the current setting applies to. When this switch is not specified, the dedicated wrapper cell inferring setting is applicable to all primary Input and Output ports.
port_spec can be a Tcl list of one or more ports or a collection of one or more port objects.
- **-input_module_name *module_spec***
An optional switch and string that specifies a library model to be used to instantiate a dedicated Input wrapper cell.
module_spec can be the name of a library model or a collection containing a library model object.
- **-output_module_name *module_spec***
An optional switch and string that specifies a library model to be used to instantiate a dedicated Output wrapper cell.
module_spec can be the name of a library model or a collection containing a single library model object.
- **-clock_source *port_pin_spec***
An optional switch and string that specifies an internal pin or top level port to be used as the clock source for the inserted dedicated wrapper cells. This clock source will be applied only to the dedicated wrapper cells of the specified primary IOs when the -ports switch is specified, or to the dedicated wrapper cells of all primary IOs when the -ports switch is not specified.
port_pin_spec can be the name of a pin/port, or a collection containing a single pin/port object.

This switch is ignored when combined with “off”, and the tool will issue the following error message:

```
// Error: -clock_source has no effect when dedicated wrapper cells
are off (disabled).
```

Note

For more information, see [Clock Selection for Dedicated Wrapper Cells](#) in the *Tessent Scan and ATPG User’s Manual*.

Examples

Example 1

In this example, all driven Primary IOs will receive dedicated wrapper cells. Undriven IOs will not receive dedicated wrapper cells:

```
set_dedicated_wrapper_cells on
```

Example 2

In this example, all Primary IOs will receive dedicated wrapper cells, including undriven IOs.

```
set_dedicated_wrapper_cells on
set_wrapper_analysis_options –register_undriven_output on
```

Example 3

In the following example:

Ports A, B, C, D, excluded_1 are driven.

Ports undriven_1, undriven_2 are undriven.

Ports A, D, undriven_1 will receive dedicated wrapper cells.

Ports B, C, undriven_2, excluded_1 will not receive dedicated wrapper cells.

```
set_wrapper_analysis_options –exclude_ports excluded_1
set_dedicated_wrapper_cells on
set_dedicated_wrapper_cells off –ports {A B C}
set_dedicated_wrapper_cells on –ports {A undriven_1}
```

Related Topics

[set_wrapper_analysis_options](#)

set_defaults_value

Context: dft, patterns, unspecified

Mode: setup, analysis, insertion

Sets the default value of a property in one of the DefaultsSpecification (policy) wrappers.

Usage

```
set_defaults_value property_path_name {value | -unspecify} [-policy policy]
```

Description

This command has access to and sets default values for the properties of the sub-wrappers in the top [DefaultsSpecification\(<policy>\)](#) to match your preferences and requirements. The [DefaultsSpecification\(<policy>\)](#) sub-wrappers are [DftSpecification](#) and [PatternsSpecification](#).

The set_defaults_value command automatically manages the priority of the <policy> and sets the value of the highest priority by default. The policies, in order of highest priority to lowest are: user, group, and company.

Note

 The values set using this command impact the default values used by the [create_dft_specification](#) command. They do not impact existing dft specifications.

Use the command “[report_config_syntax](#) DefaultsSpecification” to see all the available properties you can set. You can use the -level 1 and -wrapper_only switches to see the next level of sub wrappers and add the wrapper name you care about to the path to limit the size of the report as follows:

```
> report_config_syntax DefaultsSpecification/DftSpecification -level 1 \
  -wrappers_only
DefaultsSpecification(<policy>) { // legal: company group user
  DftSpecification {
    IjtagNetwork {
    }
    BoundaryScan {
    }
    MemoryBisr {
    }
    MemoryBist {
    }
  }
}

> report_config_syntax DefaultsSpecification -level 1 -wrappers_only
DefaultsSpecification(<policy>) { // legal: company group user
  PatternsSpecification {
  }
  DftSpecification {
  }
}
```

```
> report_config_syntax DefaultsSpecification/DftSpecification -level 1 \
-wrappers_only
DefaultsSpecification(<policy>) { // legal: company group user
  DftSpecification {
    IjtagNetwork {
    }
    BoundaryScan {
    }
    MemoryBisr {
    }
    MemoryBist {
    }
  }
}

> report_config_syntax DefaultsSpecification/DftSpecification/\
IjtagNetwork -level 1 -wrappers_only
DefaultsSpecification(<policy>) { // legal: company group user
  DftSpecification {
    IjtagNetwork {
      ImplementationOptions {
      }
      HostScanInterface {
      }
    }
  }
}

SETUP> report_config_syntax DefaultsSpecification/DftSpecification/\
IjtagNetwork/ImplementationOptions -level 1
DefaultsSpecification(<policy>) { // legal: company group user
  DftSpecification {
    IjtagNetwork {
      ImplementationOptions {
        scan_path_retiming : <string> ; // legal : (latch) flop
      }
    }
  }
}
```

Arguments

- *property_path_name*

A required string that specifies a configuration pathname *without* the DefaultsSpecification prefix. For the DftSpecification, this path starts with “DftSpecification/”prefix. For the PatternsSpecification, this path starts with “PatternsSpecification/”. For example:

```
set_defaults_value \
DftSpecification/MemoryBist/ControllerOptions/gate_bist_clock_in_functional_mode off
```

- *value*

An optional value that specifies the value of the specified property.

- **-unspecify**

An optional value that unspecifies the property instead of setting its value. Use this option to remove a property setting for a policy.

- **-policy *policy***

An optional switch and value pair that specifies for which DefaultsSpecification (policy) wrapper the property is to be set or unspecified. The available policies, in order from highest priority to lowest, are: user, group, and company. When this switch is not specified, the user policy is used.

Examples

Example 1

The following example sets the rtl_extension property in the company DftSpecification policy and unspecifies the same property in the user policy.

```
set_defaults_value DftSpecification/rtl_extension vb -policy company
```

Unspecify the rtl_extension property in the DftSpecification user policy.

```
set_defaults_value DftSpecification/rtl_extension unspecify -policy user
```

Because the user policy for this property was just unspecified and assuming the group policy for this property was not set, it will return vb:

```
get_defaults_value DftSpecification/rtl_extension
```

Example 2

This example shows using set_defaults_value and get_defaults_value that, when automatically resolving the priority, the default value of the property being set is accessed.

```
get_defaults_value PatternsSpecification/MaufacturingOptions/manufacturing_patterns_format
```

The command returns STIL, the default, because the property, in this case, is not set for any of the PatternsSpecification priorities.

This command sets the value of the “group” policy for this property to Wgl:

```
set_defaults_value PatternsSpecification/ManufacturingOptions/manufacturing_patterns_format Wgl \
-priority group
```

This command returns the default value for the PatternsSpecification/ManufacturingOptions/manufacturing_patterns_format property:

```
get_defaults_value PatternsSpecification/ManufacturingOptions/manufacturing_patterns_format
```

The command returns wgl because only the PatternsSpecification/ManufacturingOptions/manufacturing_patterns_format group priority property has been set. The get_defaults_value command first looks for a value for the property in the user priority and if not set, it looks in the group priority and finds, in this case, wgl.

This command demonstrates that the tool uses the default value for the property when it has not been set:

```
get_defaults_value PatternsSpecification/ManufacturingOptions/manufacturing_patterns_format \
-policies company
```

This returns STIL, the default for the “company” policy,

set_design_include_directories

Context: unspecified, all contexts

Mode: setup

Specifies one or more directory paths that contain `include files for use by subsequent read_verilog commands.

Usage

```
set_design_include_directories include_dir ... | [-Clear]
```

Description

Specifies one or more directory paths that contain `include files for use by subsequent read_verilog commands.

This command provides equivalent functionality to the –Incdir invocation switch. If you issue this command multiple times, the last set of include directories is used. When you issue this command without arguments, the command reports the list of include directories.

Each *include_directory* must be relative to the current tool invocation directory or an absolute directory pathname. Include files are searched for in the following order of precedence:

1. Absolute pathnames specified by `include directives in the Verilog design.
2. Directories specified with the command.

For relative `include file targets, directories are searched in the order they are listed, left to right, in the command. If identically named files exist in multiple directories, the first file found is used and the others are ignored.

3. Directory where the Verilog design file is located.
4. Directory in which you invoked the tool.

Arguments

- *include_dir*
A string that specifies one or more directory paths.
- -Clear
An optional switch that removes the current list of include directories.

Examples

The following commands specify that the tool search for `include files contained in ..dir1 when loading the top.v module:

```
set_design_include_directories ./dir1
read_verilog top.v
```

[set_design_level](#)

Context: dft, patterns

Mode: setup, insertion

Prerequisites: You can set the level can only after the design is elaborated.

Specifies the level of the current design.

Usage

```
set_design_level {chip | physical_block | sub_block}
```

Description

Specifies the level of the current design.

You must specify the design level with this command when you are in the “dft -rtl” or “dft -no_rtl” contexts and want to change to analysis system mode. There is no default setting, so you must specify the appropriate level because this setting affects the [create_dft_specification](#) and [process_dft_specification](#) commands, as well as some design rules checks that the tool performs when changing to the analysis system mode.

If you issue the [extract_icl](#) command immediately after having issued the [process_dft_specification](#) command, and if you specified the design level as chip or physical_block while in dft context, the tool uses the specified design level during [extract_icl](#) to set the [tessent_is_physical_module](#) attribute to true on the top ICL module. If you did not run the [extract_icl](#) command in the same tool session as the dft step, you must set the design level prior to issuing the [extract_icl](#) command.

Understanding the difference between a physical block and a sub-block is critical. A physical block is synthesized and laid out as a separate entity. When a physical block is instantiated below another physical block, the netlist view of the child physical block is not loaded into the synthesis or layout tool when synthesizing the parent physical block. Instead, a timing model for the child physical block is used. This means the SDC created for the parent physical block can only refer to pins of the child physical block. It is not possible to reference any elements within the child physical block. You cannot on the other hand refer to pins of a sub-block using -to or -from when synthesizing it within its parent physical block. Instead you refer to the elements inside the sub-block. Another major difference is the fact that the netlist of the sub-block will typically only exist as part of the parent physical netlist. You will do scan insertion from the physical block boundary and insert the scan chains into the sub-block at the same time. If the lower block is a physical block, you insert the chains inside the lower physical block first and then you connect to those scan chains when inserting scan chains in the parent physical block.

In the RTL DFT flow, the sub-block is treated pretty much the same way as if it was a physical block. If you want to use the [read_def](#) command to extract the placement information of the memories to build one memoryBIST controller per physical cluster, you have to use the “-instance_of_current_design” switch in the [read_def](#) command if you are inserting memoryBIST in a sub-block. You only can get a DEF file for a physical block. By definition,

you cannot get a DEF file for a sub-block because it is synthesized within the parent physical block. You use the DEF file of the parent physical block and use the “-instance_of_current_design” switch to specify what is the instance path of your sub-block within the parent physical block DEF file.

During signoff simulation, the simulation test benches are separated per physical block to optimize performance during simulation. See the [create_patterns_specification](#) command description and the [simulate_instruments_in_lower_physical_instances](#) property in the DefaultsSpecification/PatternsSpecification/SignOffOptions wrapper for more information about the signoff simulation. If you have sub-block modules, they are simulated as part of their parent physical block because by the time you get to gate-level simulation, you will only have a netlist and an SDF file per physical block as the sub-blocks are synthesized within their parent physical block.

When you use [read_design](#) to load a sub-block inside the tool, the [is_hard_module](#) Module-level attribute is automatically inferred to “true” on the sub-block modules if they are not the current_design and the -rtl context is used. When you insert DFT elements inside the current design, you are only allowed to make connections to the pins of the sub-block modules. If you need to add something inside the sub-block, you have to make the sub-block module the current design and do the additions at that level. You also extract the ICL file for the sub-block at that level. Remember that ICL extraction in the parent physical region is performed by re-using the ICL description of the sub-block and tracing outward from the pins of the sub-block instances. If edits were done in the sub-block module from the parent level, the changes would not be reflected in the extracted ICL. When you reach the gate-level DFT flow, as was described above, the scan insertion is performed from the parent physical block level and the scan chains are inserted inside the sub-block at the same time as in the parent physical block. Inserting scan chains and test points in the netlist has no impact on the ICL network. You do not need to re-run ICL extraction post-synthesis unless you are inserting IJTAG nodes after synthesis. Just like the rest of your functional logic, the equivalence between the pre- and post-synthesis views is verified using formal verification tools. The ICL network is functional logic to formal verification tools.

Arguments

- **chip | physical_block | sub_block**

A required literal that specifies the design level:

chip — The design is intended to be used at the chip level. This implies that all ports have a pad buffer and a TAP is inserted during the execution of the [create_dft_specification](#) command. A chip is by definition also a physical block. You can use value “top” as a synonym to “chip”.

physical_block — The design is intended to be used for blocks that are synthesized and laid out as independent blocks. There are several implication when defining a module as a physical block vs a sub-block. Those are described above. Make sure to specify the right value.

sub_block — The design is intended to be used for blocks that are synthesized and laid out as part of a parent physical block. There are several implication when defining a module as a physical block vs a sub-block. Those are described above. Make sure to specify the right value.

Note that there is no default setting, so you must specify one of these design levels.

Examples

The following example sets the level of the current design to `physical_block`.

`set_design_level physical_block`

Related Topics

[get_design_level](#)

[set_current_design](#)

set_design_macros

Context: unspecified, all contexts

Mode: setup

Specifies one or more defined macros for use by subsequent commands.

Usage

```
set_design_macros macro_name[=macro_value] ... | [-Clear]
```

Description

Specifies one or more defined macros for use by subsequent commands.

This gives you the convenience of using macros rather than having to edit the netlist to explicitly add the `define statements to control which parts of `ifdef statements are compiled. This command provides functionality equivalent to the –Define invocation switch.

If you issue the command multiple times, then the last set of macros is used. When you issue the command without arguments, the command reports the list of defined macros, including the default macros MGC_TESSENT and SYNTHESIS.

Arguments

- *macro_name[=macro_value]*
An optional string that specifies one or more macros.
- -Clear
An optional switch that clears the current list of all defined macros.

Examples

The following commands specify that the tool use a custom macro named macro_1 set to a value of 20 when loading the top.v module:

```
set_design_macros macro_1=20
read_verilog top.v
```

- [read_flat_model](#)

set_design_sources

Context: unspecified, all contexts

Mode: setup

Specifies where the tool should look for the definition of undefined modules in the list of files specified by the [read_verilog](#) command.

Usage

```
set_design_sources {[ -format verilog ] {[ -V file_path ... ] [-Y dir_path ... -extensions ext ... ] [-append] } | { [-clear] } }

set_design_sources -format {icl | tcd_bscan | tcd_scan | tcd_fusebox | tcd_memory
| tcd_memory_cluster} {[ -search_design_load_path {on | off} ]
[-Y dir_path ... -extensions ext ...] [-append]} [-clear]

set_design_sources { -format {icl | tcd_bscan | tcd_scan | tcd_fusebox | tcd_memory
| tcd_memory_cluster} [-clear]}
```

Description

Specifies where the tool should look for the definition of undefined modules in the list of files specified by the [read_verilog](#) command when -format is specified as or defaults to “verilog”. It specifies where files are searched for during module matching for the other formats.

For more information about the module matching process, see the description of the [set_module_matching_options](#) command. If the tcd_scan, tcd_memory, tcd_memory_cluster, tcd_bscan, or tcd_fusebox wrappers are located in files with names that do not match the module_name of the Core wrapper, or if they do not have unique extensions for each format, use the [read_core_descriptions](#) command to load them in explicitly instead of trying to have them auto-loaded.

The -v, -y, and -extensions switches have similar behavior to standard Verilog compilers like ModelSim.

When you issue the command multiple times, the tool uses only the last set of -v/-y/-extension lists. You can set the -y/-v/-extension list independently of the -search_design_load_path option, but the -y/-v/-extension forms a set for each format.

Table 6-8 shows the default extensions for the various input formats.

Table 6-8. Default Extensions for set_design_sources

Format	Default Extension
icl	icl icl.gz
tcd_bscan	tcd_bscan lvbscan tcd_bscan.gz lvbscan.gz
tcd_scan	tcd_scan tcd_scan.gz
tcd_fusebox	tcd_fusebox tcd_fusebox.gz

Table 6-8. Default Extensions for set_design_sources (cont.)

Format	Default Extension
tcd_memory	tcd_mem_lib tcd_mem_lib.gz
tcd_memory_cluster	tcd_mem_cluster_lib tcd_mem_cluster_lib.gz

Arguments

- **-format verilog | icl | tcd_bscan | tcd_scan | tcd_fusebox | tcd_memory | tcd_memory_cluster**
An optional switch that specifies which format the setting applies to. When unspecified, the format verilog is assumed.
See the description of the [set_module_matching_options](#) command for more information about the module matching process that is done using the design sources for formats other than verilog.
- **-search_design_load_path on| off**
An optional switch and literal pair that specifies whether the directory into which Verilog and VHDL design modules are loaded or searched are automatically used as valid search directories for the specified format. In cases where the tool adds the Verilog path to the search path, the tool also adds the paths used for the cell libraries. This option is on by default.
- **-V file_path**
An optional repeatable switch that specifies one or more files in which to search for definitions of undefined Verilog modules. You can specify multiple –v options, multiple –y options, or both. The order of the –v/-y files and directories specified in the command determines the search order during parsing.
- **-Y dir_path ... -extensions ext ...**
An optional repeatable switch that specifies one or more directories in which to search for definitions of undefined modules when -format is defined as or defaults to “verilog”. Any file inside the –y directory should be named as *module_name.extension* in order to be parsed. You can specify multiple –v options, multiple –y options, or both. The order of the –v/-y files and directories specified in the command determines the search order during parsing.
When you use the –y switch one or many times, you are required to also use the -extensions switch once to instruct the tool to check only the files with the specified extensions. The value is a Tcl list of one or more extension names. The tool supports compressed files by expanding the extension name or list of extension names to include those names with a .gz suffix. That is, if you specify “-extensions v”, the tool expands it to “-extensions v v.gz”. You can use this switch only once per command execution.
For formats other than Verilog, the directories are searched during the module matching process. See the description of the [set_module_matching_options](#) command for more information about the module matching process that is done using the design sources for formats other than Verilog.

- **-append**

The **-append** adds the new settings of **set_design_sources** to the previous settings of previous **set_design_sources**.

- **-clear**

An optional switch that clears the list of files and directories previously specified with the **-v** or **-y** switches. The **-clear** switch operates on only one format per command execution. If you do not use the **-format** switch, the **-clear** switch operates on Verilog files.

Examples

Example 1

To illustrate how the switches work, consider the following example:

top.v	f1.v	directory d1
module top;	module foo();	foo.v bar.v foo.sv zar.v
foo i();	endmodule	
endmodule	module bar();	
	endmodule	

When you issue these commands:

```
report_design_sources
set_design_sources -v f1.v
report_design_sources
read_verilog top.v
```

then the module foo in file f1.v is parsed, but not the module bar in f1.v.

When you issue these commands:

```
report_design_sources
set_design_sources -y d1 --extensions v
report_design_sources
read_verilog top.v
```

then the file foo.v is parsed, but not the other files in the d1 directory. Note that file foo.v is parsed but not foo.sv because the specified **--extensions** is v.

In the previous example, when you issue the following commands:

```
report_design_sources
set_design_sources -y d1 --extensions v -v f1.v
report_design_sources
read_verilog top.v
```

then foo.v in d1 directory is parsed. If the commands are:

```
report_design_sources  
set_design_sources -v f1.v -y d1 -extensions v  
report_design_sources
```

then module foo in f1.v is parsed.

Example 2

In the following example, the set_design_sources command specifies to look for undefined module definitions in the dir1, dir2, and dir3 directories and to check only those files with a v_ts or v extension.

```
set_design_sources -y {dir1 dir2 dir3} -extensions {v_ts v}
```

set_dft_enable_options

Context: patterns -scan

Mode: setup

Enables or disables the control or observe points.

Usage

```
set_dft_enable_options -type {xbounding_en | control_point_en | observe_point_en |  
mcp_bounding_en | test_en} -pin_name pin_name [-value {on | off}]
```

Description

Enables or disables the control or observe points.

In the hybrid TK/LBIST flow, the tool uses this command during fault simulation to specify the static enable signals inside the LogicBIST controller and during the IP creation phase to specify the creation of static TDR bits inside the LogicBIST controller that will control the static enable signals.

Note that disabling either X-bounding or MCPs for LogicBIST is not allowed since it can result in Xs being captured in the scan cells.

Disabling the control or observe points enable signal can have an impact on coverage.

Arguments

- **-type xbounding_en | control_point_en | observe_point_en | mcp_bounding_en | test_en**
A required switch and literal pair that specifies the static enable type.
- **-pin_name *pin_name***
A required switch and string pair that specifies the name of the pin to enable or disable.
- **-value {on | off}**
An optional switch and literal pair that enables (on) or disables (off) the action for the specified pin. This switch is not used during IP creation.

Examples

The following example turns off observe points for transition fault simulation.

```
set_dft_enable_options -type control_point  
-pin_name /my_core_lbist_i/my_core_lbist_ctrl_signals_i/control_point_en -value on  
  
set_dft_enable_options -type observe_point \  
-pin_name /my_core_lbist_i/my_core_lbist_ctrl_signals_i/observe_point_en -value off  
  
// Warning: Disabling 'observe_point' enable signal may have an impact  
// on coverage.
```

The following example generates TDR bits inside the LogicBIST controller and uses them to drive design pins during IP creation:

```
set_dft_enable_options -type xbounding_en -pin_name xbnd_en
set_dft_enable_options -type control_point_en \
    -pin_name [get_pins {core_i*/cp_en core_i*/obs_en}]
    # A single TDR bit controls both the control point and
    # observe point enable pins.
```

Related Topics

[set_lbist_controller_options](#)

[set_lbist_pins](#)

[set_dft_specification_requirements](#)

Context: dft

Mode: setup

Specifies the requirements to be checked when the [check_design_rules](#) command runs, and those to be included into the [DftSpecification](#) when the [create_dft_specification](#) command is run.

Usage

```
set_dft_specification_requirements [-memory_test {on | off}] [-memory_bist {auto | off}]
[-memory_bisr_chains {auto | on | off}]
[-memory_bisr_controller {auto | on | off}]
[-boundary_scan {on | off}]
[-ac_boundary_scan {auto | off}]
[-logic_test {on | off}]
[-tck_injection {on | off | internal_sources_only}]
```

Description

Specifies the requirements to be checked during the [check_design_rules](#) command and the instrument types that are to be included into the [DftSpecification](#) when the [create_dft_specification](#) command runs.

You typically only need to used the “-memory_test on” option when you want to implement memory test at a given level. When memory_test is on, memory_bist, memory_bisr_chains, and memory_bisr_controller default to auto; otherwise, they default to off. When boundary_scan is on, ac_boundary_scan defaults to auto; otherwise, it defaults to off.

These defaults mean that if the current level either instantiates blocks that contain memory BIST or itself contains memories not already connected to a memory BIST controller, the memory BIST pre-DFT DRC rules ([Scan Cell Data Rules \(D Rules\)-DFT_C5](#)) will be executed during the [check_design_rules](#) command, and the required specification will be added to the [DftSpecification](#) when the [create_dft_specification](#) command runs.

Arguments

- -memory_test on | off

An optional switch and value pair that specifies whether memory test is to be design rule checked and implemented. Specifying “-memory_test on” is a short cut to setting the three options -memory_bist, -memory_bisr_chains, and -memory_bisr_controller to auto.

- -memory_bist auto | off

An optional switch and value pair that specifies whether memory BIST clocking and, potentially, memory BIST controllers are to be considered. When set to auto, if the current design instantiates blocks containing memory BIST or itself contains memories not already connected to a memory BIST controller, then the memory BIST pre-DFT DRC rules ([Scan](#)

Cell Data Rules (D Rules)-DFT_C5) will be executed during the [check_design_rules](#) command, and the required specification will be added to the [DftSpecification](#) when the [create_dft_specification](#) command runs.

- **-memory_bisr_chains auto | on | off**

An optional switch and value pair that specifies whether memory BISR chains are to be inserted or connected in the current level. When set to auto, if the current design instantiates blocks containing memory BISR chains or itself contains repairable memories not already connected to a memory BISR register, the bisr_order_file will be validated or created during the [check_design_rules](#) command and the required specification will be added to the [DftSpecification](#) when the [create_dft_specification](#) command runs. The bisr_order_file is created taking into account physical placement when a DEF file is read in using the [read_def](#) command prior to running the [check_design_rules](#) command. You can also partition the BISR chains into power domains if you read in a UPF or CPF file using the [read_upf](#) or [read_cpf](#) command prior to running the [check_design_rules](#) command.

- **-memory_bisr_controller auto | on | off**

An optional switch and value pair that specifies whether a memory BISR controller is to be inserted in the current level. When set to auto, a controller will be inserted if the design level was specified as “chip” using the [set_design_level](#) command and either memory BISR chains exist on blocks instantiated in the current design or repairable memories exist in the current design. You can force the insertion of a controller at design levels other than chip by setting the -memory_bisr_controller option to on.

- **-boundary_scan on | off**

An optional value pair that specifies whether boundary scan is to be design rule checked and implemented. When you set -boundary_scan to on, the -ac_boundary_scan option is automatically set to auto.

If the design level is not “chip”, you can use the [set_boundary_scan_port_options](#) command to define the list of ports for which boundary scan is needed.

- **-ac_boundary_scan auto | off**

An optional switch and value pair that specifies whether ac boundary scan is to be inserted. When set to auto, AC boundary scan is inserted as soon as a pad with AC functions is present. When set to off, AC boundary scan (IEEE 1149.6) is not implemented and only IEEE 1149.1 cells are inserted.

- **-logic_test on | off**

An optional switch and value pair that specifies whether logic test is to be design rule checked and implemented. When set to on, the [DFT_C2](#), [DFT_C3](#), [DFT_C6](#), [DFT_C8](#), and [DFT_C9](#) DRC rules are run and the AsyncSetReset auto corrections implemented.

Specifying [add_dft_control_points](#) -type `async_set_reset` has no impact unless the [DFT_C9](#) rule is run and the active polarity of the asynchronous set or reset sources extracted by the DRC.

- **-tck_injection on | off | internal_sources_only**

An optional switch and value pair that specifies whether TCK muxing is to be inserted in the current level. When enabled, it will identify clock locations where TCK should be injected to drive child block ports and memories that have [use_in_memory_bist_dft_specification](#) set to “on”, or “auto” that will resolve to “on” in analysis mode. These locations will be added to the [MemoryBist](#) wrapper of the DftSpecification when the [create_dft_specification](#) command is run. Specifying this option to a value other than off requires the [-memory_bist](#) option to be set to auto.

When set to off, the pre-DFT DRC rules [DFT_C11](#), [DFT_C12](#) and [DFT_C13](#) will not be run. This value is typically used if you intend to insert OCC in a later insertion pass, or if you do not intend to run memory BIST TCK mode.

When set to on, the pre-DFT DRC rules [DFT_C11](#), [DFT_C12](#) and [DFT_C13](#) will run and identify all asynchronous, generated and branch clocks in the direct fanin of memories and blocks for TCK injection. This value is typically used for chip design levels in which you wish to run memory BIST TCK mode by using the [tck_clock_only](#) Patterns property.

When set to [internal_sources_only](#), the pre-DFT DRC rules [DFT_C11](#), [DFT_C12](#) and [DFT_C13](#) will run and identify all generated and branch clocks in the direct fanin of memories and blocks for TCK injection. This value is typically used for [sub_block](#) and [physical_block](#) design levels in which you wish to run memory BIST TCK mode though use of the [tck_clock_only](#) Patterns property.

Clocks that already have TCK injection will not be identified for additional muxing if it is detected that it already exists in the [DFT_C11](#) analysis, even if this option is specified with the on or [internal_sources_only](#) values. Existing TCK injection points will only be identified if they are controlled by the [tck_select](#) DFT signal.

Note

 This option should not be used if you intend to add OCC’s to your design. The OCC’s will implement the TCK muxing if the [ijtag_host_interface](#) property in the [OCC](#) wrapper is not set to “none”. Additionally for this usage, the OCC TCK muxing must be described in ICL by specifying the [include_clocks_in_icl_model](#) property to “on” if you wish to use the [tck_clock_only](#) Patterns property.

Examples

The following example specifies that memory test is to be considered in the current DFT insertion pass. Notice that specifying memory test is equivalent to setting the other three related options to auto.

```
set_dft_specification_requirements -memory_test on
```

is equivalent to

```
set_dft_specification_requirements -memory_bist auto \
                                  -memory_bisr_chains auto \
                                  -memory_bisr_controller auto
```

The following example only sets memory BIST to auto which means that even if the current design contains repairable memories, memory BISR chains will not be inserted. You can use the “[set_memory_instance_options -use_in_memory_bisr_dft_specification](#)” command to control this on a per memory basis.

```
set_dft_specification_requirements -memory_bist auto
```

Context: patterns -scan_diagnosis

Mode: setup, analysis

Specifies the type of diagnosis performed by the diagnose_failures command.

Usage

```
set_diagnosis_options
[-Mode Auto | Scan | Chain | Iddq ]
[-Verify_patterns ON [Noverbose | Verbose] | OFF]
[-Report Default | percentage]
[-AT_speed ON | OFF]
[-MAX_suspects Default | limit]
[-Time_limit OFF | seconds]
[-WALL_time_limit OFF | seconds]
[-Pattern_sampling {failing_pattern_limit | OFF} {passing_pattern_limit | OFF}]
[-FAILurefile_mismatch_verbosity Default | number | All]
[-BRidge_analysis ON | OFF]
[-CHEck_last_shift_value ON | OFF]
[-X2B_mismatch Ignore Warning [Noverbose | Verbose] | Error]
[-B2X_mismatch Ignore Warning [Noverbose | Verbose] | Error]
[-CELL_internal_analysis ON | OFF]
[-MAX_Faulty_chains failed_chain_threshold]
[-Chain_diagnosis_result Cell | CHain]
[-CHAIN_LIB_internal_pathname OFF | ON]
[-ABORT_DIAGNOSE_COMPOUND_faults ON | OFF]
[-ABORT_DIAGNOSE_MANY_faulty_chains ON | OFF]
[-ABORT_DIAGNOSE_MINIMUM_Chain_failing_probability number]
[-ABORT_DIAGNOSE_MINIMUM_Scan_pattern_failing_probability number]
[-IGNORE_TOOL_version OFF | ON]
[-INCLude_fail_signatures_size maximum_rows_per_table | MAX]
[-INCLUDE_BRIDGE_to_power ON | OFF]
[-GRoss_delay ON | OFF]
[-COMPOUND_Hold_time_fault_diagnosis ON | OFF]
[-INCLUDE_DFM_rules ON | OFF]
[-INCLUDE_RCD_constants ON | OFF]
[-EXPected_value ON | OFF]
[-internal_failing_cells ON | OFF]
[-cycle_offset offset]
[-dynamic_partition master]
[-missing_rcd_action Ignore | Warn | Error ]
[-cell_port_bridge_analysis auto | on | off] [-cell_faults udfm_file]
[-landmark_polygon_limit integer]
[-include_core_instance_name ON | OFF]
```

Description

Specifies the type of diagnosis performed by the diagnose_failures command.

The set_diagnosis_options command specifies global settings that determine the behavior of subsequent [diagnose_failures](#) commands. These global settings remain in effect until another set_diagnosis_options command is issued.

The set_diagnosis_options command is optional, as there are invocation defaults for all the settings. If no arguments are specified, a list of the current settings displays.

Arguments

- **-Mode** [**Auto**](#) | [**Scan**](#) | [**Chain**](#) | [**Iddq**](#)

A switch and literal pair that determines what type of diagnosis is performed. The following options are available:

Auto — A literal that enables Tesson Diagnosis to determine what type of diagnosis to run based on the contents of the failure file. If the failure file contains a *chain_test* keyword and chain test failures, a chain diagnosis is performed. If the failure file contains scan test failures, a scan diagnosis is performed.

If the failures include a padding cycle of a scan chain, a chain diagnosis is run.

If chain failures are not preceded by a *chain_test* keyword, use the -faulty_chain switch with the [diagnose_failures](#) command to run chain diagnosis.

If the failure file contains both chain failures and scan failures, you must use the *scan_test* and *chain_test* keywords to identify the data. This is the default.

In Auto mode, the tool automatically detects IDDQ failure data from the fail log and runs IDDQ diagnosis.

Scan — A literal that enables scan diagnosis only. If the failure file contains scan test failures, a scan diagnosis is performed.

If a padding cycle of a scan chain fails, the scan chain is defective, and the entire chain is masked out before running logic diagnosis. The diagnosis resolution may suffer due to masked chain(s). You should run chain diagnosis in this situation.

Chain — A literal that enables chain diagnosis only. If the failure file contains a *chain_test* keyword and chain test failures, a chain diagnosis is performed otherwise the failure file is skipped.

Iddq — A literal that enables IDDQ diagnosis only.

- **-Verify_patterns** [**ON**](#)[[**Noverbose**](#) | [**Verbose**](#)] | [**OFF**](#)

A switch and literal pair that enables or disables verification of the external patterns specified with the [diagnose_failures](#) command. Test pattern verification is critical to accurate diagnosis results, so you should not disable it unless patterns have been previously verified.

ON — A literal that enables verification of the external patterns. If verification is enabled, the first [diagnose_failures](#) command entered simulates the external patterns

and compares the capture values with the expected values in the external patterns. When a mismatch occurs, verification stops and an error is issued. Use the [report_failures](#) -Pdet command to determine the complete set of failing patterns.

This verification is performed only once per session for a particular set of patterns.

ON Noverbose — When pattern verification is enabled and a failure file mismatch occurs, then the tool does not print out the cell pathname associated with the mismatched bit. When you use this switch, the ‘read failure’ does not produce the cell paths either.

ON Verbose — When pattern verification is enabled and a failure file mismatch occurs, then the tool prints out the cell pathname associated with the mismatched bit. This is the default.

OFF — A literal that disables verification of the external patterns.

- -Report **Default** | *percentage*

A switch and value pair that changes the diagnosis report generated by the tool. You have the following two report choices:

Default — A literal that specifies to report the following for each symptom:

- All suspects with score greater than or equal to 80.
- Up to top three suspects even if the suspects’ scores are less than 80.
- If the suspect beyond the top three has the same score with the 3rd suspect, the tool will report the suspect only if:
 - i. The suspect has same score as suspect #3, and the suspect can explain same or higher number of failing patterns.
 - a. In the case the suspect has same score and fail_match, the suspect will be reported only if it has the same passing pattern mismatch.

Note

 For definitions of the terms “symptom” and “suspect”, refer to the [Tessent Glossary](#).

percentage — An integer in the range 1 to 100 that specifies a percentage of the suspects the tool should report for each symptom. If you specify 75, for example, and there are four suspects for a particular symptom, the tool will report the top 75% (top three) of them.

- -AT_speed **ON** | **OFF**

A switch and literal pair that specifies performing at-speed failure diagnosis. See “[At-Speed Failure Diagnosis](#)” in the *Tessent Diagnosis User’s Manual* for complete information, including the conditions Tessent Diagnosis uses when diagnosing at-speed failures.

- **-MAX_suspects Default | limit**

A switch and value pair limiting the number of suspects per symptom in the diagnostics report. Choose one of the following options:

Default — A literal that specifies reporting 100 suspects per symptom.

limit — An integer that specifies to report this number of suspects per symptom.

- **-Time_limit Off | seconds**

A switch and value pair that specifies a time limit, in seconds, for diagnosing a single failure file. This time includes the failure file verification time, but not the pattern verification time. By default, the test patterns and each failure file is verified for consistency when a diagnosis is run.

If the specified time limit is reached before completion of the diagnosis, the diagnosis is aborted. A “Diagnosis aborted due to time limit (<time>)” message displays and no suspects are reported.

- **-WALL_time_limit Off | seconds**

A switch and value pair that specifies a wall time limit, in seconds, for diagnosing a single failure file. When you specify a wall time limit (**seconds**) and a diagnosis job exceeds the limit, then the tool aborts the diagnosis run with an error message.

Note

 The wall time limit is independent of the CPU time limit (using the **-Time_limit** switch). If you set to both the CPU and wall time limit, then the tool aborts the diagnosis when either limit is reached.

If the wall time limit is reached during diagnosis, the tool produces an incomplete diagnosis report file. If you specify the [diagnose_failures](#) command with the **-csv** switch, then the tool also creates an empty CSV file.

- **-Pattern_sampling {*failing_pattern_limit* | Off} {*passing_pattern_limit* | Off}**

Optional switch and value pair that specifies pattern limits for logic diagnosis. Use this switch to limit the patterns used for logic diagnosis and reduce run time. By default, all failing and passing patterns are used for diagnosis. To ensure adequate diagnosis resolution, the pattern sample must be 32 or greater.

Logic diagnosis patterns with several capture cycles require more simulation time and have less resolution. To avoid losing resolution, Tessent Diagnosis selects patterns with the least amount of capture cycles for the diagnosis. Pattern sampling options include:

failing_pattern_limit — Must be an integer of 32 or higher.

passing_pattern_limit — Must be an integer of 32 or higher. Specified number of passing patterns are selected from the first passing patterns in the set.

- **-FAILurefile_mismatch_verbosity Default | number | All**

A switch and value pair that controls the number of pattern mismatches displayed during the verification of the failure file. You have the following report choices:

Default — A literal that specifies to display 20 failing patterns.

This is the default.

number — An integer that specifies to report this number of failing patterns.

All — A literal that specifies to report all failing patterns.

- **-BRidge_analysis ON | OFF**

A switch and literal pair that determines if diagnosis includes an analysis to identify bridge suspects. A bridge suspect is identified when faulty behavior is observed for the implicated nets and the appropriate aggressor-victim conditions are met. Currently 2-way and 3-way bridges are considered and this switch is applicable to both.

Options include:

ON — Bridge analysis is enabled. Default setting.

OFF — Bridge analysis is disabled.

There are two cases where it may be desirable to disable bridge analysis.

- **Case 1** — Because the analysis is currently based only on logical responses, it is possible that a bridge suspect may not be physically possible. In cases where bridge suspects are verified as not physically possible, you may want to rerun the diagnosis with bridge analysis turned off.
 - **Case 2** — In cases where very few failing patterns are captured for a failing device, and bridge analysis may return a large number of suspects, you can turn off the bridge analysis to reduce the number of suspects.
- **-CHEck_last_shift_value ON | OFF**

An optional switch and literal pair that controls whether last shift values are considered for transition launching in resistive open diagnosis as well as cell internal diagnosis.

ON — Enables last shift values consideration for transition launching in resistive open diagnosis. This is the default.

OFF — Disables considering last shift values for transition launching in resistive open diagnosis. Use this option if you believe that the shift is very slow speed such that the transition launched from last shift is irrelevant.

- **-X2B_mismatch Ignore Warning [Noverbose | Verbose] | Error**

A switch and literal pair that determines how X2B mismatches are handled during diagnosis. X2B mismatches occur during pattern verification when the simulator returns binary values instead of the expected X values.

The tool most likely introduces X2B mismatches because it removes cell constraints when performing pattern verification and diagnosis. This allows the tool to perform diagnosis using one flat model for potentially multiple modes, each of which have different

constraints, or to use flat models that were written at different times. You can ignore these X2B mismatches.

Options include:

Ignore — This is the default. Does not display X2B mismatch information. Pattern verification will pass.

Warning Noverbose — Warns at the end of pattern verification of any X2B mismatches. Pattern verification can still pass.

Warning Verbose — Prints during pattern verification any mismatched X2B bits. Pattern verification can still pass.

Error — Prints the X2B mismatches for the first mismatched pattern and pattern verification will fail, which terminates the diagnosis or verify_patterns command.

- **-B2X_mismatch** **Ignore** **Warning[Noverbose| Verbose]** | **Error**

A switch and literal pair that determines how B2X mismatches are handled during diagnosis. B2X mismatches occur during pattern verification when the simulator returns X values instead of the expected binary values. These mismatches could be introduced by different problems, for example, software enhancements to the simulator or using a mask file when reading patterns.

Options include:

Ignore — Does not display B2X mismatch information. Pattern verification will pass.

Warning Noverbose — This is the default. Warns at the end of pattern verification of any B2X mismatches. Pattern verification can still pass.

Warning Verbose — Prints during pattern verification any mismatched B2X bits. Pattern verification can still pass.

Error — Prints the B2X mismatches for the first mismatched pattern and pattern verification will fail, which terminates the diagnosis or verify_patterns command.

- **-CEL1_internal_analysis** **ON** | **OFF**

An optional switch and literal pair that determines if the tool performs analysis to diagnose defective library cells and distinguish them from defects on nets interconnecting library cells.

- **-MAX_Faulty_chains** *failed_chain_threshold*

An optional switch and integer pair that specifies the maximum number of failing scan chains within a single datalog that are diagnosed using chain fault model. When a failure log has multiple failed_chains, there can either be multiple defects in scan chains, or a single defect affecting the scan control signals. The default *failed_chain_threshold* is 2.

- If there are one or two failed_chains, then the tool assumes the defect is on each individual chain and uses the scan chain fault model to run diagnosis. This is the default behavior of the tool.
- If failed_chains is greater than two, then the tool assumes the defect is on a global control signal. If “**set_diagnosis_options** -

“ABORT_DIAGNOSE_MANY_faulty_chains” is OFF, it uses the clock/scan_enable fault model to run diagnosis. Otherwise, the tool aborts diagnosis for this case.

Changing *failed_chain_threshold* from the default value (2) causes the following effects:

- If *failed_chains* is greater than *failed_chain_threshold*, then the tool assumes the defect is on a global control signal. If “set_diagnosis_options -ABORT_DIAGNOSE_MANY_faulty_chains” is OFF, it uses the clock/scan_enable fault model to run diagnosis. Otherwise, the tools aborts diagnosis for this case.
- If there are one, two, ... *failed_chain_threshold* faulty chains, then the tool assumes the defect is on each individual chain and uses the scan chain fault model to run diagnosis on each of the defects.

For example, a failure file contains six failed_chains. You can diagnose each of these six failed-chains as individual defects by setting this switch as follows:

```
set_diagnosis_options -max_faulty_chains 6
```

Note

 The run time is roughly linearly increased with the total number of failed_chains.

- -Chain_diagnosis_result **CELL** | **CHain**

Optional switch and literal pair that determines if a preliminary high-level chain diagnosis is performed versus a standard diagnosis. A preliminary high-level chain diagnosis only reports one failure per chain; the dominant failure.

Options include:

CELL — Runs the standard diagnosis of chain plus scan patterns and chain plus scan failures to determine cell defects. Default setting.

CHain — Runs a preliminary high-level diagnosis of the chain failures in the failure file and reports the name, length, and fault type of the chains that failed.

- -CHAIN_LIB_internal_pathname **OFF** | **ON**

An optional switch and literal pair that reports the internal instance pathname within the library for each scan latch in a suspect scan cell.

When set to ON, the tool reports this information in the chain diagnosis report’s “lib_internal_pathname” column. If there is no instance name, the tool reports “”. If you specify the **diagnose_failures** command with the -csv switch, then the tool also includes this information in the CSV output.

See “[Chain Diagnosis Section](#)” in the *Tessent Diagnosis User’s Manual* for complete information.

- **-ABORT_DIAGNOSE_COMPOUND_faults ON | OFF**

An optional switch and literal pair that specifies whether or not the tool diagnosis the logic part of compound defects during chain diagnosis. The default to “ON”, meaning the tool does not diagnose the logic portion of compound defects.

See “[Compound Diagnosis Abort Logic Diagnosis Part](#)” in the *Tessent Diagnosis User’s Manual* for a complete discussion.

- **-ABORT_DIAGNOSE_MANY_faulty_chains ON | OFF**

An optional switch and literal pair that instructs the tool to skip diagnosing when #faulty_chains is larger than the *failed_chain_threshold* specified with the set_diagnosis_options -MAX_Faulty_chains switch. The default is “ON”.

When you set this option to OFF and the number of faulty chains it greater than specified, the tool does not report each faulty chain.

See “[Abort Conditions for Chain Diagnosis](#)” in the *Tessent Diagnosis User’s Manual* for a complete discussion.

- **-ABORT_DIAGNOSE_MINIMUM_Chain_failing_probability *number***

An optional switch and integer pair that specifies the minimum chain fail probability for the tool to abort chain diagnosis. The default is 1. The minimum is 0, which means no abort. The maximum value you can specify is 100.

See “[Abort Conditions for Chain Diagnosis](#)” in the *Tessent Diagnosis User’s Manual* for a complete discussion.

- **-ABORT_DIAGNOSE_MINIMUM_Scan_pattern_failing_probability *number***

An optional switch and floating point pair that specifies the minimum scan pattern fail probability for the tool to abort chain diagnosis. The default is 0.1. The minimum is 0, which means no abort. The maximum value you can specify is 100.

See “[Abort Conditions for Chain Diagnosis](#)” in the *Tessent Diagnosis User’s Manual* for a complete discussion.

- **-IGNORE_TOOL_version OFF | ON**

An optional switch and literal pair that instructs the tool to ignore the tool version when loading a startup cache. If the tool versions are different—that is, the startup cache was created by an older version—the tool issues a warning. By default, this option functions as follows with the following verify_patterns options:

- With -create_startup_cache: Has no impact. The tool creates the same startup cache whether -ignore_tool_version is on or off.
- With -update_startup_cache: Causes a conflict error.
- With -load_startup_cache: Disables the tool version check and uses the startup cache regardless of the tool version used to generate or update the cache.

When set to OFF, the tool issues an error and does not load the startup cache if the tool version used to create the startup cache is older than the current tool version.

- **-INCLude_fail_signatures_size *maximum_rows_per_table* | MAX**

An optional switch and integer pair that specifies the maximum number of rows per table for reporting failure signature information in the diagnosis report. The default is 256. If you do not want the failure signatures included in the diagnosis report, then specify 0 (zero) with this switch. Conversely, if you require all signature information, then use the keyword MAX with this switch. See “[Failure Signature Information in the Diagnosis Report](#)” in the *Tessent Diagnosis User’s Manual* for complete information.

- **-INCLUDE_BRIDGE_to_power ON | OFF**

An optional switch and literal pair that specifies performing analysis and reporting of potential bridging defects between the STUCK suspect net, and a power or ground line during layout-aware diagnosis. The default is “ON”.

See “[Power and Ground Bridge Reporting](#)” in the *Tessent Diagnosis User’s Manual* for complete information.

- **-GRoss_delay ON | OFF**

An optional switch and literal pair that specifies performing analysis and reporting of gross delay defects. The default is “OFF”.

See “[Gross Delay Defect Diagnosis](#)” in the *Tessent Diagnosis User’s Manual* for complete information.

- **-COMPOUND_Hold_time_fault_diagnosis ON | OFF**

An optional switch and literal pair that specifies performing analysis and reporting of slow clock compound hold-time defects. The default is “OFF”. This option only applies to hold times on shift paths, not capture paths.

See “[Slow Clock Compound Hold-Time Diagnosis](#)” in the *Tessent Diagnosis User’s Manual* for complete information.

- **-INCLUDE_DFM_rules ON | OFF**

An optional switch and literal pair that specifies to perform DFM hit reporting. The default is “ON”.

See “[Diagnosis for Design for Manufacturability Analysis](#)” in the *Tessent Diagnosis User’s Manual*.

- **-INCLUDE_RCD_constants ON | OFF**

An optional switch and literal pair that specifies to populate the LDB with RCD constants. The default is “ON”.

See “[Diagnosis for Root Cause Deconvolution Analysis](#)” in the *Tessent Diagnosis User’s Manual*.

- **-EXPECTED_value ON | OFF**

An optional switch and literal pair that specifies whether to verify expected pattern values against actual pattern values and return the results in the failure log. When set to OFF, the tool suppresses this check and ignores any missing expected values.

Caution

 The -expected_value switch turns off failure log verification, which means that you will not know whether there is a discrepancy between the failure log and the patterns. Use this switch with extreme caution.

- **-internal_failing_cells ON | OFF**

An optional switch and literal pair that specifies whether to enable internal scan cell profiling. See “[Internal Scan Cell Profiling for Compressed Patterns](#)” in the *Tessent Diagnosis User’s Manual*.

- **-cycle_offset *offset***

An optional switch and integer pair that specifies to adjust the cycles in a cycle-based failure file by the value *offset*. Tessent Diagnosis uses the adjusted cycles for failure verification and diagnosis. See “[Cycle Offset Adjustment for Failure Files](#)” in the *Tessent Diagnosis User’s Manual*.

- **-dynamic_partition master**

An optional switch and literal pair that specifies to generate a startup cache for dynamic partitioning-based diagnosis. You must specify this command before you load the test patterns. It signals the tool to extract clock signatures during read_patterns.

You must use this option for dynamic partitioning-based diagnosis. Tessent Diagnosis supports startup caches generated using this option for all diagnosis uses.

- **-missing_rcd_action Ignore | Warn | Error**

An optional switch and literal pair that checks whether the LDB is populated with RCD constants. The tool checks the LDB at the beginning of the diagnosis run and performs one of the following actions when the RCD constants for the current flat file and pattern set are not present:

Ignore — Takes no action and diagnosis proceeds.

Warn — Issues a warning and diagnosis proceeds. This is the default.

Error — Issues an error and diagnosis halts.

Use this switch to ensure that the LDB contains the RCD constants required for RCD analysis with Tessent YieldInsight. The warning and error outputs remind you to run create_feature_statistics, as needed, to generate the RCD constants.

- **-cell_port_bridge_analysis auto | on | off**

An optional switch and literal pair that specifies whether to perform cell port bridge diagnosis. By default, the tool does not perform cell port bridge diagnosis for layout-aware

diagnosis but does perform cell bridge diagnosis for cell-aware diagnosis. For more information, refer to “[Cell Bridge Port Diagnosis Reporting](#).”

- **-cell_faults *udfm_file***

An optional switch and string pair that, when specified, enables cell-aware diagnosis. Specify only one UDFM with Diagnosis View file. Refer to “[Running Cell-Aware Diagnosis](#).”

- **-landmark_polygon_limit *integer***

An optional switch and integer that controls the number of landmark polygons that are written. The tool uses a proximity-to-defect algorithm to limit the number of landmark polygons for global signals such as power, ground, and scan enable. Specify an integer greater than 99. The default is 10000.

- **-include_core_instance_name **ON** | **OFF****

An optional switch and literal pair that specifies whether to generate the layout-aware hierarchical diagnosis report with chip-level pin and net names rather than the default core-level names. For more information, refer to “[Running Layout-Aware Diagnosis Using a Core-Level LDB](#)”.

Examples

Example 1

The following example loads patterns from two files into the external pattern database for the tool. The failure file, *scan_failure_file*, contains just a *scan_test* section, so the tool only performs a scan diagnosis for that file.

```
read_patterns pat_file1
read_patterns pat_file2 -append
set_diagnosis_options -mode scan
diagnose_failures scan_failure_file -output scan_diag.ascii -csv scan_diag.csv
```

Example 2

The following example runs a preliminary diagnosis on *my_failure_file*.

```
read_patterns pat_file1
set_diagnosis_options -chain_diagnosis_result chain
diagnose_failures my_failure_file
```

Example 3

The following example shows a preliminary diagnosis report.

```
tracking_info_begin
tracking_info_end
#faulty_chains=2 #symptoms=0 #suspects=0 CPU_time=0.00sec
fail_log=fail_logs/my_failure_file
Chain chain1 has error, fault type is STUCK_AT_0, the length of this chain
is 102.
Chain chain3 has error, fault type is STUCK_AT_1, the length of this chain
is 101.
```

set_display

Context: unspecified, all contexts

Mode: all modes

Sets the DISPLAY environment variable from the tool's command line.

Usage

`set_display display_name`

Description

Sets the DISPLAY environment variable from the tool's command line.

The set_display command sets the DISPLAY environment variable to display_name without exiting the currently running application. If you invoke the tool in command line mode (the default), then the DISPLAY variable is not required in order to use most commands successfully. If the variable is not set, however, and you issue a command such as open_visualizer that requires a GUI, the tool will not be able to show the applicable window. This is because the display connection provided by the variable is absent. The set_display command enables you to set the variable, if needed for the display, without the inconvenience of exiting to the shell in order to set it.

Note

-  This command affects the DISPLAY setting within the currently running application only.
When you exit the tool, the setting in the invocation shell will be what it was when you invoked the tool.
-

Arguments

- ***display_name***

A required string that specifies a valid display setting for the machine on which the tool is running.

Examples

The following example sets the DISPLAY variable when “open_visualizer” fails to open DFTVisualizer. The example also uses the system command to pass a Linux “echo \$DISPLAY” command to the shell in order to check the variable’s setting.

```
open_visualizer
//=====
// Warning: The DFTVisualizer window(s) will not be accessible
// for this session due to the lack of a valid X display
// connection.
//
// Try using the set_display command to set your DISPLAY
// variable. OR start/restart your Xserver.
//=====
```

```
system echo $DISPLAY  
set_display my_workstation:0.0  
system echo $DISPLAY  
my_workstation:0.0
```

[system](#)

set_dofile_abort

Context: unspecified, all contexts

Mode: all modes

Specifies whether the tool aborts or continues dofile execution if it detects an error condition.

Usage

`set_dofile_abort ON | OFF | exit`

Description

Specifies whether the tool aborts or continues dofile execution if it detects an error condition.

By default, if an error occurs during the execution of a dofile, processing stops, and the line number causing the error in the dofile is reported. The `set_dofile_abort` command lets you turn this functionality off so that the tool continues to process all commands in the dofile. In this case, the tool aborts the current Tcl construct (if/for/while) but continues to process the remaining commands in the dofile. You can use the Tcl `catch` command or the Tesseract `catch_output` command to manage errors and prevent the tool from aborting the current construct.

Arguments

- **ON**

A literal that halts the execution of a dofile upon the detection of an error. When in batch mode the tool exits on error, but when in interactive mode the tool returns to the session prompt. This is the default upon invocation of the tool.

- **OFF**

A literal that forces dofile processing to complete commands in a dofile regardless of error detection. If an error is encountered in a Tcl if, for, or while construct within the dofile file, the tool exits the construct immediately but continues execution of the next sequential command outside the construct. Note, this option does not affect the Tcl `source` command which completely stops execution of the source file when an error is encountered.

- **exit**

A literal that directs the tool to exit the session if it detects an error while executing a dofile regardless of whether invoked in batch or interactive mode.

Examples

Example 1

The following example sets the `set_dofile_abort` command off to ensure that all commands in `test1.dofile` are executed.

```
set_dofile_abort off
dofile test1.dofile
```

Example 2

In the following example dofile, if cmd1 returns an error and set_dofile_abort is set to On, cmd2 does not execute and the tool exits the dofile.

If cmd1 returns an error and set_dofile_abort is set to Off, cmd2 still does not execute but the tool processes the remainder of the dofile. You can use the Tcl catch command or the tesseract catch_output command around cmd1 to manage the errors generated by cmd1 and allow the tool to continue with cmd2 even if cmd1 generated an error. The set_dofile_abort command only affects how the error is handled when it propagates up the nested command stack and reaches the dofile level.

```
if {1} {
    cmd1
    cmd2
}
if {1} {
    cmd3
    cmd4
}
```

set_drc_handling

Context: unspecified, all contexts

Mode: all modes

Specifies how the tool handles design rule violations.

Usage

```
set_drc_handling {drc_id} [Error | Warning | NOTe | Ignore]
  [NOVerbose | Verbose]
  [NOAtpg_analysis | Atpg_analysis] // C{1,3,4,5,6}, D9, E{4,5,8,10,11,12}
  [ATPGC] // E10
  [-Mode A clk_name] // C3, C4
  [-Interval number] // C3, C4
  [-CONSERvative {ON | OFF}] // C6
  [-IGNORE_SYNChronous_clock_groups {ON | OFF}] // C6
  [-SKip_procedure {TEst_setup | OFF}] // E4
  [-TIMing_exception_check {ON | OFF | Auto}] // E5
  [-CONSIDer_primary_outputs_observable {ON | OFF}] // E5
  [-MASk_interactions {ON| OFF }] // C22
  [-INteractions {edge | any)} // C22
  [-Mode {Sequential | Combinational}] // E10
  [-SIMULATE_ACROSS_Internal_primary_inputs {ON | OFF}]
  [-auto_fix]
  [-INITialization_cycle {ON | OFF}]
  [-ALLOW_COMMon_scan_cells_in_multiple_chains {ON | OFF}]
  [-SCan_chain_tracing {Aggressive | Conservative})
```

Description

Specifies how the tool handles design rule violations.

The set_drc_handling command specifies the handling of the messages for the following design rule checks:

- Scan cell RAM rules checking (A rules)
- Some BIST rules checking (B2 and B4 rules)
- Clock rules checking (C rules)
- Certain Pre-DFT Clock Rules (DFT_C Rules)
- Custom DRC rules you may have registered using the [register_drc](#) command
- Data rules checking (D rules)
- Extra rules checking (E rules)
- EDT Finder rules checking (F rules)

- EDT rules checking (K rules)
- Some Procedure rules checking (P rules: P29-P33, P86, P89, P90, P92, and P94)
- Some Scan Pattern Retargeting rules checking (R rules)
- Trace rules checking (T rules)
- Some Power-aware rules checking (V rules)
- Certain Timing rules checking (W rules)

You can specify that the violation messages for these checks be either error, warning, note, or ignore. If you do not specify error, warning, note, or ignore, then the tool uses either the handling from the last set_drc_handling command or, if you did not change the handling, the Design Rules Checker's invocation default.

Note

 The set_drc_handling command does not support the scannability (S) rules except for the S3 and S5 rules. Unlike the other DRC rules, setting the handling type to "Error" does not turn on the transcript verbosity for the S3 rule. The verbosity can only be turned on via the optional literal "verbose".

The set_drc_handling command does not support any Flattening design rules (FN, FP, and FG rules). Use the [set_flattener_rule_handling](#) command to specify how design rule violations are handled for the Flattening rules.

The set_drc_handling command does not support the K15 rule.

Each rules violation has an associated occurrence message and summary message. The tool only displays the occurrence message for either error conditions or if you specify the Verbose option for that rule. The tool also displays the rule identification number in all rules violation messages.

The Atpg_analysis option provides test generation analysis when performing rules checking for some clock (C) rules, for some data (D) rules, and for some extra (E) rules. For example, if Atpg_analysis is enabled for clock rule C1, and the tool simulates a clock input as X, the rule violation occurs when it is possible for the test generator to create a test pattern while that clock input is on, all defined clocks are off and all constrained pins are at their constrained state.

Note

 When Atpg_analysis is enabled, the tool requires some additional CPU time and memory to perform the test generation analysis. (The Atpg_analysis option is enabled by default for rules C1, E10, E11 and E13; you can disable it for these rules by specifying the Noatpg_analysis option.)

Arguments

- ***drc_id***

A required non-repeatable literal that specifies the identification of the exact design rule violation whose message handling you want to change.

For more information on the design rules, refer to “[Design Rule Checking](#)”.

- Error

An optional literal that specifies for the tool to both display the error occurrence message and immediately terminate the rules checking.

- Warning

An optional literal that specifies for the tool to display the warning summary message indicating the number of violations for that rule. If you also specify the Verbose option, the tool displays the occurrence message for each occurrence of the rules violation.

- NOTe

An optional literal that specifies for the tool to display the summary message indicating the number of violations for that rule. If you also specify the Verbose option, the tool also displays the occurrence message for each occurrence of the rules violation

- Ignore

An optional literal that specifies for the tool not to display any message for the rule’s violations. The tool must still check some rules and they must pass to allow later performance of certain functions.

- **NOverbose**

An optional literal that, for a DRC whose handling is set to Warning or Note, specifies to display a summary message indicating the total number of occurrences of the rule violation. This is the default.

If DRC handling is set to Error or Ignore, the tool will behave as follows regardless of whether you specify the Noverbose (or Verbose) option:

- Error—The tool will stop at each error and display detailed instance-specific violation information to help you debug it.
- Ignore—The tool will not perform the check and therefore, the consequences of the check on ATPG, whether good or bad, will not occur. Also, the tool will not display or store instance-specific violation information.

- Verbose

An optional literal that, for a DRC whose handling is set to Warning or Note, specifies to display the occurrence message for each occurrence of the rule violation. All instance-specific violations (maybe hundreds or thousands) will be listed, one message per instance violating the rule. To obtain a summary message instead, use the Noverbose option.

If the DRC's handling is set to Error or Ignore, the tool will behave as follows regardless of whether you specify the Verbose (or Noverbose) option:

- Error—The tool will stop at each error and display detailed instance-specific violation information to help you debug it.
- Ignore—The tool will not perform the check and therefore, the consequences of the check on ATPG, whether good or bad, will not occur. Also, the tool will not display or store instance-specific violation information.

- **NOatpg_analysis**

An optional literal that specifies for the tool not to use test generation analysis when performing rules checking. This is the default except for rules C1, E4, E10, E11 and E13.

- **Atpg_analysis**

An optional literal that specifies for the tool to use test generation analysis when performing rules checking for clock rules (such as C1, C3, C4, C5 and C6), some D rules (such as D6 and D9) and some E rules (such as E4, E5, E8, E10, E11 and E12). This is the default for rules C1, E4, E10, E11 and E13.

For clock rules C3 and C4, the Atpg_analysis option generates a check of the clocks of the source and sink to see if they are gated off.

Note

 To use the constraint values during the D6 rule analysis, you must use the Atpg_analysis option.

- **ATPGC**

An optional literal that specifies for the design rules checker to use all the current ATPG constraints when analyzing E10 rule violations. You can also use the “[add_atpg_constraints -Static](#)” command to do the same thing.

- **-Mode A *clk_name***

A switch, a literal (A), and a string triplet that specifies the name of a clock on which you want the tool to perform further analysis to screen out false C3 and C4 clock rules violations. The tool performs this extra analysis on one clock only.

For more information on using the -Mode option, refer to the [C3](#) and [C4](#) descriptions.

- **-Interval *number***

An optional switch and integer pair that you can only use with C3 and C4 clock violations to specify how often you want the tool to display a message during the ATPG analysis of those violations. The *number* argument indicates multiples of violation occurrences that cause the tool to display a message. The default is 0.

The message includes the number of sequential elements that the tool checked, the number of sequential elements remaining to check, the current number of ATPG passes during the

C3 or C4 clock rules checking, and the current CPU time used by the tool for clock rules checking.

The value of the *number* parameter must be either zero or a positive integer. You can only specify one *number* value that the tool uses for both the C3 and C4 violations. If you issue multiple set_drc_handling commands (one for C3 and one for C4) that specify different values for the *number* argument, the tool uses the last interval value you specified.

- **-CONSERvative {ON | OFF}**

An optional switch and literal for [C6](#) DRC analysis. The default is OFF.

The default C6 checking may miss some C6 violations when [set_clock_restriction](#) OFF is used. A more conservative analysis can be enabled by setting the -CONSERvative to ON and will identify those C6 violations. However, it is generally recommended not to turn off clock restriction such that the -CONSERvative switch does not usually need to be used.

- **-IGNORE_SYNChronous_clock_groups {ON | OFF}**

An optional switch and literal for the [C6](#) DRC analysis. The default is OFF.

By default, C6 DRC analysis treats clocks in the same synchronous clock group as if they are equivalent. You can use the “set_drc_handling C6 -ignore_synchronous_clock_groups on” to turn off this behavior.

For more information on synchronous clock groups, see [add_synchronous_clock_group](#).

- **-SKip_procedure {TEst_setup| OFF}**

An optional switch and literal pair that affects the tool's handling of the E4 rule. The default option specifies to skip these checks when simulating the test_setup procedure. The tool will continue to check for contention during other test procedures. The Off option specifies for the tool to perform E4 rule checks for the test_setup procedure, as well as other procedures, during DRC.

It is very common during test_setup, when a design is being initialized, to have valid but momentary bus contention before the design reaches its initialized state. The E4 rule often detects these momentary occurrences of bus contention, and the tool may issue many E4 violation messages. If you wish to be notified about this type of bus contention during test_setup, use the Off option to include test_setup for E4 rule checks. This switch has no effect if you have previously set E4 handling to Ignore.

- **-TIMing_exception_check { ON | OFF | Auto}**

An optional switch and literal that enables the timing exception check for the E5 DRC. The default is Auto, in which case the tool will consider timing exception paths during E5 DRC (checking for X sources) when the tool is in the patterns -scan context and will make the handling of E5 DRC an error when the tool is in “Logic_bist” context. When the setting is Auto and the tool is not in “Logic_bist” context, the tool will ignore timing exception paths for E5 DRC.

- **-CONSIDer_primary_outputs_observable { ON | OFF }**

An optional switch and literal that enables checking the propagation of X sources to a primary output for the E5 DRC. The default is off, in which case the tool does not check whether X sources reach a primary output during E5 DRC.

- **-MASK_interactions { ON | OFF }**

An optional switch and literal pair that enables or disables the addition of false paths to avoid simulation mismatches due to C22 DRC violations. The default on, enables the tool to add the cross domain false paths. The tool generates these messages as part of DRC to summarize the C22 false path addition:

```
// 2 cross domain false paths are added to prevent simulation
mismatches due to C22 DRC violations.
// Use "set_drc_handling C22 -mask_interactions off" in SETUP mode
to disable automatic addition of false paths.
```

- **-INTERactions { edge | any }**

An optional switch and literal pair that specifies the interaction type for C22 cross clock path checks. When the default, edge, is used, the tool will only check same edge interactions for C22. Use “-interactions any” to check cross clock path checks with any interactions.

- **-Mode {Combinational | Sequential}**

An optional switch and literal for the E10 rule.

Combinational — Default upon invocation. This option performs bus contention mutual-exclusivity checking. This checking differs from rule E4 in that it does not check for this condition during test procedures.

Sequential — Considers the inputs to a single level of sequential cells behaving as “staging” latches in the enable lines of tri-state drivers. All of the latches found in a back trace must share the same clock. There must also be only a single clocked data port on each cell, and both set and reset inputs must be tied (not pin constrained) to the inactive state. This check ensures that there is no connectivity from the cells in the input cone of the sequential cells and enables of the tri-state devices except through the sequential cells.

- **-SIMULATE_ACROSS_Internal_primary_inputs { ON | OFF }**

An optional switch and literal pair that changes how the tool simulates internal PI's during DRC. Internal PIs are primary inputs you previously defined using the [add_primary_inputs](#) or [add_clocks](#) commands.

After you set this switch to ON in setup mode, during test procedure simulation the tool starts off simulating an internal PI as an internal signal by carrying over its driver's simulation value until the point when you first supply a simulation value by explicitly forcing this PI in any of the following test procedures: test_setup, load_unload, or shift.

This switch is needed for cases where you may have a cut point (such as for capture modeling), yet you need test_setup to be simulated normally as if the cut point were not present. This is commonly needed when using IJTAG within test_setup, where you want the IJTAG network simulated normally even if the network includes a cut point. For more

information about using IJTAG and test procedures, refer to “[Test Setup and Test End Procedures](#)” in the *Tessent IJTAG User’s Manual*.

- **-auto_fix {ON | OFF}**

An optional switch used to enable or disable auto fixing for specific DRC rules. Currently only [DFT_C9](#) supports this feature and the auto fix is ON by default. Use this switch to disable auto corrections for DFT_C9 as follows:

```
set_drc_handling dft_c9 -auto_fix off
```

If you are registering your own DRC rules using the [register_drc](#) command and you have used the -allow_auto_fix switch, it will be possible to disable the auto_fix using the set_drc_handling command.

- **-INITialization_cycle {ON | OFF}**

An optional switch and literal pair that controls whether the tool forces all clocks to their off states and all constrained pins to their constrained values prior to simulation of the test_setup procedure during DRC. By default, the tool performs these forces, so you do not have to explicitly specify the forces, which matches the default initialization cycle the tool includes in saved patterns. If you have occasion to write patterns without this initialization cycle ([write_patterns](#) -Noinitilization), issue a set_drc_handling -Initialization Off command and rerun DRC before saving patterns.

Tip

 If DRC is run with initialization enabled, turning off initialization when saving patterns ([write_patterns](#) -Noinitilization) may result in simulation mismatches during pattern verification in a timing based simulator. The converse (DRC run with initialization disabled and patterns saved with initialization enabled) is typically not a problem.

The argument choices are as follows:

ON — A literal that specifies to initialize the clocks and constrained pins to their off states and constrained values, respectively, prior to DRC simulation of the test_setup procedure. This is the invocation default.

OFF — A literal that specifies not to initialize the clocks and constrained pins prior to DRC simulation of the test_setup procedure.

- **-ALLOW_COMMON_SCAN_CELLS_IN_MULTIPLE_CHAINS {ON | OFF}**

An optional switch and literal pair that specify whether or not to allow scan cells to be shared among scan chains. Note that there are some restrictions on scan cell sharing, which result in a T2 violation when not observed:

- Scan cell sharing is not allowed for compressed chains driven by a decompressor.
- The shared scan cells must be at the logical scan cell boundary. A library model with multiple scan cells cannot be partially shared. In other words, you cannot have the merged point within the state elements of a logical scan cell.

-
- **-SCan_chain_tracing{Aggressive | Conservative}**

An optional switch and literal pair that specify whether or not scan chain tracing passes with a T25 violation. The choices are as follows:

Aggressive — Scan chain tracing passes with a T25 violation. This is the default. For more information on T25 violations, see the “[T25](#)” section.

Conservative — Scan chain tracing does not pass with a T25 violation. In this case, scan chain tracing fails, design rule checking stops, and the tool issues a T3 violation. For information on correcting T3 violations, see the “[T3](#)” section.

Examples

The following example specifies rule checking E4 to be an error:

```
add_scan_groups group1 scanfile
add_scan_chains chain1 group1 indata2 outdata4
add_clocks 1 clock1
add_clocks 0 clock2
set_drc_handling e4 error
set_system_mode analysis
```

Related Topics

[report_drc_rules](#)

[get_drc_handling](#)

[set_driver_restriction](#)

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies whether the tool allows multiple drivers on buses and multiple active ports on gates.

Usage

`set_driver_restriction Off | ON`

Description

Specifies whether the tool allows multiple drivers on buses and multiple active ports on gates.

The `set_driver_restriction` command lets you specify for the tool to report a contention problem whenever there are multiple nets driving values onto a bus, or when multiple ports are active on an individual gate. The default upon tool invocation is to allow multiple driving nets on a bus or multiple active ports on a gate as long as the signals are driving the same value. If multiple signals are on and are not driving the same values, then the tool flags it as contention.

However some design processes only allow a single driver to be on at a time regardless of whether the signals are driving the same values. The `set_driver_restriction` command lets you place this same restriction on the tool.

Arguments

- **Off**

A literal that specifies to allow multiple drivers to be on for a bus and multiple ports to be active for a gate as long as the driving signals are of the same value, and therefore there is no contention. This is the default behavior when you invoke the tool.

- **ON**

A literal that restricts buses to only have one driver on at a time and gates (dff and latches with multiple clocks) to only have one active port; the tool flags multiple active drivers or ports as contention problems.

Examples

The following example creates a strict contention checking environment. The first command specifies for the tool to check for contention on both multiple port gates and buses. If there is a contention problem where signals are driving different values, the tool reports an error and stops the simulation. The second command further restricts the contention checking environment by not allowing multiple drivers to even drive the same values.

```
set_contention_check on -error -all
set_driver_restriction on
```

Related Topics

[set_contention_check](#)

set_edt_abort_analysis_options

Context: dft -edt, patterns -scan (EDT On)

Mode: all modes

Specifies the number of EDT Aborted (EAB) test cubes on which to perform EAB fault analysis.

Usage

```
set_edt_abort_analysis_options -max_cubes_to_analyze {unlimited | maxCubes}
```

Description

Specifies the number of EAB test cubes on which to perform EAB fault analysis.

The `set_edt_abort_analysis_options` command is used to set the maximum number of allowed EAB test cubes to be stored during the EDT session. By default, up to 1000 test cubes are stored. If you specify the unlimited keyword, then the tool stores all EAB test cubes generated from the EDT session.

You must issue this command before using the [create_patterns](#) command.

See “[EDT Aborted Fault Analysis](#)” in the *Tessent TestKompress User’s Manual* for a complete discussion.

Arguments

- **-max_cubes_to_analyze**{unlimited | *maxCubes*}

A required switch and value pair that specifies the number of EAB test cubes. Choose one from the following:

unlimited — A literal that specifies all EAB test cubes for analysis.

maxCubes — An integer that specifies the number of EAB test cubes for analysis. The default is 1000.

[report_edt_abort_analysis](#)

set_edt_finder

Context: patterns -scan (EDT On), patterns -scan_diagnosis

Mode: setup

Controls whether the tool automatically identifies EDT logic and updates scan chain pins during test pattern generation.

Usage

```
set_edt_finder [OFF | ON] [-Verbose {OFF | ON}]
```

Description

Controls whether the tool automatically identifies EDT logic and updates scan chain pins during test pattern generation. This capability is referred to as EDT Finder. By default, EDT Finder is “on”.

When EDT Finder is on, the F DRCs are enabled, in addition to the normal K DRCs. The F DRCs provide more precise identification of EDT logic errors. Additionally, when EDT Finder is on, EDT DRC run time is greatly reduced.

This command can be used in conjunction with Core Mapping for ATPG. For more information, see “[Core Mapping for ATPG Process Overview](#)” in the *Tessent Scan and ATPG User’s Manual*.

You can use this command to get updated scan pin information when your design hierarchy changes after the EDT logic is generated. For more information, see “[Updating Scan Pins for Test Pattern Generation](#)” in the *Tessent TestKompress User’s Manual*.

EDT Finder uses the defined scan chain pins if they match what EDT Finder itself found in the logic. That is, if in shift mode EDT Finder determines that there is a controlling path between the defined scan chain pin and the pin that EDT Finder found, EDT Finder will use the defined scan chain pin.

If no arguments are specified, the current EDT Finder settings display.

Note

 EDT Finder is automatically disabled in cases that are not supported—for example, in BIST mode. Because EDT Finder is enabled by default, DI faults are automatically identified in EDT logic. You can disable this behavior by executing the following command:

```
set_fault_subclass_analysis -disable DI.EDT
```

For more information, see “[Fault Sub-classes](#)” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- **OFF**
An optional literal that disables EDT Finder.
- **ON**
An optional literal that enables EDT Finder. This is the default.
- **-Verbose {OFF|ON}**
An optional switch and literal pair that enables the transcription of informational messages about the EDT logic found. The transcription of informational messages is disabled upon invocation of the tool.

Examples

The following example shows the output of EDT Finder for a design with two channels and eight internal scan chains. EDT Finder output is highlighted in bold.

```
dofile results/generated_edt.dofile
add_scan_groups grp1 results/generated_edt.testproc
add_scan_chains -internal chain1 grp1 /top_i/si1 /top_i/so1

add_scan_chains -internal chain2 grp1 /top_i/si2 /top_i/so2
set_edt_pins update EdtUpdate
set_edt_pins input_channel 1 ChannelInput_1
set_edt_pins output_channel 1 ChannelOutput_1
set_edt_pins input_channel 2 ChannelInput_2
set_edt_pins output_channel 2 ChannelOutput_2
set_mask_decoder_connection -mode_bit 1 5
...
set_system_mode analysis

// Flattening process completed, cell instances=221, gates=471, PIs=16,
// POs=11, CPU time=0.00 sec.
// -----
// Begin circuit learning analyses.
// -----
//
// -----
// Begin EDT finder analyses.
// -----
// EDT Finder completed, EDT blocks=1, scan chains=8, CPU time=0.02 sec.
// -----
// Begin scan chain identification process, memory elements = 54.
// -----
...
```

[report_edt_finder](#)

set_edt_instances

Context: dft -edt, patterns -scan (EDT On), patterns -scan_diagnosis

Mode: setup, analysis

Specifies the location in which the tool places the EDT logic.

Usage

```
set_edt_instances [-Edt_logic_top edt_instance_name_or_pathname]
                  [-Compactor compactor_instance_name_or_pathname]
                  [-Decompressor decompressor_instance_name_or_pathname]
                  [-Block_location path_to_top_of_block]
```

Description

IP Creation phase:

Specifies the location in which the tool places the EDT logic.

In the IP Creation phase, you use this command with the -Block_location switch to specify the parent instance in which the EDT logic is to be inserted. See Example 1. Note, if you use any switch except -Block_location in this phase, the tool ignores the switch and issues a warning.

By default, the EDT logic is instantiated at the top level of the design.

Pattern Generation phase:

Specifies an instance name/location for existing EDT logic or for the design block that contains the EDT logic (EDT block).

You can use this command in the Pattern Generation phase to:

- Tell the tool the new name of an already renamed EDT logic block, decompressor, or compressor. See Example 3.
- Name each EDT block uniquely, using the -Block_location switch, when an EDT block is used multiple times. See Example 4.

The set_edt_instances command operates only on the current EDT block which is the last block specified by either the [add_edt_blocks](#) or [set_current_edt_block](#) commands. For more information, see “[Modular Compressed ATPG](#)” in the *Tessent TestKompress User’s Manual*.

Arguments

- **-Edt_logic_top *edt_instance_name_or_pathname***

A required switch and string pair that specifies an instance name or pathname for the design block containing the EDT logic (EDT block). Names specified with this switch must be

unique. If the specified `edt_instance_name_or.pathname` is not unique in the design, the tool issues a message; in this case, you can specify the full pathname.

- **-Compactor** `compactor_instance_name_or.pathname`

A required switch and string pair that specifies an instance name or pathname for the compactor sub-block within the current EDT block. Names specified with this switch must be unique. If the specified `compactor_instance_name_or.pathname` is not unique in the design, the tool issues a message; in this case, you can specify the full pathname.

- **-Decompressor** `decompressor_instance_name_or.pathname`

A required switch and string pair that specifies an instance name or pathname for the decompressor sub-block within the current EDT block. Names specified with this switch must be unique. If the specified `decompressor_instance_name_or.pathname` is not unique in the design, the tool issues a message; in this case, you can specify the full pathname.

- **-Block_location** `path_to_top_of_block`

A required switch and string pair that specifies the location of the current EDT block within the top-level netlist.

During EDT IP Creation, use this switch to specify the location in which the tool places the EDT logic.

During Pattern Generation, use this switch to identify each EDT block uniquely when an EDT block is used multiple times, by specifying its parent instance pathname.

Examples

Example 1

The following command is issued during EDT logic creation to insert the EDT logic in the instance, `pad_east/test_blk`, instead of at the top level of the design:

```
set_edt_instances -block_location pad_east/test_blk
```

Example 2

The following example specifies the name of the instance that contains the EDT logic:

```
set_edt_instances -edt_logic_top my_core_edt_i
// Found edt_logic_top at path: "/my_core_edt_top/my_core_edt_i".
```

Example 3

The following example specifies the instance names of the decompressor and compactor for the EDT logic and reports the current instance locations:

```
set_edt_instances -decompressor my_core_edt_decompressor_i \
                  -compactor my_core_edt_compactor_i
// Found compactor at path:
//      "/my_core_edt_top/my_core_edt_i/my_core_edt_compactor_i".
// Found decompressor at path:
//      "/my_core_edt_top/my_core_edt_i/my_core_edt_decompressor_i".
```

report_edt_instances

```
// edt_logic_top
//   Setting: my_core_edt_i
//   Path    : /my_core_edt_top/my_core_edt_i
//
// decompressor
//   Setting: my_core_edt_decompressor_i
//   Path    : /my_core_edt_top/my_core_edt_i/my_core_edt_decompressor_i
//
// compactor
//   Setting: my_core_edt_compactor_i
//   Path    : /my_core_edt_top/my_core_edt_i/my_core_edt_compactor_i
```

Example 4

The following example specifies unique names for instances of the same EDT block in a top-level modular netlist:

```
set_edt_mapping on
add_edt_blocks my_core1_a

// my_core1_a is the current EDT block.

set_edt_instances -block_location /my_core1_a_edt_i
dofile my_core1_edt.dofile
...
report_edt_instances

// edt_logic_top
//   Setting: my_core1_edt_i
//   Path    : /my_core1_a_edt_i/my_core1_edt_i
...

add_edt_blocks my_core1_b

// my_core1_b is the current EDT block.

set_edt_instances -block_location /my_core1_b_edt_i
dofile my_core1_edt.dofile
...
report_edt_instances

// edt_logic_top
//   Setting: my_core1_edt_i
//   Path    : /my_core1_b_edt_i/my_core1_edt_i
...
```

The set_edt_mapping command enables the requisite mapping of block-level dofile commands to the top-level.

Related Topics

[add_edt_blocks](#)
[report_edt_instances](#)
[set_current_edt_block](#)

[**set_edt_mapping**](#)

[set_edt_mapping](#)

Context: dft -edt, patterns -scan (EDT On), patterns -scan_diagnosis

Mode: setup

Enables or disables automatic mapping of block-level dofile commands so block-level dofiles can be reused without modification for top-level pattern creation.

Usage

```
set_edt_mapping {Off | ON} [-Verbose {Off | ON}]
```

Description

Enables or disables automatic mapping of block-level dofile commands so block-level dofiles can be reused without modification for top-level pattern creation.

Note

 This command and the EDT Mapping functionality have been superseded by the newer Core Mapping for ATPG feature. Please use the newer capability described in “[Core Mapping for ATPG Process Overview](#)” in the *Tessent Scan and ATPG User’s Manual*.

The set_edt_mapping command determines whether or not the tool performs the automatic mapping necessary to reuse, for top-level pattern generation, the dofiles the tool generated during block-level IP creation. You must set this command to “on” prior to running block-level dofiles to set up for top-level pattern creation.

For more information about the modular Tessent TestKompress flow or the reuse of block-level dofiles, refer to the “[Modular Compressed ATPG](#)” chapter of the *Tessent TestKompress User’s Manual*.

Note

 Switch settings for this command are cumulative; that is, switches retain their settings over multiple set_edt_mapping commands until you specify a different setting

Arguments

- **Off**

A literal that turns off automatic mapping necessary to reuse the block level dofiles generated during the IP Creation Phase. This is the default upon invocation of the tool.

- **ON**

A literal that enables the automatic mapping necessary to reuse the block level dofiles generated during the IP Creation Phase.

- -Verbose {**OFF** | **ON**}

An optional switch and literal pair that enables or disables the tool's transcription of informational messages whenever it changes any of the following block-level dofile objects as a result of automatic mapping:

scan group name
 scan chain name
 pin pathname
 pin name

The transcription of informational messages is disabled upon invocation of the tool.

Examples

Example 1

The following example enables the automatic mapping of commands from the block-level dofiles to the top-level design hierarchy, then executes the commands in one of the block-level dofiles:

```
set_edt_mapping on
delete_edt_blocks -all
// All blocks deleted. No EDT block now selected as current block.

add_edt_blocks created_core1
// created_core1 is the current EDT block.

set_edt_instances -block_location /x1
dofile created_core1_edt.dofile
// command: add_scan_groups grp1 ./edt_ip/created_core1_edt.testproc
// Note: Ignoring "add_scan_groups" command for grp1. Will use top-level
// definition since scan group mapping is active.
// command: add_scan_chains -internal chain1 grp1 /m8_i/scan_in1
// /m8_i/scan_out1
...
// command: add_scan_chains -internal chain4 grp1 /m8_i/scan_in4
// /m8_i/scan_out4
// command: add_clocks 0 SCLK
// command: add_clocks 0 CCLK
...
```

Example 2

The following example shows the transcription that would have occurred had the -Verbose switch been in effect for the commands of the preceding example:

```
set_edt_mapping on -verbose on
delete_edt_blocks -all
```

```
// All blocks deleted. No EDT block now selected as current block.

add_edt_block created_core1
// created_core1 is the current EDT block.

set_edt_instances -block_location /x1
dofile created_core1_edt.dofile

// command: add_scan_groups grp1 ./edt_ip/created_core1_edt.testproc
// Note: Ignoring "add_scan_groups" command for grp1. Will use top-level
// definition since scan group mapping is active.
// command: add_scan_chains -internal chain1 grp1 /m8_i/scan_in1
// /m8_i/scan_out1
// Note: Block level chain name (chain1) automatically translated to
// created_core1_chain1.
// Note: Block level path (/m8_i/scan_in1) automatically translated to
// /x1/m8_i/scan_in1.
// Note: Block level path (/m8_i/scan_out1) automatically translated to
// /x1/m8_i/scan_out1.
...
// command: add_scan_chains -internal chain4 grp1 /m8_i/scan_in4
// /m8_i/scan_out4
// Note: Block level chain name (chain4) automatically translated to
// created_core1_chain4.
// Note: Block level path (/m8_i/scan_in4) automatically translated to
// /x1/m8_i/scan_in4.
// Note: Block level path (/m8_i/scan_out4) automatically translated to
// /x1/m8_i/scan_out4.
// command: add_clocks 0 SCLK
// Note: Block level "add_clocks" command for SCLK will be verified
// during DRC.
// command: add_clocks 0 CCLK
// Note: Block level "add_clocks" command for CCLK will be verified
// during DRC.

set_edt_options

Context: dft -edt, dft -scan, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis (dft -edt, dft -scan, and patterns -scan contexts only)

Determines whether compression is on and specifies parameters for the EDT logic, including scan channels, bypass circuitry, lockup cells, pipeline stages, and compactor type.

Usage

```
set_edt_options [OFF | ON | Auto]
  [-CHannels integer]
  [-INPut_CHannels integer]
  [-Used_input_channels integer]
  [-OUtput_CHannels integer]
  [-LOCATION {External | Internal}]
  [-BYPASS_Chains integer]
  [-OVERShift_cycles integer]
  [-SIngle_bypass_chain {ON | OFF}]
  [-BYpass_logic {ON | OFF | Use_existing_bypass_chains}]
  [-Clocking {Edge | Level}]
  [-PIpipeline_logic_levels_in_compactor {OFF| integer}]
  [-LOCKup_cells {ON | OFF}]
  [-LONGest_chain_range {min_number_cells max_number_cells}]
  [-RESET_signal {OFF| Asynchronous}] [-COMpactor_type {XPress | BAsic}]
  [-PULSE_EDT_Before_shift_clocks {ON | OFF}]
  [-FOrce_1hot_masking {OFF | ON}]
  [-RETIme_chain_boundaries {ON | OFF}]
  [-SEParate_control_data_channels ON | OFF]
```

For dft -scan

```
set_edt_options [-Location {External | Internal}]
  [-Channels integer]
```

For Hybrid TK/LBIST Flow IP Creation

```
set_edt_options -lbist_misr_input_ratio { integer | auto }
  [-reset_signal asynchronous]
  [-SIngle_bypass_chain {ON | OFF}]
  [-BYpass_logic {ON | OFF}]
  [-chain_mask_register_ratio ratio]
```

For Hybrid TK/LBIST Flow Fault Simulation

```
set_edt_options [-decompressor_seed hex_string]
```

Description

Determines whether compression is on and specifies parameters for the EDT logic, including scan channels, bypass circuitry, lockup cells, pipeline stages, and compactor type.

To create EDT logic for a basic application, you only need to specify the number of channels.

When set to Off, the tool can be used for ATPG and behaves the same as Tesson FastScan in command-line mode.

Use the [report_environment](#) command to display the current settings.

Settings are retained over multiple `set_edt_options` commands until a different setting is specified.

Hybrid TK/LBIST Flow Specifics

Sets options for EDT IP creation and LogicBIST fault simulation.

IP Creation: This command specifies options specific to the EDT/LogicBist blocks.

Fault Simulation: This command describes the initial seed of the PRPG.

Refer to the [Hybrid TK/LBIST Flow User's Manual](#) for complete information.

Arguments

- **OFF**
An optional literal that disables compression (EDT) mode and enables analysis mode.
- **ON**
An optional literal that enables compression (EDT) mode.
- **Auto**
An optional literal that enables automatic detection of EDT mode (compression). Note, this option is only available in the patterns -scan context.
- **-CHannels *integer***
An optional switch and integer pair that specifies the number of external scan channels. Use this switch when the number of input channels is the same as the number of output channels.
Use this switch to set up the number of scan channels the EDT logic is configured with. During pattern generation, this switch is used to specify the number of scan channels the EDT logic contains. The dofile created when the EDT logic is generated, contains a `set_edt_options` command that specifies the number of channels for test pattern generation.
- **-INPut_CHannels *integer***
An optional switch and integer pair that specifies the number of scan input channels. Use this switch only if the number of input channels differs from the number of output channels.
- **-Used_input_channels *integer***
An optional switch and integer pair that specifies the number of EDT IP input channels used for pattern generation. This option is not valid during IP creation. This switch can only be used in setup mode.

You can configure the EDT IP to use a subset of the input channels. For example, you might generate the EDT IP to support some number of input channels, but then when the IP or core is embedded into the design, only a subset of the channels can be driven due to scan port limitations.

Note

 It is important to know that, during EDT IP creation, the tool considers all channels as possible inputs/outputs for the bypass chains. If you plan to tie any of the input channels at some point, you need to consider constraining the used input channels prior to EDT IP creation.

Use of this option can provide a flexible test compression planning flow. Since a core could be designed independent of the rest of the SoC, it could be difficult to determine the optimal number of scan input channels during the core design phase. You may pick a conservative compression ratio by using enough scan input channels at the IP creation phase. When integrating all cores into the SoC, if using only a subset of the input channels is sufficient for a core, you can use this feature to specify the used input channels and apply a specific constant value on the unused input channels on the boundary of the EDT IP during shift.

The following usage conditions apply:

- To use this switch, you must set the following in the IP Creation Phase:

```
set_edt_options -separate_control_data_channels ON
```

The only exception is if you are using the basic compactor and no low-power controller.

- Only data channels with highest channel indexes can become unused. For example, an EDT block has one control channel (channel1) and three data channels (channel2, channel3, channel4). If you want to only use 3 input channels, you can only tie channel4 to “0”. If you want to only use 2 input channels, you can only tie both channel 3 and channel4 to “0”. You must have at least one data channel.
- If the unused input channels are connected to top-level primary inputs, patterns at these pins must hold at “0”s. This can be accomplished by constraining the unused input channels using the add_input_constraints command:

```
add_input_constraints XXX -C0
```

or

```
add_input_constraints XXX -C1 (if there is an inversion
between the tied pin and the EDT channel input)
```

Otherwise, the tool issues DRC violations during system mode transition.

- If the unused input channels are driven by internal signals, these channels must be controlled in the design to ensure that “0”s are injected into the decompressor from these unused channels.

- If the unused input channels are driven by logic that is setup to provide constant values during shift (for example, a TDR that is loaded with “0” in test_setup), then you need to apply the appropriate setup patterns.

Refer to “[Core Instance Parameters](#)” in the *Tessent TestKompress User’s Manual*.

- **-OUtput_CHannels *integer***

An optional switch and integer pair that specifies the number of scan output channels. Use this switch only if the number of output channels differs from the number of input channels.

- **-BYPASS_Chains *integer***

An optional switch and integer pair that determines how many scan chains are created for bypass mode. The specified value must be equal to or less than the number of bypass chains created by default. By default, the number of bypass chains created equals the number of input/output channels. If the number of input and output channels differ, the smaller number is used.

For dual compression configuration applications, this switch must be issued after both configurations are defined.

- **-OVERShift_cycles *integer***

An optional switch and integer pair that adds a specified number of shift cycles to a test pattern set. Use this switch to balance out core test pattern sets when integrating them at the chip level in the SoC flow.

This switch can be used before saving out a particular pattern set to adjust the number of shift cycles. This is typically useful for mapping core level patterns to the chip level in the SoC pattern mapping flow. During core level pattern generation, the patterns can be saved as is. While integrating core level patterns at the chip level, the differences in the number of shift cycles for the different pattern sets corresponding to the different cores will be known. The switch can then be used to add the additional cycles to the pattern set with lesser number of cycles to balance out all the pattern sets. This facilitates pattern merging at the chip level.

- **-SIngle_bypass_chain {ON | OFF}**

An optional switch and literal pair that creates compression logic with a dual bypass chain configuration. Use this option to create a bypass configuration that concatenates all scan chains together into one bypass chain in addition to the default bypass configuration. For more information, see “[Dual Bypass Configurations](#)” in the *Tessent TestKompress User’s Manual*.

Hybrid TK/LBIST Flow Only: -SIngle_bypass_chain {ON | OFF} The default is ON.

Turn this switch off to turn off generating single bypass chain logic on a per-block basis.

Caution

 Turning this switch off is not recommended because doing so also turns off LBIST pattern diagnosis.

- **-LOCAtion {External | Internal}**

An optional switch and literal pair that specifies a location for the EDT logic relative to the netlist read in. Options include:

External—Creates a new top level “wrapper” module and instantiates both the design netlist read in and the EDT logic within it. The logic is thus kept external to the design netlist. This is the default.

Internal—Instantiates the EDT logic in the existing top level of the design netlist.

- **-BYpass_logic{ON | OFF | Use_existing_bypass_chains}**

An optional switch and literal pair that specifies a location for the bypass logic. Bypass logic allows you to bypass the compression circuitry and run traditional ATPG with a tool such as Tesson FastScan. Bypass logic is transparent during normal operation. Options include:

ON—Includes bypass logic in the EDT logic. This is the default.

OFF—The tool does not add any logic; it assumes that a bypass does not exist and inserts no logic.

Use_existing_bypass_chains—Uses bypass logic already in the core logic. In this case, the tool inserts two muxes for each EDT channel (not chain) in order to select between the compressed and uncompressed path. [Example 3](#) demonstrates how to use this option.

Hybrid TK/LBIST Flow Only: Turn this switch off to turn off generating bypass logic. When you do so, the tool also automatically turns off generating single bypass chain logic.

Caution

 Turning this switch off or specifying Use_existing_bypass_chains is not recommended because doing so turns off LBIST pattern diagnosis.

- **-CLocking {Edge | Level}**

An optional switch and literal pair that determines what type of architecture logic is used for the EDT logic. Options include:

Edge—Specifies DFF-based logic. You can use DFF-based logic for designs that are LSSD-based, mux-DFF-based, or that incorporate a mixture of these two architectures. This is the invocation default.

Level—Specifies latch-based logic. This option is for pure LSSD designs only.

- **-PIpipeline_logic_levels_in_compactor {OFF | integer}**

An optional switch and literal pair that enables pipeline stages in the compactor of the EDT logic. Options include:

OFF—Disables pipeline stages in the EDT logic. This is the default.

integer—Includes pipeline stages in the EDT logic compactor(s), and specifies the maximum number of logic levels (2-input XOR gates) allowed in the compactors before inserting a pipeline stage.

- -LOCKup_cells {**ON** | **OFF**}

An optional switch and literal pair that determines whether lockup cells are inserted in the EDT logic.

Caution

 You should leave this switch set to *on*. Disabling lockup cell synthesis can lead to DRC violations in the pattern generation phase and inability to generate valid patterns. For more information, see “[Understanding Lockup Cells](#)” in the *Tessent TestKompress User’s Manual*.

Options include:

ON — Includes lockup cells in the EDT logic as needed between the decompressor and the core, between the core and the compactors (if pipelining is used), and between scan chains when they are concatenated for bypass mode. This is the default setting.

OFF — Disables lockup cells in the EDT logic.

- -LONGest_chain_range *min_number_cells max_number_cells*

An optional switch and integer pair that defines a range for the length of the longest scan chain. Use this switch to avoid having to regenerate the logic for minor changes in the length of the chains after the logic is created.

Note

 This switch should be used when creating EDT logic with the skeleton flow. For more information, see “[Longest Scan Chain Range Estimate](#)” in the *Tessent TestKompress User’s Manual*.

Options include:

min_number_cells — Specifies the minimum number of cells in the longest scan chain. When you use the -longest_chain_range switch with separate control and data channels, the *min_number_cells* impacts the number of control channels that are created, according to this formula:

$$\text{Number of EDT control channels} = \text{Ceil}(\text{total number of control bits} / \text{min_number_cells})$$

This can result in higher pattern count if the final design has more control channels than necessary.

For example: If you specify the minimum longest chain length as 50, and the design has 100 control bits, the generated hardware will have two control channels. However, if the actual longest chain length in the final design is 100 or more, one control channel is sufficient, but the EDT IP wastes one control channel and has one fewer data channel, which increases the pattern count unnecessarily. You should estimate the *min_number_cells* as close as possible to its final design.

max_number_cells — Specifies the maximum number of cells in the longest scan chain. A too large *max_number_cells* value may increase the decompressor size a little.

- -RESet_signal {**OFF** | **Asynchronous**}

An optional switch and literal pair that specifies whether an asynchronous reset signal, `edt_reset`, is included in the EDT logic. In most cases such a signal is not needed, but it can be used if design requirements dictate that all the sequential elements in the design are resettable. Options include:

OFF—Disables the asynchronous reset. This is the default.

Asynchronous—Includes an asynchronous reset signal for all sequential elements in the EDT logic and a new top-level pin named “`edt_reset`” to control it. You can rename this pin or share it with a functional pin in the design core using the [set_edt_pins](#) command.

Note

 You should define the reset as a clock primary input using the [add_clocks](#) command during logic creation. This accounts for the signal off state (high or low) when writing out the EDT logic. If the signal is undefined, an active high is assumed at the boundary of the EDT logic. If the signal is shared with a global reset that is active low, you must manually insert an inverter for the reset signal before it arrives at the EDT logic boundary.

- -COMpactor_type {**XPress** | **BASIC**}

Optional switch and literal pair that determines which compactor is used in the EDT logic. Options include:

XPress—Xpress compactor. The Xpress compactor increases compression, especially for designs that generate unknown (X) values. Default setting.

BASIC—Basic compactor. The basic compactor is the first generation compactor.

For more information, see “[Understanding Compactor Options](#)” in the *Tessent TestKompress User’s Manual*.

- -PULse_EDt_Before_shift_clocks {**ON** | **OFF**}

Optional switch and literal pair that determines whether the EDT logic clock is pulsed before the scan chain clock. By default, the EDT logic and scan chain clock are pulsed simultaneously. For more information, see the “[Pulse EDT Clock Before Scan Shift Clocks](#)” section in the *Tessent TestKompress User’s Manual*.

- -FOrce_1hot_masking {**OFF** | **ON**}

Optional switch and literal pair that determines whether Tessent TestKompress generates test patterns that observe a single scan chain or multiple scan chains on each channel of the Xpress compactor. Options include:

OFF—Depending on unknown states and targeted faults, Tessent TestKompress determines which scan chains to observe. Default behavior.

ON—One scan chain is observed on each compactor channel. This setting should be used for debug purposes. Generating test patterns with this setting increases test pattern count.

This switch is only valid when the Xpress compactor is used. Observing only one scan chain output per channel allows you to easily map a failure on a channel to a specific scan cell. For more information on the Xpress compactor, see “[Understanding Compactor Options](#)” in the *Tessent TestKompress User’s Manual*.

- **-SEParate_control_data_channels on| off**

An optional switch that when enabled (set to on) specifies that the tool automatically determines the number of control channels and inserts control bits behind the control channels only. This is needed for channel sharing between non-identical blocks. For more information, see “[EDT IP Creation With Separate Control and Data Input Channels](#)” *Tessent TestKompress User’s Manual*.

You apply this setting per EDT block. For a design with multiple EDT blocks, you can enable some of the blocks using “-separate_control_data_channels on” and disable the remaining blocks using “-separate_control_data_channels off”.

Note

 You can only use this option if the user-specified number of input channels is greater than or equal to one plus the number of control channels; otherwise, the tool issues an error and aborts.

- **-RETIme_chain_boundaries ON | Off**

An optional switch that specifies whether to add retiming cells (lockup cells) at scan chain inputs and outputs. These cells are added to ensure that each scan chain starts with an LE register and ends with a TE register. This switch replaces bypass lockup cells with retiming lockup cells that are part of the EDT scan chains; this eliminates the need for bypass-only lockup cells. For more information on bypass cells as part of the EDT logic, see “[Differences Based on Inclusion/Exclusion of Bypass Lockup Cells in EDT Chains](#)” in the *Tessent Shell Reference Manual*.

Retiming cells are added only when lockup cells are inserted with the “-lockup_cells ON” option. These cells are included as part of both EDT and EDT-bypass scan chains.

ON — Specifies to include retiming cells in EDT chains. This is the default for the Hybrid TK/LBIST flow (dft -edt -logic_bist context).

Off — Specifies to *not* include retiming cells in EDT chains. This is the default for TestKompress EDT IP creation (dft -edt context).

For complete information on including retiming cells in EDT chains, see section “[Lockup Cell Analysis For Bypass Lockup Cells Included as Part of the EDT Chain](#)” in the *Tessent TestKompress User’s Manual*.

- **-lbist_misr_input_ratio { integer | auto } (Hybrid TK/LBIST Flow IP Creation Only)**

A required switch that specifies the ratio of the number of scan chains over number of MISR inputs. The specified value should be a power of 2.

If the value is 1, then all scan chain outputs are connected to the MISR. This is the default value. Setting this property to auto reverts the input ratio to the default 1 value.

If the value is greater than or equal to #scan_chains/#channels, then all EDT channel outputs are connected to the MISR.

If any value in between is used, then taps are taken from the middle of EDT compactor XOR tree corresponding to the value specified.

This argument only specifies the number of MISR inputs; the size of the MISR is implicitly determined based on this input. The minimum size of the MISR is at least 24 bits.

If this switch is not specified, a default MISR of 24 bits is used. When the design has more than 24 output channels, the default MISR size is increased to be greater than or equal to the number of output channels.

- **-chain_mask_register_ratio *ratio***

An optional switch and integer pair that specifies the number of scan chains controlled by a single EDT chain mask register bit. By default, the ratio is 1:1; there are as many bits in the chain mask register as there are number of scan chains.

You can use the -chain_mask_register_ratio switch to minimize the area impact of the chain mask register. For example, specifying 3 for *ratio* means a 3:1 ratio with each chain mask register bit controlling 3 scan chains. Specify the ratio on a per EDT block basis.

The larger the ratio you specify, the more you trade off resolution for area impact. When any scan chain connected to a chain mask register bit is masked, all the other scan chains connected to the bit are also masked automatically.

Refer to “[Scan Chain Masking](#)” in the *Hybrid TK/LBIST User’s Manual* for more information.

- **-decompressor_seed *hex_string* (Hybrid TK/LBIST Flow Fault Simulation Only)**

An optional switch and hexadecimal pair that specifies the initial seed of the PRPG. This seed applies to both the warm-up patterns and the actual patterns.

The LogicBIST fault simulation dofile includes this switch with the hardware default value for arguments.

If you intend to perform fault simulation with a different starting PRPG seed, then modify the *hex_string* argument to specify the desired seed.

Examples

Example 1

The following example sets up a EDT logic for a design with four scan chains. The EDT logic is set up for one scan channel and no bypass circuitry.

```
add_scan_groups grp1 atpg.proc
add_scan_chains chain1 grp1 edt_si1 edt_so1
add_scan_chains chain2 grp1 edt_si2 edt_so2
add_scan_chains chain3 grp1 edt_si3 edt_so3
add_scan_chains chain4 grp1 edt_si4 edt_so4
add_clocks 0 clk
set_edt_options -channels 1 -bypass_logic off
set_system_modeanalysis
```

Example 2

The following example generates EDT logic with two input channels and one output channel. The number of bypass chains defaults to 1, corresponding to the smaller of the two specified channel values.

```
set_edt_options -input_channels 2 -output_channels 1
```

Example 3

The following example demonstrates the use of the use_existing_bypass_chains option to the -bypass_logic switch. In this example, you have two bypass chains since you plan to insert EDT with two input and two output channels. In this example, your my_bypass signal is active low.

1. Tell the tool about the bypass chains:

```
set_edt_options -bypass_logic use_existing_bypass_chains -bypass_chains 2
```

2. Tell the tool about the input and output of each chain:

```
set_bypass_chains -bypass_chain_number 1 -pins scan_in1 scan_out1 \
-edt_chains chain1 chain2 chain3 chain4
```

```
set_bypass_chains -bypass_chain_number 2 -pins scan_in2 scan_out2 \
-edt_chains chain5 chain6 chain7 chain8
```

The tool inserts a mux on scan_in1 and scan_in2 to select between the EDT channels and the bypass path. The tool inserts a mux on the output so that you will have two muxes for each EDT channel.

The tool will control the newly inserted bypass muxes using the default edt_bypass pin which will be added unless you use the set_edt_pins command to tell the tool about your bypass control. If you do use the set_edt_pins command as shown here, the tool will use my_bypass instead of the default edt_bypass pin.

```
set_edt_pins bypass my_bypass
```

The tool assumes that the pin you specify here (my_bypass) is active high. If your bypass enable pin is active low, you must edit the generated RTL for EDT and add an inversion on the my_bypass signal coming into the EDT logic. With this change, when you set your bypass pin low, it will configure all of your bypass muxes and the tool-inserted muxes to be in bypass mode.

Example 4 (Hybrid TK/LBIST Flow IP Creation)

This command during IP creation is used to connect the scan chains to MISR by combining four scan chain outputs using XOR gates to each MISR input.

```
set_edt_options -lbist_misr_input_ratio 4
```

Example 5 (Hybrid TK/LBIST Flow IP Creation)

For a design with 20 scan chains, specify the following command during IP creation to group 4 scan chains per chain mask register bit:

```
set_edt_options -chain_mask_register_ratio 4
```

The resulting chain mask register will be a 5-bit register instead of a 20-bit register (the default).

Example 6 (Hybrid TK/LBIST Flow Fault Simulation)

The following example shows how to modify the PRPG seed in analysis mode during fault simulation:

```
set_edt_options -decompressor 00000001  
set_system_mode analysis  
simulate_patterns -source bist -store_patterns all  
set_edt_options -decompressor 00110101  
simulate_patterns -source bist -store_patterns all
```

[report_scan_volume](#)
[set_bypass_chains](#)
[set_compactor_connections](#)
[set_edt_pins](#)
[write_edt_files](#)

[set_edt_pins](#)

Context: dft -edt, patterns -scan (EDT On), patterns -scan_diagnosis

Mode: setup, analysis (dft -edt and patterns -scan contexts only)

By default, all EDT pins are created as dedicated pins with default names and no inversions. The same set_edt_pins command must be used for both the pattern generation phase and the EDT logic creation phase to generate patterns correctly for modified pins.

Usage

Specifying a new or shared EDT pin

```
set_edt_pins {{Input_channel | Output_channel} {index [pin_name] [internal_node_name]} |
  {edt_pin [pin_name] [internal_node_name]} |
  {pin_name -ON_edt_module}}
```

Renaming and/or inverting EDT pins

```
set_edt_pins {{Input_channel | Output_channel} {{index [pin_name]} | {edt_pin}} |
  [-Noinv | -Inv]}
```

Inserting channel pipeline stages

```
set_edt_pins {{Input_channel | Output_channel} {[index]{-Pipeline_stages #stages}}}
```

Specifying the change edge for compactor outputs

```
set_edt_pins [Output_channel -CHange_edge_at_compactor_output
  {Any | LEading_edge_of_edt_clock
  | TRailing_edge_of_edt_clock}]
  | [Output_channel index -CHange_edge_at_compactor_output
  {Any | TRailing_edge_of_edt_clock}]
```

Specifying internally driven EDT control pins

```
set_edt_pins {edt_pin} {-} [internal_node_name]}
```

Description

By default, all EDT pins are created as dedicated pins with default names and no inversions. The same set_edt_pins command must be used for both the pattern generation phase and the EDT logic creation phase to generate patterns correctly for modified pins.

Except for added channel pipeline stages, a dofile generated during the EDT logic creation phase contains the correct set_edt_options commands for the pattern generation phase. If you add channel pipeline stages, you must specify those changes in the pattern generation phase with another set_edt_pins command.

Use the set_edt_pins command for the following operations:

- **Specify a new or shared EDT pin**

When an EDT channel output pin is shared with a functional output pin, a multiplexer is inserted in the top-level wrapper to share the signals between the output pins. The multiplexer is controlled by the `scan_enable` signal. If you rename an EDT pin with a name already used by a functional pin in the core design, the EDT pin shares the functional pin.

- **Rename an EDT control pin**

To rename an EDT pin, specify the `edt_pin` along with a `pin_name` argument that specifies the new name. To rename an EDT channel, specify an input/output channel and index number for the channel along with a `pin_name` argument that specifies the new name. To apply the new name to the pin at the EDT module level in the RTL, use the `pin_name -On_edt_module` switch.

- **Specify an inverted signal between the chip pin and the EDT logic**

I/O pads added outside the EDT logic sometimes invert their signal. Use the `-Inv` switch to specify the inversion of the EDT control pins during EDT logic creation. This ensures that generated test procedures and dofiles operate correctly in the pattern generation phase after the I/O pads are synthesized. The `pin_name` argument is optional if you are only changing the inversion status of an EDT pin.

- **Specify that an EDT control pin is driven internally**

For more information, see “[Internally Driven EDT Pins](#)” in the *Tessent TestKompress User’s Manual*.

- **Specify channel pipeline stages**

Channel pipeline stages are pipeline stages added outside the EDT logic between a top level channel input pin/pad and the decompressor input or compactor output.

Channel pipeline stages are typically added during top-level design integration to reduce signal propagation time between the top-level pads and the channel inputs and outputs. Channel pipeline stages are not created as part of the EDT logic, but they must be specified to generate the correct test patterns.

To specify channel pipeline stages for a particular channel during the pattern generation phase, use the `index` number of the channel, the `-Pipeline_stages` switch, and the number of pipeline stages.

- **Specify the change edge for compactor outputs**

You can use this feature to specify whether compactor output data changes on the LE time or whether the tool aligns the change edge at compactor output with the TE of the EDT clock.

By default, the compactor output data changes on the TE time of the EDT clock. There are two usage scenarios as follows:

Without compactor pipelining (compactor pipeline register has not been inserted)

- If LE is specified for all channels, a pipeline stage clocked by edt_clock (LE) is added at the compactor output; the pipeline stage is only added if any of the last scan cells change at any time other than the LE of the EDT clock. Lockup cells are added if necessary either before the pipeline stage or at the output of the scan chains on a per-compactor basis.
- When TE is specified for all output channels, a pipeline register driven by the LE of the EDT clock and a lockup cell driven by the TE of the EDT clock are added to all channels. When TE is specified for a subset of output channels, only a lockup cell driven by the TE of the EDT clock is added for the channels specified as needed.

With compactor pipelining (compactor pipeline register has been inserted)

- The compactor pipeline guarantees the compactor output changes on the LE of EDT clock because the pipeline stage inside the compactor is driven by edt_clock (LE). If the number of levels of logic is less than or equal to the number of pipeline levels specified with set_edt_options, a pipeline stage is added only when necessary to ensure an LE change. In addition, lockup cells are added when needed.
- If TE is specified for a channel, an additional lockup cell is added on the output of every compactor to ensure the TE change edge.

The dofile written out during EDT logic creation reflects the pipeline stages added to meet the speed objectives or to ensure that the output of the compactor changes at the positive edge of the EDT clock.

For more information, see “[EDT Control and Channel Pins](#)” and “[Using Pipeline Stages Between Pads and Channel Inputs or Outputs](#)” in the *Tessent TestKompress User’s Manual*.

Arguments

- **Input_channel**
Optional literal that specifies an EDT input channel pin.
- **Output_channel**
Optional literal that specifies an EDT output channel pin.
- **index**
Optional integer that specifies the index number for a specified channel pin. The index must be positive and have a valid range from one up to the total number of scan channels.
- **pin_name**
Optional replaceable string that specifies a pin name. Depending on usage, the *pin_name* may reflect the name of an existing functional pin in the core design or EDT logic, an existing pin on the EDT module, or the new name for an existing pin. This is a required argument if you are using the internal_node_name argument to create a connection between this pin and an internal node.

- *internal_node_name*

Optional replaceable string that specifies the hierarchical name of an internal node to connect an EDT pin to. This argument defines the connection between an EDT pin and the internal node of an I/O pad for internally placed EDT logic.

When defining the connection, you must also include a *pin_name* argument in the same command. If only one string is specified, the tool interprets it as the *pin_name*.

- *edt_pin*

Optional literal that specifies an EDT control pin. Literal options include:

Clock — *edt_clock* pin.

Reset — *edt_reset* pin.

Scan_enable — top-level *scan_en* pin.

Bypass — *edt_bypass* pin.

Single_bypass_chain — *edt_single_bypass_chain* pin.

Update — *edt_update* pin.

COnfiguration — *edt_configuration* pin for dual configuration applications.

Master_clock — *master_clock* pin. Use in latch-based EDT logic for LSSD designs only.

Slave_clock — *slave_clock* pin. Use in latch-based EDT logic for LSSD designs only.

Low_power_shift_en — low power shift enable pin for low-power decompressor.

Note

The tool assumes that the pin you specify for the bypass enable signal is active high. If you have pre-existing bypass logic, specified with the “*set_edt_options -bypass_logic use_existing_bypass_chains*” command, and your bypass enable pin is active low, you must edit the generated RTL for EDT and add an inversion on the bypass signal coming into the EDT logic. With this change, when you set your bypass pin low, the tool will configure all of your bypass muxes and the tool-inserted muxes to be in bypass mode.

- **[-Noinv | -Inv]**

Optional switch that specifies an EDT pin signal is inverted between the point where it is connected during EDT logic creation and the chip boundary in the final netlist used for pattern generation. The default is no inversion.

You should specify *-inv* in the following situations:

- **External flow** — Inversion between the wrapper created by the tool and the chip boundary.
- **Internal flow** — Inversion between the internal connection node for the EDT pin and the chip boundary.

Specifying this inversion information during the EDT logic creation phase generates the correct dofiles and test procedure files for the pattern generation phase but has no effect on the EDT logic.

- **-ON_edt_module**

Optional switch that specifies a pin on the EDT module in the EDT RTL. Use this argument to apply a change to a specified pin at the EDT module level only.

- **-Pipeline_stages #stages** (Pattern Generation Phase only)

An optional switch and non-negative integer pair that specifies the number of pipeline stages on specified input or output channels. Use the channel *index* argument to apply a number of channel pipeline stages to a specific channel. If no *index* argument is used, the specified number of channel pipeline stages applies to all input or all output channels for the current EDT block.

Use this argument during the pattern generation phase to specify the number of pipeline stages inserted between top-level pins or pads and EDT channel inputs or outputs.

If your design contains channel pipeline stages, you must also make some changes in the test procedure file to accommodate them.

Note

 The tool updates the number of pipeline stages with what was traced even if you have specified a different number using the -pipeline switch. Note, if you have disabled EDT Finder, the tool will not update the number of pipeline stages.

You must generate test patterns for existing bypass scan chains from scratch. You cannot create test patterns for existing bypass chains from identical test patterns created for EDT. For more information on using bypass chains defined in the core logic, see “[Generating EDT logic When Bypass Logic is Defined in the Netlist](#)” in the *Tessent TestKompress User’s Manual*.

For more information, see “[Using Pipeline Stages Between Pads and Channel Inputs or Outputs](#)” in the *Tessent TestKompress User’s Manual*.

- [Output_channel -CHange_edge_at_compactor_output
 {Any | LEading_edge_of_edt_clock | TRailing_edge_of_edt_clock}] |
 [Output_channel *index*-CHange_edge_at_compactor_output
 {Any | TRailing_edge_of_edt_clock}]

Optional switch and literal pair that specifies which edge the compactor output data changes on. This switch does not support latch-based EDT. Options include:

Any — Specifies that data can change at either edge and no additional logic is required.

TRailing_edge_of_edt_clock — Specifies that compactor outputs need to change on the TE edge of the EDT clock. You can use the *index* option to specify a change edge for individual channels because it does not introduce an additional shift.

When all scan chain outputs change at the same time as the LE of EDT clock, or when the compactor already has pipelining, the tool will only add a lockup cell, without a pipeline, to the end of the compactor.

When the scan chain outputs do not change at the same time as the LE of EDT clock, the tool adds a pipeline and a lockup cell. Adding a pipeline for trailing_edge only happens when all channel outputs are specified with trailing edge.

LLeading_edge_of_edt_clock — Specifies that all compactor outputs need to change on the LE edge of the EDT clock. An *index* cannot be specified because it may introduce varying amounts of shift cycles across output channels. When you specify this option and all scan chain outputs already change at LE, the tool adds a lockup cell and LE compactor pipeline register.

- **-edt_pin**

Optional switch that specifies there is no top-level pin associated with an *edt_pin* that is driven internally. Use this switch during EDT logic creation and test pattern generation for the internal flow and during test pattern generation for the external flow to prevent false K5 DRC violations.

Note

 Input and output channels must always have a corresponding top-level pin.

For more information, see “[Internally Driven EDT Pins](#)” in the *Tessent TestKompress User’s Manual*.

Examples

Example 1

The following example configures the EDT logic with two scan channels, reports the names and inversion status of the EDT pins, and issues four set_edt_pins commands that:

1. Share the EDT clock pin with a functional pin, a1.
2. Rename the dedicated EDT bypass pin to my_bypass and specifies the bypass signal is inverted between the PI pin and the EDT logic.
3. Share EDT channel 1 input pin with functional pin, portain[7].
4. Change the inversion status of the edt_update pin.

A final report_edt_pins command displays the new EDT pin settings.

```
set_edt_options -channels 2
report_edt_pins
```

```
//          Pin description      Pin name      Inversion
//          -----
//          Clock                edt_clock     -
//          Update               edt_update    -
//          Bypass mode          edt_bypass   -
//          Scan channel 1 input edt_channels_in1 -
//          "        "        " output  edt_channels_out1 -
//          Scan channel 2 input edt_channels_in2 -
//          "        "        " output  edt_channels_out2 -
//
```

```
set_edt_pins clock a1
set_edt_pins bypass my_bypass -inv
set_edt_pins input_channel 1 portain[7]
set_edt_pins update -inv
report_edt_pins
```

```
//          Pin description      Pin name      Inversion
//          -----
//          Clock                a1           -
//          Update               edt_update   inv
//          Bypass mode          my_bypass   inv
//          Scan channel 1 input portain[7]  -
//          "        "        " output  edt_channels_out1 -
//          Scan channel 2 input edt_channels_in2 -
//          "        "        " output  edt_channels_out2 -
//
```

Assume the settings defined by the preceding example are specified by similar `set_edt_pins` commands during the pattern generation phase. The next example specifies there are three pipeline stages between the scan channel 1 input pin (`portain[7]`) and the corresponding top level pad, and changes the inversion status of the pin. The example then displays the updated settings. (The Pin description column is not shown in this example in order to show the reporting command's output when pipeline stages are defined.)

```
set_edt_pins input_channel 1 -inv -pipeline_stages 3
report_edt_pins
```

```
//          Pin name      Inversion      Channel pipeline stages
//          -----
//          a1           -              -
//          edt_update   inv           3
//          my_bypass   inv           0
//          portain[7]  inv           0
//          edt_channels_out  -         0
//          edt_channels_in2 -         0
//          edt_channels_out2 -         0
```

set_edt_pins

The next example specifies new pin names to be used at the “edt” module interface for the two EDT input channels, the two EDT output channels, and the EDT clock signal:

```
//Input ch: use the name, ch_in_bus, at the edt-IP RTL module interface.
set_edt_pins input_channel ch_in_bus -on_edt_module

//Output ch: use the name, ch_out_bus, at the edt-IP RTL module interface.
set_edt_pins output_channel ch_out_bus -on_edt_module

//EDT clock: use the name tk_clk_P at the edt-IP RTL module interface.
set_edt_pins clock tk_clk_P -on_edt_module
```

The next example shows a complete dofile for an external logic location flow that implements user-specified EDT pin names at the “edt” module level:

```
dofile scan_setup.dofile

set_edt_options -channels 2 -bypass off

//
//clock: design level=PSEI, edt module level=tk_clk_P
set_edt_pins clock PSEI
set_edt_pins clock tk_clk_P -on_edt_module

//
//channel inputs: design level = AI[1]/AI[2], edt module level=ch_in_bus
set_edt_pins input_channel 1 AI[1]
set_edt_pins input_channel 2 AI[2]
set_edt_pins input_channel ch_in_bus -on_edt_module

//
//channel outputs: design level=OA[1]/OA[2], edt module level=ch_out_bus
set_edt_pins output_channel 1 OA[1]
set_edt_pins output_channel 2 OA[2]
set_edt_pins output_channel ch_out_bus -on_edt_module

set_system_mode analysis
report_edt_pins

write_edt_files created -verilog -replace
```

The next example shows “edt” and “edt_top” modules (external logic location flow), with RTL changes resulting from the use of the **-On_edt_module** switch highlighted in bold. For brevity, only the relevant portions of the “edt_top” module are shown.

...
endmodule

```

Example 2

The following example specifies that the output of the compactor should change at the LE of the clock.

set_edt_pins output -change_output leading

If the compactor has any outputs that change data on TE, a pipeline stage and the necessary lockup cells are added at the output of every compactor.

Example 3

The following example uses a design with 100 scan chains and the following parameters for compression:

set_edt_options -channels 10 -pipeline_logic_levels_in_compactor 2
set_edt_pins output -change_output leading

Pipeline stages are added after the second XOR gates stage in the compactor. Accordingly, lockup cells are also added. However, no other pipeline stages are added at the output of the compactor because the compactor pipelining guarantees that the output of the compactors will change with respect to the LE of the clock.

Assume the same design and change the pipeline stages to:

set_edt_options -channels 10 -pipeline_logic_levels_in_compactor 6
set_edt_pins output -change_output leading

Now, no compactor pipeline stages are needed due to the minimum logic levels allowed in the compactor by the user. Under such circumstances, the last scan cell of all chains in the design are analyzed and if any of the scan outputs change at a TE edge, then the tool adds a pipeline stage at the output of all the compactors along with necessary lockup cells.

Example 4

The following example shows the commands used for a design with 100 chains and 10 channel inputs/outputs with some channel pins with pipelining.

set_edt_options -channels 10
set_edt_pins output 1 -change_edge trailing
set_edt_pins output 5 -change_edge trailing

Lockup cells are added in the compactors that have pipeline stages in the corresponding channels.

Example 5

The following example sets the output of all compactors to change at LE except for one that changes on TE because of channel output pipelining.

```
set_edt_options -channels 10
set_edt_pins output -change_edge leading
set_edt_pins output 5 -change_edge trailing
```

This guarantees that all compactor outputs will change at LE except for channel 5, which would change at TE with respect to the EDT clock.

Example 6

The following example specifies the EDT update control pin is internally driven by the */top/xyz/out* node for Tessent TestKompress logic created with the internal flow.

```
set_edt_options -location internal
set_edt_pins update - /top/xyz/out
```

The following example specifies the EDT update control pin has no corresponding top-level pin during test pattern generation.

```
set_edt_pins update -
```

Example 7

The following example specifies the connections between the channel input and output pins and their internal connection points for an internal flow. Notice that the top-level pins *port_x* and *port_y* are specified because the *internal_node_name* argument is used.

```
set_edt_options -location internal
set_edt_pins input_channel 1 port_x /ip_pad_block/port_x_pad/Z
set_edt_pins output_channel 1 port_y /ip_pad_block/port_y_pad/A
```

set_edt_power_controller

Context: dft -edt, patterns -scan (EDT On), patterns -scan_diagnosis

Mode: setup, analysis

Generates and inserts a power controller in the compression logic to enable low-power shift.

Usage

```
set_edt_power_controller Shift {None | Enabled | Disabled}  
    [-MIN_Switching_threshold_percentage percentage_integer]  
    [ -Full_control { OFF | ON } ]
```

Description

Generates and inserts a power controller in the compression logic to enable low-power shift.

This command controls the bias of the low-power decompressor in the EDT IP creation phase. For more information, see “[Low-Power Shift and Switching Thresholds](#)” in the *Tessent TestKompress User’s Manual*.

In the IP Creation phase, you can use this command to create the power controller, to specify its hardware capability (switching threshold), and to configure the generated dofile and test procedure file.

In the Pattern Generation phase, you can only use this command to indicate that the controller is present and whether it is enabled in the test procedure file read by the tool.

The power controller may be configured in both phases as either “enabled” or “disabled”. If you are using the same configuration (enabled/disabled) during both IP creation and pattern generation, then this command is already included in the generated dofile and you do not need to make any changes to the controller configuration. However, if you want to change how it was configured during IP creation, you need to specify the opposite value (enabled/disabled).

To generate patterns with the low power controller hardware enabled, you must do the following:

1. In the test procedure file, ensure the `edt_low_power_shift_en` is forced to the correct values during the shift procedure. For more information on the `edt_low_power_shift_en` signal, see “[Power Controller Logic](#)” in the *Tessent TestKompress User’s Manual*.
2. Issue a “`set_edt_power_controller Shift Enabled`” command in Setup mode to enable the power controller before you generate test patterns.

To generate patterns with the low power controller hardware disabled, you must do the following:

1. In the test procedure file, ensure the `edt_low_power_shift_en` is forced to the correct values during the shift procedure. For more information on the `edt_low_power_shift_en` signal, see “[Power Controller Logic](#)” in the *Tessent TestKompress User’s Manual*.
2. Issue a “`set_edt_power_controller Shift Disabled`” command in Setup mode to disable the power controller before you generate test patterns.

Note

 You cannot use this command during ATPG to change the switching threshold of an already created controller; instead, use the `set_power_control` command to change the actual switching percentage during ATPG.

For more information, see “[Low-Power Test](#)” in the *Tessent TestKompress User’s Manual*.

Arguments

- **Shift**

Required literal that specifies the generated power controller should enable low-power shift.

- **None**

Required literal that disables creation of the power controller in the compression logic. This is the default setting.

- **Enabled**

Required literal that during IP creation creates the power controller hardware as part of the compression logic and writes the ATPG dofile that enables the hardware and a test procedure file that forces the `edt_low_power_shift_en` control signal to its enabled value.

During ATPG, this option tells the tool that the low power controller is enabled in the test procedure file read by the tool.

- **Disabled**

Required literal that during IP creation creates the power controller hardware as part of the compression logic and writes the ATPG dofile that disables the hardware and a test procedure file that forces the `edt_low_power_shift_en` control signal to its disabled value.

During ATPG, this option tells the tool that the low power controller is disabled in the test procedure file read by the tool.

- **-MIN_Switching_threshold_percentage *percentage_integer***

Optional switch and integer that specifies the minimum switching threshold value used to determine power controller parameters, such as input shift register size. Valid integer options are 1 to 50. If an integer greater than 50 is specified, the tool uses 50. The default setting is 15%.

The tool uses this value to calculate the size of the power controller. The power controller must be large enough to control the number of scan chains required to achieve the minimum switching threshold specified. For more information, see “[Low-Power Shift and Switching Thresholds](#)” in the *Tessent TestKompress User’s Manual*.

- **-Full_control {OFF|ON}**

Optional switch and literal that adds one bit per scan chain to control whether that chain loads a constant value or not. This allows you to have complete control over the scan chain input masking. Choose one of the following options:

OFF — Literal that disables adding these bits to the scan chain. This is the default.

ON — Literal that enables adding one bit per scan chain.

Normally, you would only use this when your design has very few chains such that:

- The low-power register count is not significant.
- You need to control power to low thresholds or fine granularity even for those low-chain-count designs.

When you set this switch to ON, any value specified with the

-MIN_Switching_threshold_percentage switch is ignored.

Examples

Example 1

The following example creates compression logic with a power controller configured to accommodate a minimum of 20% switching threshold, and creates the dofile and test procedure file that enable the hardware during pattern generation.

```
set_edt_power_controller shift enabled -min_switching_threshold_percentage 20
...
set_system_mode analysis
write_edt_files low_power_enabled
```

Given the compression logic created with the preceding command, use the following commands during ATPG phase to turn the power controller on with a 22% switching threshold for scan chain loading and to generate test patterns.

```
set_power_control shift -switching_threshold_percentage 22
set_system_mode analysis
...
create_patterns
```

Example 2

The following example creates compression logic with a power controller configured to accommodate a minimum of 20% switching threshold, and creates the dofile and test procedure file that disable the hardware during pattern generation.

```
set_edt_power_controller shift disabled -min_switching_threshold_percentage 20
...
set_system_mode analysis
write_edt_files low_power_disabled
```

Given the compression logic created with the preceding command, use the following commands to enable the power controller and set it to a 22% switching threshold. This application also requires that you modify the edt_low_power_shift_en pin value in the test procedure file.

```
set_edt_power_controller shift enabled
set_power_control shift -switching_threshold_percentage 22
set_system_mode analysis
...
create_patterns
```

set_external_capture_options

Context: dft -edt, patterns -scan, patterns -scan_retargeting,
patterns -scan_diagnosis

Mode: setup (patterns -scan context only), analysis

Specifies the number of tester cycles to be used in the capture window of all patterns.

Usage

```
set_external_capture_options {OFF | -MINimum_cycles cycles | -FIXed_cycles cycles
| {-PLL_cycles cycles timeplate_name} } | {-CAPture_procedure procedure_name}
```

Description

Specifies the number of tester cycles to be used in the capture window of all patterns.

The set_external_capture_options command allows you to specify a minimum or fixed number of external tester capture cycles when saving -mode_external patterns for the current test session, including chain test patterns with capture cycle and retention test patterns. The integer you supply with this command specifies the minimum or fixed number of tester cycles that must be present between the end of the load_unload procedure and the start of the next pattern, or next load_unload procedure for multi-load patterns. When saving -mode_internal patterns for purposes other than pattern retargeting, the tool ignores set_external_capture_options settings and saves the patterns created by the ATPG engine, using the clock_sequential and capture procedures as is normally done.

For techniques to handle slow scan enable transitions, see “[Delaying Clock Pulses in Shift and Capture to Handle Slow Scan Enable Transitions](#)” in the *Tessent Scan and ATPG User's Manual*.

Note

 The options you specify with the set_external_capture_options command apply to all pattern retargeting patterns, including mode_internal.

The integer you supply, for fixed or minimum, adds extra padding cycles to the end of the capture window if the number of tester cycles used in the pattern is less than the specified number when saving mode-external simulation or tester interface format patterns. The ASCII and binary format patterns are not affected by these padding cycles. The number of tester cycles you designate also applies to scan loads used in multi-load patterns, so the launch cycles used between scan loads in the multi-load pattern is also padded to ensure the same number of tester cycles between scan loads.

The padding cycle is created from a copy of the last cycle from the capture procedure with all clocks turned off, all measure data removed, and all pulse-always clocks turned on. This padding cycle is added after the last cycle of the capture procedure and before the first cycle of the next pattern.

When using **-PLL_cycles**, instead of an annotation that lists the number of padding cycles being added, there is an annotation that lists the original ATPG sequential depth for this pattern.

When STIL and WGL patterns are read back into the ATPG tools, the tool flags padding cycles added to the end of the capture window as added dummy cycles and does not use those padding cycles when converting the test cycles into ATPG pattern data. However, the tool uses these cycles when converting cycle-based fail information into pattern-based fail data.

As an alternative to directly specifying the number of external tester capture cycles, you can use the **-CAPture_procedure** switch and string pair to specify an external capture procedure that defines the external capture cycles to use with clock control definitions.

Issuing the command with no options reports the current settings. Any subsequent use of this command overrides all previous settings.

IDDQ Fault Type Usage Issues

If the fault type is set to IDDQ prior to using the **set_external_capture_options** command, and if you use the command to specify the **fixed_cycles**, **pll_cycles**, or **external_capture** option, the tool issues an error and does not set the option. This error is as follows:

```
// Error: The <option_name> option is not valid when generating IDDQ  
// patterns.
```

Arguments

- **OFF**
An optional literal that turns off any previous tester cycle settings. Note, however, that this option does not automatically disable maximum sequential depth. You have to issue **set_pattern_type –Max_sequential Off** to disable the setting for the maximum sequential depth.
- **-MINimum_cycles *cycles***
An optional switch and integer pair that specifies the minimum number of cycles present in the capture window when saving patterns in STIL or WGL format.
- **-FIXed_cycles *cycles***
An optional switch and integer pair that specifies the fixed number of tester cycles that needs to be present in the capture window when saving patterns in STIL or WGL format. The tool automatically calls “**set_pattern_type –Max_sequential**” to set the maximum sequential depth to be *integer* if the setting for maximum sequential depth is disabled or the maximum sequential depth is less than *cycles*.
- **-PLL_cycles *cycles timeplate_name***
An optional switch that specifies the fixed number of PLL capture cycles (integer value) and string that specifies the name of a timeplate that was loaded with the procedure file when saving patterns in STIL or WGL format. **PLL_cycles** can be used with **clock_control** definitions or with named capture procedures when they only have an internal mode. The

restrictions for PLL_cycles for the hold_pi and mask_po also apply to -CAPture_procedure as well.

This switch is intended to be used with clock_control definitions only. To use the switch, all clocks must either be controlled by clock_control definitions, be constrained, or be pulse-always or pulse-in-capture. In addition, hold_pi must be on, and mask_po must be on for all outputs. The -PLL_cycles switch replaces the ATPG cycles with a set number of external capture cycles using the specified timeplate. It is somewhat similar to internal_mode and external_mode of the named capture procedures. The internal_mode is what is generated by the ATPG engine using the above restrictions, and the external_mode is the number of cycles specified with the designated timeplate, and the clocks that pulse are the pulse_always or pulse_in_capture clocks. It is possible to specify the number of pll_cycles to be less than the max_sequential_depth setting. As with the -MINimum_cycles or -FIXed_cycles, -PLL_cycles is only used when saving -Mode_external patterns.

- -CAPture_procedure *procedure_name*

An optional switch and string pair that specifies the name of an external_capture procedure, which is used for all capture cycles between each scan load, even when the pattern is a multi-load pattern. For more information about the external_capture procedure, refer to the section “[Capture Procedures \(Optional\)](#)” in the *Tessent Shell User’s Manual*.

Examples

The following example adds one PLL capture cycle to the end of the capture window:

```
set_external_capture_options -pll_cycles 1 pll_timeplate
```

Related Topics

[set_pattern_type](#)

set_external_simulator

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies the shell command to use to invoke an external simulator for verifying tool-produced patterns.

Usage

```
set_external_simulator {-SIMulation_script script_filename} | {vsim [options...]}
```

Description

Specifies the shell command to use to invoke an external simulator for verifying tool-produced patterns.

The command string must be valid for the simulator; therefore, you may need to refer to the simulator's user documentation for correct syntax and arguments.

Arguments

- **-SIMulation_script *script_filename***

A required switch and string pair that specifies a simulation script to use for verifying patterns. This script will be used automatically for the [analyze_simulation_mismatches](#) command. Supported simulation tools include vsim, ncverilog, and vcs.

For a script example, refer to this “[Example](#)” in the *Tessent Scan and ATPG User’s Manual*.

- **vsim [*options...*]**

A required literal and optional string that specifies a basic invocation command for ModelSim in batch mode.

Examples

Example 1

The following example checks the current external simulator setting, then specifies to invoke ModelSim in batch mode with loading messages disabled, when verifying simulation results:

```
report_external_simulator
./vsim -c

set_external_simulator vsim -c -quiet
report_external_simulator
./vsim -c -quiet
```

ModelSim supports simulation with Standard Delay Format (SDF) back-annotation. Generally, you can apply the timing information in an SDF file to any instance in a design.

Example 2

The following example includes arguments that direct the simulator to annotate maximum timing values from the SDF timing file *cpu1.sdf* to instance /my_design/inst1, and minimum timing values from the SDF timing file *cpu2.sdf* to instance /my_design/inst2:

```
set_external_simulator vsim -c -sdfmax /my_design/inst1=cpu1.sdf
-sdfmin /my_design/inst2=cpu2.sdf
```

Example 3

The following example includes an argument that provides visibility into nets, ports, and registers while decreasing run time:

```
set_external_simulator vsim -c -voptargs+=acc=npr
```

The visibility provided by the “+acc=npr” option should be sufficient for debugging advanced test benches. For even more visibility but with less performance gain, you can modify the above example as follows:

```
set_external_simulator vsim -c -voptargs+=acc
```

[report_measure_cycles](#)

[setfails_report](#)

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies whether the design rules checker displays clock rule failures.

Usage

`setfails_report Off | ON`

Description

Specifies whether the design rules checker displays clock rule failures.

The `setfails_report` command displays all clock rule failures of the design rules checker. The default mode upon invocation of the tool is Off.

Arguments

- **Off**

A literal that specifies for the design rules checker to not display clock failures. This is the default upon invocation of the tool.

- **ON**

A literal that specifies for the design rules checker to display clock failures.

Examples

The following example displays clock failures from the design rules checking process:

```
add_scan_groups group1 scanfile
add_scan_chains chain1 group1 indata2 outdata4
add_clocks 1 clock1
add_clocks 0 clock2
setfails_report on
set_system_mode analysis
```

Related Topics

[add_clocks](#)

[delete_clocks](#)

[report_clocks](#)

set_failure_mapping_options

Context: patterns -failure_mapping

Mode: analysis

Specifies filters you can apply when performing reverse mapping of top-level failures to the core in hierarchical designs flows.

Usage

```
set_failure_mapping_options [-cycle_offset offset] [-short_core_name on | off]
```

Arguments

- **-cycle_offset *offset***

An optional switch and integer pair that specifies to adjust the cycles in the top-level cycle-based failure file by the value *offset*. In hierarchical flows, Tesson Diagnosis uses the adjusted cycles during reverse mapping to the core-level failure cycles/patterns. For more information, refer to “[Cycle Offset Adjustment for Failure Files](#)” in the *Tesson Diagnosis User’s Manual*.

- **-short_core_name on | off**

An optional switch and literal pair that specifies whether to truncate the names of core-level failure files so that they do not include the core instance pathnames of the files. At times, the addition of the core instance pathnames (the default behavior) can cause the filenames to exceed the maximum of 255 characters. When you turn this option on, the tool replaces the core instance pathnames with an index counter, “_*N*”, where *N* is an integer.

Description

For hierarchical design flows, use this command to adjust the way that Tesson Diagnosis performs reverse mapping of the top-level failures to the core.

[set_fault_mode](#)

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies whether the fault mode is collapsed or uncollapsed.

Usage

`set_fault_mode Uncollapsed | Collapsed`

Description

Specifies whether the fault mode is collapsed or uncollapsed.

The `set_fault_mode` command specifies whether the tool uses collapsed or uncollapsed fault lists for fault counts, test coverages, and fault reports. The default fault mode upon invocation of the tool is Uncollapsed. When you display a report on uncollapsed faults, the tool lists the representative fault first followed by its equivalent faults.

The DFTVisualizer Browser and Library Browser windows display fault information based on this setting.

Note

 This command is not valid for the bridge logic fault model (specified with the [set_fault_type](#) Bridge -Static command).

Arguments

- **Uncollapsed**

A literal specifying that the tool include equivalent faults in the fault lists. This is the default mode upon invocation of the tool.

- **Collapsed**

A literal specifying that the tool not include equivalent faults in the fault lists.

Examples

Example 1

The following example sets the fault mode to collapsed and then displays only the collapsed faults:

```
set_system_mode analysis
add_faults -all
set_fault_mode collapsed
report_faults -all
```

Example 2

The following shows an example when reporting uncollapsed tied faults as compared to reporting collapsed tied faults:

Uncollapsed:	Collapsed:
0 TI /I_140/I	0 TI /I_140/I
1 TI /II_140/O	1 TI /II_140/O
1 EQ /II_140/I

[report_faults](#)
[report_testbench_simulation_options](#)
[set_fault_sampling](#)
[set_fault_type](#)
[write_faults](#)

[set_fault_sampling](#)

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies the fault sampling percentage used for circuit evaluation or scan identification.

Usage

```
set_fault_sampling {Off | percentage} [-Seed integer]
```

Description

Specifies the fault sampling percentage used for circuit evaluation or scan identification.

Fault sampling enables you to process a fraction of the total faults to decrease processing time for evaluating large circuits. For faults other than bridge faults, once you specify a percentage, the tool randomly picks the fault samples to process. For bridge faults, the tool randomly picks bridges to process; if a particular bridge is included in a bridge sample, all faults associated with that bridge are included.

Arguments

- **Off**

A switch that turns off fault sampling. This is the invocation default.

- *percentage*

A required, positive number that specifies the fault sampling percentage used for circuit evaluation or scan identification. Any number greater than 0 and less than or equal to 100 can be specified. The default is 100.

- -Seed *integer*

A switch and hex number pair that specifies a seed value to use in the selection of fault samples. Specifying unique seed values for different runs can provide more accurate fault sampling results. The number value must be a lower case, 32-bit hex representation. 0 is not a valid seed value. The default is 0XCCCCCCCC.

Examples

Example 1

The following example performs a trial ATPG run in Tessent FastScan using a fault sampling of one percent of the total faults. Because the set_fault_sampling command overwrites parts of the

original fault list, after the test run the example restores the fault list to the state it was in prior to the set_fault_sampling command:

```
set_system_mode analysis
add_faults -all
set_fault_sampling 1
create_patterns
delete_faults -all
set_fault_sampling 100
add_faults -all
```

Example 2

The following example performs the trial ATPG run, as in the preceding example, but uses faults from an external fault file named my_fault_file. The example then recovers from the set_fault_sampling command by clearing the internal fault list and reloading faults from the external file:

```
set_system_mode analysis
read_faults my_fault_file
set_fault_sampling 1
create_patterns
delete_faults -all
set_fault_sampling 100
read_faults my_fault_file
```

[write_faults](#)

set_fault_subclass_analysis

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Turns on or off the analysis for the specified fault class(es).

Usage

```
set_fault_subclass_analysis {-Enable | -Disable} {fault_class ... }
```

Description

Turns on or off the analysis for the specified fault class(es).

The **set_fault_subclass_analysis** command supports all of the fault classes and sub-classes supported by the [set_relevant_coverage](#) command, as well as the DI.EDT fault sub-class. To enable the analysis of a class of faults, you must issue this command *before* adding the faults.

By default, AU and DI sub-classes analysis are enabled; in fact, there is no way to disable any DI sub-class other than DI.EDT. By default, the DI.EDT fault sub-class is enabled unless you have turned off EDT Finder (in which case, you cannot enable the DI.EDT fault sub-class). You can override this default and disable DI.EDT analysis. For more information about EDT Finder, refer to the [set_edt_finder](#) command.

You can use the [set_relevant_coverage](#) command to add or remove the AU and UU fault classes from the relevant test coverage reported by the tool. The UU sub-class is automatically enabled using the [set_relevant_coverage](#) command as shown in “[Example 2](#)” on page 2123. When enabled, the UU sub-class analysis is performed only for stuck, transition, and bridge fault types.

Note that AU.EDT and AU.FP sub-classes are enabled by default only if the tool can identify the EDT-related faults and false path faults. The tool can identify EDT-related faults if the EDT logic was generated with the default name or if you specified the naming of the EDT module. The tool can identify false path faults if you defined them using the [add_false_paths](#) command, or if you read the SDC file into the tool.

For more information about fault sub-classes, refer to “[Fault Sub-classes](#)” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- **-Enable**
Switch that enables analysis for the specified fault class.
- **-Disable**
Switch that disables analysis for the specified fault class. Note that there is no way to disable any DI sub-class other than DI.EDT.

- *{fault_class ... }*

Repeatable string that specifies the fault class or the DI.EDT fault sub-class. [Table 6-18](#) on page 2346 lists the fault classes that can be specified with this command. You can specify a fault class either by name or code.

Examples

Example 1

The following example shows the [report_statistics](#) output when UU faults are classified into two sub-classes. Note, the `set_fault_subclass_analysis` command is issued first to enable UU analysis prior to adding faults.

```
SETUP> set_fault_subclass_analysis -enable UU
SETUP> set_system_mode analysis
...
ANALYSIS> add_faults -all
ANALYSIS> report_statistics

[report_statistics](#)
[set_relevant_coverage](#)

set_fault_type

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies the fault model type for ATPG.

Usage

```
set_fault_type {  
    Stuck  
    | TOGGLE  
    | {Iddq [-NO_SEquential_inputs_blocked | -SEquential_inputs_blocked]  
        | [-ALLOW_IDDQ_MEASURE_when_clock_active {ON | OFF}]}  
    | {Transition [-ALLOW_Shift_launch]  
        [-APPLY_HOLD_PI_attribute_to_shift_launch {ON | OFF}]}  
    | {Path_delay [-Mask_nonobservation_points] [-ROBust_detection_only]  
        | [-NO_Functional_detection] [-HAZARD_free_robust_detections]}  
    | Bridge  
    | {Udfm [-STATIC_faults]}  
    | {Udfm -DELAY_faults [-ALLOW_Shift_launch]  
        [-APPLY_HOLD_PI_attribute_to_shift_launch {ON | OFF}]}  
    | {Udfm -IDDQ_faults [-NO_SEquential_inputs_blocked | -SEquential_inputs_blocked]  
        | [-ALLOW_IDDQ_MEASURE_when_clock_active {ON | OFF}]}  
}
```

Description

Specifies the fault model type for ATPG.

The fault sites of all models are the input and output pins of the design cells in addition to external pins. 0 and 1 values are used to indicate the type of fault at the fault site for all fault models. Each fault model has its own separate fault collapsing according to the model's rules of equivalence.

When you change the fault type, both the current fault list and the internal pattern set are deleted.

Use the [set_multiple_detection](#) command to set the number of detections for each fault.

For more information on the different fault models, refer to the [Tessent Scan and ATPG User's Manual](#).

Arguments

- **Stuck**

A literal that specifies the single stuck-at fault model. This is the default upon invocation of the tool.

- TOGGLE

A literal that specifies the toggle fault model. The tool supports multiple detection for the toggle fault type. If you are using a legacy simulator, the tool will issue an error to indicate that it does not support toggle multiple detection.

- Iddq [-NO_SEquential_inputs_blocked] -SEquential_inputs_blocked | -ALLOW_IDDQ_MEASURE_when_clock_active {ON | OFF}]

Optional literal and switch pair that specifies the Iddq fault model. Optional switches that control the treatment of Iddq faults include:

-NO_SEquential_inputs_blocked — An optional switch that specifies a pseudo-stuck-at model and prevents *a priori* categorization of faults as BLocked, which must propagate through sequential primitives. This can allow creation of test patterns that would not otherwise be created, and can improve defect coverage. The additional tests created can improve defect coverage, especially for Iddq-detectable defects in scan cells. This is the default.

For the pseudo-stuck-at model, many faults are marked BLocked during pre-analysis. This is done for cells where the tool cannot predict the transistors inside the cell and cannot know how to observe to a cell output, such as a Ram cell. Such faults are not considered part of the fault population and do not show as undetected for test_coverage.

-SEquential_inputs_blocked — An optional switch that specifies a pseudo-stuck-at model and that retains historical behavior of *a priori* categorization of faults as BLocked which must be observed by propagation into or through a sequential primitive, such as a SL in a scan cell.

For the pseudo-stuck-at model, many faults are marked BLocked during pre-analysis. This is done for cells where the tool cannot predict the transistors inside the cell and cannot know how to observe to a cell output, such as a Ram cell. Such faults are not considered part of the fault population and do not show as undetected for test_coverage.

-ALLOW_IDDQ_MEASURE_when_clock_active ON | OFF — An optional switch and literal pair that specifies the tool is allowed to measure Iddq when the clock(s) is active while generating Iddq patterns. This switch is on by default.

Note

 The -no_sequential_inputs_blocked, -sequential_inputs_blocked, and -allow_iddq_measure_when_clock_active switches behave the same for the UDFM fault model as for IDDQ faults.

The tool supports multiple detection for the IDDQ fault type. If you are using a legacy simulator, the tool will issue an error to indicate that it does not support IDDQ multiple detection.

- **T**ransition

A literal that specifies the transition fault model. The default behavior prevents the tool from creating transition tests that launch off of the last shift when it is unable to generate clock sequential tests. It will only consider generating transition patterns that launch in some cycle after the shift is completed (broadside).

Note

 By default, the transition option does not prevent the tool from asserting the scan enable signal during at-speed tests. You must use other means (scan_enable pin constraint or capture procedure, for example) to prevent inappropriate assertion of the scan enable pin during the at-speed part of a multiple cycle sequential transition fault test.

The default behavior described applies to “udfm -delay_faults” and transition fault types.

- **-ALLOW_Shift_launch**

An optional switch, available for transition faults and “udfm -delay_faults”, used to enable the generation of native launch-off-shift (LOS) patterns where the transition is launched by the last shift cycle of the scan load operation. It is only practical to use when the clock(s) are controlled directly from the primary inputs and not from an on-chip source such as a PLL. Since using a PLL as the internal clock source for at-speed test is very common, you will rarely use this switch.

Even without using the -allow_shift_launch switch, a test pattern may launch a transition fault through a shift operation. For example, the tool may generate a 2-cycle transition test pattern with the scan_enable asserted in the first capture cycle to launch the transition of the targeted fault and de-asserted in the second cycle for capture. This is referred to as pseudo-LOS. Unless you have designed your scan_enable to allow at-speed transition of this signal (for example, through pipelining), you will normally not want ATPG to generate this type of pattern. To prevent generating pseudo-LOS patterns, you need to constrain scan_enable to 0.

- **-APPLY_HOLD_PI_attribute_to_shift_launch ON | OFF**

An optional switch and literal pair that determines if the hold attribute defined at primary inputs for launch-off-shift patterns is used. The default for this switch is ON.

During test generation for launch-off-shift patterns, the tool forces primary inputs with hold attribute to have the same value as the value in the last shift cycle except for the following conditions:

- The PI is a clock pin or a read/write control pin.
- The PI is explicitly forced in the last shift cycle by load/unload and/or shift procedures and the forced value is not the same as the pin constraint value if there is any.
- All scan input pins will be treated as TIE-X during test pattern generation.

For these exception pins, the tool ignores the hold attribute defined at these pins.

- **Path_delay**

A literal that specifies the path delay fault model.

- **-Mask_nonobservation_points**

An optional switch that masks all non-observation points so path delay patterns are generated with values only at observation points. If there is already an internal pattern set in the tool and the fault type is already set to path delay, re-issuing the command with this switch alters the internal pattern response values by masking the non-observation points. If this switch was specified previously when setting the fault type to Path_delay, re-issuing the command without the switch causes the tool to re-simulate the internal patterns to restore the capture values at the non-observation points.

- **-ROBust_detection_only**

An optional switch that generates only robust tests for path delay faults. By default, the tool first tries to detect a path delay fault using a robust test, but if unable to generate a robust test, will use a non-robust test or a functional test. This switch overrides the default behavior, forcing the tool to use only robust tests. If you include this switch, the tool will classify as ATPG_untestable (AU) all path delay faults that can only be tested non-robustly or functionally. For more information about robust, non-robust, functional, and hazard-free detections, refer to “[Path Delay Fault Detection](#)” in the *Tessent Scan and ATPG User’s Manual*.

Note

 This switch is not cumulative; you must include it with each subsequent set_fault_type command or the tool returns to the default behavior.

- **-NO_Functional_detection**

An optional switch that disables the generation of functional tests for path delay faults. By default, the tool first tries to detect a path delay fault using a robust test, but if unable to generate a robust test, will use a non-robust test or a functional test. This switch overrides the default behavior, forcing the tool to use robust tests or non-robust tests, but not functional tests. If you include this switch, the tool will classify as ATPG_untestable (AU) all path delay faults that can only be tested with functional tests. For more information about robust, non-robust, functional, and hazard-free detections, refer to “[Path Delay Fault Detection](#)” in the *Tessent Scan and ATPG User’s Manual*.

Note

 This switch is not cumulative; you must include it with each subsequent set_fault_type command or the tool returns to the default behavior.

- **-HAZARD_free_robust_detections**

An optional switch that specifies that the tool holds off-path inputs of the gates in a stable state when it propagates the transition through the path. When creating robust path delay patterns, this switch provides a delay test with additional restrictions than when just using

the `-robust_detection_only` switch. This switch can be used with the `-robust_detection_only` switch to guarantee that any robust detection patterns created by the tool are hazard-free.

Hazard-free robust detections reduce the chance of glitches because the output arrival time is not hampered by the arrival time of the off-path input. For more information about robust, non-robust, functional, and hazard-free detections, refer to “[Path Delay Fault Detection](#)” in the *Tessent Scan and ATPG User’s Manual*.

- **Bridge**
A literal that specifies the static bridge fault model.
- **Udfm**
Optional literal that specifies a user-defined fault model (UDFM).
- **-STATIC_faults**
Optional literal that enables static faults only. This is the default.
- **-DELAY_faults**
Optional literal that enables delay faults only. Optional switch details are described in the [Transition](#) fault model argument description.
- **-IDQ_faults**
Optional literal that enables IDQ faults only. Optional switch details are described in the [Idq](#) fault model argument description.

Examples

Example 1

The following example performs ATPG using the stuck fault model:

```
set_system_mode analysis
set_fault_type stuck
create_patterns
```

Example 2

The following example performs ATPG with the transition fault model and, by default, prevents the tool from generating basic combinational patterns that launch off the last shift:

```
set_system_mode analysis
set_fault_type transition
create_patterns
```

Example 3

The next patterns -scan example performs ATPG with the transition fault model, specifying to target three detections per fault during pattern generation, and to detect each DS fault three times during simulation before dropping it from the fault list. Data resulting from the multiple detection setting is highlighted in bold.

Tip

- i** When multiple detection is enabled, the number shown in the “#faults in list” column in the transcript is the cumulative tally of faults not yet detected the specified number of times. When multiple detection is not enabled, this column lists the number of faults not yet detected once. In either case, the “test cvrg” and “#faults detected” columns refer to faults detected at least once.
-

```
set_system_mode analysis
set_fault_type transition
set_multiple_detection -guaranteed_atpg_detections 3
set_pattern_type -sequential 2
create_patterns
```

```

Example 4

The next example performs ATPG with the path delay fault model and only robust detection patterns. The example then repeats the pattern creation run after enabling the tool to use both robust and non-robust detection patterns. Be aware that when you change the type of test the tool can use to detect path delay faults, the tool automatically resets all AU faults identified in the preceding pattern creation run.

```

set_system_mode analysis
set_fault_type path_delay -robust_detection_only
read_faults my_path_delay_faultlist
create_patterns
...
set_fault_type path_delay -no_functional_detection
create_patterns

```

Example 5

The following example generates launch-off-shift patterns by holding all PIs:

```
set_pattern_type -sequential 0 -ram_sequential off
add_input_constraints -hold -all
set_fault_type transition -apply_hold_pi_attribute_to_shift_launch on
create_patterns
```

Example 6

The following example sets the UDFM as the current fault type:

```
set_fault_type udfm
```

set_flattener_rule_handling

Context: unspecified, all contexts

Mode: setup

Specifies how the tool globally handles flattening violations.

Usage

```
set_flattener_rule_handling rule_id [Error | Warning | NOTE | Ignore] [Verbose | Noverbose]
```

Description

Specifies how the tool globally handles flattening violations.

The set_flattener_rule_handling command specifies the handling of the messages for net checking, pin checking, and gate checking. You can specify that the violation messages for these checks be either error, warning, note, or ignore. If you do not specify error, warning, note, or ignore, then the tool uses either the handling from the last set_flattener_rule_handling command or, if you have not changed the handling, the initial invocation setting as specified in the following list of rules.

Each rules violation has an associated occurrence message and summary message. The tool displays the occurrence message only for either error conditions or if you specify the Verbose option for that rule. The tool displays the rule identification number in all rules violation messages.

Arguments

- ***rule_id***

A required, non-repeatable literal that specifies the identification of the exact flattening rule violations whose message handling you want to change.

The flattening rule violations and their identification literals are divided into the following three groups: net, pin, and gate rules violation IDs.

- Net flattening violations are described in sections “[FN1](#)” through “[FN9](#)”.
- Pin flattening violations are described in sections “[FP1](#)” through “[FP13](#)”.
- Gate flattening violations are described in sections “[FG1](#)” through “[FG8](#)”.

- **Error**

An optional literal that specifies for the tool to display both the error occurrence message and immediately terminate the rules checking.

If you do not specify the Error, Warning, Note, or Ignore option, then the tool uses either the handling from the last set_flattener_rule_handling command or, if you have not changed the handling, the tool uses the initial invocation setting.

- Warning

An optional literal that specifies for the tool to display the warning summary message indicating the number of times the rule was violated. If you also specify the Verbose option, the tool displays the occurrence message for each occurrence of the rules violation.

If you do not specify the Error, Warning, Note, or Ignore option, then the tool uses either the handling from the last set_flattener_rule_handling command or, if you have not changed the handling, the tool uses the initial invocation setting.

- NOTE

An optional literal that specifies for the tool to display the summary message indicating the number of violations for that rule. If you also specify the Verbose option, the tool also displays the occurrence message for each occurrence of the rules violation.

If you do not specify the Error, Warning, Note, or Ignore option, then the tool uses either the handling from the last set_flattener_rule_handling command or, if you have not changed the handling, the tool uses the initial invocation setting.

- Ignore

An optional literal that specifies for the tool to not display any message for the rule's violations. The tool must still enforce some rules and they must pass to allow certain functions to be performed later.

If you do not specify the Error, Warning, Note, or Ignore option, then the tool uses either the handling from the last set_flattener_rule_handling command or, if you have not changed the handling, the tool uses the initial invocation setting.

- NOVerbose

An optional literal that specifies for the tool to display the occurrence message only once for the rules violation and give a summary of the number of violations.

If you do not specify the Noverbose or Verbose option, then the tool uses either the handling from the last set_flattener_rule_handling command or, if you have not changed the handling, the tool uses the initial invocation setting.

- Verbose

An optional literal that specifies for the tool to display the occurrence message for each occurrence of the rules violation.

If you do not specify the Noverbose or Verbose option, then the tool uses either the handling from the last set_flattener_rule_handling command or, if you have not changed the handling, the tool uses the initial invocation setting.

Examples

The following example changes the handling of the FG7 flattening rule to warning and specifies that each occurrence should be listed:

```
set_flattener_rule_handling fg7 warning -verbose
```

[set_drc_handling](#)

set_gate_level

Context: unspecified, all contexts

Mode: setup, analysis

Specifies the hierarchical level of gate reporting and displaying.

Usage

`set_gate_level Primitive | Design`

Description

Specifies the hierarchical level of gate reporting and displaying.

The `set_gate_level` command specifies the hierarchical gate level at which the tool operates. This includes the reporting and schematic display of gate information. Once you set the gate level, the tool processes all subsequent commands using the new gate level.

Whenever you issue a command which invalidates the flat model, the tool also invalidates the hierarchical gate display structure. This causes DFTVisualizer to clear the schematic view area. You can rebuild the hierarchical gate structure by creating a new flat model. To do so, either enter and exit the Setup mode, or use the [create_flat_model](#) command.

Arguments

- **Primitive**

A literal that specifies to display gate information at the built-in primitive gate level.

- **Design**

A literal that specifies to display gate information at the design library hierarchical gate level. These are the top-level cells of the design library which are instantiated in your design. This is the default upon invocation of the tool.

Note

DFTVisualizer shows gate identification numbers (ID#s) with displayed instances only if the design level is set to Primitive.

Examples

The following example sets the gate report level so that reporting and display show the simulated values of the gate and its inputs (assuming a rules checking error occurred when exiting the Setup system mode):

```
set_system_mode analysis
set_gate_level primitive
set_gate_report error_pattern
report_gates i_1006/o
```

  STate_stability | STABle_after_setup | STABle_Capture | STABle_Load_unload
  | STABle_Shift [time | -All]} } | {DELay_data {LOcal_delay_data
  | STATIC_Arrival_time | STATIC_Propagation_time | STATIC_Slack
  | STATIC_PAth_delay | ACTUAL_Arrival_time pattern_number
  [-Internal | -External] | ACTUAL_Propagation_time pattern_number
  [-Internal | -External] | ACTUAL_Slack pattern_number [-Internal | -External] |
  ACTUAL_PAth_delay pattern_number [-Internal | -External]} }
  [-Timing_exceptions {ON | OFF}] [-COnstrain_value {ON | OFF}] [-MAX_Fanouts
  {number | UNlimited}] [-CLOCK_domains_in_capture_cycles {ON|OFF}]
```

When EDT is On

```
set_gate_report Normal | SImulation_context | Trace | Error_pattern |
  {PATtern_index pattern_index [-Internal | -External] [-SCan_test | -CHain_test]} |
  {Parallel_pattern pattern_number} | Fault_status | Test_data | TlE_value |
  SEq_depth_data | {Clock_cone pin_name} |
  {CAPTURE_PROCedure named_capture_procedure} |
  {Drc_pattern {{Test_setup | TEST_End} [{-Cycle | -Time} n1 [n2 | End]}}}
  | {Load_unload | SHIft | SKew_load | SHADOW_Control |
  Master_observe | SHADOW_Observe | STState_stability | STABle_after_setup |
  STABle_Capture | STABle_Load_unload | STABle_Shift [time | -All]} |
  {K19 [-Initial | -FIRst_random | -SECond_random |-Post_capture |
  -Low_power lp_sim#] [-All | Load_unload | {Shift [-All | cycle [cycle]]}]} | {K22 [-Mask
  {No_mask | mask#}] [-All | Load_unload | {Shift [-All | cycle [cycle]]}] | F_rule_name}
  | DELay_data {LOcal_delay_data | STATIC_Arrival_time |
  STATIC_Propagation_time | STATIC_Slack | STATIC_PAth_delay |
  ACTUAL_Arrival_time pattern_number [-Internal | -External]
  | ACTUAL_Propagation_time pattern_number [-Internal | -External] |
  ACTUAL_Slack pattern_number [-Internal | -External]} |
```

ACTUAL_PATH_delay pattern_number [-Internal | -External]}}
[-Timing_exceptions {ON | OFF}] [-COnstrain_value {ON | OFF}]
[-CLOCK_domains_in_capture_cycles {ON|OFF}] [-MAX_Fanouts {number | UNlimited}]

For dft -scan

```
set_gate_report Normal | Trace | Error_pattern | TlE_value | {Drc_pattern {{Test_setup  
[{{-Cycle | -Time} n1} [n2 | End]]}} | Load_unload | SHIft | SKew_load |  
SHADOW_Control | Master_observe | SHADOW_Observe | STate_stability  
| STABle_after_setup | STABLE_Capture | STABLE_Load_unload | STABLE_Shift}  
[-All | time]} [-CLOCK_domains_in_capture_cycles {ON|OFF}]  
[-MAX_Fanouts {number | UNlimited}]
```

Description

Specifies the information displayed by the report_gates command and the DFTVisualizer schematic windows.

When you exit the Setup system mode, the trace and any rules-checking error pattern results will not be available with this command. For information on the format output by the different options in this command, refer to the [report_gates](#) command description.

The data field of the report created by the report_gates command displays one character for each event within the cycle.

Note

 When EDT is On, the tool does not explicitly simulate the EDT logic during scan loading and capture cycles. Therefore, report_gates cannot report simulation values for the EDT logic during these cycles regardless of the option set with the set_gate_report command.

Arguments

- **Normal**

A literal that specifies for the report_gates command to display only its standard information. This is the default mode upon invocation of the tool.

- **simulation_context**

A literal that specifies for the report_gates command to display the simulated values from the current simulation context. Refer to “[Example 11](#)” on page 2169.

- **Trace**

A literal that specifies for the report_gates command to display the simulated values of the gates during the scan chain tracing. The format of these values depends on the contents of the shift procedure. If the shift procedure contains additional frames, the additional frames will also be displayed in the gate report data. The trace data relates to the simulation performed during the scan chain tracing. Use the Trace option to determine why a scan chain was not properly sensitized during the shift procedure.

Using this option will display scan path “don’t cares” as an S in the gate report to distinguish them from non-scan path “don’t cares” which display as X.

For an example of the information displayed, refer to “[Example 2](#)” on page 2156.

- **Error_pattern**

A literal that specifies for the report_gates command to display the simulated value of the gates and its inputs for the pattern at which an audit error occurred.

- **PATtern_index pattern_index [-Internal | -External] [-SCan_test | -CHain_test]**

A literal, integer, and optional switch triplet that specifies the pattern the [report_gates](#) command uses when displaying the value of a gate. The *pattern_index* must be a non-negative integer.

When reporting a sequential element, the gate report also displays in a pair of brackets ([]) at each output of the element. For non-scan elements, this is the value that resulted from capture and always matches the simulation value in the last frame. For scan elements, this value is the scan cell unload value, which may be different than the capture value (for example, for EDT masking values or cell constraints). For a multicycle pattern, the captured value is reported for the last cycle only, since for cycles that precede the last cycle, the captured value is already shown in the last frame.

The bracketed value is useful because it gives you a direct view of the results of good machine simulation, which sometimes changes the value captured in the last cycle such as the examples mentioned in the previous paragraph.

Glitch Reporting

When a leading-edge DFF clock is gating a leading-edge DFF structure, the tool displays the glitch on the CLK line as 0(1)00 and lets the downstream DFF capture. For example:

```
//  /sff9_pulse_inter (366)  DFF
//    "S"      I  (000-000)  188-
//    "R"      I  (000-000)  32-
//    CLK     I  (010-0(1)00)  298-/AND02_pulse_inter/Y
//    "D0"    I  (000-111)  284-
//    "OUT"   O  (100-011-[1])  152-  153-
```

The glitch 0(1)00 on the clock only shows up as the input pin values of the state element. The glitch does not show up as the output value of the clock driver.

False Path Reporting

The tool indicates in the pattern report if a false path is defined. One possible example is “1(X0)0”. The (X0) values in 1(X0)0 indicate that at the beginning of the second frame (leading edge frame), the value is unstable. The instability is due to the hold time effect, and the X occurs due to the leading edge (LE) clock event on the false path source flop FF. Because the LE clock event occurs at the second frame, (X0) are to indicate the value these are the values at the LE frame.

Primitive or Design Level Gate Reporting

Depending on whether the tool is set up for primitive or design level gate reporting, you may see additional information as follows (use the [report_environment](#) command to check the current gate level):

- Primitive level ([set_gate_level](#) Primitive):

If the sequential element you report on is part of a scan cell and the value captured by the element is not what is observed/unloaded from the scan cell for that particular pattern, the display shows “Unobs” next to the captured value and explanatory text is included indicating which element *is* observed for that scan cell and that pattern. “Unobs” and extra explanatory text is displayed, for example, if you report on the slave latch within an LSSD scan cell and the test procedure file includes a master_observe procedure (the slave is not observed when a master_observe procedure exists).

Note

 When reporting gates at the primitive level, the tool displays captured/unload values only for the outputs of DFF and LA primitives, both scan and non-scan. Captured/unload values are not reported for transparent latches (TLAs).

- Design level ([set_gate_level](#) Design):

If the sequential element you report on is a scan cell and an output value resulting from capture does not correspond to what is observed/unloaded from the scan cell for that particular pattern, the display shows “Unobs” next to the captured value. Explanatory text is not displayed for these “Unobs” values.

For examples of captured/unload displays for different scan cells and reporting levels (primitive or design), see the Examples section.

If, after setting the gate report with this option, you alter the tool environment, be sure to reissue the “set_gate_report” command. This will cause the tool to re-simulate the patterns, ensuring the values reported for a gate are up to date with the latest tool settings.

You can select from four pattern sources as specified here:

- Internal — An optional switch that specifies use of the tool’s internal pattern set. This is the default.
- External — An optional switch that specifies use of the tool’s external pattern set.
- Scan_test — An optional switch that specifies the report of the scan test pattern.
- Chain_test — An optional switch that specifies the report of the chain test pattern.

Together with the *pattern_index* argument, your option selection specifies the exact pattern to be reported as shown in [Table 6-9](#).

Table 6-9. Pattern Sources

Display Pattern Type	scan_test	chain_test
internal	internal scan pattern (default)	internal chain pattern

Table 6-9. Pattern Sources (cont.)

Display Pattern Type	scan_test	chain_test
external	external scan pattern	external chain pattern

- **VCD *time_value***

A literal and numerical pair that sets the gate report source to the VCD file used with the [analyze_simulation_mismatches](#) command. The Verilog simulation values after the specified simulation *time_value* can be seen using the [report_gates](#) command.

The possible reported values are:

- 0 — Logic 0
- 1 — Logic 1
- Z — Tristate
- X — Unknown
- U — Unused
- . — No VCD data

- **Parallel_pattern *pattern_number***

Note

 Use this option only if another command directs you to use it; for example, the [analyze_bus](#) command might transcript a message that explicitly says to use “set_gate_report parallel_pattern 0”. If you use this option, be sure [report_gates](#) is the first command you enter after simulation; bogus simulation values may be reported if you enter any other tool command after simulation, but before you [report_gates](#). The *Pattern_index* argument is the recommended way to specify a pattern for the [report_gates](#) command to use when displaying the value of a gate.

A literal and integer pair that specifies the pattern number from the last simulation pass that you want the [report_gates](#) command to use when displaying the value of a gate. The *pattern_number* must be an integer between 0 and 63.

When reporting a sequential element, the gate report also displays in a pair of brackets ([]) at each output of the element. For non-scan elements, this is the value that resulted from capture and always matches the simulation value in the last frame. For scan elements, this value is the scan cell unload value, which may be different than the capture value (for example, for EDT masking values or cell constraints). For a multicycle pattern, the captured value is reported for the last cycle only, since for cycles that precede the last cycle, the captured value is already shown in the last frame.

The bracketed value is useful because it gives you a direct view of the results of good machine simulation, which sometimes changes the value captured in the last cycle such as the examples mentioned in the previous paragraph.

- **Fault_status**

A literal that specifies for fault detection status of all gates to be preserved. Subsequent commands that cause the gate to be displayed will annotate the pins with fault status data. If a schematic is currently displayed in a DFTVisualizer schematic window and you change the gate report data (by issuing the [set_gate_report](#) command), all fault sites will be annotated with their fault detection status.

Note that this switch is not valid for the bridge logic fault model.

The format of the fault status data is as follows:

<sa0-status:sa1-status> — for stuck-at faults

<slow_to_rise-status:slow_to_fall-status> — for transition faults

where sa0-status and sa1-status are one of the following:

DS — Detected by simulation

DI — Detected by implication

PU — Possible detect untestable

PT — Possible detect testable

AU — Atpg untestable

UC — Undetected uncontrolled

UO — Undetected unobserved

UU — Untestable unused

BL — Untestable blocked

TI — Untestable tied

RE — Untestable redundant

F — Recognized fault site, but no fault has been added yet

N — Site isnofaulted; either because the fault site is inside a library model and internal faults are off, or because a user hasnofaulted it with the [add_nofaults](#) command

“-” — Nothing known about this pin; used for pins created by the flattening process or pins that are not fault sites (for example, the pins of an unnamed internal instance of a library cell)

When you use the Fault_status option, subsequent [report_gates](#) commands display the fault sub-class for untestable faults (AU/UC/UO). For a complete list of these fault sub-classes, see [Table 6-18](#).

The DFTVisualizer command, [report_display_instances](#), will report the fault detection status in the tool transcript.

- **Test_data**

A literal that specifies for the [report_gates](#) command to display previously-calculated control and observe values. To set the Test_data option, you must do so prior to rules

checking, and you must re-execute the design rules checking process; otherwise, no data (-) from this option will be available for gate reporting.

This option is primarily for logic BIST purposes (when inserting control and observation points). The data for each pin of a reported gate consists of three integers indicating how many times the pin was controllable to 0, how many times it was controllable to 1, and how many times it was observable during the preceding analysis. The data is displayed in the following format:

(# of times controlled to 0-# of times controlled to 1, # of times observed)

Note

 When the Test_data option is in effect, the [report_environment](#) command will show “BIST data” as the current gate report setting.

- **TIE_value**

A literal that specifies for the report_gates command to display the simulated values that result from all natural, tied gates and learned constant value non-scan cells.

Tie_value is available at any time the flat model exists. The value displayed on the TIE node is set by simulation. All internal nodes are initially set to X for simulation. Subsequently, ATPG or various commands may put values on the nodes. Occasionally, a set of circumstances may occur where an X shows up on a TIE node.

During operation, ATPG typically marks for simulation only those gates which are of interest for sensitization and propagation of a particular fault. If a gate is not marked, it will not be simulated, and any nodes associated with it may remain at an “X” value, even though they are connected to a TIE gate.

While tie_value reports the status of node values once it comes out of the DRC checks, the constrain_value tells you what the gate is suppose to act like for future consideration.

- **SEQ_depth_data**

A literal that specifies for the report_gates command to display the calculated gate sequential depths.

When you select a non-zero sequential depth, the tool performs a learning process to identify the minimum depths necessary to satisfy controllability and observability requirements for all gates using the current clock_sequential cells. The tool calculates both the 0-state and 1-state controllability depths. At the end of the analysis, the tool displays a summary message that indicates the largest sequential test depth, along with the largest control and observe depth. The test generator uses the sequential depth information in making decisions and avoiding paths whose sequential depth exceeds the maximum allowed sequential depth.

The report_gates command includes three values separated by a comma and a dash. The first value is the 0-state controllability depth, the second value is the 1-state controllability depth, and the third value is the observability depth. The maximum reported depth is 255. If

controllability or observability is logically impossible or exceeds 255, the report displays an asterisk (*) in the corresponding fields.

- **Clock_cone pin_name**

A literal and string pair that specifies the clock pin for which the report_gates command displays the clock cone data.

The clock cone data from the report_gates command is the same data that is available as error data for clock rules violations. You can only use this option after flattening the simulation model using the [create_flat_model](#) command.

The *pin_name* must be a valid clock pin or an error condition occurs. For example:

```
set_gate_report clock_cone {{\atpgclk[0] }}
```

The tool considers the pin equivalents when calculating the clock cones. State elements that the tool identifies as capturing on the clock's trailing edge will not propagate the clock effect cone. During the Setup system mode, this information is not available and the tool assumes all state elements capture with the leading edge of the selected clock.

When you try to report gates with the *clock_cone* source selected and the clock cone data is no longer present, the tool issues a warning message and sets the gate report source to the default before executing the command. This can happen, for instance, when you re-read the design or issue another command that causes the flat model to be regenerated. This is the warning:

```
// Warning: The precomputed clock cone data is no longer available.  
// Resetting the gate reporting mode.  
// Please reissue the set_gate_report command to see clock  
// cone data.
```

- **CAPTURE_PROCedure named_capture_procedure**

A literal that reports the value at each gate implied by forced and conditional assignments defined in the named capture procedure (NCP). This is useful for debugging NCP-specific issues like the inability to detect a fault or prevent bus contention.

- **Drc_pattern procedure_name [-All | time]**

Two literals and an optional time triplet that specifies the name of the procedure and the time in the test procedure file that the report_gates command uses to display a gate's simulated value.

The valid literal choices for the *procedure_name* option (for use with Drc_pattern) are as follows:

Test_setup — A literal that specifies the use of the test_setup procedure. In the test procedure file, this procedure sets non-scan elements to the state you desire for the **load_unload** procedure. The tool uses the entire test_setup procedure unless you restrict the report to a certain portion using the -Cycle or -Time switch. In order to conserve screen width, time values are listed vertically in Test_setup gate reports.

TEST_End — A literal that specifies the use of the test_end procedure. In the test procedure file, test_end is used to add a sequence of events to the end of a test pattern

set. The tool uses the entire test_end procedure. In order to conserve screen width, time values are listed vertically in test_end gate reports.

-Cycle — A switch that indicates *n1* is a cycle number and specifies to start the report at cycle *n1*.

-Time — A switch that indicates *n1* is a time and specifies to start the report at time *n1*. The time units are based on the timescale defined in the test procedure file, which by default is 1 nanosecond.

n1 — An integer that specifies a cycle or time at which to start reporting. When used with the -Time switch, *n1* specifies a time. When used with the -Cycle switch, *n1* specifies a cycle. The tool numbers cycles beginning with 0; so, for example, to specify the second cycle, you would use “-cycle 1”.

n2 — An optional integer that specifies to report from cycle (or time) *n1* to cycle (or time) *n2* and stop reporting.

End — An optional literal that specifies to report from cycle (or time) *n1* to the end of the test_setup procedure.

Note

 When using the -Cycle or -Time switch, if you do not include either the *n2* or End argument, gate reports will show data for only the *n1* cycle (or time).

Load_unload — A literal that specifies the use of the load_unload procedure. The test procedure file must contain this procedure, which describes how to load and unload data in the scan chains.

Shift — A literal that specifies the use of the shift procedure. The test procedure file must contain this procedure, which describes how to shift data one position down the scan chain.

Using this option will display scan path “don’t cares” as S in the gate report to distinguish them from non-scan path “don’t cares” which display as X.

The data in the report created by report_gates for shift data normally has three values, but if the procedure file defines four events, report_gates reports four values. One example may be when the force_pi occurs at some other time than at the beginning of the cycle. See [Example 15](#).

Skew_load — A literal that specifies the use of the skew_load procedure. In the test procedure file, this procedure describes how to propagate the output value of the preceding scan cell into the master memory element of the current cell (without changing the slave), for all scan cells.

SHADOW_Control — A literal that specifies the use of the shadow_control procedure. In the test procedure file, this procedure describes how to load the contents of a scan cell into the associated shadow.

Master_observe — A literal that specifies the use of the master_observe procedure. In the test procedure file, this procedure describes how to place the contents of a master into the output of its scan cell.

SHADOW_Observe — A literal that specifies the use of the shadow observe procedure. In the test procedure file, this procedure describes how to place the contents of a shadow into the output of its scan cell.

STate_stability — A literal that specifies the display of the simulation values for the **load_unload** procedure and the capture clock cycle that the tool used to determine the constant value state elements at the initial load time. The report separates the **shift** procedure values, **load_unload** procedure values, and the capture clock cycle with parentheses. This format provides information that is helpful when you are trying to debug boundary scan.

Note

 Only the simulation values for the first **load_unload** procedure that follows the **test_setup** procedure are displayed. Use the **load_unload** literal to display the final stable values in the **load_unload** procedure.

The **state_stability** option is not a procedure.

For detailed information about state stability reporting, refer to the “[State Stability Issues](#)” appendix in the *Tessent Scan and ATPG User’s Manual*.

STABLE_Capture — A literal that specifies the display of the values that are constant throughout the capture procedures.

0, 1, or Z — Indicates a constant value exists throughout the capture cycles.

X — Indicates a constant value does not exist throughout the capture cycles.

STABLE_Load_unload — A literal that specifies the display of the values that are constant throughout the **load_unload** cycles.

0, 1, or Z — Indicates a constant value exists throughout the **load_unload** cycles.

X — Indicates a constant value does not exist throughout the **load_unload** cycles.

STABLE_Shift — A literal that specifies the display of values that are constant throughout the shift cycles.

0, 1, or Z — Indicates a constant value exists throughout the shift cycles.

X — Indicates a constant value does not exist throughout the shift cycles.

STABLE_after_setup — A literal that specifies the display of the values that are constant in the period following the end of the **test_setup** procedure and the beginning of the **test_end** procedure. For scan patterns, the value is constant throughout scan and capture cycles. For ijtag patterns, the value is constant throughout any ijtag operations.

If a **load_unload** procedure exists, the values established at the end of **test_setup** are verified for stability using the **add_input_constraints -c1** and **c0** values which are also forced to a constant value during the **load_unload** procedure.

If a **load_unload** procedure does not exist, as in the ijtag context, stability analysis is only performed with the **add_input_constraints -c1** and **-c0** values.

0, 1, or Z — Indicates a constant value exists at the end of test_setup and is maintained for all subsequent events up to the beginning of test_end, if one exists, or through the end of the test if test_end does not exist.

X — Indicates a constant value does not exist in the period following the end of test_setup and the beginning of test_end, if one exists, or through the end of the test if test_end does not exist.

-All — An optional switch that specifies use of all times in the test procedure file. This is the default.

time — An optional positive integer, greater than 0, that specifies a time in the test procedure file.

This subsection describes Tessent FastScan and Tessent TestKompress gate reporting when Drc_pattern specifies a procedure.

When you set the gate report to a DRC pattern and procedure, most of the data reported by the report_gates command is simulation data regarding the specified procedure. For example, if you specify the load_unload procedure, you will get simulation data regarding the load_unload procedure immediately following the test_setup procedure. Statements like **apply shift** are broken out by surrounding ()s.

The last group of data is more specialized. Its contents depend on the capture clock being set with the -atpg switch. The starting state for this simulation results from simulating the events of the test setup procedure, followed by the load_unload procedure and its apply procedures (shift and shadow_control).

- Case 1: No Capture Clock

There will be 1 or 2 values in the last pair of ()s. The first value is the simulation state that results from holding all PIs at their pin constrained value and setting all clocks to X at the end of load/unload.

If any state element has a different binary value than the one it had at the end of simulating test setup, its value will be changed to X, the effect propagated, and the final values saved in the second value between the ()s. See the following examples:

```
timeplate gen_tp1 =
    force_pi 0;
    measure_po 100;
    pulse myclk 200 100;
    period 400;
end;
procedure shift =
    scan_group grp1;
    timeplate gen_tp1;
    cycle =
        force_sci;
        measure_sco;
        pulse myclk;
    end;
end;
procedure load_unload =
    scan_group grp1;
    timeplate gen_tp1;
    cycle =
        force scan_en 1;
        force myclk 0;
    end;
    apply shift 2;
end;
report_gates clk
// /CLK primary_input
//      CLK      O (0)(0X0)(0)(X)
```

The first (0) is the simulation of the events in the load_unload procedure prior to the apply shift, (0X0) is the simulation of the shift procedure, (0) is the simulation of the events in the load_unload after the shift, and finally (X) is the simulation of the clocks at X.

- o Case 2: Capture Clock -Atpg

There will be 3 or 4 values in the last pair of ()s. The first three values result from simulating a pulse of the capture clock with all other clocks set to the off value.

If any state element has a different binary value than the one it had at the end of simulation test setup, its value is changed to X, the effect is propagated, and the final values are saved in the fourth value between the ()s.

K19 [-Initial | -FIRst_random | -SECond_random | -Post_capture | -Low_power
lp_sim#] [-All | Load_unload | {Shift [-All | cycle [cycle]]}]

Note

 Use this argument only when necessary. For most common K19 debug tasks, such as checking for correct values on EDT control signals as well as sensitized paths from channel pins to the decompressor and from the decompressor to the scan chains during shift, the Drc_pattern argument will be sufficient and less time-consuming than this one.

A literal and an optional, procedure pair that specifies to include a gate's simulation data resulting from the K19 design rules check (DRC) in the output displayed by the report_gates command. If you specify "K19" without any options, *all* K19 simulation values for every event specified in the test procedure file are displayed except test_setup events.

Note

 The test_setup simulation data is available after you use the "set_gate_report drc_pattern test_setup" command.

The options enable you to limit the content of the display to the data for a certain procedure and/or for a certain cycle or range of cycles. For a detailed explanation of the K19 DRC, refer to "[K19](#)" and to "[Understanding K19 Rule Violations](#)" in the Tesson TestKompress User's Manual.

K19 reporting can slow EDT DRC run time and increase memory usage compared to Drc_pattern reporting, as the tool has to log simulation data for all simulated setup and shift cycles. Use K19 reporting when you need to see the specific simulation values applied in each shift cycle. This is not commonly required as most problems are usually due to setup problems, such as path sensitization and setting of control signals, that are usually not pattern-specific or cycle-specific.

You must set this option in Setup system mode. Also, DRC handling for the K19 rule must be set to either error (the default) or warning, but not to ignore.

The following three switches specify to report simulated and emulated (where applicable) values for selected gates as described here:

- Initial — An optional switch that specifies to report the very first K19 simulation result.
- FIRst_random — An optional switch that specifies to report the first random initialization K19 simulation result.
- SECond_random — An optional switch that specifies to report the second random initialization K19 simulation result.
- Post_capture — An optional switch that specifies to report the second K19 simulation result (after capture); if low-power hardware exists and is enabled, its first simulation result is reported.
- Low_power lp_sim# — An optional switch that specifies to report the first or second simulation result for the low-power hardware, if one exists and is enabled. The lp_sim# argument can have a value of either 1 or 2.

The following three switches specify the use of the events in the test procedure file.

-All — An optional switch that specifies use of all events in the test procedure file except test_setup events. This is the default.

Load_unload — An optional literal that specifies use of the load_unload procedure.

Shift — An optional literal that specifies use of the shift procedure.

-All — An optional switch that specifies use of all shift cycles. This is the default.

cycle — A positive integer corresponding to a particular shift cycle. If you specify a single cycle number, data for only that cycle is displayed. If you provide a second integer, separated from the first by a space, the tool interprets the two integers as the endpoints of a range of cycles and displays the data for all cycles in the range. Cycles are counted from 1 and include independent shifts.

K22 [-Mask {No_mask | mask#}] [-All | Load_unload | {Shift [-All | cycle [cycle]]}]

Note

 Use this argument only when necessary. For most common K22 debug tasks, such as checking for correct values on EDT control signals as well as sensitized paths from the scan chains to the compactor and from the compactor to the channel pins during shift, the Drc_pattern argument will be sufficient and less time-consuming than this one.

An optional literal and procedure pair that include the gate simulation data resulting from the K22 design rules check (DRC) in the output displayed by the report_gates command. If “K22” is specified without any options, the K22 simulation values for every event specified in the test procedure file display. The options enable you to limit the content of the display to just the data associated with a certain procedure and/or to a certain cycle or range of cycles. For a detailed explanation of the K22 DRC, refer to “[K22](#)” and to “[Understanding K22 Rule Violations](#)” in the Tessent TestKompress User’s Manual.

K22 reporting can slow EDT DRC run time and increase memory usage compared to Drc_pattern reporting, as the tool has to log simulation data for all simulated setup and shift cycles. Use K22 reporting when debugging incorrect compactor mask settings for specific patterns simulated by the design rule check. This is not commonly required, as most problems are usually due to setup problems, such as path sensitization and setting of control signals, that are usually not pattern-specific or cycle-specific.

Note

 The K22 evaluations of compactor gates are synchronized with measure_sco statements in the test procedure file.

You must set this option in Setup system mode. Also, DRC handling for the K22 rule must be set to either error (the default) or warning.

-All — An optional switch that specifies use of all events in the test procedure file. This is the default.

Load_unload — An optional literal that specifies use of the load_unload procedure.

Shift — An optional literal that specifies use of the shift procedure.

-All — An optional switch that specifies use of all shift cycles. This is the default.

cycle — A positive integer corresponding to a particular shift cycle. If you specify a single cycle number, data for only that cycle is displayed. If you provide a second integer, separated from the first by a space, the tool interprets the two integers as the endpoints of a range of cycles and displays the data for all the cycles in the range. Cycles are counted from 1 and include independent shifts.

-Mask — An optional switch that sets the masking mode for the simulation data.

No_mask — A literal that together with -Mask specifies to report only non-masking mode simulation data.

mask# — A positive integer that, together with -Mask, specifies the identification number of a mask. The tool assigns a number to a mask according to the core scan chain the mask enables the tool to observe. Mask 3, for example, enables observation of the third core scan chain. This option thus limits reporting to the simulation data for the scan chain made observable by the specified mask.

F_rule_name — A literal that specifies an F rule between F1-F21.

Note, you must specify a specific occurrence of a F20 violation using the string “F20-occurrence#” where occurrence# is the violation occurrence. For more information, see the [report_drc_rules](#) command.

- **DEDelay_data [delay_data_option]**

A required literal pair that specifies to report delay data when using the [report_gates](#) command. For complete information, refer to “[Timing-Aware ATPG](#)” in the *Tessent Scan and ATPG User’s Manual*.

Reported delay data is one of the following data types:

Number — Indicates delay data values.

STAT (Static) — Indicates that no transition is possible on the pin so a delay value is not calculated or reported.

NA (Not Applicable) — Indicates the pin is not in the detection path so a delay value is not calculated or reported. (Static timing information)

- (dash) — Indicates the pin is not in the detection path so a delay value is not calculated or reported. (Actual timing information) For the *local_delay_data* literal, a dash (-) is reported in the case of a conditional IO path delay; in this case, the timing information is included in the report as shown in [Example 9](#).

The following *delay_data_option* literals are available:

LOCAL_delay_data

Reports the local delay data, including the wire delay (INTERCONNECT) and gate delay (IOPATH) associated with the flattened gate pin.

STATIC_Arrival_time

Reports the longest static rising and falling arrival time of the gate and direct fan-ins.
Both minimal and maximum arrival time will be reported as the following format:

(max_rising_arrival_delay, max_falling_arrival_delay) /

(min_rising_arrival_delay, min_falling_arrival_delay)

STATIC_Propagation_time

Reports the longest static rising and falling propagation time of the gate and direct fan-ins.

STATIC_Slack

Reports the static test slack of the gate and direct fan-ins. The test slack is computed as the difference between the test clock period and the summation of longest arrival time and longest propagation time. The format of the reported data is:

(test_slack_of_rising, test_slack_of_falling)

STATIC_Path_delay

Reports the longest static rising and falling path delay time through the gates.

ACTUAL_Arrival_time [-Internal | -External]

Reports the actual arrival time of the gate and direct fan-ins. This will first simulate the pattern specified by pattern_index. When there are more than two at-speed cycles, the maximum arrival time of given cycle will be reported. In addition to the actual arrival time, the simulation value of the specified pattern is also reported.

-Internal — An optional switch that specifies use of the tool's internal pattern set.

This is the default for Tesson TestKompress and Tesson FastScan.

-External — An optional switch that specifies use of the tool's external pattern set.

ACTUAL_Propagation_time [-Internal | -External]

Reports both the actual propagation time and simulation propagation time. This will first simulate the pattern specified by pattern_index. When there are more than two at-speed cycles, the maximum propagation time of given cycle will be reported.

-Internal — An optional switch that specifies use of the tool's internal pattern set.

This is the default for Tesson TestKompress and Tesson FastScan.

-External — An optional switch that specifies use of the tool's external pattern set.

ACTUAL_Slack [-Internal | -External]

Reports both the actual and simulation slack values. This will first simulate the pattern specified by pattern_index. When there are more than two at-speed cycles, the maximum slack of given cycle will be reported.

-Internal — An optional switch that specifies use of the tool's internal pattern set.

-External — An optional switch that specifies use of the tool's external pattern set.

ACTUAL_Path_delay [-Internal | -External]

Reports both the actual and simulation path delay through the gates. This will first simulate the pattern specified by pattern_index. When there are more than two at-speed cycles, the maximum path delay among all cycles will be reported.

- Internal — An optional switch that specifies use of the tool's internal pattern set.
- External — An optional switch that specifies use of the tool's external pattern set.

Note

 The calculations of arrival time and propagation time assume that all PIs change value at time 0. The delays at the clock port and the setup time of the sequential elements are ignored.

- -Timing_exceptions ON | OFF

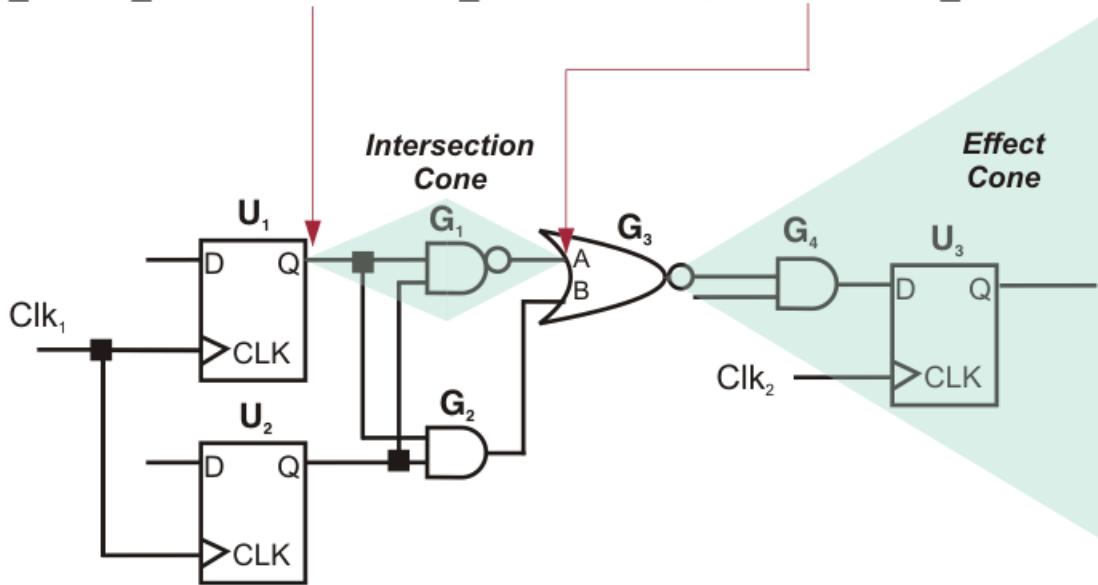

An optional switch and literal that turns on or off the timing exceptions (false paths or multicycle paths) information reporting for the [report_gates](#) command and the DFTVisualizer schematic windows. This option is only effective during non-Setup mode. The default is off.

[Figure 6-5](#) illustrates the false path definition point and the false path intersection cone and an effect cone.

Figure 6-5. False Path Intersection and Effect Cones

SDC File contains:

```
set_false_path -from [get_clocks {Clk1}] -to [get_pin {G3/A}]
```

In this figure, the false path begins from flops in clock domain Clk₁ to internal pin G₃/A. The false path's intersection cone (G₁) is the logic between all **-from** points and the **-to** point. The false path's effect cone (G₄ and U₃) is the combinational fanout cone of the **-to** point.

When you set the -Timing_exceptions switch to ON, any subsequent report_gates command can include one or more of the following false or multicycle path-related keywords in the report:

- **Fr** — Indicates the gate is a false or multicycle path from point.
- **To** — Indicates the gate is a false or multicycle path to point.
- **Th** — Indicates the gate is a false or multicycle path thru point.
- **In** — Indicates the gate is inside a false or multicycle path combinational intersection cone.
- **Ef** — Indicates the gate is in a false or multicycle path combinational effect cone.
- **--** — Indicates the gate is outside the false or multicycle path region.

The report can also include numbers, which indicate that a gate is part of at least one multicycle path. If there are two numbers, they indicate the minimum and maximum number of cycles. For example, “1,5” means the gate is on a multicycle path with minimum of 1 cycle and maximum of 5 cycles. If there is only one number, it means that the minimum and maximum number of cycles are the same. For example, “2” means the gate is on a 2-cycle path. If there is no number, then it is either on a 1-cycle path (when “--” is shown), or on a false path (when at least one of Fr, To, Th, Ef, In is shown). The following shows how the numbers display in set_gate_report command output:

```
// /I3/reg1    sff
//      D      I  (--)  /cnt[2]
//      SI     I  (--)  /I0/i0/Q
//      SE     I  (--)  /scan_en
//      CLK    I  (--)  /clock
//      Q      O  (In/1,5)  /I3/ix28/S0  /I3/ix30/S0  /I3/ix32/S0
//      QB     O  (--)  /I3/reg3/SI
```

The -Timing_exceptions argument does not reset the previous specified gate report option; consequently, you can use this argument in conjunction with other set_gate_report settings. Refer to “[Example 8](#)” on page 2166.

- **-COnstrain_value {ON | OFF}**

An optional switch and literal pair that specifies that the [report_gates](#) command displays the simulated values that result from all natural tied gates, learned constant value non-scan cells, constrained pins, and constrained cells, as well as the unused flag (UU) which indicates the gate is unreachable from any observation point.

The report_gates command displays four values that are separated by a slash (/). These values are the gate constrained value (-, 0, 1, X, or Z), the gate forbidden values (-, 0, 1, Z, or any combination of 01Z), the fault blockage status (- or B, where B indicates all fault effects of this gate are blocked), and the unused flag (UU).

The displayed values are only available at the end of DRC once the tool successfully leaves Setup Mode. While tie_value reports the status of node values once it comes out of the DRC

checks, the constrain_value tells you what the gate is supposed to act like for future consideration. Refer to [Example 14](#) for an example of this switch.

- **-MAX_Fanouts {number | UNlimited}**

An optional switch paired with either a positive integer or keyword that specifies the maximum of fanout gates to be reported by the [report_gates](#) command. When you specify the Unlimited keyword, report_gates reports all fanout gates without truncation. The default is limited to 99 fanout gates. The tool issues a message if a reported gate drives more than the limit you specified with this command.

- **-CLOCK_domains_in_capture_cycles {ON | OFF}**

An optional switch that enables the report_gates command in the primitive level to report the clock domain of the capture cycles information. The default is off and no clock domain information will be reported. When set to ON, you are allowed to display the launch and capture clocks of a given gate in non-SETUP mode. Both the launch and capture clocks are analyzed considering the constrain values and a clock will not be included when it is blocked by the constrained values.

Note

The clock domain information will not be shown in SETUP mode since the capture cycle constrain values are not analyzed in SETUP mode.

Examples

Example 1

The following example sets the gate report so that reporting and display show the simulated values of the gate and its inputs (assuming a rules checking error occurred when exiting the setup system mode):

```
set_system_modeanalysis
set_gate_report error_pattern
report_gates i_1006/o
```

Example 2

The following example illustrates a shift procedure containing two clocks that are pulsed in sequence and the corresponding gate report display when the gate report is set to trace. The data displayed is with respect to the shift procedure.

```
procedure shift =
    force_sci      0;
    measure_sco   0;
    force clk    1 1;
    force clk    0 2;
    force tclk   1 3;
    force tclk   0 4;
    period        6;
end;

report_gates 32
```

```
// /I_15 (32) NOR
//   i0    I (XXXXXX) 16-/I_16/out
//   i1    I (XXXXXX) 17-/I_6/out
//   out   O (XXXXXX) 43-/S2

report_gates tclk

// /TCLK (9) PI
//   TCLK  O (00010) 40-/I_13/clk

report_gates clk

// /CLK (4) PI
//   CLK   O (01000) 20-/I_20/I_225/i0
21-/I_23/I_225/i0
```

Example 3

The following is sample output of the report_gates command for reporting path delay patterns.

```
set_system_mode analysis
create_patterns
set_gate_report pattern_index 0
report_gates /FF1

// /FF1 SLSdffQ0ff
//   CLK   I (L0-L1-L0) /P_CLK1
//   M2SO  I (L0-L0-L0) /M2SOi0/Q
//   D     I (H1-HX-HX) /I2
//   SI2M  I (L0-L0-L0) /SI2Mi0/Q
//   SI    I (0-0-0) /FF2/SO
//   MHN   I (L1-L0-L1) /MHNi0/Q
//   Q     O (0-0-1) /IN2/A
//   SO    O (X-X-X) /P_SO1
```

The Ls and Hs in the gate report refer to clock-off values. These are only displayed for path-delay faults. They represent the clock off value and can be either X, L, H, or Z. The tool reports the clock off state prior to the actual pin value only for pins that are on a clock path.

The clock path value is a value that appears on a gate when pin constraints are considered and when all clocks are at their defined off states. For example, assume your design has an OR gate where one input is connected to primary input pin A. A is constrained to value 1, and the other pin is connected to primary input pin CLK, which is defined as a clock with off-state 0. The clock path values, where Y is the output of the OR gate, would be:

A	H
CLK	L
Y	H

Now, assume A is a regular input pin; that is, it has no pin constraint and is not a clock. The clock path values now are:

A	X
CLK	L
Y	X

Y is in the clock path and if you use “`set_gate_report clock_cone CLK`”, you will see that Y is in the clock cone. Finally, assume that this gate is now an AND gate and A is still a regular input pin. The clock path values are:

A	X
CLK	L
Y	L

Since the clock path depends on both clocks and pin constraints, a pin that is in the clock path does not necessarily have to be in the clock cone.

An S followed by 0, 1, or X appears in patterns generated when you issue the command `set_pattern_type -Multiple_load On`. The S refers to these patterns being scan load operations.

Example 4

The following example shows sample output of the `report_gates` command when the report type is changed to report simulation data using the following `test_setup` procedure.

```

timeplate gen_tp1 =
    force_pi 0;
    measure_po 10;
    pulse clk1 20 10;
    pulse clk2 20 10;
    period 40;
end;

timeplate gen_tp2 =
    force_pi 10;
    measure_po 30;
    pulse clk1 60 10;
    period 100;
end;

procedure test_setup =
    scan_group grp1;
    timeplate gen_tp1;
    // First cycle (cycle 0), one event (force)
    cycle =
        force clk1 0;
        force clk2 0;
        force reset 0;
        force A 0;
        ...
        force E 0;
    end;

```

Example 5

The following examples show sample output of the report_gates command for sequential elements when the report type is set to report simulation data for a particular pattern. For more information about what the tool displays for each cycle, refer to “[Event Simulation for DFFs and Latches](#)” in the *Tessent Scan and ATPG User’s Manual*.

- Mux-DFF—primitive level

The DFF captured 1 (shown in “[]”) at the end of the cycles. This DFF is also the observe element for this scan cell. Therefore, the captured value is also the unload value.

```
set_gate_report pattern 6
set_gate_level primitive
report_gates /re1
```

```
// /re1 (26) MUX
//   TE I (000-000) 19-/scan_en
//   D I (000-000) 2-/d[1]
//   TI I (000-000) 80-/re0/Q
//   "OUT" O (000-000) 81-
// /re1 (81) DFF
//   "S" I (000-000) 20-
//   "R" I (000-000) 21-
//   CP I (000-010) 62-/rh1/CPB
//   "D0" I (000-111) 26-
//   Q O (000-011-[1]) 103-/sout[0]
//   MASTER cell_id=0 chain=chain0 group=group0
invert_data=FFFF
// Reported all gates in instance re1
```

- Mux-DFF—design level

set_gate_report pattern 6
set_gate_level design
report_gates /re1

```
// /re1 FD1SQM1D
//   D I (000-000) /d[1]
//   CP I (000-010) /rh1/CPB
//   TI I (000-000) /re0/Q
//   TE I (000-000) /scan_en
//   Q O (000-011-[1]) /sout[0]
```

- Non-scan DFF—primitive level

set_gate_level primitive
report_gates /rh1/UDP1

```
// /rh1/UDP1 (25) INV
//   "IO" I (011-111) 79-
//   "OUT" O (100-000) 62-
// /rh1/UDP1 (79) TLA
//   "S" I (000-000) 20-
//   "R" I (000-000) 21-
//   "C0" I (010-000) 61-
//   "D0" I (111-111) 38-
//   "OUT" O (011-111) 25-
// Reported all gates in instance rh1/UDP1
```

- Non-scan DFF—design level

set_gate_level design
report_gates /rh1/UDP1

```
// /rh1 LCLKRHDELLD350D
//   CP I (101-111) /inv0/Z
//   LD I (000-000) /ld[0]
//   TE I (000-000) /scan_en
//   CPB O (100-000) /fout1 /inv1/A /rh11/CP
//                                /nonscan_d_b/D /re0/CP /re1/CP
//                                /nonscan_d_b/TI
```

- LSSD scan cell (master latch and slave latch with master_observe)—primitive level

If reporting the master, which is the observed element, the captured value is also the unload value. If reporting the slave, an “Unobs” appears beside the captured value to remind you that this captured value is not the unload value. Notice also the additional message at the end of the report for the slave, telling you that the master (217) is the observation point.

set_gate_level primitive**report_gates 217 218**

```
// /I26/L1 (217) LA
// "S" I (000-000) 26-
// "R" I (000-000) 20-
// CLOCK I (010-000) 164-/clk_regen/I_crinv_c1/I2/OUT
// "D0" I (111-111) 154-
// SCANCLOCK I (000-000) 193-/clk_regen/I_inv_aclk3/I2/OUT
// SCANIN I (111-111) 104-/testblock/msff_output/I12/OUT
// Q O (111-111-[1]) 33-/I26/I130/IN
// MASTER cell_id=1 chain=sc0 group=g1 invert_data=FFFF
// /I26/L2 (218) LA-IL
// "S" I (000-000) 130-
// "R" I (000-000) 20-
// CLOCK I (000-010) 203-/clk_regen/I_crinv_mc2/I2/OUT
// DATA I (111-111) 33-/I26/I130/OUT
// Q O (111-111-[1 Unobs]) 34-/I26/I12/IN
// SLAVE cell_id=1 chain=sc0 group=g1 invert_data=FFFF
// Latch is not the observation point for reported pattern. //
Observation point is at MASTER gate 217.
// Learned latch port types: IL
```

- Masked LSSD scan cell—primitive level

If the cell is masked (unload value = X due to an XX cell constraint added with the add_cell_constraints command, for example), the tool informs you that the cell is not observed for this pattern.

set_gate_level primitive**report_gates 311**

```
// /ix301/slave (311) LA
// "S" I (000-000) 43-
// "R" I (000-000) 206-
// "C0" I (000-010) 116-
// "D0" I (000-000) 59-
// "OUT" O (111-100 [X Unobs]) 58-
// SLAVE cell_id=5 chain=chain2 group=grp_lssd invert_data=TTFT
// Scan cell not observed for this pattern.
```

- LSSD scan cell, master and slave with master_observe—design level

Notice that the tool does not show explanatory text at the design level for “Unobs” cells.

set_gate_level design**report_gates 217 218**

```

//  /I26/L1 (217)  LA
//    "S"    I  (000-000)  26-
//    "R"    I  (000-000)  20-
//    CLOCK  I  (010-000)  164-/clk_regen/I_crinv_c1/I2/OUT
//    "D0"    I  (111-111)  154-
//    SCANCLOCK  I  (000-000)  193-/clk_regen/I_inv_aclk3/I2/OUT
//    SCANIN   I  (111-111)  104-/testblock/msff_output/I12/OUT
//    Q      O  (111-111-[1])  33-/I26/I130/IN
//    MASTER   cell_id=1  chain=sc0  group=g1  invert_data=FFFF
//  /I26/L2 (218)  LA-IL
//    "S"    I  (000-000)  130-
//    "R"    I  (000-000)  20-
//    CLOCK  I  (000-010)  203-/clk_regen/I_crinv_mc2/I2/OUT
//    DATA    I  (111-111)  33-/I26/I130/OUT
//    Q      O  (111-111-[1 Unobs])  34-/I26/I12/IN
//    SLAVE   cell_id=1  chain=sc0  group=g1  invert_data=FFFF
//    Latch is not the observation point for reported pattern. //
Observation point is at MASTER gate 217.
//    Learned latch port types: IL

```

Example 6

The following example sets the gate report so that reporting and display show all the K19-simulated values of each reported gate:

```

set_gate_report drc_pattern k19
// Warning: Data will be accessible after running DRC.

```

The report_environment command would show the following for the gate report:

```

gate report = display K19 sim data, procedure(s): test_setup,
load_unload, shift - all cycles

```

The following is sample output of the report_gates command when the report type is changed prior to DRC to report K19 simulation data for the following load_unload procedure and shift cycles 8 through 10. The example begins in Setup system mode.

set_gate_report

```

timeplate gen_tp1 =
    force_pi 0;
    measure_po 1;
    pulse clk 2 1;
    pulse edt_clock 2 1;
    period 4;
end;
procedure load_unload =
    scan_group grp1;
    timeplate gen_tp1;
    cycle =
        force clk 0;
        force edt_bypass 0;
        force edt_clock 0;
        force edt_update 1;
        force scan_en 1;
        pulse edt_clock;
    end;
    apply shift 11;
end;
procedure shift =
    scan_group grp1;
    timeplate gen_tp1;
    cycle =
        force_sci;
        force edt_update 0;
        measure_sco;
        pulse clk;
        pulse edt_clock;
    end;
end;
set_gate_report drc_pattern k19 load_unload 8 10
// Warning: Data will be accessible after running DRC.
set_system_mode
report_gates /edt_i/edt_decompressor_i/ix159/Y
// /edt_i/edt_decompressor_i/ix159 (142) NXOR
//      A0 I 130-/edt_i/edt_decompressor_i/ix241/Y
//      A1 I 84-/edt_i/edt_decompressor_i/lfsm_lockup_4/Q
//      Y O 154-/edt_i/ix90/A
// Proc: ld_un ~ shi 8 sh 9 sh10
// ----- ~ ----- -----
// Time: i0234 ~ i0123 0123 0123
// ----- ~ ----- -----
// Sim: XXX00 ~ 00000 0001 1110
// Emu: ---- ~ 0---0 ---1 ---0
// No mismatch.
// Monitor: EDT decompressor chain 1 output.

```

In the preceding report, consecutive cycles are listed from left to right, with a “~” indicating a break in the data. A blank space separates each cycle’s data from that of neighboring cycles. The numbers in the row labeled “Time” are the relative times of each event in a cycle as specified in the procedure file. An “i” indicates the start of a new sequence of events. Because the gate is one the tool monitors for the purpose of pinpointing where K19 errors first occur, the report shows the values the tool emulated for the gate and whether there were any mismatches between the emulated and simulated values.

Example 7

The following example sets the gate report so reporting and display use the K22 simulated values for the load_unload procedure of the preceding example and shift cycles 4-8 for the fourth core scan chain.

```
set_gate_report drc_pattern k22 -mask 4 4 8
// Warning: Data will be accessible after running DRC.
```

The report_environment command would show the following for the gate report:

```
gate report = display K22 sim data mask 4, procedure(s) :
    load_unload, shift - range 4 - 8
```

The following is sample output of the report_gates command when the report type is changed prior to DRC. The example begins in Setup system mode.

```
set_gate_report drc_pattern k22 -mask 4 4 8
// Warning: Data will be accessible after running DRC.
set_system_mode

report_gates /edt_i/edt_bypass_logic_i/ix7/Y

// /edt_i/edt_bypass_logic_i/ix7 (216) OR
//      "I0" I 215-
//      B0   I 76-/edt_i/edt_bypass_logic_i/ix5/Y
//      Y     O 256-/edt_channels_out1
//
// Proc: ld_un ~ shi 4 sh 5 sh 6 sh 7 sh 8
// ----- ~ ----- -----
// Time: i 234 ~ i 123 123 123 123 123
// ----- ~ ----- -----
// Sim: 11000 ~ 11100 0011 1111 1100 0011
// Emu: ---- ~ --0-- -1-- -0-- -0-- -1--
// Mism: ~ * * * * *
// Monitor: EDT module channel 1 output.
```

The report format is similar to that of the K19 report. Here too, the gate is one the tool monitors for the purpose of analyzing where K22 errors first occur, so in addition to the simulation results, the report shows the values the tool emulated for the gate and whether there were any mismatches. Notice that the emulated values occur earlier in each cycle than with the K19 DRC. The reason is that the K22 DRC synchronizes emulation comparisons with the measure_sco statements in the shift procedure, whereas the K19 comparisons always occur at the end of each shift cycle.

Note

 If you enter a constraint using a tool command, Tesson TestKompress does not apply it until the end of the test_setup procedure. You may thus see Xs up until the end of test setup; however, the tool does correctly apply the constraint before the start of load_unload or capture.

Example 8

The following example demonstrates the reporting of the timing exception and an internal pattern simulation value, and illustrates using the [report_gates](#) command to trace the transition of the pattern along the timing exception paths:

```
set_gate_report -timing_exceptions on
set_gate_report pattern_index 1
report_gates /ix21/UD1
report_gates /ix21/UD1

// /ix21/UD1 (36) DFF
// "S" I (0-0) (--) 6-
// "R" I (0-1) (--) 20-
// "C0" I (1-0) (--) 10-
// "D0" I (1-1) (To) 32-
// "OUT" O (1-1 [0]) (In/Ef) 9-
// MASTER cell_id=2 chain=chain1 group=grp1 invert_data=FFFF

f
// /ix21/UD1 (9) BUF
// "I0" I (1-1) (Fr/Ef) 36-
// "OUT" O (1-1) (In) 18- 19-

f
// /ix21 (18) BUF
// "I0" I (1-1) (In) 9-
// Q O (1-1) (To) 28-/fdgd/A 29-/ix19/A

f
// /fdgd (28) NAND
// A I (1-1) (To) 18-/ix21/Q
// B I (1-0) (--) 1-/s
// Z O (0-1) (Ef) 37-/y[2]

f
// /y[2] (37) PO
// "I0" I (0-1) (Ef) 28-/fdgd/Z
// y[2] O (0-1) (Ef)
```

Example 9

The following example reports the static propagation time of gate */U1*:

```
set_gate_report delay_data static_propagation
report_gates /U1

// /U1 (24) XOR
// AO I (5.4000, 5.5000)/(5.0000, 5.1000) 1-/PI1
// A1 I (2.4000, 2.4000)/(2.0000, 2.0000) 16-/U11/Y
// Y O (2.4000, 2.0000)/(2.4000, 2.0000) 25-/U12/Y
```

The following example reports the static slack test of /U2:

```
set_gate_report DELay_data STATIC_Slack
report_gates /U2

// /U2 sff
// D I (5.0000/2.0000) /U21/Y
// SI I (12.0000/12.0000) /U22/Q
// SE I (NA/NA) /SE
// CLK I (8.0000/8.0000) /CLK
// RB I (STAT) /U23/Y
// Q O (2.0000/3.0000) /U24/SI /U25/A0 /U26/A1
```

The following example reports the local delay data for /U3. The output in bold font highlights the timing information used by ATPG. Note, to report local delay data, you must set the gate level to primitive before executing the report_gates command as shown here:

```
set_gate_level primitive
set_gate_report delay local_delay_data
report_gates U3
```

```

//  /U3  (50)  BUF
//    "IO"    I  (-)  101-
//    Q      O  (-)  85-/U31/SI
//  /U3  (51)  INV
//    "IO"    I  (-)  101-
//    QB     O  (-)
//  /U3  (84)  MUX
//    SE     I  (-)  56-
//    D      I  (-)  78-/U32/Y
//    SI     I  (-)  48-/U34/Q
//    "OUT"   O  (-)  101-
//  /U3  (101) DFF
//    "S"    I  (-)  69-
//    "R"    I  (-)  17-
//    CLK   I  (-)  54-
//    "D0"   I  (-)  84-
//    "OUT"   O  (-)  50-  51-
//
// Sequential IOPATH delay starts through the fanin 3 of /U3/ (101):
//   1 condition delay(s) to /U3/Q (50)
//   condition delay: (1.0000, 2.0000)
//   condition variable list:
//     V[0]=54
//   condition expression in post fix format: (V[0]) posedge
// TimingCheck for data port at the fanin 2 of /U3/ (84):
//   SETUP - clock port at the fanin 3 of /U3/ (101)
//   condition delay: (0.7000, 0.7000)
//   condition variable list:
//     V[0]=54
//   condition expression in post fix format: (V[0]) posedge
// HOLD - clock port at the fanin 3 of /U3/ (101)
//   condition delay: (0.2000, 0.2000)
//   condition variable list:
//     V[0]=54
//   condition expression in post fix format: (V[0]) posedge
//
//   MASTER  cell_id=1  chain=c1  group=g1  invert_data=FFFF
// Reported all gates in instance U3

```

Example 10

The following example reports gates with MCP (multicycle path) information, listing the minimum and maximum number of cycles. This example assumes that the following MCP information has been set from an SDC (Synopsys Design Constraint) file:

```

set_multicycle_path -through { get_pin [b1/I] } -setup 2

set_gate_report -timing_exceptions on
report_gates /b1/ci2b cg2/TEN /cg2/i03

```

```
// /b1/ci2b (47) INV
//   A   I  (To/Th/1,2)  40-/b1/ci2a/Y
//   Y   O  (Ef/1,2)    49-/cg2/CLKEN
// /cg2 (49) NOR
//   CLKEN I  (Ef/1,2)  47-/b1/ci2b/Y
//   TEN   I  (--)      3-/se
//   "OUT" O  (Ef/1,2)  51-
// /cg2/i03 (51) TLA
//   "S"   I  (--)      9-
//   "R"   I  (--)      6-
//   "C0"  I  (--)      44-
//   "D0"  I  (Ef/1,2)  49-
//   "OUT" O  (Ef/1,2)  11-
```

When the minimum and maximum number of cycles are the same and larger than 1, the command reports only one number. Single cycle paths and false paths do not report any number.

Example 11

The following example specifies that a subsequent report_gates command display the simulated values from the current simulation context:

```
> set_current_simulation_context stable_after_setup
> set_gate_report simulation_context
> report_gates {I1 I2}

/I1 primary_input
  I1   O  (0)  /AND2/A0
/I2 primary_input
  I2   O  (1)  /AND2/A1
```

Example 12

The following example enables the report_gates command to show the simulation values for the first F20 violation:

```
set_gate_report drc_pattern F20-1
```

Example 13

The following example shows how to display the clock domain information of a combinational gate and a sequential gate. The -clock_domains_in_capture_clocks switch, when combined with the pattern_index switch, shows both clock domain information as well as the pattern simulation values.

```
set_system_mode analysis
create_patterns
set_gate_level primitive
set_gate_report pattern_index 0
set_gate_report -clock_domains_in_capture_cycles on
report_gate /ff1_3/D
```

set_gate_report

```
//  /ff1_3 (30) MUX
//    "SE"   I (000) 9-/scan_en
//    "D"    I (111) 11-/pi2
//    SI     I (000) 128-/latch3/Q
//    "OUT"   O (111) 129-
// Launch clock:      '/clk1' (1)
// Capture clock:    '/clk1' (1)
```

report_gate /dff10/QB

```
//  /dff10 (109) BUF
//    "I0"   I (111) 62-
//    "QB"   O (111) 121-/chain5_1/ff5_1/D 122-/or/A1
// Launch clock:      '/clk2' (2)
// Capture clock:    '/clk3' (3),'/reset' (18)
```

Example 14

This example demonstrates the effect of the `-constrain_value` switch on the `report_gates` command. When you have specified the “`set_gate_report -constrain_value on`”, the `report_gates` command will show when a gate is unreachable with the unused flag (UU). The report for the INV gate in /sdff2/lat pin QN shows (X/01/-/UU):

- X — Gate constrained value. In this case the gate is constrained to X.
- 01 — Gate forbidden values are 0 and 1.
- - (hyphen) — Fault blockage status. In this case - (hyphen) means no fault blockage.
- UU — Unused flag (indicating gate is unreachable from any observation point).

set_gate_report -constrain_value on
report_gates sdff2/lat

```
//  /sdff2/lat (18) BUF
//    "I0"   I (X/01/-) 34-
//    Q     O (X/01/-) 36-/so
//  /sdff2/lat (19) INV
//    "I0"   I (X/01/-) 34-
//    QN    O (X/01/-/UU)
//  /sdff2/lat (34) TLA
//    "S"    I (0/1/-) 9-
//    "R"    I (0/1/-) 8-
//    CLK   I (-/-/B) 26-/sdff2/u0/OUT
//    D     I (-/-/-) 29-/sdff2/u1/OUT
//    "OUT"  O (X/01/-) 18- 19-
// Reported all gates in instance 'sdff2/lat'
```

Example 15

This procedure file defines four events in the shift procedure (`force_pi` is set to occur at 5 ns rather than at the beginning of the cycle).

```

set time scale 1.000000 ns ;
set strobe_window time 1 ;
timeplate gen_tp1 =
    force_pi 5 ;
    measure_po 10 ;
    pulse CLOCK 20 10;
    period 40 ;
end;
procedure shift =
    scan_group grp1 ;
    timeplate gen_tp1 ;
    // cycle 0 starts at time 0
    cycle =
        force_sci ;
        measure_sco ;
        pulse CLOCK ;
    end;
end;
procedure load_unload =
    scan_group grp1 ;
    timeplate gen_tp1 ;
    // cycle 0 starts at time 0
    cycle =
        force scan_en 1 ;
        force CLOCK 0 ;
    end ;
    apply shift 3;
end;
procedure test_setup =
    timeplate gen_tp1 ;
    // cycle 0 starts at time 0
    cycle =
        force IN1 0 ;
    end;
end;

```

The report_gates command reports four values, one for each event in the cycle.

```

set_gate_level design
set_gate_report drc shift
report_gates .reg1

// /reg1 dfsc
// CK I (0010) /CLOCK
// D0 I (XXXX) /gate1/OUT
// D1 I (SSSS) /reg2/QBAR
// SC I (1111) /scan_en
// Q O (XXXX) /gate2/B
// QBAR O (SSSS) /scan_out1

```

set_gzip_options

Context: unspecified, all contexts

Mode: all modes

Specifies GNU gzip options to use with the GNU gzip command.

Usage

```
set_gzip_options [-Path gzip_path] [-Fast | -Best | -digit]
```

Description

Specifies GNU gzip options to use with the GNU gzip command.

The set_gzip_options command specifies GNU gzip options the tool will use when compressing or decompressing files using the GNU gzip command. When file compression handling is enabled, the tool uses GNU gzip when processing files having a .gz or .Z extension.

The default speed and amount of compression corresponds to the gzip -4 option.

Arguments

- **-Path *gzip_path***

An optional literal that specifies the full path *gzip_path* to a gzip executable file. You need to provide this pathname only if gzip is not in your normal Linux search path. If you have specified a pathname with this option, you can restore the default behavior of using your Linux path to find gzip by issuing the command with the -Path gzip option.

The following switches all control the speed of compression:

- **-Fast**

An optional switch that specifies to use the fastest compression method, which yields the least compression. This corresponds to the gzip -1 option.

- **-Best**

An optional switch that specifies to use the slowest compression method, which yields the most compression. This corresponds to the gzip -9 option.

- **-*digit***

An optional switch that specifies an integer from 1 to 9 that the tool passes to gzip to control the rate of compression. You obtain the least amount of compression with -1, the greatest amount of compression with -9.

Examples

The following example ensures file compression is enabled, sets gzip compression to the fastest method, then saves a file using the .gz file naming extension in order to activate gzip file compression handling:

```
set_gzip_options -fast
write_patterns fault.pat.gz
```

set_icl_extraction_options

Context: all contexts

Mode: all modes

Customizes the behavior of ICL extraction.

Usage

```
set_icl_extraction_options [-extract_learned_muxes {ON | OFF}]  
                         [-extract_library_muxes {ON | OFF}]
```

Description

Customizes the behavior of ICL extraction.

For more information, see “[ICL Extraction](#)” in the *Tessent IJTAG User’s Manual*.

Arguments

- **-extract_learned_muxes {ON | OFF}**

An optional switch and literal pair that specifies whether the tool creates ICL multiplexers from structures in the design that have been identified as muxes by the static learning process. The default for this switch is ON.

- **-extract_library_muxes {ON | OFF}**

An optional switch and literal pair that specifies whether the tool creates ICL multiplexers from muxes that are described in the Tessent Cell library. The default for this switch is ON.

Examples

The following command switches off the recognition of multiplexer library cells in ICL extraction:

```
set_icl_extraction_options -extract_library_muxes off
```

[set_static_learning](#)

set_icl_scan_interface_ports

Context: dft, patterns -ijtag

Mode: setup, insertion

Sets the names of the ports in the specified scan interface previously added by add_icl_scan_interfaces that ICL extraction will create in the new ICL top module.

Usage

```
set_icl_scan_interface_ports -name name -ports port_objects  
[-allowed_to_be_tied_externally | -allowed_no_source_externally]
```

Description

Sets the names and connection rules of the ports in the specified scan interface previously added by add_icl_scan_interfaces that ICL extraction will create in the new ICL top module.

Arguments

- **-name *name***

A required switch and value pair that specifies the name of scan interface for which the list of ports will be created in the new ICL top module.

- **-ports *port_objects***

A required switch and value pair that specifies the names of the ports that will be associated with the scan interface in the new ICL top module.

- **-allowed_to_be_tied_externally**

An optional switch that instructs the tool to set appropriate connection rules for the ports of the specified scan interface. Depending on the function of the port and the type of the scan interface, the following connection rules are chosen:

ScanInPort: allowed_tied

ScanOutPort: allowed_no_destination

Controls (client/client-TAP ScanInterface): allowed_tied_low

Controls (host/host-TAP ScanInterface): allowed_no_destination

By using this switch, you can request that a ScanInterface be unused at the next level up without setting that as default.

If the -allowed_to_be_tied_externally and the -allowed_no_source_externally switches are not specified, the ports in the extracted ICL inherit their connection_rule_option attributes from the ports they traced to or from. In the case of an output port with a single driver, the inheritance is one to one. In the case of an input port with potentially more than one fanout, the most restrictive value of all fanouts is used. For example, if an input port fans out to two ports where one has connection_rule_option = allowed_tied and the other allowed_no_source, the allowed_tied value will be used as it is the more restrictive. If any

port in the fanout does not define the [icl_port](#) connection_rule_option attribute, the created port will not have it either.

- -allowed_no_source_externally

An optional switch that instructs the tool to set appropriate connection rules for the ports of the specified scan interface. Depending on the function of the port and the type of the scan interface, the following connection rules are chosen:

ScanInPort: allowed_no_source

ScanOutPort: allowed_no_destination

Controls (client/client-TAP ScanInterface): allowed_no_source

Controls (host/host-TAP ScanInterface): allowed_no_destination

By using this switch, you can request that a ScanInterface be unused at the next level up without setting that as default.

If the -allowed_to_be_tied_externally and the -allowed_no_source_externally switches are not specified, the ports in the extracted ICL inherit their connection_rule_option attributes from the ports they traced to or from. In the case of an output port with a single driver, the inheritance is one to one. In the case of an input port with potentially more than one fanout, the most restrictive value of all fanouts is used. For example, if an input port fans out to two ports where one has connection_rule_option = allowed_tied and the other allowed_no_source, the allowed_tied value will be used as it is the more restrictive. If any port in the fanout does not define the connection_rule_option attribute, the created port will not have it either.

Examples

The following example creates the ports tck, tdi, tdo, tms and trst for the ScanInterface TAP, and the ports tdo, tdrEn1, fromTdr1, ce, se and ue for the ScanInterface Internal in the new ICL top module:

```
set_current_design tap1
add_icl_scan_interfaces {TAP Internal}
set_icl_scan_interface_ports -name TAP -ports {tck tdi tdo tms trst}
set_icl_scan_interface_ports -name Internal -ports {tdrEn1 fromTdr1 ce se ue}
```

The resulting ICL model will look like this:

```
Module tap1 {  
  
    TCKPort      tck;  
    ScanInPort   tdi;  
    ScanOutPort  tdo      {  Source IRMux;  }  
    TMSPort      tms;  
    TRSTPort     trst;  
    ToSelectPort tdrEn1   {  Source sel1;  }  
    ScanInPort   fromTdr1;  
    ToCaptureEnPort ce;  
    ToShiftEnPort se;  
    ToUpdateEnPort ue;  
  
    ScanInterface TAP {Port tck; Port tdi; Port tdo; Port tms; Port trst;}  
    ScanInterface Internal {Port tdrEn1; Port fromTdr1; Port ce; Port se;  
    Port ue;}  
}
```

set_iddq_checks

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies the restrictions and conditions to use when creating or selecting patterns for detecting IDDQ faults.

Usage

```
set_iddq_checks [-NONE | {[-Int_float] [-Bus] [-WEAKBus] [-Pull] [-WIre]  
[-VOLTGain] [-VOLTLoss] [-Clock] [-WRite] [-Read]}  
[-ATpg] [-NO_ATpg] [-WArning | -ERror] [-LOOP_oscillation {OFF | REPort | REject}]
```

Description

These restrictions only apply during the actual time of the IDDQ measurement; they are ignored at other times during a pattern.

To ensure no input is floating due to an unconnected module or instance input, before the design is flattened, you should issue the following commands at the beginning of Setup:

```
set_flattener_rule_handling fn1 error  
set_flattener_rule_handling fn3 error
```

When you use the tool to create Iddq patterns, a violation of any of the Iddq Check options you select causes the tool to reject an offending pattern.

During simulation, whenever violations of the restrictions occur, a message displays identifying the gate associated with the violation and the number of patterns in which the violations occurred. The handling of the violation can be either a warning or error.

When you select -Error, simulation terminates at the first occurrence of a violation. You can use the report_gates command to inspect the simulation values of all gates for patterns that violate the restrictions by first using the set_gate_report command with the Error_pattern option.

The [report_environment](#) command reports the current set_iddq_check settings.

For more information on IDDQ, see “[IDDQ Test Set Creation](#)” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- **-NONE**

An optional switch that specifies to not perform any checks. This is the default.

- **-Int_float** — An optional switch that specifies to not allow a floating (Z) value on any ZVAL primitive gate that drives any Boolean logic. A ZVAL gate is placed between a source (Z producer) and a sink (nonZ consumer).

A Z producer is any primitive that has a Z output. Z producers include top-level inputs, bidi/inouts, tristate drivers, and FETs/switches. A nonZ consumer is any gate that treats Z the same as X for all inputs. NonZ consumers include any Boolean gate. You can see the primitive truth tables for all DFT-supported primitives, in section “[Supported Primitives](#)” of the *Tessent Cell Library Manual*.

Note

 A ZVAL gate is not placed between a Z producer and a PO or the PO half of a bidi because both of these have the ability to output a Z value. However, a ZVAL gate is placed between the PI half of the bidi and any internal _buf as typifies the input path of a bidi/inout IO pad. For those pads, if the output stage is disabled (Z out), and the bidi/inout PAD is driven externally by Z from the tester, and the IO pad has no modeled pullup/down, the ZVAL in front of the _buf input path can have a Z on its inputs; it fails the **-int_float** check.

These “floating” checks only occur at buses. To ensure no input is floating due to an unconnected module or instance input, before the design is flattened, you should issue the following commands at the beginning of Setup:

```
set_flattener_rule_handling fn1 error  
set_flattener_rule_handling fn3 error
```

- **-Bus**
An optional switch that specifies to not allow contention conditions on bus gates.
- **-WEAKBus**
An optional switch that prevents contention conditions on weak-bus gates.
- **-Pull**
An optional switch that prevents contention conditions on pull gates.
- **-WIre**
An optional switch that specifies that all inputs of a wire gate must be set to the same value. There should be no contention on wires during IDDQ measurements because contention can raise the IDDQ current.
- **-VOLTGain**
An optional switch that specifies that a PMOS transistor must not be at a logic zero unless a zholt0 or zholt bus_keeper DFT library attribute is between the PMOS transistor and the BUS root. A compromised (Vss+) logic zero is pulled down to the Vss rail (zero volts).

- **-VOLTLoss**

An optional switch that specifies that a NMOS transistor must not pass a logic one unless a zhold1 or zhold bus_keeper DFT library attribute is between the NMOS transistor and the BUS root. A compromised (Vdd-) logic one is pulled up to the Vdd rail (Vdd volts).

- **-Clock**

An optional switch that specifies to not allow clock pins to be on during the IDDQ measure.

Note

 The advantage of the -Clock switch, during pattern generation, is that it prevents creation of Clock PO style patterns, one of the causes of multiple timeplates. The switch also ensures that when a clock is turned on, it is pulsed at the normal time.

- **-WRite**

An optional switch that specifies to not allow write control pins to be on during the IDDQ measure.

- **-RRead**

An optional switch that specifies to not allow read control pins to be on during the IDDQ measure.

- **-ATpg**

An optional switch that specifies to satisfy any IDDQ restrictions set using the [add_iddq_exceptions](#) command. This is the default.

- **-NO_ATpg**

An optional switch that specifies to not enforce IDDQ restrictions set using the [add_iddq_exceptions](#) command. Patterns that do not satisfy restrictions are rejected by the fault simulator.

- **-WArning**

An optional switch that treats violations of IDDQ checks as warnings. This is the default.

- **-ERror**

An optional switch that treats violations of IDDQ checks as errors and stops the simulation process immediately.

- **-LOOP_oscillation {OFF|REPort | REject}**

An optional switch and keyword pair that checks for oscillating loops when the fault type is IDDQ. The “Report” option reports on oscillating simulation values at specific gates. The “Reject” option automatically rejects any patterns that cause oscillation and issues a warning. By default, the tool does not check for oscillating loops.

Examples

Example 1

The following example creates IDDQ patterns while checking that internal buses are not floating during an IDDQ measure and requires the deterministic ATPG to ensure that this is true:

```
set_system_mode analysis
set_fault_type iddq
set_iddq_checks -int_float
create_patterns
```

Example 2

This example uses the report_environment command to report the set_iddq_checks settings:

```
// command: set_fault_type iddq
// command: set_iddq_checks -Bus -Int_float -warning
// command: report_environment
```

```

set_ijtag_instance_options

Context: dft patterns

Mode: setup analysis insertionset_icl_scan

Sets options on instances for which there is a matched ICL module.

Usage

```
set_jtag_instance_options ijtag_instance_spec [-use_in_dft_specification off | auto]  
[-connect_data_signals_already_connected_to_ports on | off | auto ]
```

Description

Sets options on instances for which there is a matched ICL module.

Arguments

- *ijtag_instance_spec*

A required literal that is a Tcl list of names of one or more Ijtag instances, or a collection containing one or many Ijtag instances as reported by the [get_instances](#) or [get_ijtag_instances](#) commands.

The instance objects must have an ICL module matched to them.

- -use_in_dft_specification off | auto

An option value pair that defines the value of the `-use_in_dft_specification` option. When set to `auto`, the instances are included in the `DftSpecification` created by the `create_dft_specification` command when it is seen to not already be connected to the network. Specifying an `off` value bypasses the analysis and forces the inclusion or exclusion of the instances. See the description of the `create_dft_specification` command for more details about the usage of this option.

- -connect_data_signals_already_connected_to_ports on | off | auto

An option value pair that specifies how DataInPorts and DataOutPorts on the specified instances are handled when they are seen to be already connected to PI/PO ports of the current design. When set to `on`, the `create_dft_specification` command adds a TDR to control the DataInPorts and observe the DataOutPorts even if they are already connected to PI/PO ports of the current design. When set to `off`, no TDR is added to control the DataInPorts and observe the DataOutPorts when they are already connected to PI/PO ports of the current design. The assumption is that they are already observable or controllable by the top level ports. When set to `auto`, the value will be taken from the [DefaultsSpecification\(policy\)/DftSpecification/IjtagNetwork/connect_data_signals_already_connected_to_ports](#) property. You set this option to `on` when you want to add observability and controllability through ijtag using an internal register even if they are already observable/controllable by ports of the current design.

Examples

The following example sets the `-use_in_dft_specification` option to off on all Ijtag instances below the instance blockA.

```
> set_ijtag_instance_options [get_ijtag_instances -below_instance blockA] \
   -use_in_dft_specification off
```

set_ijtag_retargeting_options

Context: all contexts

Mode: all modes

Enables you to configure different aspects of ijtag retargeting.

Usage

```
set_ijtag_retargeting_options [-test_setup_network_end_state {keep | reset}]  
    [-test_setup_ireset {off | first_icall | when_icl_present}]  
    [-iapply_target_annotations {off | dense | full}]  
    [-max_operations_per_iapply integer]  
    [-compare_constant_capture_values {ON | OFF}]  
    [-compare_constant_data_out_ports {ON | OFF}]  
    [-merge_irunloop_only {on | off}]  
    [-inject_cycles inject_cycles_list]  
    [-tck_ratio tck_ratio {auto | 1 | 2 | 4 | 8 | 16 | ...}]  
    [-annotation_parameter_values parameters]
```

Description

Enables you to configure different aspects of ijtag retargeting.

Arguments

- `-test_setup_network_end_state {keep | reset}`

Note

 This switch only applies to ijtag retargeting when an iCall is used in test_setup (see the [set_test_setup_icall](#) command for more details).

An optional switch and literal pair that specifies to switch off the reset and preserve the state of the ICL network after the last test_setup iCall. The default is to do the reset. This reset only affects the configuration of the scan paths and the selection of the scan interfaces. The reset does not trigger any activity on ports of type ResetPort or TRSTPort.

If you have a test mode where you are applying the load_unload data through the IJTAG network and do not want to reset the state of the ICL scan network after the last test_setup iCall, use the “set_ijtag_retargeting_options -test_setup_network_end_state keep” command to turn off the reset of the ICL network for those designs.

- `-test_setup_ireset { off | first_icall | when_icl_present }`

An optional switch and literal pair that specifies if and when an iReset will be automatically added to the beginning of the test setup procedure. Choose one of the following options:

- off

No iReset will automatically be added to the test_setup procedure

- first_icall

An iReset will be automatically added when the first iCall or iMerge is encountered in the test_setup procedure and no user-specified iReset precedes this iCall or iMerge.

- when_icl_present

An iReset will be automatically added if there is ICL for the current design. This is the default setting. It triggers the creation of an appropriate reset sequence at the ICL ports even if the test_setup procedure does not contain any iCall or iMerge statements.

- **-iapply_target_annotations {off | dense | full}**

An optional switch and literal pair that specifies the style of the annotations that show the processed iWrite and iRead targets of an iApply. Choose one of the following options:

- off

Annotations are not created.

- dense

No bit-blasting of registers and ports, binary values with many bits are abbreviated. This is the default.

- full

Registers and ports are bit-blasted, one bit per line, with no abbreviations.

- **-max_operations_per_iapply *integer***

An optional switch and integer pair that specifies the upper limit of scan loads and/or parallel I/O operations that are used to retarget one single iApply. Allowed values are in the range from 4 to 65536, the default is 64. In very complex ICL networks, it might be necessary to increase this limit in order to provide more degrees of freedom to the retargeting engine. But usually the predefined limit will only be reached if it is actually impossible to resolve the current iApply, for example, because of conflicting iWrite commands, a deadlock in the ICL network, and so forth. Please note that increasing this limit can result in very long runtimes of the iApply processing.

- **-compare_constant_capture_values {ON | OFF}**

An optional switch and literal pair that turns on or off the automatic expected value generation for the scan registers.

If turned on, the patterns will not include any extra scan loads. Instead, when a bit happens to be scan out in a given scan load and the value of this bit is known from the CaptureSource description in ICL, a compare value is automatically inferred for that bit at no extra cost. This feature is very useful for diagnosing issues with the network and should be kept on unless the ICL is incorrect.

If the test_setup procedure contains PDL commands, then the inferred compare values (when they exist) are part of the validation of the test_setup procedure (see [E14](#)), and they

are part of the pattern files that contain the vectors for the test setup. If the PDL is processed in an open pattern set in the context “patterns -ijtag”, then the inferred compare values (when they exist) are part of the generated pattern sets. Therefore they will also be part of the pattern files and the retargeted PDL files that are created from those pattern sets when using the write_patterns command. If the inferred compare values are unwanted, the related option of the set_ijtag_retargeting_options command must be turned off before the PDL retargeting happens and during retargeting run. It is not possible to suppress the inferred comparison in existing pattern files or existing retargeted PDL files, if the “-compare_constant_capture_values” or “-compare_constant_data_out_ports” switches were on during the PDL retargeting phase.

- **-compare_constant_data_out_ports {ON | Off}**

An optional switch and literal pair that turns on or off the expected value generation for the primary DataOut ports. If turned on, the patterns will not include any extra vectors. An automatic compare value is inferred on top-level DataOutPorts if its value is known from its described source in ICL. This feature is useful for confirming the correctness of the ICL but is not turned on by default to avoid increasing the number of used ports in a pattern file. For example, if you are exporting the pattern in SVF format, you typically would not want to have to compare output pins other than TDO.

The usage of the -compare_constant_data_out_ports switch impacts the validation of the test_setup procedure, the pattern files and the retargeted PDL. For more information, see the description of the -compare_constant_capture_values switch above.

- **-merge_irunloop_only {on | off}**

An optional switch and literal pair that specifies if iApply statements of concurrent iCalls are allowed to be merged during the processing of an iMerge block. Merging iApply statements can be very complex and the retargeter may spend a lot of time on this task, while the actual benefit (reduction of test time) is negligible in case of tests in which the test time is mainly determined by iRunLoop statements. In such situations, this switch can be set to “on” in order to suppress the merging of iApply statements and to speed up the iMerge computation.

- **-inject_cycles *inject_cycles_list***

An optional switch and string pair that allows the insertion of “dead” cycles (cycles without TCK activity) while the TAP controller is in a certain state. The number of injected cycles is programmable and depends on the TAP state that has just been entered. The *inject_cycles_list* can be a single number or a Tcl list with an even number of arguments, each comprising a TAP state and the related number of injected cycles in alternating order.

You can choose one or more of the following TAP states:

Table 6-10. Allowed TAP States

DRCAPTURE	IRCAPTURE
DRSHIFT	IRSHIFT
DREXIT1	IREDIT1

Table 6-10. Allowed TAP States (cont.)

DRPAUSE	IRPAUSE
DREXIT2	IREXIT2
DRUPDATE	IRUPDATE
IDLE	RESET

The names of the TAP states are consistent with SVF.

The cycles are injected immediately after the TAP state machine has entered the specified state, when the TCK is back to its off-state again. This changes the behavior of the TAP state machine such that the related control signals of a specified TAP state are active for a longer time than they would be usually. Note that the TRST control signal of the TAP is inactive during injected cycles in the RESET state.

The specification of the dead cycles refers to the duration of a TCK cycle, not to the duration of a tester cycle.

The `-inject_cycles` option only affects pattern files in which dead cycles during TAP state transitions can be represented. The output of “`write_patterns -svf`” and “`write_patterns -pdl`” is not changed.

The effect on the pattern files will be the same as using an “`iRunLoop -time`” command. This avoids the TCK pulse. iRunLoops will be inserted at the appropriate places in the unrolled version of the pattern sets. These loops will also be visible by the pattern set introspection command “`get_pattern_set_data`”.

- `-tck_ratio {auto | 1 | 2 | 4 | 8 | 16 | ...}`

An optional switch and literal pair that specifies the TCK ratio for the use of PDL in `test_setup` and `test_end` procedures and for the PDL retargeting in the context patterns `-ijtag`. The default is 4.

In `test_setup` and `test_end` procedures, the waveforms of the TCK ports are either created appropriately (if they have not been specified before) or they are checked with respect to compatibility with the `-tck_ratio` specification.

In the context patterns `-ijtag` the TCK ratio specification of the command `set_ijtag_retargeting_options` becomes effective only if the TCK ratio specification in the command `open_pattern_set` is omitted (“auto” results in a TCK ratio of 1 in this case).

- `-annotation_parameter_values parameters`

An optional switch and list of values to configure the behavior of notes, annotations and comments in Tesson IJTAG. The list must consist of an even number of elements, keys and

values in alternating order. The following table shows an overview of the various configuration possibilities, default values are underlined:

Table 6-11. Annotation Parameter Values

key	possible values	explanation
user	<u>on</u> off	iNote specifications
iapply_targets	off <u>dense</u> full	Annotations about iApply targets, the same as set_ijtag_retargeting_options -iapply_target_annotations
scan_path_registers	<u>on</u> off	Annotations about the scan registers of a scan path
scan_load_unload_value	<u>on</u> off	Annotations about the values of a scan load/unload
tap_states	<u>on</u> off	Annotations about the TAP state transitions in pattern files in which each scan load is unrolled into a series of test vectors. The vectors that correspond to a TAP state transition are annotated with the destination TAP state
network_end_state	<u>on</u> off	Comment indicating that the following test vectors establish the specified network end state, see close_pattern_set -network_end_state set_ijtag_retargeting_options -test_setup_network_end_state
pragma_annotation	<u>on</u> off	The output of “tessonPragma annotation” in the pattern files, that is, the annotation with the original iRead targets, per scan load
pragma_bit_annotation	<u>on</u> off	The output of “tessonPragma bit_annotation” in the pattern files, that is, the annotation with the original iRead targets, per cycle
pragma_variable	<u>on</u> off	The output of “tessonPragma variable” in the pattern files
pragma_bit_variable	<u>on</u> off	The output of “tessonPragma bit_variable” in the pattern files
pragma_icl_checksum	<u>on</u> off	The output of “tessonPragma icl_checksum” in the pattern files
pragma_clock	<u>on</u> off	The output of “tessonPragma clock” in the pattern files
pragma_pattern_set	<u>on</u> off	The output of “tessonPragma pattern_set” in the pattern files
pragma_tester_period	<u>on</u> off	The output of “tessonPragma tester_period” in the pattern files

Table 6-11. Annotation Parameter Values (cont.)

key	possible values	explanation
pragma_expect_z	<u>on</u> off	The output of “tessent_pragma expect_z” in SVF files
svf_command_number	<u>on</u> off	A comment with the command number in SVF files
icl_network_verify_activate	<u>on</u> off	Comments indicating that the following test vectors establish a scan path in the ICLNetworkVerify patterns
icl_network_verify_flush	<u>on</u> off	Comments indicating that the following test vectors are flush patterns, that is, patterns that are loaded and unloaded without performing an “update” and a “capture” operation in between

Examples

Example 1

The following example loads the ICL and turns off the reset of the ICL network after the last test_setup PDL command.

```
SETUP> read_icl ..\data\chip.icl
SETUP> set_ijtag_retargeting_options -test_setup_network_end_state keep
```

Example 2

The following example uses the -inject_cycles option to extend the time in which the TAP rests in “capture-DR” state or “capture-IR” state for the duration of three TCK cycles.

```
set_ijtag_retargeting_options -inject_cycles {DRCAPTURE 3 IRCAPTURE 3}
```

The resulting pattern set will contain three extra cycles without TCK pulse after each vector that brings the state machine to Capture-DR, and three extra cycles without TCK pulse after each vector that brings the state machine to Capture-IR.

To inject five dead cycles in all of the twelve allowed TAP states, omit the state when you issue the -inject_cycles command.

```
set_ijtag_retargeting_options -inject_cycles 5
```

If you want to reset everything, you can do so as follows:

```
set_ijtag_retargeting_options -inject_cycles 0
```

set_insertion_options

Context: unspecified, all contexts

Mode: all modes

Specifies the values for the insertion options. The option settings affect the behavior of the insertion commands.

Usage

```
set_insertion_options [-auto_uniquify_edited_modules {on | off | when_needed }]
[-edited_module_prefix edited_module_prefix]
[-net_uniquification_suffix net_uniquification_suffix]
[-module_uniquification_suffix module_uniquification_suffix]
[-instance_uniquification_suffix instance_uniquification_suffix]
[-allow_assigns {on | off}]
[-inserted_object_comment_label label]
[-treat_common_ancestor_as_unique {on | off}]
[-preserve_paths_for_unrolled_v2001_loops {on | off}]
[-vhdl_port_pin_net_type {bit | std_logic | std_ulogic}]
[-open_input_pins {tie0 | filler_nets}]
[-remove_inactive_sections_in_unrolled_generate_loops {on | off}]
[-trace_across_module_boundaries_to_find_functional_drivers {on | off}]
```

Description

Specifies the values for the insertion options. The option settings affect the behavior of the insertion commands.

Arguments

- `-auto_uniquify_edited_modules {on | off | when_needed }`

An optional switch and literal pair that enables Tesson Shell to uniquify any module that is edited, either unconditionally or only when needed. This will only occur if a module has more than one instance in the current design.

When set to on, a module will be uniquified on the first edit. For example if all instances are edited, the number of unique copies created will equal the number of instances, in addition to the original.

When set to when_needed, a copy of a module is created and uniquified for each parameterized view rather than for each instance. For example if all instances are edited and they are instantiated over two parameterized views, the number of unique copies created will equal two, in addition to the original.

Note

The current design is the design that was specified using the `set_current_design` command.

During uniquification, the new module name is constructed by prefixing the original module name with the specified or default module_uniquification_suffix. The instantiation call of the module in its parent module is automatically changed to use the new module name. If the parent module is also non-unique, it is uniquified until a unique parent module is reached.

- **-edited_module_prefix *edited_module_prefix***

An optional switch and string pair that specifies a prefix to add to every edited module. A valid prefix contains numbers, letters, or underscores. The value you specify is also applied as an optional prefix for ICL module matching and automatically take place in the tool flow when assigning related ICL modules to the new prefixed modules.

By default, the -edited_module_prefix switch puts an underscore character between the prefix and the original module name. For example, if the module name is “xyz” and the prefix is set to “abc”, the resultant module name after editing is “abc_xyz”, not “abccxyz”. When using the [set_module_matching_options -prefix_pattern_list](#) command and switch, the module prefix underscore is not assumed by default. You must explicitly specify the underscore.

Specifying a prefix is advisable when a module is used in multiple designs that are modified by Tessent Shell independently. For example, you have a module called Counter that is used in CoreA and CoreB, and those two cores are processed in isolation, adding a prefix that is a unique string to the module called Counter when editing the module in context of each core will prevent you from having different views of the same module with the same name if CoreA and CoreB are loaded together into a tool such as a simulator.

The -edited_module_prefix defaults to a null string, which means that no module name prefixing is done by default.

- **-net_uniquification_suffix *net_uniquification_suffix***

An optional switch and string pair that defines the string that Tessent Shell uses to uniquify a net when the net that is trying to be created already exists in the design. The string must contain letters, numbers, or underscores and one and only one # symbol at the end identifying a counter that is auto-incremented starting from 1 until the net name does not already exist. For example, specifying -net_uniquification_suffix of _TS# will append the string _TS# to the net where # is replaced by the first integer above 0, making the net name unique. If net A, B, and B_TS1 already exist in the design, Tessent Shell would use A_TS1 if it needed to create a new net with default name A and would use B_TS2 if it tried to create a new net with default name B.

The net_uniquification_suffix defaults to "_ts#". If defined, the [create_connections -net_uniquification_suffix](#) command takes precedence.

- **-module_uniquification_suffix *module_uniquification_suffix***

An optional switch and string pair that defines the string that Tessent Shell uses to uniquify a module. The string must contain letters, numbers, or underscores and one and only one # symbol at the end identifying a counter that is auto-incremented starting from 1 until the module name does not already exist. For example, specifying

-module_uniquification_suffix of _TS# will append the string _TS# to the module name where # is replaced by the first integer above 0, making the module name unique. If module A, B, and B_TS1 already exist in the design, Tesson Shell would use A_TS1 if it needed to create a new module with default name A and would use B_TS2 if it tried to create a new module with default name B.

The module_uniquification_suffix defaults to "_#".

- **-instance_uniquification_suffix *instance_uniquification_suffix***

An optional switch and string pair that defines the string that Tesson Shell uses to uniquify a leaf instance which uses the create_instance command. The string must contain letters, numbers, or underscores and one and only one # symbol at the end identifying a counter that is auto-incremented starting from 1 until the module name does not already exist. For example, specifying -instance_uniquification_suffix of _TS# will append the string _TS# to the instance name where # is replaced by the first integer above 0, making the leaf instance name unique. If leaf instance A, B, and B_TS1 already exist in a module, Tesson Shell would use A_TS1 if it needed to create a new instance with default name A and would use B_TS2 if it tried to create a new instance with default name B.

- **-allow_assigns *on/off***

An optional switch and literal pair that specifies that assign statements are to be converted into Verilog primitive buffers when writing out the design. For example, creating a connection between nets that are also pins causes the creation of an assign statement. Those assign statements will show up as assign statements in the output netlist unless the -allow_assigns is set to off, in which case they will be replaced by buffer primitives.

- **-inserted_object_comment_label *label* (-rtl context only)**

An optional switch and string pair that defines a label that the tool adds to comments appearing before and after each inserted object in the netlist. By default, the label is the null string "" which means no comments are inserted. For more information, refer to [Example 2](#).

- **-treat_common_ancestor_as_unique *on/off***

An optional switch and literal pair that specifies whether the create_connection command treats the common ancestor module of a one-to-many connection as unique. By default, the tool does not lift the connections as if the common ancestor is unique (that is, instantiated only once). This results in the same one-to-many connections being made in all instances of the common ancestor module. This is the setting used when instantiating the instruments as part of the process_dft_specification command.

When set to off, the connection is lifted above the common ancestor if the common ancestor is non-unique and the connection does not include all repeated instances of the destinations. This allows the remaining destinations to be connected to a different source. This functionality is only available when auto-uniquify is off.

If defined, the create_connections -treat_common_ancestor_as_unique command takes precedence.

- **-preserve_paths_for_unrolled_v2001_loops on | off**

An optional switch and literal pair that specifies whether or not to preserve SDC paths to objects found inside unrolled generate loops in Verilog 2001 design files. If you issue the [uniquify_instances](#) command on an instance that is inside a generate loop or if the [set_insertion_options -auto_uniquify_edited_modules](#) option is on, the generate loop will be unrolled as shown below based on the fact that **-preserve_paths_for_unrolled_v2001_loops** is on or off.

For a detailed discussion of the pros and cons of the two option values, refer to “[Unrolling of Generate Loops Side Effects](#)” on page 4021 in “[HDL Limitations in the Tessent Shell Flow](#)” on page 4005.

When on, each loop count is replaced by an if generate block where the block ID is the original block id with the original loop count. This block ID is escaped but the SDC path remains the same as before because in SDC paths, the escape characters are stripped out. In this format, the genvar that existed in the generate loops is no longer present so any occurrence of the genvar in the original Verilog or VHDL code is replace by the literal value of the genvar.

When you set it to off, the unrolled loops are all replaced with single count loops such that the genvar is preserved, allowing the Verilog or VHDL code that reference to the genvar to be preserved unaltered.

Original loop:

```
wire [1:0] in1, in2;
generate
genvar i;
for( i = 0; i < 2; i++ )
begin : joe
`ifndef TECHNOLOGY_32NM
    DUT io ( .A(in1[i]), .B(in2[i]), ... );
`else
    DUT1 io ( .A(in1[i]), .B(in2[i]), ... );
`endif
end for
end generate
```

Unrolled loop when **-preserve_paths_for_unrolled_v2001_loops** is on:

```
wire [1:0] in1, in2;
if(1) begin : \joe[0]
    DUT1 io ( .A(in1[0]), .b(in2[0]), ... );
end
if(1) begin : \joe[1]
    DUT1 io ( .A(in1[1]), .b(in2[1]), ... );
end
```

Unrolled loop when -preserve_paths_for_unrolled_v2001_loops is off:

```
wire [1:0] in1, in2;
genvar i;
for( i = 0; i <=0 ; i++ ) begin : \joe[0]
`ifndef TECHNOLOGY_32NM
    DUT io ( .A(in1[i]), .b(in2[i]), ... );
`else
    DUT1 io ( .A(in1[i]), .b(in2[i]), ... );
`endif
end for
for( i = 1; i <= 1; i++ ) begin : \joe[1]
`ifndef TECHNOLOGY_32NM
    DUT io ( .A(in1[i]), .b(in2[i]), ... );
`else
    DUT1 io ( .A(in1[i]), .b(in2[i]), ... );
`endif
end for
```

- **-vhdl_port_pin_net_type** bit | std_logic | std_ulogic

An optional switch and literal pair that sets the type for new ports, pins, and nets that are created in VHDL. This option has no default. If the option is specified, then new ports, pins, and nets will get the specified type with two exceptions:

- If a new signal is connected to an output pin, then the type of the signal will be the same as the type of the pin.
- If a new signal is connected to another signal with a user-defined type, then the type of the new signal will be the same as the type of the other signal.

If the option is not specified, then the types of new ports, pins, and nets will be determined as follows:

- If the port, pin, or net is to be connected to an existing VHDL signal, then the type of the new signal will be governed by the type of the existing signal to which it is to be connected.
- If the port, pin, or net will not be connected to an existing VHDL signal, then the type of the new signal will be 'bit'.

- **-open_input_pins** tie0 | filler_nets

An optional switch and literal pair that specifies how Tesson Shell handles unconnected input pins for inserted objects. When the option tie0 is specified, the unconnected inputs will be tied low. When filler_nets is specified, the unconnected inputs are tied to a common filler net that is not driven.

- **-remove_inactive_sections_in_unrolled_generate_loops** {on | off}

An optional switch and literal pair that removes inactive parts of loops if the loop contains a part that is inactive for certain values of the loop index.

The switch has only an effect when a VHDL loop is unrolled. Use this option to avoid parsing errors with the inactive section that can happen when the index value is substituted for the unrolled loop.

- **-trace_across_module_boundaries_to_find_functional_drivers {on | off}**

An optional switch and literal pair that specifies whether the tool traces across module boundaries to identify the driver for the [has_functional_source](#) pin attribute. The default is off.

When set to on, the tool continues tracing across module boundaries until it finds a cell driver, an RTL driver, or an open or a tie value to determine the value of the attribute.

Examples

Example 1

The following example sets various insertion options that will affect the behavior of the insertion commands.

```
SETUP> set_insertion_options -edited_module_prefix MyCoreName_ \
           -module_unification_suffix _uniq# -allow_assigns Off
```

Example 2

The following example sets the comment label for inserted objects to “myFlow”.

```
SETUP> set_insertion_options -inserted_object_comment_label myFlow
```

A resulting netlist would then look like this:

```
module top(a, z, b);
    input a;
    output z;
    /* myFlow Ports Start */
    inout b;
    wire b;
    /* myFlow Ports End */
```

Example 3

The following example deactivates automatic commenting of inserted objects. This is the same as the default behavior if you do not specify the `-inserted_object_comment_label` argument at all.

```
SETUP> set_insertion_options -inserted_object_comment_label {}
```

[get_insertion_option](#)

set_insert_test_logic_options

Context: dft -scan, dft -test_points

Mode: setup, analysis

Sets new prefix/infix values that will be used when logic is created by the insert_test_logic command.

Usage

```
set_insert_test_logic_options
  [ -inserted_object_prefix inserted_object_prefix ]
  [ -persistent_cell_prefix persistent_cell_prefix ]
  [ -persistent_clock_cell_prefix persistent_clock_cell_prefix ]
  [ -logic_type
    [ generic
      | clock_gater_fix
      | clock_control_fix
      | dedicated_input_wrapper
      | dedicated_input_holding_wrapper
      | dedicated_output_wrapper
      | lockup
      | pipeline
      | ram_fix
      | testpoint_control
      | testpoint_observation
      | tri_state_fix
      | x_bounding ] ]
  -logic_infix logic_infix ]
```

Description

The set_insert_test_logic_options command sets new prefix/infix values that will be used when logic is created by the insert_test_logic command.

Arguments

- **-inserted_object_prefix *inserted_object_prefix***
An optional switch and string pair that specifies the prefix of HDL objects created during “insert_test_logic”. The default is “ts_”.
- **-persistent_cell_prefix *persistent_cell_prefix***
An optional switch and string pair that specifies the prefix of persistent cell instances created during “insert_test_logic”. The default is “tessent_persistent_cell_”.
- **-persistent_clock_cell_prefix *persistent_clock_cell_prefix***
An optional switch and string pair that specifies the prefix of persistent clock cell instances created during “insert_test_logic”. The default is “tessent_persistent_cell_”.

- **-logic_type**

An optional switch and literal pair that specifies the logic type for which the infix must be set. The possible logic types are as follows:

generic — Used for generic logic and has the default infix “logic_”.

clock_gater_fix — Used for clock gater control and has the default infix “cgfix_”.

clock_control_fix — Used for clock control and has the default infix “clkfix_”.

dedicated_input_wrapper — Used for dedicated input wrapper cells and has the default infix “diw_”.

dedicated_input_holding_wrapper — Used for dedicated input holding wrapper cells and has the default infix “dihw_”.

dedicated_output_wrapper — Used for dedicated output wrapper cells and has the default infix “dow_”.

lockup — Used for scan chain retiming cells and has the default infix “lockup_”.

pipeline — Used for scan chain pipeline cells has the default infix “pipeline_”.

ram_fix — Used for ram control and has the default infix “ramfix_”.

testpoint_control — Used for control testpoint and has the default infix “cp_”.

testpoint_observation — Used for observation testpoint and has the default infix “op_”.

tri_state_fix — Used for tristate and bidi control and has the default infix “trifix_”.

x_bounding — Used for X-bounding and has the default infix “xb_”.

Note

 The -logic_type switch must be used in conjunction with the -logic_infix switch.

- **-logic_infix *logic_infix***

An optional switch and string pair that specifies the infix to use when implementing HDL objects of a specified logic type during “insert_test_logic”.

Note

 The -logic_infix switch must be used in conjunction with the -logic_type switch.

Examples

The following example demonstrates the use of the set_insert_test_logic_options command.

```
SETUP> get_insert_test_logic_option -logic_type dedicated_input_wrapper
diw_
SETUP> set_insert_test_logic_options -logic_type dedicated_input_wrapper -logic_infix
inreg_
SETUP> get_insert_test_logic_option -logic_type dedicated_input_wrapper
inreg_
```

SETUP> report_insert_test_logic_options

// 'insert_test_logic' Command Option	Current Value
// -----	-----
// -inserted_object_prefix	ts_
// -logic_type clock_control_fix	clkfix_
// -logic_type clock_gater_fix	cfgfix_
// -logic_type dedicated_input_holding_wrapper	dihw_
// -logic_type dedicated_input_wrapper	inreq_
// -logic_type dedicated_output_wrapper	dow_
// -logic_type generic	logic_
// -logic_type lockup	lockup_
// -logic_type pipeline	pipeline_
// -logic_type ram_fix	ramfix_
// -logic_type testpoint_control	cp_
// -logic_type testpoint_observation	op_
// -logic_type tri_state_fix	trifix_
// -logic_type x_bounding	xb_
// -persistent_cell_prefix	tessent_persistent_cell_
// -persistent_clock_cell_prefix	tessent_persistent_clock_cell_

[get_insert_test_logic_option](#)
[report_insert_test_logic_options](#)

set_internal_fault

Context: dft -edt, dft -scan, patterns -scan, patterns -scan_diagnosis

Mode: setup

Specifies whether the tool allows faults within or only on the boundary of library models.

Usage

`set_internal_fault OFF | ON`

Description

Specifies whether the tool allows faults within or only on the boundary of library models.

The `set_internal_fault` command specifies whether the tool allows faults on internal nets of library models (internal faulting) or only on the library model boundary. The default upon invocation of the tool is to allow faults only on the library model boundary.

Note

 This command is not valid for the bridge logic fault model (specified with the “[“set_fault_type Bridge -Static” command](#)”).

Arguments

- **OFF**
A required literal that allows faults only on the boundary of the library models. This is the default.
- **ON**
A required literal that allows faults on the internal nets of library models.

Examples

The following example performs ATPG using a fault list that includes internal nets within the library cells. These internal nets will be shown as fault sites when the `report_faults` command is executed.

```
set_context patterns -scan
set_internal_fault on
set_system_mode analysis
create_patterns
report_faults -all
```

set_internal_name

Context: all contexts

Mode: setup

Specifies whether to delete or keep pin names of library internal pins containing no-fault attributes.

Usage

`set_internal_name OFF | ON`

Description

Specifies whether to delete or keep pin names of library internal pins containing no-fault attributes.

The `set_internal_name` command specifies whether to keep internal library pins with no-fault attributes. Normally, you should delete these names for memory and performance reasons. The default operation (OFF) upon invocation is to delete these names.

Arguments

- **OFF**
A literal that deletes the lowest level pin names if they have the `nofault` attribute. This is the default.
- **ON**
A literal that keeps the lowest level pin names, even if they have the `nofault` attribute.

Examples

The following example deletes pin names with the `nofault` attribute.

`set_internal_name off`

set_io_mask

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Modifies the behavior of bidirectional pins so that their expected values will always be X during test cycles in which the primary input portion of the bidirectional pin is being forced.

Usage

`set_io_mask OFF | ON`

Description

Modifies the behavior of bidirectional pins so that their expected values will always be X during test cycles in which the primary input portion of the bidirectional pin is being forced.

Typically, when the tool forces stimulus on an bidirectional pin, it will expect to measure the same value on the corresponding primary output pin. This command lets you modify this behavior in cases where this is undesirable.

Arguments

- OFF
An optional literal that disables the ability to mask the bidirectional pin output value. This is the default.
- ON
An optional literal that enables the ability to mask the bidirectional pin output value.

Examples

The following example causes the tool to mask the bidirectional pin output value.

`set_io_mask on`

[set_latch_handling](#)

Context: dft -scan

Mode: setup

Specifies whether the tool considers non-transparent latches for scan insertion while test logic is turned on.

Usage

`set_latch_handling None | Scan`

Description

Specifies whether the tool considers non-transparent latches for scan insertion while test logic is turned on.

The `set_latch_handling` command specifies whether the tool can consider non-transparent latches as candidates for scan insertion. If you determine that the tool is to consider non-transparent latches as candidates for scan insertion, you must turn on the appropriate [`set_test_logic`](#) command settings before the tool performs the rules checking process.

If you use the [`set_drc_handling`](#) command to set the D6 rule to error or warning, D6 checks the non-scannable latches for transparency. By default, if they are not transparent and you turned test logic insertion on, the tool does not consider the non-transparent latches for scan insertion. However, if you use the Scan argument with the [`set_latch_handling`](#) command, the tool will consider the non-transparent latches for scan insertion.

If you use the [`set_drc_handling`](#) command to ignore the D6 rule, then rules checking does not check the non-scannable latches for transparency and the tool will automatically consider all non-scannable latches, whose test logic you turned on, for scan insertion.

Arguments

- **None**

A literal that specifies to give no consideration to non-transparent latches for scan insertion. This is the default upon invocation of the tool.

- **Scan**

A literal that specifies to consider non-transparent latches for scan insertion when test logic is turned on.

Related Topics

[`set_drc_handling`](#)

[`set_test_logic`](#)

set_layout_core_instance

Context: patterns -scan_diagnosis

Mode: setup, analysis

Sets the current layout core instance for inter-scan cell logic reporting with the report_scan_polygons command.

Usage

`set_layout_core_instance instance_path`

Description

Sets the current layout core instance for inter-scan cell logic reporting with the report_scan_polygons command.

You must use this command when you perform inter-scan cell logic reporting in the context of hierarchical layout-aware diagnosis. The command is required because inter-scan cell logic reporting occurs outside the processing of a diagnosis report. The set_layout_core_instance command has no effect on diagnose_failures because the tool automatically sets the layout core instance based on the coreInstance keyword in the tracking_info section of the failure file when processing a diagnosis report.

See “[Diagnosis for Hierarchical Design](#)” and “[Inter-Scan Cell Polygon Reporting for Chain Diagnosis](#)” in the *Tessent Diagnosis User’s Guide* for more information.

Arguments

- ***instance_path***

A required string that specifies the path to a layout core instance.

Related Topics

[get_layout_core_instance](#)

[report_scan_polygons](#)

set_lbist_controller_options

Context: dft -logic_bist, patterns -scan, patterns -scan_diagnosis

Mode: setup

Specifies global options to configure the LogicBIST controller.

Usage

IP Creation Usage

```
set_lbist_controller_options [off | on] -max_shift_cycles {integer1 [integer2]}
  -max_capture_cycles {integer1 [integer2]}
  -max_pattern_count {integer1 [integer2]}
  [-max_warmup_pattern_count {integer1 [integer2]})
  [-controller_chain_mode {off | on} -controller_chain_clock {tck | edt_clock}]
  -capture_procedures {procname [integer%] | count | integer%}...
  [-shift_counter_resolution {bit | byte}]
  [-pre_post_shift_dead_cycles integer]
  [-tessent_occ {auto | on}] [-burn_in {off | on}]
  [-single_chain_mode_skip_edt_blocks {off | on}]
```

Fault Simulation Usage

```
set_lbist_controller_options [off | on] -capture_procedures {procname integer%}...
```

Description

Specifies global options to configure the LogicBIST controller.

This command is used with the hybrid TK/LBIST flow. Refer to the *Hybrid TK/LBIST Flow User's Manual* for complete information.

Arguments

- off | on

An optional literal that specifies enabling or disabling LogicBIST controller configuration. The default is on.

- **-max_shift_cycles** {*integer1* [*integer2*]}

A required switch and integer pair or triplet that specifies the maximum possible shift length the tool uses to synthesize the LogicBIST shift length counter.

An optional second argument, *integer2*, can be used to specify the value to be loaded in the shift length counter for the hardware default mode of operation. This value should be less than or equal to the *integer1*, the maximum shift cycles.

If you do not specify a value, then the maximum shift cycles value will be used for the hardware default mode.

- **-max_capture_cycles {integer1 [integer2]}**

A required switch and integer pair or triplet that specifies the maximum possible capture width the tool uses to synthesize the LogicBIST capture width counter.

An optional second argument, *integer2*, can be used to specify the value to be loaded in the capture width counter for the hardware default mode of operation. This value should be less than or equal to the **integer1**, the maximum capture width.

If you do not specify a value, then the maximum capture width will be used for the hardware default mode.

- **-max_pattern_count {integer1 [integer2]}**

A required switch and integer pair or triplet that specifies the maximum number of LogicBIST patterns that will be applied when the tool synthesizes the LogicBIST pattern counter.

An optional second argument, *integer2*, can be used to specify the value to be loaded in the pattern counter for the hardware default mode of operation. This value should be less than or equal to the **integer1**, the maximum pattern count.

If you do not specify a value, then the maximum pattern count will be used for the hardware default mode.

- **-max_warmup_pattern_count {integer1 [integer2]}**

An optional switch and integer pair that specifies the maximum number of Logic BIST warm-up patterns that the tool can apply. The default is 511. *integer1* gets rounded up to the next power of 2 minus 1.

You can use an optional second argument, *integer2*, to specify the number of warm-up patterns to be applied for the hardware default mode of operation. This value must be less than or equal to *integer1*, the maximum pattern count. If you do not specify a value, then no warm-up patterns will be applied for the hardware default mode.

If you do not want the tool to insert the warm-up pattern count register in the logic BIST controller, set *integer1* to 0. Refer to “[Warm-Up Patterns](#)” in the *Hybrid TK/LBIST Flow User’s Manual* for details.

- **-controller_chain_mode {off|on}**

An optional switch and literal pair that specifies whether to enable or disable the Controller Chain Mode. When enabled, the tool creates an RTL scan chain so that it can calculate test coverage for the LBIST controller and EDT/LBIST blocks. The default is off.

- **-controller_chain_clock {tck | edt_clock}**

An optional switch and literal pair that specifies whether the tool will use the tck or edt_clock clock during Controller Chain Mode. The default is edt_clock.

- **-capture_procedures {procname [integer%] | count | integer%}**

A required switch and repeatable string pair that specifies the Named Capture Procedure (NCP) name for which the NCP should be applied.

If a percentage is specified, all the NCPs are repeated according to the specified percentage once every 256 patterns. The sum of all the specified percentages should add up to 100.

You can specify the percentage in addition to the name of the NCP or the percentage on its own without naming the NCP.

Because the integer percentage may not be known at IP creation time, the integer percentage can be omitted and specified during fault simulation. At that time, you can program the percentage activity for each NCP without having to regenerate the IP. A percentage value of 0 means that the NCP will not be active for the pattern set.

The mutually-exclusive **count** option generates the LBIST controller that can support up to the "count" NCPs.

- **-shift_counter_resolution {bit | byte}**

An optional switch and literal pair that specifies whether the shift counter allows shift lengths that operate in multiples of 8 or 1. When you specify "byte", the tool rounds up the length of the longest scan chain to the next multiple of 8. For example, if the longest scan chain is 67 flops long, then the tool applies 72 shifts. This is the default.

By default, the tool applies the number of shifts equal to the length of the longest scan chain.

Note

If the shift length specified during IP generation differs from that used during fault simulation, you may be required to use the **set_number_shifts** command during fault simulation when creating HW default patterns. For example, suppose you have 29 scan chains for fault simulation, but for IP generation you specified a HW default max shift of 38. In this case you would specify the **set_number_shifts** command to create patterns for HW default mode.

- **-pre_post_shift_dead_cycles integer**

An optional switch and integer pair that specifies how many shift pause and capture pause dead cycles, at the shift clock period, will be applied before and after the capture clocks are pulsed. The specified integer can be between 2 and 8, with the default being 8. For example, specifying 5 means that the shift pause will consist of 5 dead cycles and the capture pause will consist of 5 dead cycles.

Reducing the number of pause cycles reduces the test time, but it may also make it harder to achieve timing closure of the test logic. To ensure that the shift and capture signals are staggered an integer value of 1 is not supported.

- **-tesson_occ {auto | on | off}**

An optional switch and literal that generates a Tessent OCC-compatible LBIST controller for skeleton designs that do not contain Tessent OCC instances. You specify this switch during pre-synthesis IP creation. Choose one of the following options:

auto — Infers the Tessent OCC instruments from the TCD and the ICL. This is the default.

on — Enables generation of Tessent OCC compatible LBIST controller when OCC core instances are not added.

- **-burn_in {off | on}**

An optional switch and literal pair that specifies whether to enable or disable support for wafer-level burn-in tests. When enabled, the tool creates additional RTL to allow LogicBIST to run for longer periods of time than supported by the pattern counter hardware. The default is off.

- **-single_chain_mode_skip_edt_blocks {off | on}**

An optional switch and literal pair that specifies whether to insert a SIB in each EDT block that allows optionally skipping all scan chains in a given EDT block during single chain unload. The default is on. For details, refer to “[Single Chain Mode Diagnosis](#)” in the *Hybrid TK/LBIST Flow User’s Manual*.

Examples

Example 1

The following example configures the LogicBIST controller for a maximum scan chain length of 1000 and a maximum capture width of 8 cycles. The maximum number of patterns is set to 250,000 and number of patterns run in the hardware default mode is set as 5,000. There are 4 NCPs defined for LogicBIST test such that each of them is active for 25% of the patterns. A maximum of 127 warm-up patterns will be allowed with 16 warm-up patterns run in the hardware default mode.

```
set_lbist_controller_options -max_shift_cycles 1000 -max_capture_cycles 8
set_lbist_controller_options -max_pattern_count {250000 5000}
set_lbist_controller_options -max_warmup_pattern_count {128 16}
set_lbist_controller_options -capture_procedures \
    {clkseq1 25 clkseq2 25 clkseq3 25 clkseq4 25}
```

Example 2

The following example is the same as the previous example except that the NCP percentage integer values have not been specified with the commands issued for IP creation. In this case, the NCP percentage integer values must be set by issuing the command with the desired values for fault simulation.

```
set_lbist_controller_options -max_shift_cycles 1000 -max_capture_cycles 8
set_lbist_controller_options -max_pattern_count {250000 5000}
set_lbist_controller_options -capture_procedures {clkseq1 clkseq2 clkseq3 clkseq4}
```

set_lbist_instances

Context: dft -logic_bist

Mode: setup

Specifies the instance in which the LogicBIST controller or single chain mode logic is placed.

Usage

```
set_lbist_instances [-controller_location instance_path_name]  
                  [-single_chain_mode_logic_location instance_path_name]
```

Description

Specifies the instance in which the LogicBIST controller or single chain mode logic is placed.

This command is used with the hybrid TK/LBIST flow. Refer to the [Hybrid TK/LBIST Flow User's Manual](#) for complete information.

By default, the tool places the LogicBIST controller and single chain mode logic in the top level of the design. Using this command, you can specify a different location for the LogicBIST controller or single chain mode logic.

For example, you can use this command to place the LogicBIST controller or single chain mode logic instance in a specific test logic block or in an always-ON block on a design with multiple power domains.

Arguments

- **-controller_location *instance_path_name***
An optional switch and string pair that specifies the hierarchical instance pathname where the tool instantiates the LogicBIST IP.
- **-single_chain_mode_logic_location *instance_path_name***
An optional switch and string pair that specifies the hierarchical instance pathname where the tool instantiates the single chain mode logic.

Examples

The following example instantiates the LogicBIST controller in an always ON power domain instance */pwr_always/dft_logic*:

```
set_lbist_instances -controller_location /pwr_always/dft_logic
```

The following example instantiates the LogicBIST controller and single chain mode logic in a dedicated test logic block instance */dft_test_logic_i*:

```
set_lbist_instances -controller_location /dft_test_logic_i \  
                   -single_chain_mode_logic_location /dft_test_logic_i
```

```

Rename LogicBIST Pins

```
set_lbist_pins [pin_function port_name -on_controller_module] ...
```

Description

Specifies the connection information for LogicBIST controller pins. You can also use this command to rename pins at the LogicBIST module level in the RTL.

This command is used with the hybrid TK/LBIST flow—refer to the [Hybrid TK/LBIST Flow User's Manual](#) for complete information.

Specifying LogicBIST Pin Connections

When specifying LogicBIST pin connections, the pins are connected to the single top-level LogicBIST controller. This is in a global context and not specific to the current EDT block. The

first argument is a literal string that indicates the pin being described in the command followed by one or more pin names.

If you issue this command multiple times with the same pin type, then the last pin or pins you specify are used. To specify multiple pin names corresponding to a pin type, specify all the names in a single issuance of the command.

If the signal to be connected to the LogicBIST controller is internally generated and does not have a corresponding top-level pin, use a '-' literal in place of the *top_pin_name* argument.

Renaming Pins

When renaming pins, the *-on_controller_module* switch accepts the following pin functions. The default pin names are shown. By default, the done pin is not created on the LogicBIST controller. Only when this pin is specified will the port be created on the RTL.

Note

 Pin functions shown with asterisks (*) are those for which you can also specify the pin connections.

Table 6-12. Pin Functions That Can Be Renamed

Pin Function	Default Name	Pin Function	Default Name
clock *	shift_clock_src	controller_chain_scan_out *	ccm_scan_out
tck *	ijtag_tck	controller_chain_scan_en	ccm_scan_en
setup_shift_scan_in *	ijtag_si	test_clock	test_clock
setup_shift_scan_out *	ijtag_so	edt_update	edt_update
tap_instruction_decode *	ijtag_sel	clock_out	edt_lbist_clock
test_logic_reset *	ijtag_reset	reset_out	lbist_reset
capture_dr *	ijtag_ce	enable_out	lbist_en
shift_dr *	ijtag_se	done	<i>no default value</i>
update_dr *	ijtag_ue	prpg_en	lbist_prpg_en
scan_en *	scan_en_in scan_en_out	mistr_en	mistr_accumulate_en
controller_chain_en *	ccm_en	ijtag_select_out	edt_sib_en

Table 6-12. Pin Functions That Can Be Renamed (cont.)

Pin Function	Default Name	Pin Function	Default Name
controller_chain_scan_in *	ccm_scan_in		

Arguments**Specify LogicBIST Controller Pin Connections**

- ***top_pin_name* | -**

A required string or literal that specifies the pin name to be connected to the LogicBIST controller. Choose from the following:

 - top_pin_name* — A string that specifies the name of the pin to assign to the specific signal.
 - — A literal used for internally-generated pins and do not have a corresponding top-level pin.
- ***internal_pin_name***

An optional string that specifies an internal pin name.
- **scan_en {*top_pin_name* | -} [*internal_pin_name* | -]}**

A required literal and string pair that specifies the scan enable pin and optionally the internal pin corresponding to the pad output. Multiple values can be specified if the design has multiple scan enables.
- **clock {*top_pin_name* | -} [*internal_pin_name*]**

An optional literal and string pair that specifies the LogicBIST clock pin.

When a top-level tester controllable clock is available, the same pin can be used for both EDT and LogicBIST clocks. However, when the EDT clock is internally generated, a different asynchronous free-running clock should be specified as the LogicBIST clock.
- **tck{*top_pin_name* | -} [*internal_pin_name*]**

An optional literal and string pair that specifies the JTAG TCK input and optionally the internal pin corresponding to the pad output.
- **setup_shift_scan_in {*top_pin_name* | -} [*internal_pin_name*]**

An optional literal and string pair that specifies the connection to the seeding register input. In a JTAG based design, this would typically be connected to the TDI pin.
- **setup_shift_scan_out {*top_pin_name* | -} [*internal_pin_name*]**

An optional literal and string pair that specifies the connection to the seeding register output. In a JTAG based design, this would typically be connected to the TDO pin through the DR-mux.

- **tap_instruction_decode** {*top_pin_name* |-} [*internal_pin_name*]

An optional literal and string pair that specifies the connection to the instruction decoder output that indicates when the TAP instruction that targets LogicBIST is loaded in the JTAG instruction register.

- **test_logic_reset** {*top_pin_name* |-} [*internal_pin_name*] [-active high | low]

An optional literal and string pair that specifies the connection to the test_logic_reset output of the TAP controller that indicates when the TAP is in test-logic-reset state. The default active reset state is low. Use the optional -active switch to change the active reset state to high.

- **capture_dr** {*top_pin_name* |-} [*internal_pin_name*]

An optional literal and string pair that specifies the connection to the capture_dr output of the TAP controller that indicates when the TAP is in the capture-DR state.

- **shift_dr** {*top_pin_name* |-} [*internal_pin_name*]

An optional literal and string pair that specifies the connection to the shift_dr output of the TAP controller that indicates when the TAP is in the shift-DR state.

- **update_dr** {*top_pin_name* |-} [*internal_pin_name*]

An optional literal and string pair that specifies the connection to the update_dr output of the TAP controller that indicates when the TAP is in the update-DR state.

- **xbounding_en** {*pin_name* | -no_connection}

An optional literal and string pair that specifies the xbounding enable pins. Specifying the -no_connection option instead of *pin_name* creates the pin in the LogicBIST controller but does not connect it to the design.

- **control_point_en** {*pin_name* | -no_connection}

An optional literal and string pair that specifies the control point enable pins. The pin names refer to the control_point_en pin created by Tessent Shell during test point insertion.

Specifying the -no_connection option instead of *pin_name* creates the pin in the LogicBIST controller but does not connect it to the design.

- **observe_point_en** {*pin_name* | -no_connection}

An optional literal and pin name that specifies the observe point enable pins. The pin names refer to the observe_point_en pin created by Tessent Shell during test point insertion.

Specifying the -no_connection option instead of *pin_name* creates the pin in the LogicBIST controller but does not connect it to the design.

- **test_en** {*pin_name* | -no_connection}

An optional literal and string pair that specifies the test enable pins. The pin names refer to the test_en pin created during scan insertion. Specifying the -no_connection option instead of *pin_name* creates the pin in the LogicBIST controller but does not connect it to the design.

- **mcp_bounding_en** {*pin_name* | -no_connection}
An optional literal and string pair that specifies the MCP bounding enable pins. The pin names refer to the *mcp_bounding_en* pin created during X-bounding to bound false and multicycle paths. Specifying the -no_connection option instead of *pin_name* creates the pin in the LogicBIST controller but does not connect it to the design.
- **controller_chain_en** {{*top_pin_name* | -} [*internal_pin_name* | -]}
An optional literal and string pair that specifies the controller chain mode enable pin and optionally the internal pin corresponding to the pad output.
- **controller_chain_scan_in** {{*top_pin_name* | -} [*internal_pin_name* | -]}
An optional literal and string pair that specifies the controller chain mode scan input pin and optionally the internal pin corresponding to the pad output.
- **controller_chain_scan_out** {{*top_pin_name* | -} [*internal_pin_name* | -]}
An optional literal and string pair that specifies the controller chain mode scan output pin and optionally the internal pin corresponding to the pad output.
- **wrapper_chain_input_scan_en** {{*top_pin_name* | -} [*internal_pin_name* | -]}
An optional literal and string pair that specifies the scan enable pin of the input wrapper chains and optionally the internal pin corresponding to the pad output. Multiple values can be specified if the design has multiple input scan enables for the wrapper chain. The wrapper chain input scan enable signals are held at constant 1 (specifically, shift) during LogicBIST test. For ATPG, they remain controllable from specified top or internal pins.

Rename LogicBIST Pins

- ***pin_function***
A required string for pin renaming that specifies the pin function whose default name you want to change. Refer to [Table 6-12](#).
- ***port_name***
A required string for pin renaming that specifies the new name for the specified pin function.
- **-on_controller_module**
A required switch for pin renaming that specifies to rename the specified pin on the LogicBIST module in the LogicBIST RTL. Pin renaming only applies to the specified pin at the LogicBIST module level.

Examples

Example 1

This example specifies the connections between design pins and LogicBIST controller pins, including the TAP interface. A dash is used as the first argument for the TAP generated control signals, since there is no corresponding top-level pin for these signals.

```
set_ibist_pins clock refclk
```

```
set_lbist_pins scan_en scan_en
set_lbist_pins xbounding_en lbist_en
set_lbist_pins setup_shift_scan_in tdi
set_lbist_pins setup_shift_scan_out { tdo jtag/scanCfgReg_so }
set_lbist_pins shift_dr { - jtag/shift_dr }
set_lbist_pins capture_dr { - jtag/capture_dr }
set_lbist_pins update_dr { - jtag/update_dr }
set_lbist_pins test_logic_reset { - jtag/tlr }
set_lbist_pins tap_instruction_decode { - jtag/scanCfgReg_en }
```

Example 2

In this example, the design pin “lbist_en” is used as the enable signal for x-bounding, control points, and observe points. Note that the same pin is specified for all three pin types. The LogicBIST controller will have only a single enable register named “x_bounding_en.”

```
set_lbist_pins xbounding_en lbist_en
set_lbist_pins control_point_en lbist_en
set_lbist_pins observe_point_en lbist_en
```

Example 3

This example illustrates how to specify multiple scan enable signals without pads. Since the scan enable pin names should be specified in pairs, a dash is used for each of the non-existent internal pin names.

```
set_lbist_pins scan_en {scan_en - wrp_scan_en -}
```

Example 4

The following example generates TDR bits inside the LogicBIST controller for all different enables signals for a skeleton flow in which the design enable pins are not yet available:

```
set_lbist_pins xbounding_en -no_connection
set_lbist_pins control_point_en -no_connection
set_lbist_pins observe_point_en -no_connection
set_lbist_pins test_en -no_connection
set_lbist_pins mcp_bounding_en -no_connection
```

Example 5

The following example renames LogicBIST ports back to their pre-2018.1 release versions for purposes of backwards annotation.

```
set_lbist_pins tck tck -on_controller_module
set_lbist_pins setup_shift_scan_in lbist_scan_in -on_controller_module
```

```
set_lbist_pins setup_shift_scan_out lbist_scan_out -on_controller_module
set_lbist_pins tap_instruction_decode sib_en -on_controller_module
set_lbist_pins test_logic_reset sib_reset -on_controller_module
set_lbist_pins capture_dr sib_capture_en -on_controller_module
set_lbist_pins shift_dr sib_shift_en -on_controller_module
set_lbist_pins update_dr sib_update_en -on_controller_module
set_lbist_pins edt_clock edt_clock -on_controller_module
set_lbist_pins test_clock edt_clock -on_controller_module
set_lbist_pins clock_out lbist_clock -on_controller_module
set_lbist_pins prpg_en prpg_en -on_controller_module
set_lbist_pins misr_en misr_en -on_controller_module
set_lbist_pins occ_shift_clock clk_ctrl_shift_clk -on_controller_module
set_lbist_pins occ_scan_en clk_ctrl_scan_en -on_controller_module
set_lbist_pins occ_capture_en clk_ctrl_capture_en -on_controller_module
```

[set_edt_options](#)

set_lbist_power_controller_options

Context: dft -logic_bist

Mode: setup

Specifies creation of the low-power shift controller for LogicBIST.

Usage

```
set_lbist_power_controller_options [shift {none | disabled | enabled}]  
[-min_switching_threshold_percentage sw_percentage]]
```

Description

Specifies creation of the low-power shift controller for LogicBIST.

This command is used with the hybrid TK/LBIST flow—refer to the [Hybrid TK/LBIST Flow User's Manual](#) for complete information.

This command is applicable to the current LogicBIST block.

When you specify this command during IP creation, the tool creates the low-power shift controller for LogicBIST. This command is carried forward in the generated fault simulation dofile to indicate whether the current EDT block has low-power shift logic synthesized (automatically added to the fault simulation dofile).

Arguments

- **shift none | disabled | enabled**

A literal pair that indicates the configuration parameters for controlling shift power.

Choose one of the following:

- **none** — Indicates that the low-power controller is not synthesized.
- **disabled** — Forces a LogicBIST run to bypass the low power controller.
- **enabled** — Enables the low-power controller.

When you specify either 'enabled' or 'disabled', a low-power controller with the specified switching threshold percentage is synthesized.

- **-min_switching_threshold_percentage *sw_percentage***

An optional switch and integer that specifies the switching threshold value for the hardware default mode. Valid integer values are between 1 and 50. The default value is 15 percent.

During fault simulation, you can specify any switching threshold.

Examples

This example shows three EDT/LogicBIST blocks, two of which are to be synthesized with both EDT and LogicBIST low-power logic, while the third block does not have low power shift logic.

```
add_edt_block lpblk1
set_edt_power_controller shift enabled -min_switching_threshold 20
set_ibist_power_controller_options shift enabled
add_edt_block lpblk2
set_edt_power_controller shift enabled -min_switching_threshold 8
set_ibist_power_controller_options shift enabled
add_edt_block rgblk
```

[set_power_control](#)
[set_edt_power_controller](#)

set_learn_report

Context: all contexts

Mode: setup, analysis

Prerequisites: The current design must be set.

Specifies whether the report_gates command can display the learned behavior for a specific gate.

Usage

set_learn_report OFF | ON

Description

Specifies whether the report_gates command can display the learned behavior for a specific gate.

The set_learn_report command specifies whether the report_gates command should include the information that the tool collects during the static learning process. The application automatically performs the static learning process immediately after it flattens the simulation model, which happens when you leave the Setup mode or issue the [create_flat_model](#) command. The static learning process provides general information on the design that the tool can then use in speeding up the ATPG process (such as values that are impossible on other gates if the selected gate is at a specific value.)

Once you enable access to the static learned information with the set_learn_report command, you can specify for the tool to display the learned information on a selected gate by using the report_gates command.

While you can also access the learned information with the report_gates command by using the -Type option, this method displays the information for all the gates of the specified gate type. When you enable access with the set_learn_report command, the tool automatically displays the learned information with all command options. Therefore, you can restrict the report to the learned information on an individual object.

Arguments

- OFF
An optional literal that disables access to the learned behavior information. This is the default.
- ON
An optional literal that enables access to the learned behavior information.

Examples

The following example enables access to the learned behavior and then accesses that information:

```
set_learn_report on
report_gates 28

/MX3/OR1 (28) OR
    IO      I  20-/MX3/AN2/OUT
    I1      I  24-/MX3/AN1/OUT
    OUT     O  37-/OUT0
Learned behavior:  MUX(9,13,17)
```

set_lfsr_seed

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Sets the initial value of a PRPG or a MISR.

Usage

`set_lfsr_seed name seed [-Binary | -Hexadecimal]`

Description

Sets the initial value of a PRPG or a MISR.

The `set_lfsr_seed` command initializes the value of a PRPG or MISR with a seed value. The seed value must be specified by a hexadecimal or binary number greater than zero.

Arguments

- ***name***
A required string that specifies the name of the PRPG or MISR.
- ***seed***
A required number, greater than zero, that specifies the initial state of the LFSR.
- **-Binary**
An optional switch that specifies to output the value of the *seed* argument in binary format. By default, the seed is output in hexadecimal.
- **-Hexadecimal**
An optional switch that specifies to output the value of the *seed* argument in hexadecimal format. This is the default.

Examples

`set_lfsr_seed prpg 5`

Related Topics

[add_lfsr_taps](#)

[add_lfsrs](#)

[delete_lfsrs](#)

set_lfsrs

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup

Changes the *shift_type* and *tap_type* default setting for the add_lfsrs and add_lfsr_taps commands.

Usage

```
set_lfsrs [-Both | -Serial | -Parallel] [-Out | -In | -Ca]
```

Description

Changes the *shift_type* and *tap_type* default setting for the add_lfsrs and add_lfsr_taps commands.

The set_lfsrs command controls the default setting for the *shift_type* and *tap_type* switches. You specify the LFSR's shift technique by using one of the following *shift_type* switches: -Both, -Serial, or -Parallel. You specify the placement of the exclusive-OR taps by using one of the following *tap_type* switches: -Out or -In; or you specify the type of LFSR as cellular automata using the *tap_type* switch -Ca. When you change one or both of the default settings, all future add_lfsrs and add_lfsr_taps commands use the new default.

Arguments

The following lists the three *shift_type* switches of which you can choose only one:

- **-Both**

An optional switch specifying that the LFSR shifts both serially and in parallel. This is the default behavior upon invocation of the tool.

- **-Serial**

An optional switch specifying that a serial shift LFSR shifts a number of times equal to the length of the longest scan chain for each scan pattern.

- **-Parallel**

An optional switch specifying that a parallel shift LFSR shifts once for each scan pattern.

The following lists the three *tap_type* switches of which you can only choose one:

- **-Out**

An optional switch that places the exclusive-or taps outside the register path. This is the default upon invocation of the tool.

- **-In**

An optional switch specifying that the exclusive-or taps are placed outside the register path.

- **-Ca**

An optional switch specifying that the default PRPG type is cellular automata.

Examples

The following example changes the default *shift_type* setting to Serial and the default *tap_type* switch to In:

```
set_lfsrs -serial -in
add_lfsrs lfsr1 prpg 5 13
add_lfsrs lfsr2 prpg 5 11
add_lfsr_taps lfsr1 2 3
add_lfsr_taps lfsr2 3 4
set_system_mode analysis
```

set_license_queue_timeout

Context: all contexts

Mode: all modes

Specifies the amount of time that the tool queues for one or more required licenses when not immediately available.

Usage

```
set_license_queue_timeout [{value | unlimited | no_queue}]  
[-release_and_requeue_after release_and_requeue_after]
```

Description

Specifies the amount of time that the tool queues for one or more required licenses when not immediately available.

This command configures the time the tool waits for acquiring one or more required licenses (for example, during [set_context](#)). You can specify the same value during tool startup with the command line switch `-license_wait` (for example `tessent -license_wait`).

When the tool requires more than one license or if some licenses have alternatives, the tool queues for all of the possible licenses and acquires the first available. The tool reports progress every minute, showing which licenses are still missing and how long before timeout. If the tool cannot acquire a license during the specified time, the tool reports an error and aborts the operation that requested the license. You can interrupt the license queuing with Ctrl-C, which also aborts the operation that requested the license(s).

Arguments

- *value*
A positive integer that specifies the queuing time in minutes.
- **unlimited**
An optional string that specifies that there is no time limit and the tool will wait until a license is available. This is the default behavior.
- **no_queue**
An optional string that specifies that the tool not queue for a license and issue an error if not available immediately.
- **-release_and_requeue_after *release_and_requeue_after***
A switch and positive integer pair that specifies how many minutes the tool queues before releasing already-acquired licenses and performing a re-queue of all required licenses.

When you specify this option, the Tessent Shell tool's license queuing mechanism releases licenses the tool has acquired with every `-release_and_requeue_after` minutes before re-

requesting them. This allows other tools to acquire the licenses under the following circumstances:

- The tool is queuing for more than one license.
- The tool has acquired one license.
- The tool is queuing for one or more licenses that are currently in queue state.

Examples

The following example sets the license queue timeout value to 3 minutes, then displays the timeout value that was set:

```
SETUP> set_license_queue_timeout 3  
SETUP> get_license_queue_timeout
```

3

[get_license_queue_timeout](#)

[tessent](#)

set_list_file

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies the name of the list file into which the tool places the pins' logic values during simulation.

Usage

`set_list_file [filename] [-Replace]`

Description

Specifies the name of the list file into which the tool places the pins' logic values during simulation.

The `set_list_file` command specifies the file in which the tool places the simulation values for the pins which you previously identified with the `add_lists` command. The default behavior is for the tool to display the simulation values for the pins on standard output.

You can display the list of reported pins by using the `report_lists` command.

Arguments

- *filename*
A string that specifies the name of the file in which the tool places the logic values of pins during simulation. If you do not provide a *filename*, the default is standard output.
- `-Replace`
An optional switch that replaces the contents of the file if the *filename* already exists.

Examples

The following Tessent FastScan example creates a file to store simulation values that are being reported:

```
set_system_mode analysis
add_lists /i_1006/o /i_1007/o
set_list_file listfile
create_patterns
```

set_logfile_handling

Context: unspecified, all contexts

Mode: all modes

Specifies for the tool to direct the transcript information to a file.

Usage

```
set_logfile_handling [-RESume | {filename [-Replace | -Append]}]
```

Description

Specifies for the tool to direct the transcript information to a file.

The set_logfile_handling command causes the tool to write the transcript information, which includes the commands and the corresponding output (if any), into the file you specify. You can execute the set_logfile_handling command at any time, as many times as you need.

In the logfile, the **command** keyword (or **sub-command** when a tool command is embedded in a Tcl command) precedes all commands that the tool executes. You can easily search for the executed commands, generate a separate dofile containing those commands, and then execute the dofile, thereby rerunning those commands within the tool.

When you set the logfile handling, the tool still writes the same information to the session transcript window in addition to the logfile. However, you can disable the writing of the information to the transcript window with the set_screen_display command.

If you want to stop writing to a logfile, issue the set_logfile_handling command with no options, which closes the appropriate file.

Arguments

- **-Resume**

An optional switch that specifies for the tool to resume writing transcript output to the logfile specified at invocation with the -Logfile invocation switch. You do not need to include the name of the invocation logfile with this switch; the tool will remember the name.

- **filename**

A string that specifies the name of the file to which you want the tool to write the transcript output. This string can be a full pathname or a leafname. If you only specify a leafname, the tool creates the file in the directory from which you invoked the tool.

If you do not specify a *filename*, the tool discontinues writing to the logfile and closes it.

- **-Replace**

An optional switch that forces the tool to overwrite the file if a file by that name already exists.

- **-Append**

An optional switch that causes the tool to begin writing the transcript at the end of the specified file.

Examples

The following example writes a logfile and disables the display of the transcript information in the transcript window:

```
set_logfile_handling /user/designs/setup_logfile
set_screen_display off
add_clocks 0 clk
add_clocks 1 pre clr
report_clocks
```

The following information shows what the logfile contains after running the preceding set of commands:

```
// command: set_screen_display off
// command: add_clocks 0 clk
// command: add_clocks 1 pre clr
// command: report_clocks
User-defined Clocks (2):
=====
Sync and Async Source Clocks
=====
-----  -----  -----  -----
Name    Off State Constraints Internal
-----  -----  -----  -----
'PRE'      1          No
'CLR'      1          No
'CLK/'     0          No
```

set_logical_design_libraries

Context: all contexts

Mode: setup

Defines the set of available logical libraries that can be used by the read_verilog and read_vhdl -in_library option.

Usage

```
set_logical_design_libraries -logical_library_list logical_library_list
    [-default_library default_library_name] [-force]
```

Description

Defines the set of available logical libraries that can be used by the read_verilog and read_vhdl -in_library option.

You must use this command before any design modules have been read in unless you specify the -force switch. If you specify -force, all design data that was read before is lost and must be re-read or recreated.

In the no_rtl context, this command is not allowed; a single library called “work” is used.

As you can see in the example, you can create a Tcl list of library names and use it as the *logical_library_list* value. You can sort this Tcl list from the bottom up to order the VHDL libraries into an order such that the libraries that depend on other libraries are defined after those they depend on. The default library is the last item in the list unless the -default_library is used to specify a different one.

Arguments

- **-logical_library_list** *logical_library_list*
A required switch and string pair that specifies the list of logical libraries.
- **-default_library** *default_library_name*
An optional switch and string pair that specifies the library name to be used as the default library. If this switch is not specified, the last library name in the *logical_library_list* is used as the default library.

Except for the get_modules command, all commands that accept a module name as one of their options look for the module name inside the default library. For example, to create an instance of module M1 from library L1, you use the following command:

```
create_instance instance_name -of_module [get_module M1 -
    in_library L1]
```

Using -of_module M1 creates an instance of module M1 from the default library.

- **-force**

An optional switch that suppresses the error message normally displayed when this command is executed after modules have already been read in or created. When the -force option is used, all pre-existing modules are deleted.

Examples

In this example, a Tcl list is defined with all logical library names and is ordered with the libraries that depend on other libraries defined after those they depend on. A Tcl array called vhdl_files is used to specify which files goes in which library. A simple design-independent script at the bottom is used to load those VHDL files into the right libraries. A similar technique can be used for loading Verilog into multiple design libraries.

```
set vhdl_dir design/vhdl/src
set lib_list [list utility lib1 work]
set vhdl_files(utility) [list \
    ${vhdl_dir}/f1.vhd\
    ${vhdl_dir}/f2.vhd\
]
set vhdl_files(lib1) [list \
    ${vhdl_dir}/f3.vhd\
    ${vhdl_dir}/f4.vhd\
]
set vhdl_files(work) [list \
    ${vhdl_dir}/f5.vhd\
    ${vhdl_dir}/f6.vhd\
]
set_logical_design_libraries -logical_library_list $lib_list
foreach lib $lib_list {
    if {[array names vhdl_files -exact $lib] == $lib} {
        read_vhdl $vhdl_files($lib) -in_library $lib
    }
}
```

set_loop_handling

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup

Specifies how the tool handles feedback networks.

Usage

```
set_loop_handling [{Tiex [-Duplication {ON | OFF}]} | Simulation]  
[-MAX_Stored_loops {number | UNLIMITED}]
```

Description

Specifies how the tool handles feedback networks.

The set_loop_handling command lets you perform DRC simulation of circuits containing combinational feedback networks.

The set_loop_handling command specifies the tool's loop handling behavior by either inserting a TIE-X gate or by stabilizing the loop values through an iterative simulation process.

By using the Tiex setting, you have the option to use gate duplication to reduce the impact that a TIE-X gate places on the circuit to break combinational loops. By default, this duplication switch is off.

For an iterative simulation, the tool inserts FB_BUF gates to break the combinational loops. It also optimizes the number of iterations performed to both stabilize the circuit and minimize the impact of the iterative process on performance and memory usage.

For another look at combinational feedback loops, refer to “[Feedback Loops](#)” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- Tiex
A literal that specifies that TIE-X gates are used to break combinational loops.
- Simulation
A literal that specifies for the tool to use a simulation process to stabilize values in the loop. This option gives more accurate simulation results than other options. This is the default.
- -Duplication ON | OFF
An optional switch and literal pair that specify whether the tool can insert duplicate gates to reduce the impact of the gates that the tool places to break combinational loops. The literal choices are as follows:
 - ON — An optional literal that specifies for the circuit learning process to generate duplicate gates within any identified feedback paths.

- **OFF**— An optional literal that specifies for the circuit learning process to not generate duplicate gates within any identified feedback paths. This is the default upon invocation.
- **-MAX_Stored_loops {number | UNLIMITED}**
 An optional switch and integer or keyword pair that specifies the maximum number of loops that can be stored for reporting (using the `report_loops` command). By default, the tool stores up to 1000 loops. Use this switch if you want to store a specific number or all loops for reporting after the flattening process.

Examples

Example 1

The following Tessent FastScan example inserts a TIE-X gate to break any identified combinational or sequential asynchronous loop, then performs ATPG:

```
set_loop_handling tieX
set_system_mode analysis
create_patterns
```

Example 2

The following example shows how the tool indicates a design with more than 1000 combinational loops during the flattening process, and how to store all loops and write the loops to file loops.txt.

```
create_flat_model
// Note: Number of combinational loops exceeds storage limit (1000).
// Use 'set_loop_handling -max_stored_loops' to modify the number of loops stored and
// reported by 'report_loops'.
// Flattening process completed, cell instances=28234, gates=45400, PIs=110, POs=103,
// CPU time=93.00 sec.

// -----
// Begin circuit learning analyses.
// -----
// Equivalent gates=54  classes=0  CPU time=9.00 sec.

set_loop_handling -max_stored_loops unlimited
// Warning: Flat model deleted.

create_flat_model
// Flattening process completed, cell instances=28234, gates=45400, PIs=110,
// POs=103, CPU time=93.00 sec.

// -----
// Begin circuit learning analyses.
// -----
// Equivalent gates=54  classes=0  CPU time=9.00 sec.

report loops > loops.txt
```

set_lpct_condition_bits

Context: dft -edt

Mode: setup

Specifies the condition scan cells (condition bits) in the design core to connect to the Type 3 low pin count test (LPCT) controller.

Usage

```
set_lpct_condition_bits {-Condition {Reset | Scan_enable}  
[pin_name -on_controller_module] {-From connection_name | -No_connection}}
```

Description

Specifies the condition scan cells (condition bits) in the design core to connect to the Type 3 low pin count test (LPCT) controller.

The condition scan cells (condition bits) must already exist in the design core. If no condition bits are specified, the LPCT controller fully controls the reset and scan_enable signals. When LPCT condition bits are specified, the appropriate control bits are added to the test configuration data register in the LPCT controller. For each scan enable condition and each reset condition, one bit is added to the test configuration data register.

During ATPG, the scan cell specified using set_lpct_condition_bits *-from connection_name* is justified to the correct value to ensure the correct value of reset and scan enable.

This command is used in the IP Creation phase; it can only be used to create the Type 3 LPCT controller. For more information, see the Type 3 Controller in “[LPCT Controller Types](#)” in the *TestKompress User’s Manual*.

Arguments

- **-Condition {Reset | Scan_enable}**

Required switch and literal pair that specifies the condition bit type and the condition scan cell pin pathname. Literal options include:

Reset — Condition bit for controlling design reset during capture.

Scan_enable — Condition bit for controlling design scan enable during capture.

- **pin_name -on_controller_module**

Optional string and switch pair that specifies the pin name in the controller RTL for that particular input; this does not specify the connection.

- **-From connection_name | -No_connection**

Optional switch and string or switch that specifies the pin corresponding to the condition bits. This argument specifies the input connection to the LPCT controller. The *-no_connection* switch removes a previously specified condition.

Examples

The following example defines condition bits in the design to control the reset and scan_enable signals for the LPCT controller:

```
// Condition scan cell outputs (will be connected to LPCT logic)
set_lpct_condition_bits -condition reset -from c1/Q
set_lpct_condition_bits -condition scan_en -from c2/Q
```

set_lpct_controller

Context: dft -edt, patterns -scan (EDT On), patterns -scan_diagnosis

Mode: setup

Enables the creation of and specifies the configurations for a low pin count test (LPCT) controller for use with EDT logic.

Usage

```
set_lpct_controller OFF |On [-MAX_SHift_cycles shift_cycles] [-MAX_Capture_cycles  
    capture_cycles] [-MAX_Scan_patterns pattern_count] [-MAX_Chain_patterns  
    pattern_count] [-TEst_mode_detect {signal | sequence binary_seq count}]  
    [-SHIFT_Control {Enable | Clock | None}] [-LOAD_unload_cycles count1 count2]  
    [-TAp_controller_interface {Off | ON}] [-Generate_scan_enable {Off | ON}]  
    [-TESSENT_Occ {Auto | ON}] [-TESSENT_OCC_Capture_cycle_width {1 | 2 | 3}]
```

Description

Enables the creation of and specifies the configurations for a low pin count test (LPCT) controller for use with EDT logic.

This command is used during EDT logic creation to create the necessary LPCT controller logic for a test application and during pattern generation to verify the compatibility between the LPCT controller configuration and the design core. This command is also carried forward into the dofile output for ATPG.

Arguments

- **OFF**

Required literal that disables the creation of an LPCT controller. Default setting.

- **On**

Required literal that enables the creation of an LPCT controller.

- **-MAX_SHift_cycles shift_cycles**—Required switch and integer pair that specifies the number of shift cycles in the longest scan chain. This number can be an estimate but it should take into consideration both the EDT and bypass modes. This number affects the size of the shift cycle counter.

This option can only be used for the Type 3 LPCT controller. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.

- **-MAX_Capture_cycles capture_cycles**—Required switch and integer pair that specifies the maximum number of capture cycles for all test patterns. This number should take into consideration all of the types of test patterns generated for the test application.

This option can only be used for the Type 3 LPCT controller. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.

- **-MAX_Scan_patterns *pattern_count***

Optional switch and integer pair that specifies the maximum number of scan test patterns generated for any test pattern type in the test application. You must consider all the test pattern types used when determining this number.

This number determines the size of the scan test pattern counter created for the LPCT controller. By default, a counter of size 20 bits is used which implies a maximum of 1048576 scan test patterns.

- **-MAX_Chain_patterns *pattern_count***

Optional switch that specifies the maximum number of chain test patterns generated for any test pattern type in your test application. You must consider the maximum number of test patterns generated for any chain test type when determining this number. The default size of the chain test pattern counter is 10 bits which implies no more than 1024 chain test patterns.

- **-TEst_mode_detect {*signal / sequence binary_seq count*}**

Optional switch and literal that configures how the LPCT controller enters test mode. By default, test mode is enabled when the *test_mode* signal is asserted.

signal — The Set LPCT Pin *test_mode* command specifies the name of the signal to be used to enable test mode.

sequence binary_seq count — The LPCT controller enables test mode if the specified binary sequence, specified by *binary_seq*, is detected within the first *count* cycles after reset.

- **-SHIFT_Control {Enable | Clock | None}**

Optional switch and literal pair that specifies how the LPCT controller generates the shift clock control signal. Options include:

Enable — A *lpct_shift_en* enable signal is output to generate the shift clock waveform. This is the default setting.

Clock — A *lpct_shift_clock* signal is generated when an internal clock is pulsed during shift. Note, if all shift clocks are top-level clocks, they are controllable from top-pins during both shift and capture cycles; in this case, an additional *lpct_shift_clock* is not needed and is therefore not generated.

None — No output signal. This option is used when clocks are available at the top-level.

- **-LOAD_unload_cycles *count1 count2***

Optional switch and double integer that specifies the number of cycles that precede and succeed the shift cycles in the *load_unload* procedure. Empty cycles corresponding to the specified values are added to the test procedure. This argument must be specified during IP creation.

These values are determined by the number of cycles before and after the *apply shift* in the *load_unload* procedure. Specified values should be higher than the number of cycles in the input test procedure, otherwise they are ignored.

By default, the Type 2 and Type 3 controllers have two pre-shift and two post_shift cycles. By default, the Type 1 controller has zero pre-shift and two post-shift cycles.

- **-TAp_controller_interface {Off | ON}**

Optional switch and literal that specifies to use a TAP-generated scan enable version of the controller.

- **-Generate_scan_enable {Off | ON}**

Optional switch and literal that specifies whether the scan_en signal is generated internally by the LPCT controller.

Off — If the -TAp_controller_interface argument is set to Off, the LPCT controller has a top-level scan enable signal. This is the default configuration. If the -TAp_controller_interface argument is set to On, an error is issued.

ON — If the -TAp_controller_interface argument is set to Off, the scan enable signal is internally generated by the LPCT controller. If the -TAp_controller_interface argument is set to On, the LPCT the scan enable is generated using the TAP state machine.

- **-TESSENT_Occ {Auto | ON}**

An optional switch and literal that generates a Tessent OCC-compatible LPCT controller for skeleton designs that do not contain Tessent OCC instances. You specify this switch during pre-synthesis IP creation. Choose one of the following options:

auto — Infers the Tessent OCC instruments from the TCD and the ICL. This is the default.

on — Enables generation of Tessent OCC compatible LPCT controller when OCC core instances are not added.

- **-TESSENT_OCC_Capture_cycle_width {1 | 2 | 3}**

An optional switch and literal that specifies how many bits are present in the OCC, this must be a number between 1 and 3 (corresponding to capture_window_size 2 through 6 in the OCC DftSpecification). The default is 2 specifies the capture cycle width.

Examples

The following example enables an LPCT controller and configures it to use a sequence to enter test mode:

```
//define parameters for test controller
set_lpct_controller on -max_shift_cycles 400 -max_capture_cycles 2
set_lpct_controller -test_mode_detect sequence 1100100101001110 64
```

Related Topics

[report_lpct_pins](#)

[set_lpct_instances](#)

set_lpct_instances

Context: dft -edt

Mode: setup

Inserts the low pin count test (LPCT) controller and clock gater in a specified hierarchical instance within the design core.

Usage

```
set_lpct_instances -Block_location instance_pathname
                   -Clock_gater_location instance_pathname
```

Description

Inserts the low pin count test (LPCT) controller and clock gater in a specified hierarchical instance within the design core.

The clock gater is added only if [set_lpct_controller -shift_control_clock](#) is specified.

Arguments

- **-Block_location *instance_pathname***
Optional switch and string pair that specifies an instance in the design core in which to insert the LPCT controller. By default, the LPCT controller is inserted at the top-level of the design core.
- **-Clock_gater_location *instance_pathname***
Optional switch and string pair that specifies an instance in which to insert the LPCT clock gater. By default, the clock gater is inserted at the top-level of the design core.

Examples

The following example places the LPCT controller inside the *my_design/xyz/foo* instance in the design core:

```
//define parameters for LPCT controller

set_lpct_controller on -max_shift_cycles 5000 -max_capture_cycles 4 -max_chain_patterns
1000
set_lpct_controller -shift_control_clock
set_lpct_instances -block_location my_design/xyz/foo
```

```

Specify for Type 2 LPCT controller (scan_en generated using TAP state machine only)

```
set_lpct_pins
  [SHIFT_Dr pin_name [internal_node_name] [-ON_controller_module]
   [-NOInv | -INV]]
  [CAPTURE_Dr pin_name [internal_node_name] [-ON_controller_module]
   [-NOInv | -INV]]
  [Update_dr pin_name [internal_node_name] [-ON_controller_module] [-NOInv | -INV]
   [-ON_controller_module] [-NOInv | -INV]]
  [TMs pin_name [internal_node_name] [-ON_controller_module] [-NOInv | -INV]]
  [TEST_Clock_connection [pin_name -ON_controller_module]
   {connection_name | -No_connection}]
```

Description

Specifies control pins and connections between the low pin count test (LPCT) controller and the core design.

When using the LPCT controller in which scan_en is generated using TAP states, the clock and reset inputs of the controller should be connected to TCK and the test_logic_reset pins on the TAP controller.

For hybrid TK/LBIST IP generation, the dft -edt -lbist context supports this command.

Arguments

- **Clock**

Required argument that specifies as always-pulse clock input for a flip-flop based design.

This option can be used for Type 1, Type 2, and Type 3 LPCT controllers. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.

- *pin_name*

Optional string and switch pair that specify the pin name in the controller RTL for that particular input; this does not specify the connection. Depending on the application, it may be a top-level pin, an input pin, or an output pin as follows. Use this string with the *-on_controller_module* switch to name the output pin when scan cell conditions are used to reset the LPCT controller.

- *internal_node_name*

Optional string used together with the *pin_name* argument to specify the top-level pin name and corresponding internal connection for controller input pins. You can use a literal dash “-” for the *pin_name* argument when no top-level pin exists in the design.

- **-ON_controller_module**

Optional switch used with the *pin_name* argument that specifies the pin name in the controller RTL for each input; this does not specify the connection.

- *connection_name*
Optional switch used to specify the names of one or more internal pins to connect to the controller output pins.
- **-No_connection**
Optional switch used to specify that no connection is required for a controller output pin.
- **-NOInv| -INV**
Optional switch that specifies a LPCT signal is inverted between the point where it is connected during EDT logic creation and the chip boundary in the final netlist used for pattern generation. The default is no inversion.
You should specify **-INV** when there is an inversion between the internal connection name for the LPCT pin and the chip boundary such as when specifying an inverting pad.
Specifying this inversion information during the EDT logic creation phase generates the correct dofiles and test procedure files for the pattern generation phase but has no effect on the EDT logic.
- **CLOCK_Mux_select**
Optional argument that specifies the connection to be made to the *clock_mux_select* output of the controller. This pin is a MUX select signal that selects between the shift clock generated by the LPCT controller and the capture clock. If *clock_mux_select* is high, the shift clock is selected; if *clock_mux_select* is low, the capture clock is selected.
This option can be used for Type 1, Type 2, and Type 3 LPCT controllers. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.
- **CAPTURE_Enable**
Optional argument that specifies the controller output signal that indicates when the controller is in capture mode. This option specifies the pin to which this *capture_enable* signal is to be connected.
This option can be used for Type 1, Type 2, and Type 3 LPCT controllers. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.
- **SHIFT_Enable**
Optional argument that specifies a controller output signal that indicates when the controller is in shift. The *shift_enable* option specifies the pins to which the *shift_enable* signal should be connected. If you provide clock gating using *set_lpct_controller -shift_control enable*, this option is required; it is used as the clock gater enable signal to produce the shift clock from a pulse-always clock.
This option can be used for Type 1, Type 2, and Type 3 LPCT controllers. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.
- **SHIFT_Clock**
Argument that specifies the pin is a shift clock signal.

This option can be used for Type 1, Type 2, and Type 3 LPCT controllers. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.

- INPUT_Scan_enable

Argument that specifies the top-level scan enable port.

This is used as an input only to the Type 1 LPCT controller. This option can only be used for the Type 1 LPCT controller. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.

- Reset

Required argument that specifies the reset input signal for the controller. The reset pin can be shared with the design’s functional reset. This can be either an external pin or internal power-on-reset.

This option can only be used for the Type 3 LPCT controller. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.

- OUTPUT_Scan_enable

Argument that specifies the list of internal pins to which the LPCT output scan enable pin is connected.

This option is required when generating a Type 2 or Type 3 LPCT controller.

- DATA_In

Optional argument that specifies the pin is a data input to the test controller. For the Type 3 controller, a test sequence and configuration is scanned in through this port. This port is usually shared with the edt_channel input.

This option can only be used for the Type 3 LPCT controller. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.

- TEST_Mode

Optional argument that specifies the pin is a test mode signal used to enable test mode. This signal is not used when sequence detection is used.

This option can only be used for the Type 3 LPCT controller. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.

- RESET_Out

Optional argument that specifies the reset signal to the design. This signal is generated by combining the functional reset signal (specified using “`set_lpct_pins reset`”) with the reset condition or reset control configuration inside the controller. This allows the tool to detect faults connected to the reset signal even while the top-level reset pin is constrained to OFF during capture. If this option is not specified, all the pins driven by the reset signal in the input netlist are changed to be driven by the `lpct_reset_out` output of the controller. If this option is specified, only the pins explicitly specified are driven by the `lpct_reset_out` output of the controller.

This option can only be used for the Type 3 LPCT controller. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.

- TEST_End

Optional argument that specifies the pin is an end of test signal.

This option can only be used for the Type 3 LPCT controller. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.

- TEST_Active

Optional argument that specifies an output signal from that LPCT controller that indicates the LPCT controller is active and controlling the scan test.

This option is only valid for the Type 3 controller. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.

- SHIFT_Dr

Required argument that specifies the pin is a Shift_Dr signal on the TAP controller.

This option can only be used for the Type 2 LPCT controller. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.

- CAPTURE_Dr

Required argument that specifies the pin is a Capture_Dr signal on the TAP controller.

This option can only be used for the Type 2 LPCT controller. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.

- Update_dr

Required argument that specifies the pin is an Update_Dr signal on the TAP controller.

This option can only be used for the Type 2 LPCT controller. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.

- TMs

Required argument that specifies the pin is a test mode select tms input pin of the TAP.

This option can only be used for the Type 2 LPCT controller. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.

- -Active {High|Low}

Optional switch and literal pair that specifies the active state for the input reset signal. By default, the reset is active high.

This option can only be used for the Type 3 LPCT controller. For more information, see “[LPCT Controller Types](#)” in the *Tessent TestKompress User’s Manual*.

- TEST_Clock_connection

Optional switch that specifies the test clock input pin for the user-added test_mode mux. The tool connects the output of the clock gater, added to facilitate sharing of the LPCT clock

and the scan clock, to the specified pin. The user must connect the other input of the mux to the functional clock and the select pin to the test mode signal.

Examples

Example 1

The following example defines the connections between the LPCT controller and the design core.

```
// Temporary top-level scan IO pins (removed by TK during IP creation

add_scan_chains chain1 grp1 scan_in1 scan_out1
add_scan_chains chain2 grp1 scan_in2 scan_out2

// LPCT controller input pins

set_lpct_pins clock ref_clk clk_pad/Z
set_lpct_pins reset_out - pwr_up/rst
set_lpct_pins data_in fnl_input

// Connections from LPCT logic outputs to design

set_lpct_pins output_scan_enable scan_en
set_lpct_controller -shift_control enable
set_lpct_pins shift_en clk_mux/shift_en
set_lpct_pins capture_en clk_mux/cap_en
```

Example 2

The following example defines the connections between the LPCT controller and the design core when the LPCT controller internally generates the scan_en signal.

```
set_lpct_controller -generate_scan_enable on -max_shift 1000 -max_capture 3
set_lpct_pins output_scan_enable scan_mode
```

Example 3

The following example defines the connections between the LPCT controller and the design core when a top-level scan_en signal exists.

```
set_lpct_controller on
set_lpct_pins input_scan_enable scan_en
```

Example 4

The following example defines the connections between the LPCT controller and the design core when a top-level scan_en signal exists and the user has implemented clock control.

```
set_lpct_controller -shift_control enable
set_lpct_pins capture_en pll/capture_start
set_lpct_pins clock_mux_select pll/select
set_lpct_pins shift_en pll/shift_en
```

Example 5

The following example defines the connections between the LPCT controller and the design core when a TAP generated scan_en signal exists.

```
set_lpct_controller -tap_controller on -generate_scan_enable on
set_lpct_pins output_scan_enable scan_mode
set_lpct_pins shift_dr - tap/shiftEn
set_lpct_pins capture_dr - tap/captureEn
set_lpct_pins update_dr - tap/updateEn
set_lpct_pins test_mode - tap/atpgInstruction
set_lpct_pins reset - tap/resetl -active low
```

Example 6

The following example defines the connections between the LPCT controller and design core when a TAP is used to generate scan_en signal

```
set_lpct_pins clock refclk -on_controller_module      // input pin
set_lpct_pins capture_en pll_start -on_controller_module // output pin
```

Example 7

The following example specifies to use a top-level scan clock as the LPCT clock for a Type 1 controller.

```
set_context dft -edt
add_clocks 0 clk           // There is a single clock in the design
add_scan_chains ...
set_lpct_controller on -shift_control_clock
set_lpct_pin clock clk     // LPCT clock is shared with scan clock
set_lpct_pin input_scan_enable scan_en
set_lpct_pin test_clock_connection test_mode_mux/B
set_system_mode analysis
report_lpct_pins
write_edt_files created -replace
```

Example 8

The following example specifies to use tck as the scan shift clock in a Type 2 LPCT controller. Note, the test mode mux that selects between the LPCT-generated scan clock and the functional clock already exists in the design. The test clock connection pin on the mux is specified with the test_clock_connection pin type.

```
set_context dft -edt
add_clocks 0 tck
add_scan_chains ...
set_lpct_controller -tap_controller_interface on
set_lpct_controller -shift_control clock
set_lpct_pins output_scan_enable scan_en
set_lpct_pins clock tck pad_tck/Z // LPCT clock is tck
set_lpct_pins tms tms pad_tms/Z
set_lpct_pins reset - tap_i/tlr
set_lpct_pins capture_dr - tap_i/capturedr
set_lpct_pins shift_dr - tap_i/shiftdr
set_lpct_pins update_dr - tap_i/updatedr
set_lpct_pins test_mode - tap_i/edt_scan_inst
set_lpct_pins test_clock_connection test_mode_mux/B
set_edt_options -channel 1
set_edt_pins input 1 tdi pad_tdi/Z
set_edt_pins output 1 tdo tap_i/tap_edt_channel_reg_in
set_system_mode analysis
report_lpct_pins
report_lpct_configuration
write_edt_files created -replace
```

[report_lpct_configuration](#)

[report_lpct_pins](#)

[set_lpct_controller](#)

[set_macrotest_options](#)

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Prepares a black box macro to allow MacroTest conversion of patterns at the boundaries of that instance.

Usage

`set_macrotest_options {OFF | ON}`

Description

Prepares a black box macro to allow MacroTest conversion of patterns at the boundaries of that instance.

The `set_macrotest_options` command changes two normal behaviors of the tool's DRC. To obtain a pulse from a macro, a PI of the circuit that has been declared as a clock, read control, or write control must drive the pin of the macro. If the black box is an empty instantiation of a RAM, it is likely that the tool needs to pulse the write control to write into the RAM. Normally, if a write control does not connect to a `_ram` or `_cram` primitive, DRC issues a G5 violation and does not take you out of Setup until the write control is deleted. The `set_macrotest_options` command prevents this and treats any write control as valid (as if it were connected to a `_ram` or `_cram`).

Another DRC aspect that the tool modifies occurs if a transparent latch (TLA) is on the control (input) side of a black box macro, and is unobservable due to the macro. Tessent FastScan converts a black box macro to a set of TieX gates, one per output. As a result, if the TLA only fans out to the macro, the tool cannot observe it (it has no sensitizable path to some PO or scan cell). Normally, DRC converts such a TLA to a TieX gate, preventing MacroTest from justifying values on the input side of the black box macro backward through the TLA. This is because it thinks the TieX means the primitive cannot be controlled. The `set_macrotest_options` command prevents this and keeps unobservable TLAs as TLAs.

If in doubt, issue the `set_macrotest_options` command in setup mode before proceeding with macro testing. No errors occur if DRC does not encounter the situations resolved by this command. Therefore, you can issue the `set_macrotest_options` command before every MacroTest run if you desire.

Arguments

- `{OFF | ON}`

A required Boolean that specifies whether to modify DRC as described in the preceding description.

OFF—Disables DRC modification (normal DRC is performed). This is the default at invocation.

ON — Enables modified DRC analysis to avoid potential macrotest-specific ATPG issues.

Examples

The following example shows the command issued to allow black box macro testing:

```
set_macrotest_options on
```

[macrotest](#)

set_memory_identification_options

Context: dft

Mode: setup

Sets options and pattern expressions to validate memory TCD are associated with memory modules to be tested by MemoryBIST.

Usage

```
set_memory_identification_options {name_patterns [-regexp] [-nocase]} | [-off]
```

Description

Sets regular expression or wildcard naming patterns to identify memory module names in the design technology library. When `check_design_rules` is run, Tessent MemoryBIST will use this information to identify the memories instantiated in the design that have not been declared as memories and will not be tested by MemoryBIST. This condition can be caused by a missing memory TCD for a design's memory module. When a memory library file is read in, the tool will automatically associate the memory TCD to the design module and will declare it as a memory to be tested by MemoryBIST.

The options specific to the `set_memory_identification_options` command are used by the `check_design_rules` command to ensure that all modules that should be declared as memories are properly recognized after a successful system mode transition. An error is issued if a design module matches the provided *name_patterns* argument, but no associated memory TCD is found. A warning is issued if there are design modules recognized as memories, but they do not match the *name_patterns* argument. In cases where errors or warnings are issued, the tool automatically displays a tabular report from the validation. The validation report can always be displayed with the [report_memory_identification](#) command.

Arguments

- ***name_patterns***

A required string or Tcl list of strings that specifies one or more patterns to be used to identify memories in the design. A non-empty string must be provided or an error is issued.

- **-regexp**

An optional switch that directs the tool to interpret the value of the *name_patterns* argument as a regular expression instead of a simple wildcard pattern. Refer to the “[Glob and Regular Expression Pattern Matching Syntax](#)” section for a description of the regular expression syntax.

- **-nocase**

An optional switch that directs the tool to perform case-insensitive pattern matching when searching for modules matching the *name_patterns*.

- -off

An optional switch that is mutually exclusive with all other arguments. Specifying the -off switch eliminates module matching validation that was previously enabled with a set_memory_identification_options command executed with a valid *name_patterns* expression.

Examples

Assume the following memory modules exist in a design and it is desired to identify them as memory modules:

```
SYNC_1R1W_16x8, SYNC_1R1W_32x4, RAM_32x4, RAM_128x128
```

The following use of set_memory_identification_options can be used to match these memory modules:

```
set_memory_identification_options {SYNC.* RAM.*} -regexp
```

[report_memory_identification](#)

set_memory_instance_options

Context: dft

Mode: setup

Prerequisite: The current design must be set with the [set_current_design](#) command.

Set options on or for memory instances to be used by the [check_design_rules](#) and [create_dft_specification](#) commands.

Usage

```
set_memory_instance_options {memory_instances}  
  [-bist_data_in_pipelining on | off | int] [-physical_cluster_override string]  
  [-test_clock_override domain_label]  
  [-repair_sharing off | on | auto]  
  [-use_in_memory_bist_dft_specification off | on | auto]  
  [-use_in_memory_bisr_dft_specification off | on | auto]} |  
  [-bisr_segment_order_file file_path] |  
  [-physical_cluster_size_ratio int]
```

Description

Sets options on or for memory instances to be used by the [check_design_rules](#) and [create_dft_specification](#) command, when the [set_dft_specification_requirements](#) command was used to enable the memory BIST and or memory BISR feature.

This command is used to set options on memory instances as returned by the [get_memory_instances](#) command. Most options can be set differently for each memory instance. The `-bisr_segment_order_file` and the `-physical_cluster_size_ratio` options apply to all instances.

Arguments

- ***memory_instances***

A string that contains a Tcl list of one or more names of memory instances, or a collection of one or more memory instances. The memory instances are the instances on which the `tcd_memory_name` [Instance](#) attribute is defined as a result of a TCD Memory description having been matched to its module name—see “[Tessent Core Description](#)” on page 3755. You can use the [get_memory_instances](#) command to get a collection of all memory instances.

- **-bist_data_in_pipelining on | off | *int***

An optional switch and value pair that specifies the number of data-in pipelining stages the specific memories are to use during memory BIST. It is specified here as it affects the memory BIST partitioning because only memories with equal data-in pipelining can be tested in the same controller step. The value off is equivalent to 0 and the value on is equivalent to 1.

- **-physical_cluster_override *string***

An optional switch and value pair that associates one or more memory instances to a given cluster ID. The string is allowed to contain any number of letters, numbers, and underscores; it cannot start with the word “def” and be followed by an integer because those strings are reserved for the clusters computed from the DEF file. If you read a DEF file using the [read_def](#) command, physical clusters will be created for all memory instances for which a physical cluster override string was not specified. See the description of the **-physical_cluster_size_ratio** option below for more information about the clustering process. The automatic cluster generation computed from DEF is performed when running the [check_design_rules](#) commands.

- **-test_clock_override *domain_label***

An optional switch and value pair that associates one or more memory instances to a clock domain label. By default, the clock domain label associated to the memory is one of the clock domains connected to the clock ports of the memory. When the clocks have different frequencies, one of the fastest ones is selected. You can use this option when the memory instance has no clocks (that is, asynchronous memory) or to force the selection of a given clock when more than one clock has the same frequency. Clock ports receiving a clock that is different than the selected clock domain will have a multiplexer inserted on it to inject a common clock during memory BIST.

- **-repair_sharing off | on | auto**

An optional switch and literal pair that specifies whether the memory instance will have memory repair sharing enabled. By default, the value of “auto” will use the global enable value specified in the **DefaultsSpecification/DftSpecification/MemoryBist/RepairOptions/repair_sharing** property. A value of “auto” will also use the global repair group scope specified by the **repair_group_scope** property in the **DefaultsSpecification/DftSpecification MemoryInterfaceOptions** or **MemoryClusterOptions** wrappers. Specifying “off” or “on” will override the global values specified in the **DefaultsSpecification** for the memory instance.

- **-use_in_memory_bist_dft_specification off | on | auto**

An optional switch and literal pair that specifies whether the memory instance is to be considered by DRC and as a part of the **DftSpecification/MemoryBist** wrapper that the **create_dft_specification** command will create. When set to auto, the memory instance is considered if it is not seen as already connected to a memory BIST interface module. If it is already connected to a memory BIST interface module, it is excluded from the new **DftSpecification/MemoryBist** wrapper.

This feature is useful when doing multi-pass insertion in the case where you initially added memory BIST for a set of memories and then, later, edited the RTL and inserted new memories. When you specify the default value of auto, re-running the memory BIST insertion process on this RTL will only consider the new memory. You can force the exclusion of a memory instance even if it is not already connected to a memory BIST interface module by specifying the off value.

- `-use_in_memory_bisr_dft_specification off | on | auto`

An optional switch and literal pair that specifies whether the memory instance is to be part of the [DftSpecification/MemoryBisr](#) wrapper that the [create_dft_specification](#) command will create. When set to auto, the memory instance is considered if it is not seen as already connected to a memory BISR register module. If it is already connected to a memory BISR register module, it is excluded from the new [DftSpecification/MemoryBisr](#) wrapper.

This feature is useful when doing multi-pass insertion in the case where you initially added memory BISR for a set of memories and then, later, edited the RTL and inserted new repairable memories. When you specify the default value of auto, re-running the memory BISR insertion process on this RTL will only consider the new repairable memory. You can force the exclusion of a memory instance even if it is not already connected to a memory BISR register module by specifying the off value.

- `-bisr_segment_order_file file_path`

An optional switch and value pair that references a [MemoryBisr](#) bisr_segment_order_file following the format described in [Figure 10-53](#) on page 3480. By default, a BISR segment order file is created when the [check_design_rules](#) command is run if repairable memories and/or child blocks with BISR chains are present in the current design. If you read a DEF file using the [read_def](#) command, this file is automatically created with an ordering extracted from the DEF file in order to minimize routing. If you did not provide a DEF file, you must order the BISR segment order file manually and then reference the file using this option. The specified BISR Segment Order File applies to all memories in the design that will be processed by the next [create_dft_specification](#) command.

This option cannot be combined with the `memory_instances` option or any of the memory instance-related options explained before.

- `-physical_cluster_size_ratio int`

An optional switch and value pair that specifies the parameter used to create memory clusters for Memory BIST partitioning. If you read a DEF file using the [read_def](#) command, memory clusters are created and memories not belonging to the same cluster are assigned to different memory BIST controllers when the [create_dft_specification](#) command creates the [DftSpecification/MemoryBist](#) wrapper.

A rectangle is created to fully enclose the current design and the length of its diagonal is extracted. The ratio is the percentage of a cluster's diameter with respect to this diagonal distance. A memory instance will be added to a given cluster, if it does not cause the diameter of the cluster to exceed the threshold ratio. Otherwise, a new cluster is created. The default ratio is 20% but you can change this percentage value by specifying an integer between 0 and 100 using the `-physical_cluster_size_ratio` option. A value of 0 causes each memory instance to be in its own cluster, and a value of 100 results in all memory instances being in the same (single) cluster.

Examples

Example 1

The following example sets the number of data in the pipelining stages to 3 for the memory instances found below instance u1/u2. It also sets the **-physical_cluster_size_ratio option to 30%**.

```
set_memory_instance_option [get_memory_instances -below_instance u1/u2] \
    -bist_data_in_pipelining 3
set_memory_instance_option -physical_cluster_size_ratio 30
```

Example 2

The following example defines the BISR segment order file that the tool will use for all memories in the design.

```
set_memory_instance_options -bisr_segment_order_file ./top.bisr_segment_order
```

set_misr_connections

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Describes the connections between the scan chain outputs and the MISR.

Usage

```
set_misr_connections misr_name -tap integer -chain chain_name
```

Description

Describes the connections between the scan chain outputs and the MISR.

This command is used with the hybrid TK/LBIST flow—refer to the [Hybrid TK/LBIST Flow User's Manual](#) for complete information.

If you map multiple scan chains to the same MISR position, then the tool infers a XOR spatial compactor that maps from those multiple scan chain outputs to the specified MISR feedback position.

Arguments

- ***misr_name***

A required string that specifies the name of the MISR specified with the add_misrs command.

- **-tap *integer***

A required switch and required and repeatable integer that specifies the tap points for the MISR feedback network. The tap index starts from 1, to be consistent with the decompressor commands.

- **-chain *chain_name***

A required switch and string that specifies the name of the scan chain pin that you want to connect to the MISR specified by ***misr_name***.

Examples

This example describes the hardware connection from scan chain outputs to MISR inputs through a 4-to-1 XOR compactor.

```
set_misr_connection misr -chain /my_core_edt_i/my_core_edt_compactor_i/edt_scan_out[0] -tap 1
set_misr_connection misr -chain /my_core_edt_i/my_core_edt_compactor_i/edt_scan_out[1] -tap 1
set_misr_connection misr -chain /my_core_edt_i/my_core_edt_compactor_i/edt_scan_out[2] -tap 1
set_misr_connection misr -chain /my_core_edt_i/my_core_edt_compactor_i/edt_scan_out[3] -tap 1
set_misr_connection misr -chain /my_core_edt_i/my_core_edt_compactor_i/edt_scan_out[4] -tap 2
set_misr_connection misr -chain /my_core_edt_i/my_core_edt_compactor_i/edt_scan_out[5] -tap 2
```

set_misr_connections

```
set_misr_connection misr -chain /my_core_edt_i/my_core_edt_compactor_i/edt_scan_out[6] -tap 2
set_misr_connection misr -chain /my_core_edt_i/my_core_edt_compactor_i/edt_scan_out[7] -tap 2
set_misr_connection misr -chain /my_core_edt_i/my_core_edt_compactor_i/edt_scan_out[8] -tap 3
set_misr_connection misr -chain /my_core_edt_i/my_core_edt_compactor_i/edt_scan_out[9] -tap 3
set_misr_connection misr -chain /my_core_edt_i/my_core_edt_compactor_i/edt_scan_out[10] -tap 3
set_misr_connection misr -chain /my_core_edt_i/my_core_edt_compactor_i/edt_scan_out[11] -tap 3
set_misr_connection misr -chain /my_core_edt_i/my_core_edt_compactor_i/edt_scan_out[12] -tap 4
set_misr_connection misr -chain /my_core_edt_i/my_core_edt_compactor_i/edt_scan_out[13] -tap 4
set_misr_connection misr -chain /my_core_edt_i/my_core_edt_compactor_i/edt_scan_out[14] -tap 4
set_misr_connection misr -chain /my_core_edt_i/my_core_edt_compactor_i/edt_scan_out[15] -tap 4
```

set_module_matching_options

Context: all contexts

Mode: all modes

Defines the acceptable prefixes and suffixes or regular expressions to use when matching an ICL module to a design module within ICL extraction.

Usage

```
set_module_matching_options [-prefix_pattern_list prefix_pattern_list]
                           [-suffix_pattern_list suffix_pattern_list] [-regexp] [-nocase] [-append]
```

Description

Defines the acceptable prefixes and suffixes or regular expressions to use when matching an ICL or a TCD module to a design module. The module matching is performed in those situations as follows:

1. With a [set_current_design](#) command call. This forces the tool to perform a complete elaboration, which resets other settings such as already defined black boxes.
2. With a [set_context](#) command call, and the design is already elaborated.
3. With an [extract_icl](#) command call.

During module matching, the list of all design modules found below the current design is used to search for corresponding ICL and TCD modules. The ICL and TCD modules are then attached to the design modules.

If the ICL or TCD modules refer to the RTL names of the design modules and module matching is done on the synthesized view, the design modules that are used more than once are likely to have been unqualified with an integer suffix. You may also have instructed the synthesis tool to prefix every synthesized module with a common prefix. The default suffix list will handle the unification suffix inserted by synthesis automatically. If you instructed the synthesis tool to prefix every synthesized module with a common prefix, you need to describe the used prefix using the *-prefix_pattern_list* switch.

See the `instrument_name`, `tcd_bscan_name`, `tcd_fusebox_name`, `tcd_memory_cluster_name`, and `tcd_memory_name` [Instance](#) attribute descriptions. Those attributes are set on the design instances and modules when they are matched to an ICL or TCD module. See also the [get_ijtag_instances](#) and [get_memory_instances](#) command descriptions.

Arguments

- *-prefix_pattern_list *prefix_pattern_list**

An optional switch and string pair that specifies the prefix patterns taken into account when matching ICL modules to design modules. The *prefix_pattern_list* string or Tcl list of strings lists the prefix strings or regular expressions to be used as a prefix to the ICL module name when matching it against the design module names.

Note

 By default, the `set_insertion_options -edited_module_prefix` command and switch inserts an underscore character between the prefix and the original module name. When using the `-prefix_pattern_list` switch, you must explicitly specify this underscore.

- `-suffix_pattern_list suffix_pattern_list`

An optional switch and string pair that specifies the suffix strings or regular expressions to be used for unqualified design module mapping. This switch can only be used once. The `suffix_pattern_list` string or Tcl list of strings lists one or more patterns to be used for unqualified design module mapping. By default, the tool matches any module name with a suffix that matches the regular expression “`{[_]+[0-9]+}`”. This means that, by default, the tool will match all names of the format `<module_name>_<number>`.

- `-regexp`

An optional switch that directs the matching patterns as a regular expression instead of as a simple wildcard pattern. See section “[Glob and Regular Expression Pattern Matching Syntax](#)” on page 3164 for a description of the regular expression syntax.

- `-nocase`

An optional switch that forces the pattern matching to be case insensitive. The presence of the `-nocase` switch in the most recent `set_module_matching_options` command determines the behavior of the module matching. If the `-nocase` switch is used in the most recent `set_module_matching_options` command, then the pattern matching is case insensitive. If the `-nocase` switch is omitted, the case sensitivity depends on the hardware description language (Verilog or VHDL) that has been used to describe the design module.

- `-append`

An optional switch that specifies to append the newly specified pattern list to the existing list or to replace the existing list.

Return Values

None

Examples

In the following example, this command is used to allow matching ICL modules with an optional prefix "mycore_" and an optional suffix matching `_ts[0-9]+`. In this example, an ICL module InstrumentA will be allowed to match `mycore_InstrumentA_ts1` and `mycore_InstrumentA_ts2`.

```
set_module_matching_options -prefix_pattern_list {mycore_}
                           -suffix_pattern_list {_ts[0-9]+} -regexp
```

[report_module_matching](#)

[report_module_matching_options](#)

set_multiple_detection

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Enables the multiple detection of faults.

Usage

```
set_multiple_detection
  [-Guaranteed_atpg_detections guaranteed_atpg_detections]
  [-Desired_atpg_detections desired_atpg_detections]
  [-Simulation_drop_limit simulation_drop_limit]
  [-REPort_incremental_statistics {ON | OFF}] [OFF]
```

UDFM Usage:

```
set_multiple_detection
  [-Simulation_drop_limit simulation_drop_limit] [OFF]
```

Description

Enables the multiple detection of faults.

Multiple detection is a statistical way to gain bridge fault coverage. By default, the tool generates a single detection pattern set, where a fault is detected once, then dropped from the simulation.

When multiple detection is enabled, the DS fault category represents faults detected one or more times, not just faults detected the threshold number of times. The [create_patterns](#) command includes a cumulative Bridge Coverage Estimate (BCE) in the statistics transcription for each batch of patterns. Use the *simulation_drop_limit* argument to increase the accuracy of the BCE, being aware that the improved accuracy entails more run time.

The BCE, which is based on simulation results, is calculated as follows:

$$\text{BCE} = \left[\sum_{i=1}^n \frac{f_i}{TE} \cdot (1 - 2^{-i}) \right] + \frac{N_{DI}}{TE}$$

where:

f_i = number of faults detected i times by the test pattern set

TE = number of total testable faults in the target fault list

N_{DI} = number of DI faults in the target fault list
 $n = atpg_detections$ (or
 $fault_drop_detections$ if used)

Enabling multiple detections changes the behavior of the following commands:

- [analyze_compression](#) — If the `-Preserve_faults_from_analysis` switch is specified, preserves the N-detection information for all the detected faults during the `analyze_compression` operation.
- [create_patterns](#) — Performs multiple iterations (loops) as needed to ensure every testable fault is detected *guaranteed_atpg_detections* times and includes a cumulative bridge coverage estimate (BCE) in the statistics transcription for each batch of patterns simulated. Each pattern counts at most only one detection for any particular fault.
- [report_statistics](#) — Lists the final BCE in reports and additionally includes a histogram that shows the profile of the number of detections for multiple detection DS faults.
- [report_environment](#) — Lists a “multiple detection = ...” line that shows the current multiple detection settings. If this line is absent, it means multiple detection is disabled.
- [report_faults](#) — Displays a “num_detections...” line for each DS fault that shows the number of detections for that fault.
- [write_faults](#) — Writes a “num_detections...” line for each multiple detection DS fault that shows the number of detections for that fault.

Issue this command without any arguments to report the current setting. If you issue this command with arguments more than once, the last command overwrites the previous settings.

Note that when the fault type is UDFM, the `set_multiple_detection` command works only for simulation and not for ATPG.

Arguments

- `-Guaranteed_atpg_detections` *guaranteed_atpg_detections*

An optional switch and integer pair that specifies the number of detections required for each testable fault. The *guaranteed_atpg_detections* can be any integer between 1 and 255 and determines the number of detections for each fault that the [create_patterns](#) command should target during pattern generation. The specified number of detections for each fault are guaranteed during fault simulation before the tool drops the fault from the fault list.

The default value of *guaranteed_atpg_detections* is 1. Increasing the number of guaranteed detections can significantly increase the pattern count and ATPG run time.

- `-Desired_atpg_detections` *desired_atpg_detections*

An optional switch and integer pair that specifies the number of detections desired for each testable fault. These faults are detected using Embedded Multi-Detect (EMD) functionality. The *desired_atpg_detections* can be any integer between 1 and 255.

Setting *desired_atpg_detections* to 1 disables EMD.

By default, *desired_atpg_detections* is equal to *guaranteed_atpg_detections*.

The *desired_atpg_detections* cannot be less than the *guaranteed_atpg_detections* except when EMD is disabled (*desired_atpg_detections* set to 1).

Unlike the number of guaranteed detections, increasing the number of desired detections does not increase the pattern count. However, it may increase the ATPG run time. For optimal performance, it is not recommended to set the *desired_atpg_detections* to greater than 5.

- **-Simulation_drop_limit simulation_drop_limit**

An optional switch and integer pair that specifies the maximum number of detections for a fault. The tool drops the fault from the simulation after the *simulation_drop_limit*.

When the fault type is UDFM, you can set the *simulation_drop_limit* to any positive integer. By default, the *simulation_drop_limit* is 1.

For all other fault types, the *simulation_drop_limit* cannot be less than the *guaranteed_atpg_detections* or *desired_atpg_detections* values. If you do not specify a value, the *simulation_drop_limit* is automatically set to one of the following:

- **guaranteed_atpg_detections = desired_atpg_detections = 1**

The *simulation_drop_limit* is set to 1.

- **guaranteed_atpg_detections <= 10 AND 2 <= desired_atpg_detections <= 10**

The *simulation_drop_limit* is set to 10.

- **guaranteed_atpg_detections > 10 OR desired_atpg_detections > 10**

The *simulation_drop_limit* is set to the greater of the *guaranteed_atpg_detections* or *desired_atpg_detections* values.

- **-REPort_incremental_statistics {ON | OFF}**

An optional switch and literal pair that enables the tool to report incremental multiple-detect test coverage statistics at the end of each multiple-detect ATPG loop. The default is for the tool to not report such statistics.

- **OFF**

An optional literal that disables the multiple detection of faults.

Examples

Example 1

The following example generates a 3-detection pattern set without EMD, where a fault is dropped from the simulation after 5 detections:

```
set_multiple_detection -guaranteed_atpg_detections 3 -desired_atpg_detections 1  
-simulation_drop_limit 5
```

Example 2

The following example generates a pattern set where each testable fault must be detected twice and should be detected at least 8 times:

```
set_multiple_detection -guaranteed_atpg_detections 2 -desired_atpg_detections 8
```

The simulation drop limit is automatically set to 10.

Example 3

The following example disables the multiple detection of faults:

```
set_multiple_detection off
```

set_multiprocessing_options

Context: unspecified, dft -edt, patterns -scan

Mode: setup, analysis, insertion

Sets the values of several variables that affect multiprocessing commands for ATPG or simulation.

Usage

```
set_multiprocessing_options [-generic_delete string] [-generic_scheduler string]
[-license_timeout {integer | unlimited | no_queue}] [-lsf_heuristics {on | off}]
[-lsf_learning {on | off}] [-lsf_options string] [-multithreading {on | off}]
[-processors_per_grid_request integer] [-remote_shell {rsh | ssh}]
[-result_time_limit integer] [-scheduler_timeout {integer | unlimited}]
[-sge_options string]
```

Description

Sets the values of several variables that affect multiprocessing commands for ATPG or simulation.

Note

 Take care to exclude any unsupported platforms that exist in your grid environment by specifying appropriate grid job submission constraints. For a list of supported platforms, refer to “[Supported Hardware and Operating Systems](#)” in *Managing Mentor Graphics Tessent Software*.

For more information about setting up for multiprocessing, refer to “[Multiprocessing to Reduce Runtime](#)” in the *Tessent Scan and ATPG User’s Manual* and “[The Tessent Tcl Interface](#)” in the *Tessent Shell User’s Manual*.

Arguments

- **-generic_delete *string***

An optional switch and string that specify a command to delete a slave process. You create a slave process via the generic job scheduler when you issue commands such as “[add_processors generic](#)”. The string consists of a command that the tool uses to delete a job with the generic job scheduler. It also contains a placeholder which has the format %*x*, where “*x*” is a single-word string. The tool looks for the single-word string in the output of the command specified for the generic jobs submission via the -generic_scheduler switch and expects to find a number following the string that represents the job number used by the generic scheduling system. The command specified by the -generic_scheduler switch is issued when each slave is added, and the number parsed by the tool is then stored and substituted for the placeholder in the generic_delete commands issued to the generic scheduling system to delete each slave.

If you specify, for example:

```
set_multiprocessing_options -generic_delete \
{ $SGE_ROOT/bin/lx24-x86/qdel %job }
```

Then running the command specified by the `-generic_schedule` switch should produce output that contains a job number following the word “job”, such as:

```
Your job 32335 ("mentortask") has been submitted
```

The tool parses the number after ‘job’ in the output and substitutes it for the placeholder `%job`, when it deletes the slave process. In this case, the tool will form the command:

```
$SGE_ROOT/bin/lx24-x86/qdel 32335
```

The placeholder can be any word, as long as it matches the word that is output prior to the job number in the output of the command specified by the `-generic_scheduler` switch. If that word is “task” instead of “job” as in the following:

```
Your task 33435 ("mentortask") has been submitted
```

Then you would specify a `generic_delete` command containing `%task` as in the following:

```
set_processing_options -generic_delete \
{ $SGE_ROOT/bin/lx24-x86/qdel %task }
```

The tool parses the number after ‘task’ in the output and substitutes it for the placeholder `%task`, when it deletes the slave process. In this case, the tool will form the command:

```
$SGE_ROOT/bin/lx24-x86/qdel 33435
```

Please note that the string that the tool looks for in the output is case sensitive. For example, if the scheduler command output was:

```
Task 3343 ("mentortask") has been submitted
```

The command specified by the `-generic_delete` switch would have to contain the string “%Task” rather than “%task”.

The tool uses this command to delete jobs when they are no longer needed, such as when you issue a `delete_processors` command, when the tool shuts down, or when the scheduler exceeds its timeout setting or is interrupted by Ctrl-C. This explicitly notifies the generic scheduling system that the job can be terminated or has already completed. If you use the generic scheduler without specifying a `generic_delete` command, the tool will simply tell the running slave processes to terminate and leave it up to the generic scheduling system to detect the termination of the slave processes.

- **-generic_scheduler *string***

An optional switch and string that specifies a command script that requests a slave process from the generic job scheduler (that is used for grid systems other than LSF or SGE). The string value you set for this switch replaces the current value. Setting a correct value for the string requires a knowledge of the scheduler configuration at your site and the job control submission syntax. Applies only to subsequent `add_processors` commands, not currently

running processes. An incorrect specification can prevent the correct operation of the add_processors command.

- **-license_timeout {integer | unlimited | no_queue }**

An optional switch and non-negative integer that specifies the number of minutes the tool waits when attempting to acquire a license. The default value is 5 minutes.

integer—A non-negative integer that specifies the queuing time in minutes. A zero value will cause the tool to not wait for a license, the same behavior as specifying “no_queue”. The tool reports when it is unable to acquire a license in the specified amount of time.

unlimited—An optional string that specifies no time limit. The tool waits until a license becomes available.

no_queue—An optional string that specifies that the tool not wait for a license and reports when a license is not available immediately.

- **-lsf_heuristics {on | off}**

An optional switch and keyword that enables or disables LSF heuristics learning when you add a processor by LSF grid request. The tool uses LSF heuristics learning in an attempt to automatically choose machines on the LSF grid that are compatible with the tool if you did not specify an LSF “type” constraint with -lsf_options and if either LSF scheduler learning has failed or you disabled that feature using “-lsf_learning off.”

LSF heuristics learning may be able to determine tool compatibility based on the names of the types and models available and successfully identify some type/model combinations that the tool can use; however, this may also result in specifying incompatible combinations or miss some compatible combinations. If LSF heuristics learning is turned off or fails, then the tool submits the job anyway without specifying any type/model restrictions.

LSF heuristics learning is enabled by default. For more information about using this switch, refer to “[Processor Addition to the LSF Grid](#)” in the in the *Tessent Scan and ATPG User’s Manual*.

- **-lsf_learning {on | off}**

An optional switch and keyword that enables or disables LSF scheduler learning when you add a processor by LSF grid request. When this switch is on and you have not specified an LSF “type” constraint with -lsf_options, the tool asks the LSF system what machines and type/model combinations are available, after which the tool runs the **lsrun** command to log onto likely machines to determine which are compatible with the tool.

LSF scheduler learning cannot succeed if your LSF system is configured to prevent use of **lsrun**. If LSF scheduler learning is turned off or fails, the tool then uses LSF heuristics learning unless you have disabled this feature with “-lsf_heuristics off.”

LSF scheduler learning is enabled by default. For more information about using this switch, refer to “[Processor Addition to the LSF Grid](#)” in the *Tessent Scan and ATPG User’s Manual*.

- **-lsf_options** *string*

An optional switch and string that specifies command options for the tool to append to the job submission command for the LSF job scheduler. The string value you set for this switch replaces the current value. Setting a correct value for the string requires a knowledge of the scheduler configuration at your site and the job control submission syntax. Applies only to subsequent add_processors commands, not to currently running processes. An incorrect specification can prevent the correct operation of the add_processors command.

When you add the “verbatim” key symbol at the beginning of the string, the tool interprets the rest of the line as the submission specification for each grid request it makes, overriding any memory and swap availability requirements it would otherwise attempt to add (see the note for the add_processors **hostname** argument). When you use this keyword, be sure to include any needed memory and swap requirements in the rest of the -lsf_options string. For more information, refer to “[Example 8](#)” on page 2274.

- **-multithreading** {on | off}

An optional switch and keyword that disables multithreading functionality. Multithreading is enabled by default.

- **-processors_per_grid_request** *integer*

An optional switch and integer value that specifies the maximum number of processors (slots) to group into one single request for the grid system, either for SGE, LSF, or GENERIC requests. The default value is “unspecified” (-1) because there are different default values for SGE, LSF, and GENERIC. The default for LSF requests is 4. The tool can use LSF job submission switches to ensure that this number of processors is requested per grid request. For SGE and GENERIC processor requests, the syntax for requesting a specific number of processor slots per grid request is site-specific, so the tool defaults to one processor per request.

If you want to specify the number of processors per request when using SGE or a generic grid scheduler, you must supply the needed syntax using the -sge_options, -generic_scheduler, and (optionally) the -generic_delete switches. You can do this by hardcoding a value in the -sge_options or -generic_scheduler string, or by using the pseudo variable %processors_per_grid_request, which allows you to change the value of processors_per_grid_request later without also having to change the corresponding grid command variable value. For an example of using this variable for the -lsf_options switch, refer to “[Example 3](#)” on page 2272.

The requested number of processors (for example, add_processors sge:20) results in the following number of grid requests: the requested number of processors divided by processors_per_grid_request. The result of the division is rounded up, and the last grid request can request fewer processors than the number of “processors_per_grid_request.”

Note

The use of job schedulers requires certain environment prerequisites to be satisfied before you invoke the tool. For more information, refer to “[Multiprocessing to Reduce Runtime](#)” in the *Tessent Scan and ATPG User’s Manual*.

- **-remote_shell {rsh | ssh}**

An optional switch and keyword that specifies the shell command that the master host should use to create processes on slave hosts. Applies only when you specify hosts manually rather than using a job scheduler. By default, the tool uses the **rsh** command.

- **-result_time_limit *integer***

An optional switch that specifies a time limit in minutes for detecting non-responsive slaves while waiting for certain types of job results. If the tool detects that the time limit has been exceeded for a specific result needed to make further progress, the tool issues a warning about the non-responsive slave and waits again for the same result. (This gives you the opportunity to investigate and correct the problem.) If the **result_time_limit** is again exceeded, the tool kills the slave and reassigns the job to another processor, and the cycle starts over. In most cases, you do not have to change the default value. Note that if you set the value too low, the tool could possibly kill all of its slaves needlessly. A value of 0 disables the time limit, but otherwise the command does not accept a value of less than 15. The default value is 45.

- **-scheduler_timeout {*integer* | unlimited}**

An optional switch and non-negative integer value or the string “unlimited” that specifies a time limit allowed, in minutes, for the tool to attempt to add processors using a job scheduler. If the tool does not receive all the requested processors within the specified time, it will proceed with the processors it has received.

integer—A non-negative integer that specifies the time limit, in minutes, for the tool to attempt to add processors using a job scheduler. A zero value indicates the same as specifying the “unlimited” string. The default value is 10 minutes.

unlimited—An optional string that specifies that the tool waits until all requested processors are received from the grid.

- **-sgc_options *string***

An optional switch and string that specifies command options for the tool to append to the job submission command for the SGE or OGE job scheduler. The string value you set for this switch replaces the current value. Setting a correct value for the string requires a knowledge of the scheduler configuration at your site and the job control submission syntax. Applies only to subsequent **add_processors** commands, not currently running processes. An incorrect specification can prevent the correct operation of the **add_processors** command.

Command Variables

The following variables are available for use in this command. You can define these variables in your dofile for convenience.

%command—Represents a substring you use with the **-generic_scheduler** switch to specify the location to substitute the Mentor Graphics command script that launches a slave process. For more information, refer to “[Example 5](#)” on page 2273.

%job—A placeholder, rather than a variable. For more information, on this placeholder, refer to the description of [-generic_delete *string*](#).

`%processors_per_grid_request` — Specifies the maximum number of processors (slots) to group into one single request for the grid system, either for SGE, LSF, or GENERIC requests. For more information, refer to “[Example 3](#)” on page 2272.

Tcl Notes

When using Tcl constructs with the `set_multiprocessing_options` command, the tool’s logfile reports the evaluated command and strips any Tcl special characters (quotes, braces, and brackets) from the logfile. If you need to replay a session from the logfile, you must add the Tcl syntax.

Enclosing any expression in braces (`{ }`) prevents the tool from evaluating the expression. Enclosing any expression in double quotes (`“ ”`) causes the tool to resolve any variables in the expression.

Examples

Example 1

The following example controls type and memory constraints that would normally be supplied automatically:

```
set_multiprocessing_options -lsf_options { -R \
    select[type==LINUX64 && mem> 200 && swp > 200 ] }
get_multiprocessing_option -lsf_options
-R select[type==LINUX64 && mem> 200 && swp > 200]
```

This setting would constrain LSF to select hosts meeting the specified requirements. The “type” specification also inhibits the automatic learning that would normally take place to discover all the type/model names in an LSF cluster. (This is useful if your site prevents the use of the `lrun` command or if the learning hits non-responsive hosts.) You can specify any legal LSF constraints for the installation, which overrides any related specifications the tool would have provided otherwise. It is up to you to supply syntactically and semantically correct LSF options.

Example 2

The following example specifies that LSF use queue *myqueue*:

```
set_multiprocessing_options -lsf_options "-q myqueue"
```

Example 3

The following example specifies that LSF reserve `%processors_per_grid_request` processors or slots:

```
set_multiprocessing_options -lsf_options "-n %processors_per_grid_request"
```

Note, however, that the `-n` specification would probably be only a subset of the `bsub` options assigned to the `-lsf_options` variable, and that the above example command line serves only as an example of how to use the `%processors_per_grid_request` variable. If you don’t use the `-n` switch in the `-lsf_options` string, the tool still specifies `-n` with the `processors_per_grid_request` value to the LSF job scheduler by default (value of 4). Note than when requesting additional processors per grid request, the number of grid requests decreases accordingly.

Example 4

The following example specifies that SGE impose a 6 hour time limit on slave processes:

```
set_multiprocessing_options -sgc_options {-l h_rt=6:00:00}
```

Example 5

The following example specifies an alternative interface to SGE for launching slave processes:

```
set_multiprocessing_options -generic_scheduler \
{ $SGE_ROOT/bin/lx*-amd64/qsub %command }
```

The *%command* represents a substring you must use with the *-generic_scheduler* switch to specify the location to substitute the Mentor Graphics command script that launches a slave process. Variables can be defined in the dofile to make this more convenient, as in the following example dofile excerpt:

```
set SUBMIT { $SGE_ROOT/bin/lx*-amd64/qsub }
set _multiprocessing_options -generic_scheduler "${SUBMIT} %command"
```

Example 6

The following example specifies an alternative interface to SGE for terminating slave processes:

```
add_processors generic
set_multiprocessing_options -generic_delete { $SGE_ROOT/bin/lx24-x86/qdel %job }
```

The *%job* is a placeholder that specifies a word, in this case “job”, that the tool uses to locate the job number in the generic scheduler’s output. The job number is substituted for the placeholder and used with the command *\$SGE_ROOT/bin/lx24-x86/qdel* when deleting processors.

The place holder does not need to be *%job*. It is whatever was used when the slave process was started. This is a variation of this example using a different placeholder, in this case, *%task*:

```
add_processors generic
set_multiprocessing_options -generic_delete { $SGE_ROOT/bin/lx24-x86/qdel %task }
```

Example 7

The following example specifies that the master host should use the **ssh** shell command to create processes on slave hosts (manual specification of hosts only):

```
set_multiprocessing_options -remote_shell ssh
```

Tip If you encounter errors trying to use SSH, refer to “[SSH Environment and Passphrase Errors](#)” in the *Tessent Scan and ATPG User’s Manual*.

Example 8

The following example specifies that LSF job requests should specify the use of hosts with type LINUX64 and should not specify any additional job constraints:

```
set_multiprocessing_options -lsl_options { verbatim -R "select[ type==LINUX64 ]" }
```

Related Topics[add_processors](#)[delete_processors](#)[get_multiprocessing_option](#)[report_multiprocessing_options](#)[report_processors](#)

set_net_dominance

Context: all contexts

Mode: setup, analysis (dft -edt and patterns -scan contexts only)

Specifies the fault effect of bus contention on tri-state nets.

Usage

`set_net_dominance Wire | And | Or`

Description

Specifies the fault effect of bus contention on tri-state nets.

The `set_net_dominance` command specifies the fault effect of bus contention on tri-state nets. This provides the capability to detect some faults on tri-state driver enable lines when those drivers connect to a tri-state bus. These faults would be ATPG-untestable unless the tool can use the Z-state for detection.

When using Tessent FastScan or Tessent TestKompress, the Wire behavior is the same where any different binary value results in an X-state.

The truth tables for each type of bus contention fault effect are given in Tables [6-13](#), [6-14](#), and [6-15](#). This command does not affect Good machine behavior.

Table 6-13. WIRE Bus Contention Truth Table

	X	0	1	Z
X	X	X	X	X
0	X	0	X	0
1	X	X	1	1
Z	X	0	1	Z

Table 6-14. AND Bus Contention Truth Table

	X	0	1	Z
X	X	0	X	X
0	0	0	0	0
1	X	0	1	1
Z	X	0	1	Z

Table 6-15. OR Bus Contention Truth Table

	X	0	1	Z
X	X	X	1	X
0	X	0	1	0
1	1	1	1	1
Z	X	0	1	Z

Arguments

- **Wire**

A literal that specifies for the tool to use unknown behavior for the fault effect of bus contention on tri-state nets. This is the default behavior upon invocation of the tool.

- **And**

A literal that specifies for the tool to use wired-AND behavior for the fault effect of bus contention on tri-state nets.

- **Or**

A literal that specifies for the tool to use wired-OR behavior for the fault effect of bus contention on tri-state nets.

Examples

The following Tessent FastScan example specifies that the fault effect on tri-state nets is wired-AND during ATPG:

```
set_net_dominance and  
set_system_mode analysis  
create_patterns
```

set_net_resolution

Context: all contexts

Mode: setup

Specifies the behavior of multi-driver nets.

Usage

`set_net_resolution Wire | And | Or`

Description

Specifies the behavior of multi-driver nets.

The `set_net_resolution` command specifies the behavior of non-tri-state, multi-driver nets. The default upon invocation of the tool is `Wire`, which requires all inputs be at the same value to achieve a value. If you can model your nets using the `And` or `Or` option, you can improve your test coverage results.

Arguments

- **Wire**

A literal that specifies for the tool to use unknown behavior for non-tri-state, multi-driver nets. This requires all inputs to be at the same value to achieve a value other than X. This is the default upon invocation of the tool.

If you are using Tessent FastScan or Tessent TestKompress with E9 rule checking enabled, the tools do not perform checking on wire gates if you use the `set_net_resolution` command to change their behavior to AND or OR.

- **And**

A literal that specifies for the tool to use wired-AND behavior.

- **Or**

A literal that specifies for the tool to use wired-OR behavior.

Examples

The following Tessent FastScan example specifies that the behavior of non-tri-state, multi-driver nets is wired-AND during ATPG:

```
set_net_resolution and  
set_system_mode analysis  
create_patterns
```

set_number_shifts

Context: dft -edt, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup, analysis

Sets the number of shifts for loading or unloading the scan chains.

Usage

set_number_shifts *shift_number*

Description

Sets the number of shifts for loading or unloading the scan chains.

Note

 For diagnosis, you can only use the set_number_shifts command to modify the number of shifts for an EDT design. There is no support in the diagnosis tool for non-EDT designs.

By default, the number of shifts used for loading or unloading the scan chains in a scan group is the same as the largest number of scan cells in any scan chain in that scan group. The tool determines this number once it traces all scan chains. However, you can use the set_number_shifts command to increase the default number.

You normally issue this command in setup mode. If the specified number of cycles is more than the number determined during DRC, the tool adds the extra cycles as overshift cycles. If the specified number of cycles is less than required, the tool issues an error.

If EDT is enabled, you can issue this command in either setup or analysis mode. The number of shift cycles specified in analysis mode does not impact the pattern generation process, which uses the number determined during DRC. The generated external patterns are padded with the additional cycles when they are saved using the “[write_patterns -edt_external](#)” command.

For edt_internal patterns, you must use the parameter file keyword ALL_EDT_INTERNAL_USE_NUMBER_SHIFTS in order to apply the number of shift cycles specified by set_number_shifts. For more information, refer to “[ALL_EDT_INTERNAL_USE_NUMBER_SHIFTS](#)” on page 3945.

Here are some considerations for using the set_number_shifts command:

- The set_number_shifts command is mutually exclusive with the “set_edt_options -OVERShift_cycles *integer*” command. If you attempt to issue both commands in the same session, the tool issues an error and resets the number of shifts to zero.
- The set_number_shifts command does not affect parallel test benches.
- The set_number_shifts command has no effect on WGL patterns if both the WGL_FULL_CHAIN and WGL_FULL_SCANGROUP parameter file keywords are

set to 0. By default, WGL_FULL_CHAIN is set to 1 and WGL_FULL_SCANGROUP is set to 0.

Arguments

- ***shift_number***

Specifies the number of shifts. If the number specified is smaller than the default number determined by the tool, the tool issues an error message.

Examples

Example 1

The following example sets the number of shifts for loading or unloading the scan chains to 2.

set_number_shifts 2

Example 2

The following example adjusts the number of shifts for a given pattern set and runs diagnosis:

```
set_number_shifts 100
read_patterns my_patterns/pat.wgl
diagnose_failures flogs/fail_1.log
```

[set_edt_options](#)

set_observation_point

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies the observation point for random pattern fault simulation.

Usage

`set_observation_point Master | SLave | SHadow | Clockpo`

Description

Specifies the observation point for random pattern fault simulation.

The `set_observation_point` command specifies whether Tessent FastScan observes master latches, slave latches, shadow latches, or clock primary outputs during random pattern fault simulation. If you select Master, Slave, or Shadow, Tessent FastScan also observes the primary outputs that do not connect to clock lines. The default behavior upon invocation of Tessent FastScan is Master.

Arguments

- **Master**

A literal that specifies observation of master latches and normal primary outputs. This is the default behavior upon invocation of Tessent FastScan.

- **SLave**

A literal that specifies observation of slave latches and normal primary outputs.

- **SHadow**

A literal that specifies observation of observable shadow latches and normal primary outputs.

- **Clockpo**

A literal that specifies observation of only primary outputs directly connected to clocks.

Examples

The following Tessent FastScan example specifies slave latches as the observation point for random pattern fault simulation:

```
set_system_mode analysis
set_observation_point slave
add_faults -all
simulate_patterns -source random
```

Related Topics

[set_capture_clock](#)

[simulate_patterns](#)

set_random_patterns

set_output_masks

Context: dft, dft -edt, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup, analysis

Ignores any fault effects that propagate to the primary output pins you select.

Usage

```
set_output_masks Off | ON [-Bidi_exclude] [-Exclude pin.pathname...]
```

Description

Ignores any fault effects that propagate to the primary output pins you select.

The tool uses primary output pins as the observe points during the fault detection process. When you mask a primary output pin, you inform the tool to mark that pin as an invalid observation point during the fault detection process. This command allows you the ability to flag all or a portion of the primary output pins that do not have strobe capability (are not observable). The tool classifies the faults whose effects only propagate to that observation point as Atpg_Untestable (AU).

You can use set_output_masks in setup mode or analysis mode, but not both. The tool behaves as follows:

- When output masks are enabled in setup mode and you disable them in analysis mode, the tool reports, “Error: Output masks enabled in setup mode cannot be disabled in analysis mode.”
- When output masks are enabled in setup mode and you enable them in analysis mode, the tool reports, “Note: Output masking was already enabled in setup mode.”
- When output masks are enabled in analysis mode and you return to setup mode, the tool disables the output masks.

You can use the [report_output_masks](#) command to display the current setting of the output masks.

Arguments

- **Off**

A required literal that specifies for the tool to use primary output pins as the observe points during the fault detection process. In addition, the tool will give possible credit for fault effects that reach a pin that the pattern set specifies as being at an unknown value. This is the default behavior upon invocation.

- **ON**

A required literal that specifies for the tool to mask the simulated primary output pin values with Xs for all patterns. As a result, the tool does not give any credit for fault effects that reach those masked primary output.

- **-Bidi_exclude**

An optional switch that modifies how the command treats bidirectional pins.

Note

 The meaning of the **-Bidi_exclude** switch is different for each setting (“off” or “on”) of the command. It basically specifies to do the opposite, for bidirectional pins, of what is done for other pins.

When used with the *Off* literal, the **-Bidi_exclude** switch specifies for the tool to `set_output_masks "on"` for bidirectional pins. Thus, the command “`set_output_masks off -bidi_exclude`” results in the tool masking bidirectional pins and no others.

Conversely, if you use the *On* literal, then adding the **-Bidi_exclude** switch causes the tool to `set_output_masks "off"` for bidirectional pins. The command “`set_output_masks on -bidi_exclude`”, therefore, results in the tool masking all pins except bidirectional pins.

- **-Exclude pin_pathname...**

An optional switch and repeatable string that modifies how the command treats a specific pin.

Note

 Similar to the **-Bidi_exclude** switch, the **-Exclude** switch specifies for the tool to do the opposite, for each specified pin, of what is done for other pins.

When used with the *Off* literal, the **-Exclude** switch will cause the tool to `set_output_masks "on"`, but only for the specified pin(s). The command “`set_output_masks off -exclude my_pin`”, for example, will result in the tool masking the pin whose pathname is “`my_pin`” and not masking any others.

Conversely, when used with the *On* literal, the **-Exclude** switch will cause the tool to `set_output_masks "off"` for the specified pin(s). In this case, “`set_output_masks on -exclude my_pin`” will apply masking to all pins except the pin “`my_pin`”.

Examples

The following example reports all the primary outputs of a design having one primary output, / `y_inout`, that is bidirectional. It then specifies to mask all the primary outputs *except* any that are bidirectional, and the three pins, `y_out[3]`, `y_out[2]`, and `x_out[1]`. The example then displays the masked primary output pins. As you would expect, none of the pins excluded from masking are listed.

report_primary_outputs

```
SYSTEM: /x_out [3]
SYSTEM: /x_out [2]
SYSTEM: /x_out [1]
SYSTEM: /x_out [0]
SYSTEM: /y_out [3]
SYSTEM: /y_out [2]
SYSTEM: /y_out [1]
SYSTEM: /y_out [0]
SYSTEM: /my_out
SYSTEM: /y_inout
```

set_output_masks on -bidi_exclude -exclude y_out[3] y_out[2] x_out[1]

report_output_masks

```
TIEX /x_out [3]
TIEX /x_out [2]
TIEX /x_out [0]
TIEX /y_out [1]
TIEX /y_out [0]
TIEX /my_out
```

[report_environment](#)

[report_output_masks](#)

set_parallel_load_subchains

Context: dft -edt, patterns -scan, patterns -scan_retargeting,
patterns -scan_diagnosis

Mode: setup, analysis

Specifies whether the internal parallel access functionality is enabled or disabled.

Usage

```
set_parallel_load_subchains [OFF|ON]
```

Description

Specifies whether the internal parallel access functionality is enabled or disabled.

By default, internal parallel access is disabled. In this case, when a netlist contains a subchain in a library model, the parallel test bench can only apply serial shifts to load the scan data and compare the capture values because internal pin names (where the parallel value is forced and observed) of the library models cannot be accessed. This limitation can increase parallel simulation runtime and significantly increase the size of the parallel test bench file.

If this command is enabled in Setup mode, the parallel test bench is written to access internal pin names of the library models. When you exit Setup mode, a DRC warning is issued if the netlist contains a subchain. In this case, you should enable this command. You can use the + command to display detailed information about the subchains in the netlist.

Arguments

- OFF
An optional literal that disables internal parallel access. This is the default.
- ON
An optional literal that enables internal parallel access. This command can be disabled or re-enabled in analysis mode to write out different parallel test benches if necessary, but only if it was initially enabled in Setup mode. If this command was not enabled in Setup mode, you cannot change the setting in analysis mode because internal access points can only be learned during DRC when switching from Setup mode to a non-Setup mode.

Note

 When this command is enabled, extra memory is required for storing the internal names of the library cells. Also, internal pin names of the Tessent Cell library models must match the internal pin names of the Verilog library model; otherwise, test bench compile errors or incorrect results from a Verilog simulation can occur. If you used LibComp to translate the Verilog libraries to ATPG libraries, then internal pin names should match because LibComp preserves these internal names.

Examples

The following example enables internal parallel access in Setup mode, sets the system mode to ATPG, creates test patterns, and saves the test patterns with parallel loading of subchains.

```
set_parallel_load_subchains on
set_system_mode analysis
create_patterns
write_patterns trans_pat.gz -verilog -parallel
```

If the test bench is not compiled because the internal pin names of the Verilog library do not match those of the Tessent Cell library, parallel loading can be disabled. Then the test bench loads the subchain cells serially.

```
set_parallel_load_subchains off
write_patterns trans_pat2.gz -verilog -parallel
```

[report_environment](#)

[report_scan_chains](#)

set_pathdelay_holdpi

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies whether the ATPG keeps non-clock primary inputs at a constant state after the first force.

Usage

set_pathdelay_holdpi OFF | ON

Description

Specifies whether the ATPG keeps non-clock primary inputs at a constant state after the first force.

The set_pathdelay_holdpi command lets you specify for the tools to ignore non-clock primary input changes after the first force in each pattern.

Arguments

- **OFF**
A literal specifying that the tool can change non-clock primary input values at any time. This is the default behavior upon invocation of the tool.
- **ON**
A literal that specifies for the tool not to change non-clock primary input values after the launch of the transition into the path.

Examples

The following example enables Tessent FastScan to ignore changes to non-clock primary inputs:

set_pathdelay_holdpi on

Related Topics

[set_transition_holdpi](#)

set_pattern_buffer

Context: unspecified, dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Stores run-time pattern data in temporary files in the directory specified.

Usage

set_pattern_buffer {*directory_name...*} | -Off

Description

Stores run-time pattern data in temporary files in the directory specified.

The **set_pattern_buffer** command allows you to specify a directory where the tool can store temporary run-time pattern data. When the tool accesses a pattern, it is then automatically retrieved from the specified directory, as opposed to virtual memory, conserving the memory for other tool processing tasks. This provides a run-time processing advantage when there is not ample swap space.

You can specify multiple directories. As individual buffer files approach their file size limit or volume space runs out, the tool searches the specified directory list for available space. The tool deletes these buffer files when you exit the application.

Note

 Buffer files may be multiple gigabytes large. Choose directories on volumes that have enough disk space to handle expected amount of pattern data.

Arguments

- ***directory_name***

A required repeatable string that specifies the full path directory names in which the tool saves buffer files, thus enabling the usage of temporary buffer files for pattern data. Reissuing this command with additional directories causes the tool to add the directories to the current list of directories available for buffer files.

- **-Off**

A required switch that disables the use of temporary buffer files, causing the tool to save run-time data in virtual memory. This is the default upon invocation. Disabling the usage of pattern buffers can only be done when there is no pattern data, such as after issuing the **reset_state** or **set_system_mode** commands.

Examples

The following example places buffer files in the specified directories.

```
set_pattern_buffer /usr/jdoe/buffers /usr2/jdoe/morebuffers
```

[report_resources](#)

set_pattern_classification

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies the order in which to store test patterns.

Usage

`set_pattern_classification ON | OFF`

Description

Specifies the order in which to store test patterns.

When set to “on,” each pattern is stored by its classification, according to the following ordered list:

basic
read only (a type of basic pattern)
ram sequential
clock sequential and multi-load

When set to “off,” test patterns are stored in the order in which they were generated. Note that when simulating the external patterns (by issuing the [simulate_patterns](#) command), the tool automatically turns off pattern classification.

Arguments

- **ON**
A literal that enables pattern classification. If the current internal pattern set is not classified, the pattern is automatically classified after the command is executed.
- **OFF**
A literal that turns off pattern classification. When pattern classification is disabled, patterns are stored in the same order in which they were generated.

Examples

The following example stores patterns in the order in which the tool generates them:

`set_pattern_classification off`

Related Topics

[write_patterns](#)

[set_pattern_filtering](#)

Context: patterns -scan, patterns -scan_diagnosis

Mode: analysis

Creates a temporary set of sampled scan patterns.

Usage

```
set_pattern_filtering [-EXternal] -Off
| [-LList pattern_index...]
| [{-PATtern_type keyword}...]
| [{-NOPattern_type keyword}...]
[-SAMple_per_type integer]
[-CAPture]
[{-RANge begin_int end_int}...]
[{-NORange begin_int end_int}...]
[{-NAmed_capture_procedures {procedure_name ... | ALL}}}
| {[{-CLocks clock_name...} [-NO_CLocks clock_name ...]}]
| [-RESTRICT_CLocks clock_name...}]
[{-CAPTURE_Power operator percentage [ST_Peak | ST_Average | WSA_Peak
| WSA_Average] [-INSTance object_name...] [-MODULE module_name...]...]}
[{-SHIFT_Power {LOAD | RESPonse} operator percentage] [-INSTance object_name...]
[-MODULE module_name...]...]
```

Description

Creates a temporary set of sampled scan patterns.

You can then save the sampled patterns in all supported formats with the [write_patterns](#) command. To restore the original non-sampled patterns, issue `set_pattern_filtering -Off`. If the content of the original pattern set changes while pattern filtering is on, pattern filtering is turned off automatically.

By default, this command preserves the original pattern order. When you use the -list switch, the user-specified pattern order will be enforced. Also, the filtering and ordering only applies to scan (ATPG) patterns, and is not performed for chain test patterns.

Note

 Because MacroTest patterns are order dependent, they are sampled sequentially, beginning at the first pattern. Non-MacroTest patterns are re-ordered.

Arguments

- **-EXternal**

An optional switch that applies sampling to external patterns. Before using this switch, you must specify the name of the external pattern file with the [read_patterns](#) command. The tool also re-orders the patterns.

- **-Off**

An optional switch that restores the original non-sampled patterns.

- **-L***ist pattern_index...*

An optional switch and repeatable, non-negative, integer pattern indexes that creates a sample consisting of patterns with the specified pattern indexes, and orders the sampled patterns in the same order the indexes appear (left to right) in the command. The *pattern_index* refers to original pattern indexes in the pattern set before filtering by the `set_pattern_filtering` command. This switch cannot be combined with any other pattern filtering options.

This switch enables you to arrange patterns in any order. For example, during IDDQ test, if the current of every pattern is measured to sort them in order of increasing current, the result is a list of pattern indices (for example, 13, 2, 24, and so on) that does not match any of the tool's built-in ordering criteria. You could use this switch to order the patterns according to the IDDQ sort.

- **-PATtern_type keyword**

An optional switch and keyword pair that applies sampling based on the keyword pattern type. Multiple “-Pattern_type keyword” pairs are allowed; however, you cannot combine this switch with the -Nopattern_type switch in the same command. Keywords are listed in [Table 6-16](#). If you specify neither this switch nor the -Nopattern_type switch, the default is to sample all pattern types.

Valid pattern type keywords are:

Table 6-16. Keywords for Pattern Types

Pattern Type	Keyword
Basic	BASIC
Clock PO	CLOCK_Po
Clock Sequential	CLOCK_Sequential
MacroTest	MacroTest
Multi-load	MULTI_load
RAM Sequential	RAM_sequential

- **-NOPattern_type keyword**

An optional switch and keyword pair that specifies to not sample the keyword pattern type. Multiple “-Nopattern_type keyword” pairs are allowed; however, you cannot combine this switch with the -Pattern_type switch in the same command. Keywords are listed in [Table 6-16](#).

- **-SAMple_per_type integer**

An optional switch and positive integer pair that specifies how many patterns of each type to sample. The default is 1.

- **-CAPture**

An optional switch that samples the patterns by capture clock rather than pattern type. It samples patterns based upon the capture clock of each capture cycle so that each clock pulse in different capture cycles are sampled n times, where n is selected by the “-sample_per_type n” option (default is 1). See [Example 9](#).

If you specify the -Capture switch with the -Pattern_type switch, the command only samples patterns by capture clock within the specified pattern types.

- **-RANge beg_int end_int**

An optional, repeatable switch and pair of integers that creates a sample of patterns beginning with pattern beg_int and ending with pattern end_int. Patterns are numbered beginning with 0; for example, to restrict sampling to the first 100 patterns, use “-range 0 99.”

- **-NORange beg_int end_int**

An optional, repeatable switch and pair of integers that specifies to not apply sampling to the range of patterns beginning with pattern beg_int and ending with pattern end_int. Patterns are numbered beginning with 0; for example, to exclude patterns 51 through 60 from sampling, use “-norange 51 60.” You can use this switch to exclude sub-ranges within sampled ranges specified with the -Range switch.

- **-NAMED_capture_procedures procedure_name... / ALL**

An optional switch and repeatable string or literal pair that samples patterns for either the specified named capture procedures or all named capture procedures.

The number of patterns sampled depends on the number of samples specified using the -sample switch. If the -sample switch is not used, all the patterns that use the specified named capture procedures are sampled.

- **-Clocks clock_name...**

An optional switch and repeatable string pair that samples only patterns that use one or more of the specified clocks. This includes patterns that use unspecified clocks if they also use at least one of the specified clocks. For example, “set_pattern_filtering -clocks clk1 clk2 clk3” will sample a pattern that pulses clk1, clk2, or clk3. Patterns that do not pulse any clock are not sampled.

You cannot combine this switch with the -Restrict_clocks switch in the same command.

- **-NO_Clocks** *clock_name...*

An optional switch and optional, repeatable, string pair that samples only patterns that do not use any of the specified clocks. To obtain a sample that includes all the patterns that do not pulse any clock, omit the *clock_name* argument.

Note

 If you issue “`set_pattern_filtering -no_clocks clk1 clk2`,” where clk1 and clk2 are the only clocks pulsed by any pattern, the filtering result is the same as omitting the clock names and simply issuing “`set_pattern_filtering -no_clocks`.”

You cannot combine this switch with the **-Restrict_clocks** switch in the same command. If you omit the *clock_name* argument, you cannot combine this switch with the **-Clocks** switch in the same command.

- **-RESTRICT_Clocks** *clock_name...*

An optional switch and repeatable string pair that samples only patterns that use the specified clocks, or a subset of these clocks, exclusively. Patterns that use any unspecified clocks are not sampled, even if they also use some or all of the clocks specified. For example, “`set_pattern_filtering -restrict_clocks clk1 clk2 clk3`” will not sample a pattern that pulses clk1, clk2 and clk4. Patterns that do not pulse any clock are not sampled.

You cannot combine this switch with the **-Clocks** or **-No_clocks** switch in the same command.

- **-CAPTURE_Power**

Optional switch that filters test patterns based on switching activity during capture.

- **operator**

Optional literal that specifies an operation for test pattern filtering based on switching activity during shift or capture. Literal options include:

< — Less than

> — Greater than

<= — Less than or equal to

>= — Greater than or equal to

- **percentage**

Optional integer that specifies a switching threshold percentage that applies to filtering test patterns based on capture or shift power. The specified integer must be positive.

- **ST_Peak | ST_Average | WSA_Peak | WSA_Average**

Optional literal that filters the test patterns based on a specified metric. These options can only be used for switching activity during capture. Literals include:

ST_Peak — Peak of state transitions. Default.

ST_Average — Average of state transitions.

- WSA_Peak — Peak of weighted switching activity.
- WSA_Average — Average of weighted switching activity.
- **-INSTance *instance.pathname*...**
An optional switch and repeatable string that specifies one or more target instance(s) for test pattern sampling. This option is only available for sampling local switching activity during shift and/or capture. The *instance.pathname* may include any number of asterisk (*) and/or question mark (?) wildcard characters in a name.
 - **-MODULE *module.name*...**
An optional switch and repeatable string that specifies one or more target module(s) for test pattern sampling. This option is only available for sampling local switching activity during shift and/or capture. The *module.pathname* may include any number of asterisk (*) and/or question mark (?) wildcard characters in a name.
 - **-SHIFT_Power {LOAD | RESPonse}**
An optional switch and literal that filters test patterns based on switching activity during shift. Literal options include:
LOAD — filters based on switching during test pattern loading.
RESPonse — filters based on switching during the circuit response to test patterns.

Examples

Example 1

This example assumes ATPG has just been run, resulting in 125 patterns of three different types, including clock PO. There are two capture clocks. The example first saves a sample consisting of four clock PO patterns to a separate pattern file in TITDL format. The example then samples two patterns for each pattern type. Next, the same command is repeated with the addition of -Capture. This causes the tool to sample two patterns per type as before, and then add as necessary, additional patterns to ensure the sampled pattern set contains at least two samples per capture clock.

```
report_pattern_filtering
// Pattern filtering is off.

set_pattern_filtering -pattern_type clock_po -sample_per_type 4
// Pattern filtering is on: 1 pattern type(s),
// 4 selected pattern(s), 125 original pattern(s).

write_patterns clock_po.tdl -titdl -replace
// Note: pattern filtering is on, #-saved-pattern(s) = 4,
// #-total-pattern(s) = 125

set_pattern_filtering -sample_per_type 2
```

set_pattern_filtering

```
// WARNING: The previous filter option has been reset.
// Internal pattern filtering is on: 3 pattern type(s),
// 6 selected pattern(s), 125 original pattern(s).
```

set_pattern_filtering -capture -sample_per_type 2

```
// WARNING: The previous filter option has been reset.
// Internal pattern filtering is on: 3 pattern type(s),
// 7 selected pattern(s), 125 original pattern(s).
```

report_pattern_filtering

Current pattern filtering configuration

```
-----
original_patterns (internal) = 125
current_filtered_pattern(s) = 7
sampled_patterns_per_type = 2
sample_capture_clock = on
sample_pattern_type(s) = all
-----
```

Example 2

This example creates a sample of patterns 0 through 4, 6 through 10, and 20 through 29.

set_pattern_filtering -range 0 10 -norange 5 5 -range 20 29

```
// WARNING: The previous filter option has been reset.
// Internal pattern filtering is on: 20 selected pattern(s),
// 125 original pattern(s).
```

report_pattern_filtering

Current pattern filtering configuration

```
-----
original_patterns (internal) = 125
current_filtered_pattern(s) = 20
sampled_patterns_per_type = all
sample_capture_clock = off
sample_pattern_type(s) = all
include_range(s) = [20, 29], [0, 10]
exclude_range(s) = [5, 5]
-----
```

Example 3

This example creates a sample of patterns that use one or more of the clocks clk1, clk2, and clk3 and other clocks except for clk4; patterns that use clk4 are not sampled.

set_pattern_filtering -clocks clk1 clk2 clk3 -no_clocks clk4

```
// Warning: The previous filter options have been reset.
// Internal pattern filtering is on: 6 selected pattern(s),
// 125 original pattern(s).
```

report_patterns

```
//      pre-
//      filter
// patt # patt #  type    cycles loads obs_proc cap_proc capture_clk_seq
// -----
//   0     0  basic      1      1      -      -  [clk3]
//   1     3  basic      1      1      -      -  [clk1]
//   2     5  clk_seq    2      1      -      -  [clk1]  [clk2]
//   3     6  clk_seq    2      1      -      -  [clk2]  [clk3]
//   4     9  clk_seq    2      1      -      -  [clk2]  [clk5]
//   5    18  clk_seq    2      1      -      -  [clk2]  [clk6]
```

Notice that when pattern filtering is in effect, the [report_patterns](#) command displays the index numbers of the patterns prior to filtering as well as after filtering.

Example 4

This example creates a sample of patterns that do not pulse any clock.

set_pattern_filtering -no_clocks

```
// Warning: The previous filter options have been reset.
// Internal pattern filtering is on: 2 selected pattern(s),
// 125 original pattern(s).
```

report_patterns

```
//      pre-
//      filter
// patt # patt #  type    cycles loads obs_proc cap_proc capture_clk_seq
// -----
//   0     1  basic      1      1      -      -  [-]
//   1     2  basic      1      1      -      -  [-]
```

Example 5

This example creates a sample of patterns 54, 106, 34 and 125, in that order.

set_pattern_filtering -list 54 106 34 125

```
// Warning: The previous filter options have been reset.
// Internal pattern filtering is on: 4 selected pattern(s),
// 125 original pattern(s).
```

report_patterns

```
//      pre-
//      filter
// patt # patt #  type    cycles loads obs_proc cap_proc capture_clk_seq
// -----
//   0     54  basic      1      1      -      -  [clk2,clk4]
//   1    106  clk_seq    3      1      -      -  [clk1]  [clk3]  [c
//   2     34  mult_ld    4      3      -      -  [clk1]
//   3    125  clk_seq    2      1      -      -  [clk1]  [clk2]
```

Example 6

This example creates a sample of patterns that use the specified named capture procedures TranPtrn01 and TranPtrn03.

```
set_pattern_filtering -named_capture_procedures TranPtrn01 TranPtrn03
// Warning: The previous filter options have been reset.
// Internal pattern filtering is on: 17 selected pattern(s), 32 original
// pattern(s).

report_patterns

//      pre-
//      filter
// patt # patt #   type   cycles loads obs_proc cap_proc capture_clk_seq
// -----
//    0    0  clk_seq  2      1      -  TranPtrn01 [clk] [clk]
//    1    1  clk_seq  2      1      -  TranPtrn01 [clk] [clk]
//    2    2  clk_seq  2      1      -  TranPtrn01 [clk] [clk]
//    3    3  clk_seq  2      1      -  TranPtrn01 [clk] [clk]
//    4    4  clk_seq  2      1      -  TranPtrn01 [clk] [clk]
//    5    5  clk_seq  2      1      -  TranPtrn01 [clk] [clk]
//    6    6  clk_seq  2      1      -  TranPtrn01 [clk] [clk]
//    7    7  clk_seq  2      1      -  TranPtrn01 [clk] [clk]
//    8    8  clk_seq  2      1      -  TranPtrn01 [clk] [clk]
//    9    9  clk_seq  2      1      -  TranPtrn01 [clk] [clk]
//   10   19  clk_seq  2      1      -  TranPtrn03 [clk] [hclk]
//   11   20  clk_seq  2      1      -  TranPtrn03 [clk] [hclk]
//   12   21  clk_seq  2      1      -  TranPtrn03 [clk] [hclk]
//   13   22  clk_seq  2      1      -  TranPtrn03 [clk] [hclk]
//   14   23  clk_seq  2      1      -  TranPtrn03 [clk] [hclk]
//   16   25  clk_seq  2      1      -  TranPtrn03 [clk] [hclk]

report_pattern_filtering

Current pattern filtering configuration
-----
original_patterns (internal) = 32
current_filtered_pattern(s) = 17
sampled_patterns_per_type = all
sample_capture_clock = off
selected named capture proc = TranPtrn01, TranPtrn03
sample_pattern_type(s) = all
-----
```

Example 7

This example creates a sample of two patterns for each of the specified named capture procedures TranPtrn01 and TranPtrn03 and then saves the sampled patterns.

```
set_pattern_filtering -sample 2 -named TranPtrn01 TranPtrn03
write_patterns pat_TranPtrn01_TranPtrn03.ascii
```

Example 8

This example creates a sample of two patterns for all the named capture procedures and then saves the sampled patterns.

```
set_pattern_filtering -sample 2 -named ALL
write_patterns pat_all.ascii
```

Example 9

This example shows a pattern report before and after filtering the patterns using the -capture option.

report_patterns

```
//  
//   pattern #  type          cycles  load  observe_proc  capture_proc  capture_clock_sequence  
//   -----  -----  -----  -----  -----  -----  
//   0      basic           1       1      -            -            [-]  
//   1      basic           1       1      -            -            [-]  
//   2      basic           1       1      -            -            [-]  
//   3      basic           1       1      -            -            [-]  
//   4      basic           1       1      -            -            [sclk]  
//   5      basic           1       1      -            -            [sclk]  
//   6      basic           1       1      -            -            [sclk]  
//   7      basic           1       1      -            -            [sclk]  
//   8      basic           1       1      -            -            [sclk]  
//   9      basic           1       1      -            -            [reset_]  
//  10     basic           1       1      -            -            [sclk]  
//  11     basic           1       1      -            -            [sclk]  
//  12     basic           1       1      -            -            [sclk]  
//  13     basic           1       1      -            -            [sclk]  
//  14     basic           1       1      -            -            [sclk]  
//  15     basic           1       1      -            -            [reset_]  
//  16     basic           1       1      -            -            [sclk]  
//  17     basic           1       1      -            -            [sclk]  
//  18     clock_sequential 2       1      -            -            [sclk]  [clk12]  
//  19     clock_sequential 2       1      -            -            [sclk]  [clk12]  
//  20     clock_sequential 2       1      -            -            [reset_]  [clk12]
```

set_pattern_filtering -capture

```
// Internal pattern filtering is on: 4 selected pattern(s), 21 original
pattern(s).
```

report_patterns

```
//  
//   pre-filtering  
//   pattern #  pattern #  type  cycles  load  observe_proc  capture_proc  capture_clock_sequence  
//   -----  -----  -----  -----  -----  -----  -----  
//   0        0      basic   1       1      -            -            [-]  
//   1        4      basic   1       1      -            -            [sclk]  
//   2        9      basic   1       1      -            -            [reset_]  
//   3       18      clock_sequential 2       1      -            -            [sclk]  [clk12]
```

Notice that each clock pulsed in different capture cycles is sampled once, since the default sample per type is one.

set_pattern_source

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: analysis

Specifies the source of the test patterns.

Usage

When EDT is Off

```
set_pattern_source Internal | {Random | Bist | {{External filename}  
[-APPend | -Replace] [-Binary | -ASci | -STil | -WGl]}  
[-MASK mask_filename [-MASKFILE pattern_offset number]]  
[-PREserve_masked_observe_points] [-NOPadding] [-Store_patterns] [-ALL_patterns]}
```

When EDT is On

```
set_pattern_source Internal | {{External filename}  
[-APPend | -Replace] [-Binary | -ASci | -STil | -WGl]  
[-MASK mask_filename [-MASKFILE pattern_offset number]]  
[-PREserve_masked_observe_points] [-Store_patterns] [-ALL_patterns]}
```

Description

Specifies the source of the test patterns.

Note

 The set_pattern_source command followed by the “run” command has been mostly superseded by the [read_patterns](#) and [simulate_patterns](#) commands. For “set_pattern_source internal” and “run”, the replacement command is [create_patterns](#). Mentor Graphics recommends you use the newer commands.

Arguments

- **Internal**

A literal that specifies the internal set of patterns. This is the default upon invocation of the tool.

- **Random**

A literal that specifies the random patterns, capture clock, and observation point specified previously.

- **Bist**

A required literal that specifies BIST patterns.

There must be at least one defined LFSR or an error displays. The existence of such an LFSR means that the design successfully passed the BIST rules checking when leaving Setup.

- **External *filename***

A literal and string pair that specifies the set of patterns contained in *filename* when performing a simulation run. For simulation, the specified patterns are loaded into an external pattern set database.

In analysis system mode, the tool adds effective patterns from a simulation run to the internal pattern set, if there is at least one undetected fault in the fault list. When you use the -All_patterns switch, the tool adds all simulated patterns from the external pattern set to the internal pattern set, not just the effective patterns.

In analysis mode, a simulation run does not alter the internal pattern set.

The external patterns can be in ASCII, binary, STIL, or WGL test pattern format.

Note

You may notice a drop in test coverage when using an external pattern set as compared to using generated patterns. This is an artificial drop.

There is an issue regarding artificial drops in test coverage due to redundant faults. When you run ATPG, the tool classifies some faults as redundant (RE). The tool knows these faults are untestable when calculating test coverage. If you restart the tool, or go back to Setup mode before reading the patterns back in, the faults that were previously classified as RE will now be classified as UC or UO. Now, the tool does not know these faults are untestable when calculating test coverage because faults cannot be proven redundant by fault simulation. The tool will only fault simulate the external patterns. It will not target undetected faults and try to prove them redundant as it does when the pattern source is internal. Therefore, you may see a slight drop in test coverage. This drop is an artificial drop and coverage still remains the same.

The external pattern formats are described in the [Tessent Scan and ATPG User's Manual](#).

- **-APPend**

An optional switch that specifies for the tool to append the patterns contained in filename to the patterns in the tool's current external pattern set.

- **-Replace**

An optional switch that specifies for the tool to replace its current external pattern set with the patterns contained in filename. This is the default.

- **-Binary**

An optional switch that specifies the external test pattern set is in binary format. This is used when reading in a file saved with the write_patterns -BInary command.

If neither -Binary or -Ascii options are specified, the tool tries to open and process the file as a binary file. If this is unsuccessful, the tool then tries to open and process the file as an ASCII file.

- [-ASci](#)

An optional switch that specifies the external test pattern set is in ASCII format. You cannot use this option with the Internal pattern source.

- [-WGl](#)

An optional switch specifying that the external test pattern set is in WGL format. You must use this option if you specify external patterns that are in WGL format.

Restrictions:

- For Tessent FastScan and Tessent TestKompress, you must load parallel scan patterns, not serial. Patterns produced by MacroTest cannot be read back in. For more information, see the note under the External argument.
- If you re-simulate scan patterns, only serial patterns are allowed.

- [-STil](#)

An optional switch specifying that the external test pattern set is in STIL format. You must use this option if you are loading STIL functional patterns into the tool.

Restriction:

- You must load parallel scan patterns, not serial.
- The patterns must be STIL patterns originally created in these tools.

Analysis of the STIL patterns conforms to the IEEE 1450.0 specification. The following features from the IEEE 1450.0 specification are not supported:

- Multiple data elements per test cycle (See section 5.7 of IEEE 1450.0)
- Non-cyclized test data (See section 5.9 of IEEE 1450.0)
- Goto statement referring to a previous pattern label (See section 22.8 of IEEE 1450.0)
- MatchLoop statement (See section 22.7 of IEEE 1450.0)

Analysis of the STIL patterns only supports waveform descriptions in the WaveformTable that Mentor Graphics tools currently support. Therefore, a waveform description should not have more than two event edges, unless it is describing a double pulse. All other waveforms that have more than two event edges are not allowed. Also, timing expressions are limited to using only the +, -, *, /, (, and) operators on constants or variables that have time-based units.

- [-MAsk](#)

An optional switch that masks certain observation points in external patterns added to the internal pattern set after simulation. This switch enables you to salvage patterns that result in unreliable failures on certain cells at the tester, or that fail verification due to simulation mismatches at a few observation points. Rather than discard failing patterns altogether and accept the accompanying significant reduction in test coverage, you can keep the patterns,

use this switch to mask the few problem observation points, and typically see only minimal impact on test coverage.

The tool obtains the masking information from a text file you create (see the `mask_filename` argument).

This switch affects the capture values of only those patterns from the external pattern set that the tool has added to the internal pattern set after simulation. Therefore, if you write patterns using “`write_patterns -external`,” you will not see the masking information from the mask file reflected in the saved patterns; the saved patterns will be exactly the same as the original patterns.

To save a pattern set that incorporates the masking information, use the `run` command to perform a simulation of the external pattern set you specified with “`read_patterns -preserve_masked_observation_points`.” Then use the `write_patterns` command *without* the `-External` switch to write the resulting internal pattern set to a file.

Tip

 When you use the `-Mask` switch, the tool automatically executes the `-Store_patterns` switch with it; you do not need to include an explicit `-Store_patterns` in your command line.

- *mask_filename*

An optional string used with the `-Mask` switch to specify a mask file. The mask file is a text file you create that lists the patterns and locations you want masked. Use the statements and syntax described in [Table 6-17](#) to create a mask file. Use one statement per line. Precede comment text with a pair of forward slashes (//). An example mask file follows the table.

Note

 Tessent TestKompress names scan chains internally. Depending on the design architecture, you must use this internal naming format to identify Tessent TestKompress scan chains in the mask file as follows:

Modular EDT — `edt_<block_name>_channel<number>`

Top-level EDT — `edt_channel<number>`

Use the [report_edt_pins](#) command to determine the number associated with a scan chain.

The mask file must be in a pattern based format. Most ATE’s return accumulated cycle-based failure data. Use the [read_failures](#) command to convert cycle-based failure data to pattern based data for the mask file.

Table 6-17. Mask File Statements

Statement	Usage Rules
<location>	<p>Required. Specifies a location to mask or observe. Use as many location statements as you need. List all location statements that specify a pattern index in ascending order. Syntax format depends on the type statement that precedes the location statement, as follows:</p> <p>EDT Off:</p> <ul style="list-style-type: none"> • If “type mask” or “type observe” precedes the location statement, use one of these two formats: <pattern_index> <primary_output_name> <pattern_index> <chain_name> <cell_ID> • If “type pin_mask” precedes the location statement, use one of the following three formats: <primary_output_name> <chain_name> <chain_output_pin_name> <p>EDT On:</p> <ul style="list-style-type: none"> • If “type mask” or “type observe” precedes the location statement, use one of these three formats: <pattern_index> <primary_output_name> <pattern_index> <chain_name> <cell_ID> <pattern_index> <channel_name> <channel_cell_index> <p>Specify the <i>channel_name</i> argument as follows:</p> <p>For non-modular flows: <i>edt_channel<number></i>. For example, <i>edt_channel3</i>.</p> <p>For modular flows: <i>edt_<block_name>_channel<number></i>. For example, <i>edt_block1_channel3</i>.</p> <p>Note, the <i>channel_cell_index</i> argument refers to the unload cycle.</p> <ul style="list-style-type: none"> • If “type pin_mask” precedes the location statement, use one of the following three formats: <primary_output_name> <channel_name> <channel_output_pin_name>

Table 6-17. Mask File Statements (cont.)

Statement	Usage Rules
type <value>	<p>Optional. Indicates if the locations specified by subsequent location statements are to be masked (forced to X) or observed. Specify one of the following values:</p> <ul style="list-style-type: none"> • mask — specifies to mask the locations, for a specific pattern • observe — specifies to observe the locations and mask all others, for a specific pattern • pin_mask — specifies to mask the locations, for <i>all</i> patterns. Overrides other type statements that cover the same location. <p>Use as many type statements as you like. By default, the tools assume “type mask” for locations listed before the first type statement. A type statement inserted between two location statements for the same pattern does not take effect until the next different pattern.</p>

Following is an example mask file:

```
//file: my_pattern_mask.ascii
//
// The next 3 lines mask 3 locations in pattern 20.
20 primary_output_12
20 chain2 31
20 chain3 101
// The next line masks 1 location in pattern 25.
25 chain1 120
type observe
// The following 2 lines mask all but the 2 specified locations in
// pattern 40.
40 chain5 3
40 primary_output_1
// The following type statement takes effect with pattern 61.
type mask
// The next line defines a third observe location for pattern 40.
40 primary_output_2
61 chain4 120
// The next line masks chain5 for all patterns, overriding previous
// "type observe" for cell 3 of chain 5 for pattern 40, and
// subsequent "type observe" for cell 99 of chain5 for pattern 65.
type pin_mask
chain5
type observe
// The following line masks all cells in chain5 except cell 99 in
// pattern 65.
65 chain5 99
```

- **-MASKFILE _pattern_offset number**

An optional switch and integer that specifies the pattern offset number for the mask file. By default (when no offset is specified), the pattern in the mask file starts with pattern 0. This switch is useful for reducing the number of pattern files that must be loaded when only a subset need to be masked.

- **-PREserve _masked _observe _points**

An optional switch, used with external, that allows you to preserve existing masked observation points (wherever Xs appear in a pattern's unload and measure_po values) in external patterns loaded into the tool. When you use this switch to preserve existing masked observation points in the external patterns, the internal patterns stored after simulating the external patterns preserve these masked observation points. You can optionally specify “-Mask maskfile” with additional observation points to be masked.

- **-Store _patterns**

An optional switch that directs the tool to place patterns it simulates during the Good or Fault system mode into the internal pattern set. You can then use the write_patterns command to save these patterns to an external file.

You cannot use this option with the Internal pattern source.

- **-ALL_patterns**

An optional switch that, in analysis mode only, specifies for the tool to add all simulated patterns to the internal pattern set, provided there is at least one undetected fault in the fault list. The simulated patterns can be either randomly generated or can be from the specified external pattern file. Patterns that cause bus conflicts, which the tool ordinarily discards, are included when you use this switch. Without this switch, the tool adds only the effective patterns from a simulation run to the internal pattern set.

- **-NOPadding**

An optional switch specifying that the source test pattern set contains ASCII patterns that are not padded for the scan load and unload data. For example, the source pattern set may be one that you wrote with the write_patterns command using its -NOPadding switch.

You cannot use this option with the Internal pattern source.

Examples

Example 1

The following example performs fault simulation on an external pattern file:

```
set_system_mode analysis
set_pattern_source external file1
add_faults -all
simulate_patterns
report_statistics
```

Example 2

The following example fault grades transition faults using a set of path delay patterns. Assume path delay patterns generated with “`set_fault_type path_delay -mask_nonobservation_points`” are stored in the file, `path_patterns_mask.ascii`:

```
set_system_mode analysis
set_pattern_source external path_patterns_mask.ascii -mask
set_fault_type transition
add_faults -all
simulate_patterns
report_statistics
```

Example 3

The following example shows how to combine patterns from several different files into one pattern set, which you can save in any supported format. First, the example loads patterns from three separate pattern files into the tool’s external pattern set. The patterns are in the same order in which they are loaded. The example then writes the contents of the external pattern set into a new file in the WGL format. Notice the patterns loaded are in mixed formats (ASCII and binary); also, that the tool automatically knows to use the GNU gzip utility when processing the input file with the “.gz” extension.

```
set_pattern_source external my_patterns1.ascii
set_pattern_source external my_patterns2.binary -append
set_pattern_source external my_patterns3.ascii.gz -append
write_patterns my_patterns_all.wgl -wgl -external
```

Example 4

The following commands create a new pattern set using the existing pattern set `pat.ascii` and keep the mask observation points plus the additional masked bit specified in maskfile `my_mask`:

```
set_pattern_source external pat.ascii -store \
    -preserve_masked_observation_points -maskfile my_mask
create_patterns
write_patterns pat_new_masks.ascii
```

Example 5

The following example demonstrates how to specify the offset to speed up the pattern mask flow. Assume that a group of pattern files are created as follows:

Pat1.stil & Pat1.v contain pattern index 0 to 999
 Pat2.stil & Pat2.v contain pattern index 1000 to 1999
 Pat3.stil & Pat3.v contain pattern index 2000 to 2999
 Pat4.stil & Pat4.v contain pattern index 3000 to 3999

After Verilog simulation, only pattern file Pat3.v fails simulation with the following mismatch bit in maskfile Pat3.fail:

```
// This File is simulation generated (Pat3.v)
//format pattern
//failure_buffer_limit_reached none
//data_reference cell
//pattern_id chain/PO_name cell_number expected_value simulated_value
scan_test
    2001           chain1           513           L           H
// reg132/Q
last_pattern_applied      2999
// failing_patterns= 1 simulated_patterns= 1000 simulation_time= 2600000;
failure_file_end
```

The following command allows you to load only the mismatch pattern file and mask the mismatch bits, then save the pattern file without mismatches:

```
set_pattern_source external Pat3.stil -stil -store \
    -mask Pat3.fail -maskfile_pattern_offset 2000
create_patterns
write_patterns Pat3_masked.v -verilog
write_patterns Pat3_masked.stil -stil
```

set_pattern_type

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies the type of pattern(s) used by ATPG simulation.

Usage

```
set_pattern_type [-RAM_sequential {OFF|ON}] [-MAX_SEQuential {OFF|depth}]
                 [-SEQuential {OFF|depth}] [-MULTiple_load {OFF|ON}] [-CLOCK_po {ON|OFF}]
```

Description

Specifies the type of pattern(s) used by ATPG simulation.

Note

 Switch settings for this command are cumulative; that is, switches retain their settings over multiple set_pattern_type commands until you specify a different setting.

Tip

 If you use ATPG Expert (create_patterns), you do not need to issue this command. ATPG Expert will, for most designs, determine the optimal settings for this command. You may get better results by leaving this command to ATPG Expert.

The set_pattern_type command determines the type of patterns the tool uses during ATPG simulation.

The -Sequential switch provides the ability to use clock sequential cells. For example, “-sequential 2” enables the tool to create clock sequential patterns with up to two clock pulses between scan loads. Try to use the smallest possible depth, as it affects both memory requirements and performance. You can use the [report_sequential_fault_depth](#) command to obtain estimates of the maximum test coverage possible with different sequential depth settings.

When you increase the sequential depth, the tool places all current ATPG untestable faults in the untested fault class. However, multiple-clock pattern compression can be improved by increasing the sequential depth. You cannot decrease the sequential depth when there are any active patterns. You cannot set the depth greater than one if a clock procedure contains a restore_bidis statement since the procedure cannot use sequential ATPG.

If you turn on the RAM sequential option to allow RAM sequential test patterns in the test pattern file, the following rules apply:

1. You may not use RAM sequential patterns with the transition fault type.
2. You may not use RAM sequential patterns with the set_atpg_compression command, but you may use them with the compress_patterns command.

3. You may not use the RAM sequential patterns if a clock procedure contains a `restore_bidis` statement, since the procedure cannot use sequential ATPG.
4. If you are using external patterns that contain RAM sequential patterns, you must set the pattern type to RAM sequential with the `-Ram_sequential` switch.
5. Only RAMs which are proven stable during the load/unload process will be allowed to hold values from one scan load to the next and are testable with RAM sequential patterns.
6. You cannot change the pattern type from RAM or clock sequential while there are any active patterns in the internal or external pattern sets.
7. If you change the pattern type from combinational (the default) to RAM sequential, the tool places all current `atpg_untestable` faults in the `undetected_uncontrolled` class where they are available for additional fault simulation and test generation.
8. You may use failure diagnosis for pattern sets which contain RAM sequential patterns.
9. If you use the `report_gates` command with gate reporting set to `parallel_pattern`, then for the last set of 32 simulated patterns, the tool displays the values for the 2 to 4 vectors of the `ram_sequential` patterns. If you selected a RAM gate, the Report Gate command also displays the internal RAM values.
10. If you use the `write_patterns` command to save RAM sequential patterns, the tool places the argument “`ram_sequential`” on the pattern statement of the ASCII saved patterns.
11. The tool places RAM sequential patterns at the end of the internal pattern set.
12. The fault simulator can detect faults on RAM data lines during RAM sequential patterns, but the test generator will not attempt to create a RAM sequential test for a data line fault. The tool assumes that it can always detect the faults with a non-RAM sequential pattern.
13. Even when you set the pattern type to RAM sequential, the test pattern generator always attempts to find a combinational test first. The test pattern generator only attempts a sequential test generation if all of the following are true:
 - o The test pattern generator identified the fault as组合性不可测的 (combinational ATPG untestable) during the combinational test.
 - o The pattern type is set to RAM sequential.
 - o The fault is connected to an address or write line of an eligible RAM.

The test pattern generator then creates a sequential test depending on how the fault propagates to the RAM. The test pattern generator will only try to create a test that

satisfies one of the following conditions, and if unsuccessful, it will consider the fault to be aborted even if the maximum number of remade decisions has not been exceeded:

- Write Port Address Lines Faults:

Vector 1 - For the first data line of the fault write port, write 0 into the address where the fault address line is at the fault value, and the other address lines are 0 (address A).

Vector 2 - For the first data line of the fault write port, write 1 into the address where the fault address line is at the complements of the fault value, and the other address lines are 0.

Vector 3 - From the first data line of the first read port, read 0 from address A.

- Read Port Address Line Faults:

Vector 1 - For the first data line of the first write port, write 0 into the address where the fault address line is at the fault value, and the other address lines are 0.

Vector 2 - For the first data line of the first write port, write 1 into the address where the fault address line is at the complement of the fault value, and the other address lines are 0 (address A).

Vector 3 - From the first data line of the fault read port, read 1 from address A.

- Write Line Stuck-Off Faults on Multi-Write Port RAMs:

Vector 1 - For the first data line of the first non-fault write port, write 0 into address 0.

Vector 2 - For the first data line of the fault write port, write 1 into address 0

Vector 3 - From the first data line of the first read port, read 1 from address 0.

- Write Line Stuck-On Faults:

Vector 1 - For the first data line of the fault write port, write 1 into address 0.

Vector 2 - For the first data line of the fault write port, write 0 into address 0.

Vector 3 - From the first data line of the first read port, read 0 from address 0 with the first data line of the fault write port at 1.

Arguments

- -RAM_sequential OFF | ON

An optional switch and argument pair that specifies whether or not the test pattern set contains RAM sequential test patterns. This type of pattern is detailed in the “[RAM Sequential Patterns](#)” section of the Tesson Scan and ATPG User’s Manual. This switch is off upon invocation of the tool.

- **-MAX_SEQuential OFF | depth**

An optional switch and argument pair that specifies the maximum clock sequential depth if the tool automatically increases the depth during test generation. (When using the `create_patterns` command to generate test patterns, the tool may increase sequential depth automatically in order to achieve the maximal test coverage.)

When `-max_sequential` is used, ATPG expert can start a lower depth and then later increase up to the max value. It indicates the upper limit, but the tool will start from the optimal. For example:

If the optimal depth is two and you use “`-max_sequential 3`”, the tool will override the setting and start with two.

The Off option (the default) disables the restriction for clock sequential depth so that the tool can increase the clock sequential depth to any number. When using this switch to set maximum clock sequential depth, the depth set by the `-Sequential` switch cannot be greater than the maximum clock sequential depth. The maximum clock sequential depth can be an integer value from 1 to 256.

- **-SEQential OFF | depth**

An optional switch and argument pair that specifies the depth of the design’s non-scan sequential elements (its sequential depth). The integer can be a value between 0 and 255, but the best practice is to set the depth as low as possible because it affects both memory requirements and performance. The default sequential depth upon invocation is OFF which is equivalent to depth zero.

You use the `-sequential` switch most often to specifically set the depth to a specific number. It indicates the sequential start depth even if it is not the optimal number. ATPG Expert will not modify it.

The difference between `-sequential` and `-max_sequential` can be regarded as a pattern generation order strategy. For example:

If the optimal depth is two and you use “`-sequential 3`”, the tool will start with depth of three.

A setting of OFF or 0 enables the tool to create only non-sequential patterns, while a setting of 1 enables the tool also to create basic sequential patterns; with either setting resulting in patterns having a maximum sequential depth of 1. A setting of 2 or more enables clock sequential pattern generation.

Note

Clock sequential patterns must be avoided if a clock procedure contains a `restore_bidis` statement, as the procedure cannot use clock sequential ATPG.

- **-MULTiple_load OFF | ON**

An optional switch and argument pair that allows the tool to create multiple load patterns when clock sequential pattern generation is enabled (the sequential depth is set to 2 or more). This switch is an alternative to `-Ram_Sequential` for testing RAMs if the sequential depth is

set to 3 or 4. Depth 4 is required if the RAM has data hold, H or H1, in its `_cram_read` port definition. Although advisable not to set depth higher than required, it is fine to just set depth to 4 if targeting RAMs with the `-Sequential` option. The multiple load pattern capability is off upon invocation of the tool.

Refer to “[Multiple Load Patterns](#)” in the Tessent Scan and ATPG User’s Manual for additional details about the multiple load pattern type.

- `-CLOCK_po` ON | OFF

An optional switch and argument pair that enables the tool to create clock PO patterns. For a detailed description of this pattern type, refer to “[Clock PO Patterns](#)” in the *Tessent Scan and ATPG User’s Manual*. This switch is on by default.

Note

 Clock PO patterns allow two timings for clock PIs, so an additional timeplate is required to apply these patterns on a tester.

Clock PO patterns cannot be generated if you have defined any non-floating, pulse-always clocks. For more information, see the [add_clocks](#) command.

Examples

Example 1

The following example displays the current pattern type settings:

```
set_pattern_type
// Settings : -RAM_sequential OFF
//           -SEQUENTIAL 0
//           -MAX_SEquential 5
//           -MULTIPLE_load OFF
//           -CLOCK_po      ON
```

Example 2

The following example disables the restriction for clock sequential depth so that the tool can increase the clock sequential depth to any number:

```
set_pattern_type -max_sequential off
// Settings : -RAM_sequential OFF
//           -SEQUENTIAL 0
//           -MULTIPLE_load OFF
//           -CLOCK_po      ON
```

Example 3

The following example creates patterns with up to two clock pulses between scan loads:

```
set_pattern_type -sequential 2
```

```
// Settings : -RAM_sequential OFF
//           -SEQUENTIAL      2
//           -MULTIPLE_load   OFF
//           -CLOCK_po        ON
```

Example 4

The following example enables RAM sequential pattern generation, resets sequential depth to its default setting (0), and disables creation of clock PO patterns.

```
set_pattern_type -ram_sequential on -sequential 0 -clock_po off

// Settings : -RAM_sequential ON
//           -SEQUENTIAL      4/0
//           -MULTIPLE_load   ON/OFF
//           -CLOCK_po        OFF
```

For -SEQUENTIAL, the first number means that the clock sequential depth is 4 and the second number means that the maximal clock sequential depth for clock sequential test cube generation is 0.

For -MULTIPLE_load, the “ON” means that the clock sequential simulation engine allows to simulate test patterns with multiple loads, and “OFF” means that the multiple loads for clock sequential test cube generation is disabled.

Example 5

The following example specifies to create multiple load patterns for testing RAMs. Assuming RAM sequential pattern capability was enabled with a previous set_pattern_type command, the example turns off that capability (recall that the switches retain their settings over multiple commands—until you change them).

```
set_pattern_type -ram_sequential off -sequential 4 -multiple_load on

// Settings : -RAM_sequential OFF
//           -SEQUENTIAL      4
//           -MULTIPLE_load   ON
//           -CLOCK_po        OFF
```

Related Topics

[report_sequential_fault_depth](#)

set_physical_translation

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Translates special Verilog characters to SPICE-readable characters that Calibre applications can read.

Usage

```
set_physical_translation [-Path_divider path_divider] [-Substitute substitute] [-Replacement replacement] [-Global_prefix global_prefix] [-Hier_prefix hier_prefix] [-STrip_prefix strip_prefix] [-Array_delimiters array_delim]
```

Description

Translates special Verilog characters to SPICE-readable characters that Calibre applications can read.

You can restore any of these translation settings to its default setting by issuing the command without the corresponding argument. For specifics for when you use this command, see “[Net Pair Identification with Calibre for Bridge Fault Test Patterns](#)” in the *Tessent Scan and ATPG User’s Manual* for complete information.

Arguments

- **-Path_divider *path_divider***
An optional switch and string specifying the instance path divider. The default is “/X”.
- **-Substitute *substitute***
An optional switch and string for substituting a “#” (pound sign) for a leading character or set of characters for pins, wires, and instance names. By default, the tool substitutes leading “\$”s (dollar signs) with “#”s (pound signs). You can specify a maximum of 10 characters for substitution. If you specify the -Replacement switch and string, then the tool uses this character for the substitution character.
- **-Replacement *replacement***
An optional switch and string replacing the default substitution character. The default is a “#” (pound sign). If you specify a character, then the tool uses this character instead of the default when substituting a leading character or characters for pins, wires, and instance names.
- **-Global_prefix *global_prefix***
An optional switch and string for changing the default global prefix character the tool inserts for pins, wires, and instance names. The default is a “#” (pound sign).
- **-Hier_prefix *hier_prefix***
An optional switch and string changing the hierarchy prefix. The default is “ “ (space).

- **-STrip_prefix *strip_prefix***

An optional switch and string stripping the prefix. This argument is in Calibre form (for example, to strip Xbogus_top/Xmodule/net, you specify -strip_prefix Xbogus_top).

- **-Array_delimiters *array_delim***

An optional switch and string changing the array delimiter. The default is “[]” (square brackets).

set_possible_credit

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies the percentage of credit that the tool assigns possible-detected faults.

Usage

`set_possible_credit percentage`

Description

Specifies the percentage of credit that the tool assigns possible-detected faults.

The `set_possible_credit` command specifies the percentage of possible-detected faults that the tool considers as detected when calculating the test coverage, fault coverage, and ATPG effectiveness. For the equations that the tool uses in these calculations, refer to “[Testability Calculations](#)” in the *Tessent Scan and ATPG User’s Manual*.

When you invoke the tool, the default credit value for possible-detected faults is 50 percent. Note that when you set the possible credit to 0, the tool will not change any faults to PT or PU (the existing PT/PU faults will remain).

Arguments

- *percentage*

A required integer, from 0 to 100, that specifies the percentage of possible-detected faults that you want the tool to consider as detected when calculating the test coverage, fault coverage, and ATPG effectiveness. The default value upon invocation of the tool is 50 percent.

Examples

The following example sets the credit for possible detected faults as 25 percent for determining the fault coverage, test coverage, and ATPG effectiveness:

```
set_system_mode analysis
set_possible_credit 25
create_patterns
report_statistics
```

set_power_control

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Enables low-power ATPG and sets up a switching and/or capture threshold.

Usage

Specify low-power shift and capture

```
set_power_control {OFF|ON} [-SWitching_threshold_percentage percent_integer]
```

Specify low-power shift

```
set_power_control SHIFT {OFF|ON}  
[-SWitching_threshold_percentage percent_integer]  
[-REjection_threshold_percentage {percent_integer | OFF}]
```

Specify low-power capture

```
set_power_control CAPTURE {OFF|ON}  
[-SWitching_threshold_percentage percent_integer]  
[-REjection_threshold_percentage {percent_integer | ST_Peak | ST_Average | WSA_Peak  
| WSA_Average} | OFF}]
```

Hybrid TK/LBIST Flow Usage

```
set_power_control shift {off | on} [-switching_threshold_percentage percent_integer]
```

Description

Enables low-power ATPG and sets up a switching and/or capture threshold.

When the command is entered without any arguments, the current power control settings display.

Note

 When you use set_power_control, there is an impact on the ATPG test pattern count to satisfy the power constraints. There is also an impact on the tool run time because of the extra effort required to compute the switching activity for every test pattern.

For more information, see the [Low-Power ATPG](#) section in the *Tessent Scan and ATPG User's Manual*

Note

 When the [set_edt_power_controller](#) command is set to *Enabled*, the default for the set_power_control SHIFT command is ON for TestKompress only.

Note

 If during EDT IP creation, EDT lower-power controller is not enabled, but during ATPG, “set_power_control shift on” is used, the tool issues this message:

```
// Error: Shift power control is requested, but power control hardware  
// is not present or is disabled.  
// Please check the "set_edt_power_controller shift" command.
```

Note

 If during EDT IP creation, EDT lower-power controller is enabled, and during ATPG, “set_power_control shift on” is used, but they are not in the same bias range, the tool issues this message, for example:

```
// Warning: Specified software switching threshold [5] is not consistent  
// with the switching threshold used to generate the shift power  
// control hardware [20] in block "blk1".  
// The software and hardware thresholds should be in the same  
// bias range (except for the full control case).  
// The following are the valid bias ranges: [0, 11], [12, 24],  
// [25, 50].
```

For more information on using low-power ATPG with Tesson TestKompress, see “[Low-Power Test](#)” in the *Tesson TestKompress User’s Manual*.

Hybrid TK/LBIST Flow Specifics

Specifies the switching threshold in the patterns for fault simulation.

You can only use the low-power shift usage of this command for logicBIST, otherwise, the tool issues an error.

Note

 You cannot use the command’s existing -rejection_threshold_percentage switch with the low-power logicBIST controller.

Arguments

- CAPTURE OFF|ON

Optional literal and switch that enables low-power capture. Options include:

OFF—Disables low-power capture. Default.

ON—Enables low-power capture.

- SHIFT OFF|ON

Optional literal and switch that enables low-power shift. Options include:

OFF—Disables low-power shift. Default.

If the [set_edt_power_controller](#) command is set to *Enabled*, the *Off* option of `set_power_control` shift sets all masking bits to 1, which enables all internal chains; however, it does not disable low-power TestKompress hardware. To disable low-power TestKompress hardware and bypass the low power registers, you must force the `edt_low_power_shift_en` signal off in the test procedure file and execute the [set_edt_power_controller](#) *Disabled* command and option.

`ON` — Enables low-power shift.

- `-SWitching_threshold_percentage percent_integer`

Optional switch and integer pair that specifies the switching threshold for low-power ATPG. The percentage integer can be 1 to 100. By default, for Tessent TestKompress applications, the switching threshold for ATPG is set to match the maximum switching threshold defined for the power controller hardware if that threshold is equal to or greater than 15%; if maximum hardware switching is less than 15%, the software default is 15%. Note, maximum hardware switching is specified by `set_edt_power_controller Shift -MIN_Switching_threshold_percentage percentage_integer`.

For more information, see “[Low-Power Test](#)” in the *Tessent TestKompress User’s Manual*.

- `-switching_threshold_percentage percent_integer (Hybrid TK/LBIST Flow Only)`

An optional switch and integer pair that specifies the maximum switching activity during shift. The *percent_integer* value can be between 1 and 50.

The tool runs fault simulation with the appropriate control register values to implement the specified switching threshold.

When saving the tester format patterns in Tessent Shell, the registers are seeded with the same values used during pattern simulation. It is not possible to save hardware default mode tester patterns when the switching threshold specified during fault simulation is different from the switching threshold specified during IP creation. An error message will be issued if this switching threshold cannot be supported by the low-power hardware.

Refer to the [Hybrid TK/LBIST Flow User’s Manual](#) for complete information.

- `[-REjection_threshold_percentage {percent_integer | OFF}]`

Optional switch and integer pair that specifies a state element switching limit per test pattern. Test patterns that exceed the specified switching limit are discarded. By default, this option is off and if rejecting/discardng test patterns that exceed the threshold has a negative effect on test coverage, the specified threshold is violated.

- `[ST_Peak | ST_Average | WSA_Peak | WSA_Average]`

Optional literal that filters the test pattern rejection threshold based on a specified metric. When a specified metric exceeds the rejection threshold, the pattern is discarded. These options can only be used with the low-power capture feature. Literals include:

`ST_Peak` — Peak of state transitions. Default.

`ST_Average` — Average of state transitions.

`WSA_Peak` — Peak of weighted switching activity.

WSA_Average — Average of weighted switching activity.

Examples

Example 1

The following example sets low-power capture with a 30% threshold and low-power shift with a 20% switching threshold and generates test patterns:

```
set_power_control capture on -switching_threshold_percentage 30 \
    -rejection_threshold_percentage 35
set_power_control shift on -switching_threshold_percentage 20 \
    -rejection_threshold_percentage 25
create_patterns
```

Example 2

The following example creates compression logic with a power controller configured to accommodate a minimum of 20% switching threshold and enabled for test pattern generation.

```
set_edt_power_controller shift -min_switching_threshold_percentage 20
...
write_edt_files low_power_enabled_edt.v
```

Given the compression logic created with the preceding command, the following commands are used during test pattern generation to enable the controller with a 22% switching threshold for shift and generate test patterns.

```
set_power_control shift on -switching_threshold_percentage 22
set_system_mode analysis
create_patterns
```

Example 3 (Hybrid TK/LBIST Flow Only)

This example configures the low-power logicBIST logic to target a switching threshold of 10%. The actual values loaded in the low-power control registers to achieve this switching threshold can be seen using the report_edt_configuration command. The power metrics can be seen using the report_power_metrics command.

```
set_power_control shift on -switching 15
set_system_mode analysis
report_edt_configuration
```

```

set_power_metrics

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Calculates shift and capture power during test pattern generation and simulation.

Usage

```
set_power_metrics [-SHIft {OFF|ON}] [-CAPture {OFF|ON}]  
[-COMPosite_shift_power {OFF|ON}] [-X_CAPture_transition_credit float]  
[-X_SHIft_transition_credit float]
```

Description

Calculates shift and capture power during test pattern generation and simulation.

Shift power is the test power consumed during the loading of test stimuli and the unloading of responses. Capture power is the test power consumed by switching activity in the circuit during capture cycles.

Note

 When you use set_power_metrics, there is an impact to the tool run time during create_patterns and simulate patterns, because of the extra effort required to compute the switching activity for every test pattern.

Arguments

- **-SHIft OFF|ON**
An optional switch and literal pair that enables the calculation of the power consumed for switching activity in the circuit during shift.
- **-CAPture OFF|ON**
An optional switch and literal pair that enables calculation of the power consumed for switching activity in the circuit during capture cycles.
- **-COMPosite_shift_power OFF|ON**
An optional switch and literal pair that combines the load and unload switching activity in shift power calculations. By default, the load and unload switching activity is computed separately.
- **-X_CAPture_transition_credit *float***
An optional switch and floating number pair that specifies the credit given for x-to-x, x-to-known, and known-to-x capture transitions when calculating switching activity in capture cycles (the default values are 0.1, 0.05, 0.05, respectively). The specified float value must be between 0 and 1, and it applies to all three x values.

- **-X_SHIfT_transition_credit float**

An optional switch and floating number pair that specifies the credit given for x-to-x, x-to-known, and known-to-x shift transitions when calculating switching activity during shift.

The specified value applies to all x values. The float number should be between 0 and 1. The default is 0.5.

Examples

Example 1

The following example calculates shift power and capture power during test pattern generation, fault simulation, and good simulation and displays the capture power for capture cycles and the shift power for shift transitions.

```
set_power_metrics -shift on -capture on
create_patterns
```

```

Load Shift Transitions  15.38%  25.00%  30.77%
Response Shift Transitions  17.95%  21.15%  25.64%
Composite Shift Transitions  13.24%  20.08%  26.69%
```

```
set_power_metrics -composite off
report_power_metrics -external
```

Power Metrics	Min.	Average	Max.
WSA	10.62%	12.54%	13.65%
State Element Transitions	13.59%	18.71%	20.94%
Peak Cycle			
WSA	10.62%	12.54%	13.65%
State Element Transitions	13.59%	18.71%	20.94%
Load Shift Transitions	15.38%	25.00%	30.77%
Response Shift Transitions	17.95%	21.15%	25.64%

Example 3

The following example sets up power metric calculations to use composite shift, generates test patterns, and reports shift power for all the patterns:

```
set_power_metrics -composite_shift on
create_patterns
report_power_metrics -shift -patterns all

// Pattern Shift
// Pat. loaded Pat. unloadedAverage
// -----
// 0      -      10.60%
// 1      0      8.60%
// 2      1      14.20%
// 3      2      8.20%
// pad    3      9.56%
```

Example 4

The following example reports the power metrics with composite shift for both scan tests and chain tests:

```
set_power_metrics -composite_shift on
report_power_metrics -shift -all_test -patterns all
```

```
// Chain test :  
//  
//      Pattern      Shift  
// Pat. loaded Pat. unloadedAverage  
// ----- ----- -----  
// 0      -          32.89%  
// 1      0          48.60%  
// 2      1          54.20%  
// pad   2          49.56%  
//  
// Scan test :  
//  
//      Pattern      Shift  
// Pat. loaded Pat. unloadedAverage  
// ----- ----- -----  
// 0      -          10.60%  
// 1      0          8.60%  
// 2      1          14.20%  
// 3      2          8.20%  
// pad   3          9.56%
```

Related Topics

[report_power_metrics](#)

[set_power_control](#)

set_procedure_cycle_checking

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup

Enables test procedure cycle timing checking to be done immediately following scan chain tracing during design rules checking.

Usage

`set_procedure_cycle_checking ON | OFF`

Description

Enables test procedure cycle timing checking to be done immediately following scan chain tracing during design rules checking.

This command helps detect timing problems in test procedures earlier on in the ATPG process. By default, the test procedure cycle timing checking is performed after scan chain tracing. If an error condition is detected, the tool remains in the Setup mode. You can then modify the test procedures and reissue the `set_system_mode` command.

Arguments

- **ON**

A literal that specifies for the tool to `set_procedure_cycle_checking ON`. This is the default behavior upon invocation of the tool.

- **OFF**

A literal that specifies for the tool to `set_procedure_cycle_checking OFF`. In order to turn procedure cycle checking off, you must be in Setup mode.

Examples

```
set_system_mode setup
set_procedure_cycle_checking OFF
```

Related Topics

[set_system_mode](#)

set_procedure_retargeting_options

Context: patterns -scan, patterns -scan_retargeting

Mode: setup

Controls the behavior of the automatic merging and mapping (retargeting) of core-level load_unload and shift procedures to top-level test procedures and mapping of core-level test_setup and test_end IJTAG procedures.

Usage

```
set_procedure_retargeting_options [-scan {ON | OFF}]  
[-ijtag {ON | OFF}]  
[-timeplate timeplate_name]  
[-pulse_during_shift clock_port_list]
```

Description

Controls the behavior of the automatic merging and mapping (retargeting) of core-level load_unload and shift procedures to top-level test procedures and mapping of core-level test_setup and test_end IJTAG procedures.

By default, the tool automatically retargets core-level test_setup and test_end IJTAG procedures, and adds the needed iCalls to the test_setup or test_end procedure. If you disable the -ijtag behavior by setting this switch to off, you will need to manually add all core level iCalls.

In patterns -scan context, by default, the tool automatically retargets the core-level load_unload and shift test procedures to the chip-level and merges the retargeted core-level procedures with top-level procedures if top-level procedures exist.

In patterns -scan_retargeting context, by default, the tool automatically retargets the core-level load_unload and shift test procedures to the chip-level if chip-level load_unload and shift test procedures do not exist.

If you disable the -scan behavior by setting it to off, and the chip-level load_unload and shift test procedures are missing from the top-level test procedure, the tool generates an error.

Arguments

- **-scan {ON | OFF}**

A literal that specifies to the tool whether to enable test procedure retargeting. By default upon invocation, test procedure retargeting is enabled. In order to disable test procedure retargeting, you must be in Setup mode. For more information on test procedure retargeting, see “Core Mapping for ATPG Process Overview” in the *Tessent Scan and ATPG User’s Manual*.

- **-ijtag {On | Off}**

An optional switch that specifies whether automatic mapping of core-level IJTAG test_setup and test_end procedures to the next higher level of hierarchy is enabled. You should use the Off switch to disable automatic IJTAG mapping if you are manually generating the entire top-level test_setup and test_end procedures.

- **-timeplate *timeplate_name***

An optional switch that specifies the timeplate to be used in the generated load_unload and shift procedures. The tool determines the timeplate to use as follows:

- a. Uses the timeplate specified by the -timeplate switch if one is specified.
- b. If one is not specified:
 - In patterns -scan context, if the top-level load_unload and shift procedures are present, the tool uses the timeplate from the top-level procedure.
 - In patterns -scan_retargeting context or if top-level procedures are not provided, the tool uses the default test_setup timeplate.
- c. If neither a tool-generated or user-defined test_setup procedure exists, the tool uses the default timeplate. For more information on the tool-generated test_setup procedure, see the description in “[Test Procedure Retargeting for Scan Pattern Retargeting](#)” in the *Tessent Scan and ATPG User’s Manual*.
- d. If the default timeplate is not specified, the tools uses the first timeplate read in.

- **-pulse_during_shift *clock_port_list***

An optional switch that specifies to pulse the clocks specified by the *clock_port_list* argument during the shift procedure. The *clock_port_list* argument can be a Tcl list of clocks or gate_pins that are primary inputs. To reset this specification, re-invoke this option and provide an empty list.

This option is typically used to specify clocks that drive top-level pipeline stages outside the core. The tool can map the load_unload and shift procedures from the core(s) to the top. However, if top-level pipeline stages are clocked by separate clocks, the tool will not know to pulse them, and, as a result, will be unable to trace the scan channels from the cores to the top (R2 DRC violations). This option instructs the tool to additionally pulse the specified clock(s) in the created top-level shift procedure.

Examples

Example 1

The following example specifies a timeplate to use in the load_unload and shift procedures.

```
set_procedure_retargeting_options -timeplate gen_tp1
```

Example 2

The following example specifies to pulse two clocks.

set_procedure_retargeting_options -pulse_during_shift {top_clock pipe_clock}

Related Topics

[set_procfile_name](#)

[set_procfile_name](#)

Context: all contexts

Mode: setup

Specifies a new procedure file for the tool to process at a later time.

Usage

```
set_procfile_name procedure_file_name [-override_scangroup_proc]
```

Description

Specifies a new procedure file for the tool to process at a later time.

The `set_procfile_name` command reads the specified procedure file and performs basic syntax checking. The tool reports errors it finds but does not process and store the file at the time you issue the command.

Note

 The procfile may contain Tcl variable that will be substituted when the file is read. The referenced Tcl variable must exist in the Tcl global namespace scope. If you are setting the variables within a proc, make sure to use `::` as a prefix to the variable name such that it is set in the global namespace. For example, use “`set ::my_period 4`” such that `$period` exists when processing the proc files. For more info about Tcl variable substitution inside the procfile, refer to “[Additional Support for Test Procedure Files](#)” in the *Tessent Shell User’s Manual*.

You can specify only one procedure file with this command. If you issue the command again, the new procedure file overrides the one previously set.

If procedure files with scan groups exist, the tool processes the scan group procedure files first, followed by the procedure file specified in this command. You can override the scan group procedure files and only process *procedure_file_name* by specifying the `-override_scangroup_proc` option.

For scan pattern retargeting, specifies the top-level test procedure file to be used for saving top-level patterns. In this case, the following procedures are expected to be defined in this file: `test_setup`, `load_unload`, `shift`, and `external_capture`.

For core mapping for ATPG and pattern retargeting, you must provide the chip-level test procedure file; the test procedure file must minimally include the timeplate definition. You do not need to provide chip-level `load_unload` and `shift` test procedures; if they do not exist, the tool automatically generates them based on the information in the core-level test procedure files. This step merges the core test procedures if there is more than one core, and maps them to the top-level test procedures. You may also need to specify the `test_setup` procedure for the design, if you need to set up the chip. All other procedures will be automatically mapped by the tool if they are not specified.

For techniques to handle slow scan enable transitions, see “[Delaying Clock Pulses in Shift and Capture to Handle Slow Scan Enable Transitions](#)” in the *Tessent Scan and ATPG User's Manual*.

Arguments

- ***procedure_file_name***

A required string that specifies the pathname to the procedure file.

You can use the tab completion method to list possible files for *procedure_file_name* that exist in the current or specified directory. For example, specifying “`set_procfile_name`” and then pressing the Tab key will list the files in the current directory. Specifying “`set_procfile_name ..//data/test_pr`” and pressing the Tab key will list the files with names starting with `test_pr` in the `..//data` directory.

- **-override_scangroup_proc**

An optional argument that causes the tool to disregard scan group procedure files and only process *procedure_file_name*.

Examples

Example 1

The following example shows how the `set_procfile_name` command is used in an IJTAG retargeting flow.

```
set_context patterns -ijtag -no_rtl
...
set_procfile_name data/setup.proc # initial syntax checking done
set_system_mode analysis # procedure file opened and parsed here
```

Example 2

The following example shows how to override the scan group procedure files.

```
set_procfile_name data/setup.proc -override_scangroup_proc
```

Example 3

The “[Retargeting Example](#)” in the *Tessent Scan and ATPG User's Manual* demonstrates the use of this command in a design context.

set_quick_synthesis_options

Context: unspecified, dft, patterns

Mode: setup

This command sets options for quick synthesis.

Usage

```
set_quick_synthesis_options [-Parallel_synthesis {maxcpu | integer}]
                           [-Skip_synthesis_of_two_dimensional_arrays_larger_than {unlimited | integer}]
                           [-max_for_loop_size integer] [-blackbox_design_ware_modules {on | off}]
                           [-verbose {on | off}]
```

Description

The tool performs quick synthesis, if it is needed, during check_design_rules, extract_icl, or when switching to the analysis system mode. Quick synthesis creates new instance, port, pin, and net objects to implement RTL constructs so that they are usable by analysis. Objects created during quick synthesis have their created_by_synthesis attribute set to true.

Note

 You can report modules or instances that are synthesized using the `is_synthetized` [instance](#) or [module](#) attributes, respectively. For example:

```
get_module -filter is_synthetized
```

Arguments

- `-Parallel_synthesis {maxcpu | integer}`

An optional switch and literal or integer pair that sets the number of parallel processes for the quick synthesis. When specified with maxcpu, the number of parallel jobs will be the number of available CPUs. When specified with an *integer*, the number of parallel jobs is the specified number. You should use a number less than or equal to the number of available CPUs, otherwise the tool issues a warning. The default is four CPUs.

- `-Skip_synthesis_of_two_dimensional_arrays_larger_than {unlimited | integer}`

An optional switch and literal or integer pair that specifies the bit-count threshold for the compilation of memories in a module. If this total bit-count is more than the specified threshold, the module is not compiled and is treated as a black box. The default setting is 4096 bits.

The purpose of this feature is to avoid synthesizing memory models for which you have loaded the behavioral model in Tessent shell. If you have large multi-dimensional arrays in your RTL and you want to synthesize them, specify the `add_black_boxes -module module` command on all behavioral memory models and enlarge this threshold to match your requirement. Explicitly black-boxing the memory modules will exclude them from synthesis. You can also set the `exclude_from_synthesis` attribute on the memory modules if

you don't want to black box them but only prevent them from being synthesized. During quick synthesis, modules which were automatically black boxed because they contained a multi-dimensional array exceeding the threshold value are listed in a warning similar to the following:

```
// Warning: The following modules were not synthesized because they
// include multi-dimensional arrays whose bit count exceeds the
// following limit: 4096. You can increase this limit with command:
// 'set_quick_synthesis_option
// -skip_synthesis_of_two_dimensional_arrays_larger_than <int>'
// but you should first check that no memory module is listed below.
// 'SYNC_1RW_32x256_RC_BISR'
// To avoid synthesizing behavioral Verilog views of memories, you
// need to provide:
// - their tesson library description, or;
// - their verilog model along with their tcd_memory_lib
// description;
// If you run logictest DRCs, and do not have a tesson library
// description for your memory, you must provide a Verilog model
// which hides the memory core for all memory instances that have
// embedded test logic. Finally, you can add an explicit black box
// declaration for all memory instances if nothing in
// their models needs to be visible for the logictest DRC.
```

- **-max_for_loop_size *integer***

An optional switch-value pair that prevents quick synthesis on modules containing for loops that are larger than the specified *integer* parameter. The default is 5000.

- **-blackbox_design_ware_modules on | off**

An optional switch and literal pair that controls whether the tool automatically blackboxes DesignWare modules that contain no definitions. The default is off.

- **-verbose on | off**

An optional switch that writes extra information messages to stdout or the tool's log file. The default is off.

Examples

Example 1

The following example sets the number of parallel quick synthesis processes to 3:

```
set_quick_synthesis_options -parallel_synthesis 3
```

Example 2

The following example sets a new limit to avoid synthesis for modules with large multi-dimensional arrays to 128:

```
set_quick_synthesis_options -skip_synthesis_of_two_dimensional_arrays_larger_than 128
```

Example 3

The following example enables synthesis for modules with multi-dimensional arrays of any size by setting the threshold to unlimited:

```
set_quick_synthesis_options \
    -skip_synthesis_of_two_dimensional_arrays_larger_than unlimited
```

set_ram_initialization

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup

Specifies whether to initialize RAM and ROM gates that do not have initialization files.

Usage

set_ram_initialization Uninitialized | Random

Description

Specifies whether to initialize RAM and ROM gates that do not have initialization files.

The **set_ram_initialization** command allows the tool to internally generate random values and place them into all uninitialized RAM and ROM gates. This command is useful when simulating random patterns.

Arguments

- **Uninitialized**

A literal that specifies for the tool to use unknown (X) values to set the memory elements of all RAM and ROM gates which do not have an initialization file. This is the default behavior upon invocation of Tesson FastScan and Tesson TestKompress.

- **Random**

A literal that specifies for the tool to use random values to set the memory elements of all RAM and ROM gates which do not have an initialization file.

Examples

The following example places random values into all uninitialized RAM and ROM gates:

```
set_ram_initialization random
set_system_mode analysis
create_patterns
```

Related Topics

[read_modelfile](#)

[write_modelfile](#)

[set_random_atpg](#)

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies whether the tool uses random patterns during ATPG.

Usage

`set_random_atpg ON | OFF`

Description

Specifies whether the tool uses random patterns during ATPG.

The `set_random_atpg` command controls whether the tool uses random test generation techniques to create_patterns during the ATPG process.

Arguments

- **ON**
A literal that specifies for the tool to use random patterns to create test patterns. This is the default behavior upon invocation of the tool.
- **OFF**
A literal that specifies for the tool not to use random patterns to create test patterns. When you use this option, the tool only performs deterministic ATPG.

Examples

The following example turns off the random ATPG process, so only the deterministic ATPG is performed:

```
set_system_mode analysis  
set_random_atpg off  
create_patterns
```

set_random_clocks

Context: dft -edt, patterns -scan

Mode: analysis

Specifies whether Tesson FastScan uses combinational or clock_sequential patterns for random pattern simulation.

Usage

```
set_random_clocks {pin_name | pin_pathname} ...
```

Description

Specifies whether Tesson FastScan uses combinational or clock_sequential patterns for random pattern simulation.

The set_random_clocks command specifies for Tesson FastScan to either use combinational random patterns or use the pins that you specify for clock_sequential random patterns during simulation.

Combinational random pattern simulation is the default upon invocation. You specify clock_sequential by entering the set_random_clocks command with an ordered set of clock/read/write lines which Tesson FastScan exercises in the same order during the clock_sequential random pattern simulation.

You can reset Tesson FastScan to its invocation default of combinational random pattern simulation by entering the set_random_clocks command without any arguments. Also, when you re-enter the Setup system mode, Tesson FastScan deletes the random clock list and is once again ready for combinational random pattern simulation.

Arguments

- *pin_name* | *pin_pathname*

A required repeatable string that specifies the names of defined clock, read, and write lines. You must list these pins in the order in which you want Tesson FastScan to exercise them during the clock_sequential random pattern simulation. The default is none, which specifies for Tesson FastScan to perform combinational random pattern simulation.

Tesson FastScan displays an error if any specified pin is not a defined clock, read, or write line. The tool also displays an error if the number of pins that you list is equal to or exceeds the selected sequential depth.

Examples

The following example runs random pattern simulation with clock_sequential patterns:

```
set_pattern_type -sequential 10
add_scan_groups g1 seqproc.g1
add_scan_chains c1 g1 si so
add_clocks 0 sk1 sk2
set_system_mode analysis
set_random_clocks sk1
add_faults -all
simulate_patterns -source random
```

Related Topics

[set_capture_clock](#)
[simulate_patterns](#)

set_random_patterns

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies the number of random patterns that the tool simulates.

Usage

`set_random_patterns integer`

Description

Specifies the number of random patterns that the tool simulates.

The `set_random_patterns` command specifies how many random patterns you want the tool to simulate.

Arguments

- *integer*

A required integer, greater than or equal to 0, that specifies the number of random patterns you want the tool to simulate. The invocation default is 1024.

Examples

The following example sets the number of random patterns to analyze its controllability effects:

```
set_system_mode analysis
set_random_patterns 612
```

Related Topics

[set_capture_clock](#)

[set_observation_point](#)

[simulate_patterns](#)

set_read_verilog_options

Context: unspecified, all contexts

Mode: all modes

Sets certain options globally for subsequent `read_verilog` commands.

Usage

```
set_read_verilog_options [-allow_enum_relaxation {on | off}]
```

Description

Sets certain options globally for use in subsequent `read_verilog` commands.

Arguments

- `-allow_enum_relaxation on | off`

An optional switch and literal pair that, when set to “on”, instructs the tool to bypass specified LRM Verilog rules. The default is off.

The IEEE standard requires that when a driver is assigned to a variable of an enum type, the driver must itself be declared to be a variable of the same type or to be a value that lies within the enumeration set defined for that type unless an explicit cast is used or unless the enum variable is a member of a union. See section 4.10.3 in IEEE 1800-2005.

If you want to relax this rule, then set this option to “on”.

set_register_value

Context: all contexts

Mode: all modes

Allows you to specify the register value variable outside of Setup mode.

Usage

```
set_register_value value_name value_string  
[-RAdix {BInary | HEx | OCtal | Decimal}]
```

Description

Allows you to specify the register value variable outside of Setup mode.

When using this command, you must have previously specified the [add_register_value](#) command with the -Width command as well as the required arguments.

See “Serial Register Load and Unload for LogicBIST and ATPG” in the *Tessent Shell User’s Manual* for complete information.

Arguments

- ***value_name***
A required string that specifies register value variable. The variable holds a value to load into the register. The register value variable is used in the procedure file to load the value into a register through the data input pin.
 - ***value_string***
A required state string whose default radix is binary. You can specify Z or X values in addition to numerical values appropriate for the radix.
 - -Radix {**Binary** | Decimal | Octal | Hexadecimal}
An optional switch and literal that specifies a different radix.

Examples

The following example deletes all register value variables, specifies a register value variable with a decimal radix and register width of 37, and then sets the value of the register.

Related Topics

[add_register_value](#)
[report_register_value](#)

set_relevant_coverage

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Determines which sub-class(es) of untestable faults are included in or excluded from the relevant coverage reported by the tool.

Usage

```
set_relevant_coverage [{-Include | -Exclude} {fault_class[fault_subclass] ...}]
```

Description

Determines which sub-class(es) of untestable faults are included in or excluded from the relevant coverage reported by the tool.

Issue this command without any arguments to report the current settings.

Arguments

- **-Include**

An optional switch that includes the specified fault sub-class(es) in the relevant coverage reported by the tool.

- **-Exclude**

An optional switch that excludes the specified fault sub-class(es) from the relevant coverage reported by the tool.

- ***fault_class[fault_subclass]***

An optional, repeatable string that specifies the fault class or fault class/sub-class to include or exclude. [Table 6-18](#) lists the fault classes that you can specify with this command and whether they are included in the reported relevant coverage by default. [Table 6-19](#) lists the available fault sub-classes. You can specify a fault class or sub-class either by name or code. For AU faults, you can define a customized sub-class using a unique name and instruct the tool to include (default) or exclude this user-defined sub-class from the relevant fault coverage. For information about using a user-defined sub-calls, refer to “[Example 2](#)” on page 2348.

Table 6-18. Fault Classes for Relevant Coverage

Name	Code	Included in Relevant Coverage by Default?
ATPG_UNTESTABLE	AU	yes
REDUNDANT	RE	no
TIED	TI	no
BLOCKED	BL	no
UNUSED	UU	no

Table 6-19. Fault Sub-Classes for Relevant Coverage

Fault Class	Fault Sub-Class	Code	Included in Relevant Coverage by Default?
AU	BLACK_BOXES	BB	yes
	CELL_CONSTRAINTS	CC	yes
	EDT_BLOCKS	EDT	no
	FALSE_PATHS	FP	no
	HOLD_PI	HPI	yes
	HYBRID_LBIST	LBIST	no
	IJTAG	IJTAG	no
	LOW_PIN_COUNT_TEST	LPCT	no
	MASK_PO	MPO	yes
	MULTICYCLE_PATHS	MCP	yes
	ON_CHIP_CLOCK_CONTROL	OCC	no
	PIN_CONSTRAINTS	PC	yes
	SEQUENTIAL_DEPTH	SEQ	yes
	TIED_CELLS	TC	yes
	UNDRIVEN	UDN	yes
UU	USER-DEFINED	none	yes
	WIRE	WIRE	yes
UU	CONNECTED	CON	no
	FLOATING	FL	no

Examples

Example 1

The following example removes the PIN_CONSTRAINTS and CELL_CONSTRAINTS sub-classes from relevant coverage reported by the tool:

```
set_relevant_coverage -exclude AU.PC AU.CC  
set_relevant_coverage
```

```
Relevant Coverage Setting Report
-----
Fault Sub-class Relevant Coverage
-----
AU.UDN           yes
AU.BB            yes
AU.WIRE          yes
AU.EDT           no
AU.PC          no
AU.TC            yes
AU.CC          no
AU.FP            no
AU.MCP           yes
AU.HPI           yes
AU.MPO           yes
AU.SEQ            yes
AU.LBIST          no
AU.OCC            no
AU.IJTAG          no
AU.LPCT           no
UU.FL             no
UU.CON            no
TI                no
BL                no
RE                no
-----
```

Example 2

The following example shows how to use a user-defined fault sub-class to exclude specific pins from reporting. This example is based on the following fault list contained in *flist.au.usr1*:

```
//  type   code   pin_pathname
//  ----  -----
0   AU.USR1    /si7
0   EQ.USR1    /sf_1_7/SI
1   AU.USR1    /si7
1   EQ.USR1    /sf_1_7/SI
0   AU.USR1    /si8
0   EQ.USR1    /sf_1_8/SI
1   AU.USR1    /si8
1   EQ.USR1    /sf_1_8/SI
```

This fault list creates a user-defined sub-class for AU faults on two pins for both SA0 and SA1.

```
read_faults flist.au.usr1 -retain
set_relevant_coverage -exclude AU.USR1
report_statistics
```

Statistics Report Stuck-at Faults			
Fault Classes	#faults (total)	#faults (total relevant)	
FU (full)	1397	1389	
UC (uncontrolled)	27 (1.93%)	same (1.94%)

set_run_synthesis_options

Context: unspecified, all contexts

Mode: all modes

Specifies the default values for options that can be set for the run_synthesis command.

Usage

```
set_run_synthesis_options [-synthesis_output_directory directory]  
  [synthesis_tool [-compilation_options option_list]  
   [-pre_compilation_commands command_list]  
   [-post_compilation_commands command_list] [-startup_file file_name]  
   [-command_name command_name_path]]
```

Description

Specifies the default values for options that can be set for [run_synthesis](#) command. The options that are defined with set_run_synthesis_options are overridden if the are explicitly defined with the run_synthesis command. When this command is used without any options specified, all options are reset to Tesson Shell default values.

Arguments

- **-synthesis_output_directory *directory***

An optional switch and value pair that specifies the synthesis output directory. The default directory is *synthesis_outdir* and is located in the Tesson Shell invocation directory.

- ***synthesis_tools***

A required value that specifies the synthesis tool you wish to use for synthesis when setting the remaining options. The only permitted value is “dc_shell”. Other synthesis tools may be supported in future releases.

- **-compilation_options *option_list***

An optional switch and option list that specifies additional options to be added to the synthesis compile command used in the <*synthesis_tool*>.synthesis_tcl. An example would be the -boundary_optimization option for dc_shell.

- **-pre_compilation_commands *command_list***

An optional switch and command list that adds the provided commands to the <*synthesis_tool*>.synthesis_tcl so that they are executed before the compilation command is run.

- **-post_compilation_commands *command_list***

An optional switch and command list that adds the provided commands to the <*synthesis_tool*>.synthesis_tcl so that they are executed after the compilation command is run.

- **-startup_file *file_name***

An optional switch and file path that allows the user to explicitly specify the startup file that will be used by the synthesis tool. The file specified is copied into the actual synthesis directory.

Note

 If a startup file is not specified and a *.synopsys_dc.setup* file exists in the Tessent run directory, it will automatically be copied into the synthesis run directory. If relative paths are utilized within this setup file, it should be noted the synthesis run directory is two levels below where Tessent Shell is launched and these paths should account for this execution point.

- **-command_name *command_name_path***

Defines the command name to invoke the synthesis tool. The default for *dc_shell* is '*dc_shell*' and the command is assumed to be available in the search path of the operating system.

Examples

The following examples of *set_run_synthesis_options* setting some of the possible options.

Example 1

This example adds the *optimize_registers* command before *compile* in the *dc_shell.synthesis_tcl* used to synthesize the test logic.

```
SETUP> set_run_synthesis_options dc_shell -pre_compilation_commands \
          optimize_registers
```

Example 2

This example adds the *-map_effort high* option to the *compile* command in the *dc_shell.synthesis_tcl* used to synthesize the test logic.

```
SETUP> set_run_synthesis_options dc_shell -compilation_options \
          {-map_effort high}
```

set_scan_chain_options

Context: pattern -scan

Mode: setup, when LBIST is on

Specifies options for managing scan chains within the hybrid TK/LBIST flow.

Usage

```
set_scan_chain_options {-chain_name chain_name... | -INStance instance_name
                      -Block_chain_index_list block_chain_index_list ...}
                      [-decompressor_to_scan_in_inversion {on | off} ]
                      [-scan_out_to_compactor_inversion {on | off} ]
```

Description

In LogicBIST mode, no hardware rediscovery is performed. As a result, the tool can be unaware of inversions that were inserted by a third-party tool between the scan chains and the PRPG/phase shifter on the input side and the compacter and the scan chains on the output side. Before LogicBIST fault simulation, you can specify the set_scan_chain_options command to force the inversions and proceed in such situations.

This command has no effect on ATPG pattern generation.

EDT finder can automatically rediscover the inversions between the EDT logic and scan chains, which means you can use it to export the inversions and reuse them for LogicBIST fault simulation. Use either of the following commands in analysis mode with EDT enabled (after passing K-rules) to find the inversions:

- report_scan_chains -inversions — This command reports the relevant inversions in the decompressor_inversion and compactor_inversion columns.
- write_core_description — The TCD includes information about the inversions in the decompressor_to_scan_in_inversion and scan_out_to_compactor_inversion properties within ScanChain wrappers. You can read back the TCD before performing fault simulation as described in “[Fault Simulation When There Are Inversions](#)” in the *Hybrid TK/LBIST Flow User’s Manual*.

The test patterns in –mode_internal will continue to be written out with respect to scan chain input and scan chain output. If an inversion is specified after the SCO, the unload values will not reflect the inversion. However, MISR values will take that inversion into account.

Arguments

- **-chain_name***chain_name*...

Required switch and repeatable string that specifies the name of a scan chain in the current design.

- **-INStance *instance_name* -Block_chain_index_list *block_chain_index_list...***

Required set of switches and values that specifies a core instance and the list of chain indices starting with “1” on the EDT controller. When this is used, the masking applied to the specified chain is OX. Use this option in conjunction with the **-USed_chains** switch.

- **-decompressor_to_scan_in_inversion on | off**

Optional switch and literal pair that specifies whether the tool identifies inversions between the EDT decompressor and the SCI pin. The default is off.

- **-scan_out_to_compactor_inversion on | off**

Optional switch and literal pair that specifies whether the tool identifies inversions between the SCO pin and the EDT compactor. The default is off.

Examples

The following example makes Tesson Shell aware that there are inversions associated with both the SCI and SCO on chain3.

```
set_scan_chain_options -chain_name chain3 -decompressor_to_scan_in_inversion on  
-scan_out_to_compactor_inversion on
```

set_scan_enable

Context: dft -scan, dft -test_points

Mode: setup, analysis (dft -scan context); analysis (dft -test_points context)

Assigns scan_enable signals to specific scan chains.

Usage

```
set_scan_enable [scan_enable_pin.pathname [-Isolate]]  
[primary_input] [-Active {High | Low}]  
[-Single_global_scan_enable {ON | OFF}]  
[-CLUster_name cluster_name ... | -POwer_domain_name power_domain_name ...]  
[-Clock clock_pin]
```

Description

Assigns scan_enable signals to specific scan chains.

The set_scan_enable command can be issued in a sequence to either refine the scan enable signals assignments or overwrite the previous assignments (see the example section for this command). In general, the following rules are applied to determine how signal assignments are affected by subsequent commands:

- The most recent command that assigns a scan_enable signal takes precedence.
- If the most recent command operates on a disjoint set of scan chains, then the previous scan enable signal assignments remain intact.
- If the most recent command operates on previously specified scan chains, then previous scan_enable signal assignments are overwritten.

Arguments

- *scan_enable_pin.pathname* [-Isolate]

An optional string that specifies a pin pathname for the scan_enable signal driver. The specified pin can be either a top-level scan enable port or an internal instance pin (connection node). If an internal instance pin is specified, it must trace back to a primary input via a simple path (only inverters or buffers) or the primary_input argument.

-Isolate — Isolates new fanouts of the specified scan enable signal. Each new fanout connection is gated by an AND or NOR gate and controlled by the global test enable signal. This switch is applicable to a scan enable signal driven by a top-level port or a top-level internal instance pin only.

If no scan_enable signal driver is specified, the default scan enable name is used (scan_en).

- *primary_input*

An optional string that specifies a top-level scan_enable port. This argument supplies a primary input/top-level port for an internal instance pin specified by the scan_enable_pin.pathname argument. The specified top-level port is used when generating

the ATPG dofile and test procedure files. If the specified top-level port does not exist, it is created. The specified top-level port must be a primary input port.

- **-Active {High| Low}**

An optional switch and literal pair that specifies whether the scan_enable signal is active low or high. The default setting is high.

- **-Single_global_scan_enable {ON | OFF}**

An optional switch and literal pair that specifies to use a single scan enable signal for input wrapper chains, output wrapper chains and core chains. This is the default. The input wrapper chains scan enable signal is generated by ORing the specified or the default scan enable signal with INTEST mode test enable signal. The output wrapper chains scan enable signal is generated by ORing the specified or default scan enable signal with EXTEST mode test enable signal. If this switch is turned off, the tool uses three separate scan enable signals: scan_en_in for input wrapper chains, scan_en_out for output wrapper chains, and scan_en for core chains. Other switches are not accepted when the -single_global_scan_enable switch is used.

- **-CLUster_name *cluster_name***

An optional switch and string pair that specifies to assign a specified scan enable signal to scan chains in the specified cluster.

- **-POwer_domain_name *power_domain_name***

An optional switch and string pair that specifies to assign a specified scan enable signal to scan chains in the specified power domain.

- **-Clock *clock_pin***

An optional switch and string pair that associates the specified scan enable signal with the specified clock (clock domain). Clock_pin can be either an existing top level port (primary input pin) or an existing internal pin pathname.

An error message is issued when this switch is specified with either the -Clock Merge or the filename -Fixed option of the insert_test_logic command.

This switch can be used in conjunction with the -Edge Merge option of the insert_test_logic command.

Examples

Example 1

The following example defines two scan clusters: rx_clust and tx_clust, by assigning the cluster_name attribute to the selected instances. Each cluster has its dedicated scan enable defined with the set_scan_enable command. The first set_scan_enable command makes all scan chains controllable via the sen scan enable signal. The second set_scan_enable command refines the first command and makes scan chains of rx_clust controllable via the sen_rx scan enable signal. The third set_scan_enable command further refines the first command and makes scan chains of tx_clust controllable via the sen_tx scan enable signal.

```

set_scan_enable sen
set_scan_enable sen_rx -cluster rx_clust
set_scan_enable sen_tx -cluster tx_clust

set_system_mode analysis
set_attribute_value [get_scan_elements -below_instances i_rx_phy] \
  -name cluster_name -value rx_clust
set_attribute_value [get_scan_elements -below_instances i_tx_phy] \
  -name cluster_name -value tx_clust
add_scan_mode unwrapped
analyze_scan_chains
report_scan enable

```

The last command displays the following result:

```

//      command: report_scan_enable
Scan mode 'unwrapped' scan enables:
-----
Primary Input  Internal Connection Node  Scan Chain  Scan Partition
-----
/sen_rx        --                      chain0       rx_clust
-----
/sen_tx        --                      chain1       tx_clust
-----
/sen           --                      chain2       default_scan_partition
-----
```

The second set_scan_enable command operates on a set of scan chains that is entirely within the set specified in the first command; therefore, the scan chains that are in both sets will get the most recent assignment. The third set_scan_enable command operates on a set of scan chains that is disjoint from the set in the second command but is entirely contained within the first set; therefore, the scan chains that are in both the first and the third sets get the most recent assignment.

Example 2

The following example defines two scan clusters: rx_clust and tx_clust. The first set_scan_enable command makes all scan chains controllable via the sen scan enable signal. The second set_scan_enable command specifies an internal pin, rx_sen_reg/Q, associated with the primary input, sen_rx, as a driver of the scan enable signal controlling all scan chains of rx_clust. The third set_scan_enable command specifies an internal pin, tx_sen_reg/Q, associated with the primary input, sen_tx, as driver of the scan enable signal controlling all scan chains of tx_clust.

```

add_clock 0 clk2
set_scan_enable sen
set_scan_enable rx_sen_reg/Q sen_rx -cluster rx_clust
set_scan_enable tx_sen_reg/Q sen_tx -cluster tx_clust
set_scan_enable sen_clk2 -clock clk2

```

The last set_scan_enable command specifies that all scan chains in the clk2 clock domain are controllable by the sen_clk2 scan enable signal. The second and the third set_scan_enable commands overwrite the assignments of the first set_scan_enable command affecting chains

that are in rx_clust and tx_clust. Since the second and the third set_scan_enable commands operate on disjoint sets, they do not affect their assignments.

The fourth command will overwrite some of the assignments of the second and the third commands for scan chains that are in rx_clust and tx_clust and also in the clkInput clock domain. If you want to restrict the clock domain's assignments to a specific cluster, the -cluster and -clock options should be issued in the same set_scan_enable call.

set_scan_insertion_options

Context: dft -scan

Mode: setup, analysis

Specifies the high-level options for the scan insertion process.

Usage

```
set_scan_insertion_options [ -single_class_chains { on | off } ]  
[ -single_clock_domain_chains { on | off } ]  
[ -single_clock_edge_chains { on | off } ]  
[ -single_cluster_chains { on | off } ]  
[ -single_power_domain_chains { on | off } ]  
[ -single_wrapper_type_chains { on | off } ]  
[ -port_index_start_value <int> ]  
[ -port_scalar_index_modifier <int> ]  
[ -chain_length { unlimited | <int> } ]  
[ -chain_count { unlimited | <int> } ]  
[ -si_port_format <format_str> ]  
[ -so_port_format <format_str> ]  
[ -si_timing { leading_edge | trailing_edge | any_edge } ]  
[ -so_timing { leading_edge | trailing_edge | any_edge } ]  
[ -lockup_cell_type { flop | latch } ]  
[ -si_lockup_cell_type { flop | latch } ]  
[ -so_lockup_cell_type { flop | latch } ]  
[ -unused_edt_pin_handling { auto | insert_pipelining_flop | tie_compactor_input } ]  
[ -si_pipelining { all_chains | off | wrapper_chains_only } ]  
[ -si_pipelining_type { non_scan_flop | holding_scan_flop } ]  
[ -enable_scan_cell_mapping { on | off } ]  
[ -enable_retimming { on | off | skip_synchronous_clocks } ]  
[ -port_bus_range { ascending | descending } ]
```

Description

Use this command to specify the high-level options for the scan insertion process.

Note

 Many of the options of this command are also available for the [add_scan_mode](#) and [create_scan_chain_family](#) commands. If you change any of these common options using the set_scan_insertion_options command, the tool will issue a warning that the changes will only apply when creating a new scan mode or chain family, and will have no effect on existing scan modes or chain families.

Arguments

- **-single_class_chains { on | off }**
An optional switch and literal pair that controls whether to mix wrapper and non-wrapper cells in a single chain. The default is off, so the tool will allow distributing wrapper and internal cells onto the same chains.
- **-single_clock_domain_chains { on | off }**
An optional switch and literal pair that restricts a scan chain to a single clock domain. The default is off.
- **-single_clock_edge_chains { on | off }**
An optional switch and literal pair that restricts a scan chain with flops having a single edge. The default is off.
- **-single_cluster_chains { on | off }**
An optional switch and literal pair that restricts a scan chain to a single cluster using the attribute "cluster_name". The default is on.
- **-single_power_domain_chains { on | off }**
An optional switch and literal pair that restricts a scan chain to a single power domain using the attribute "power_domain_name". The default is on.
- **-single_wrapper_type_chains { on | off }**
An optional switch and literal pair that specifies that "-single_class_chains ON" controls whether to mix input wrapper and output wrapper cells in the same chain. The default is off.
- **-port_index_start_value <int>**
The starting index is 0 by default, but can be overridden by this option.
- **-port_scalar_index_modifier <int>**
An optional switch that specifies the incremental value to add to the index portion (%d) of scalar scan port names. The default is 1
- **-chain_length { unlimited | <int> }]**
An optional integer that specifies the target length of scan chains for a particular mode. By default, the no limit (unlimited) is imposed on the chain length.
- **-chain_count { unlimited | <int> }**
An optional integer that specifies the number of scan chains that should be constructed for the specified mode. By default, the chain count is set to the number of connections specified with the -si/so_connections, otherwise if the latter options were not used, then no limit (unlimited) is imposed on the chain count.
- **-si/so_port_format <format_str>**
The default si/so_port_format is set to "ts_%s_si/so[%d]" when there are more than one scan mode, otherwise it defaults to "ts_si/so[%d]". The mode placeholder "%s" gets replaced by the chain mode name, whereas the index placeholder "%d" gets substituted by

the chain index. A precision number may be used when specifying the index placeholder, for instance the format "lsi_si%2d" would cause port names like "lsi_si00", "lsi_si01", etc. to be created, note that leading zero's are inserted automatically when needed making "%2d" implicitly equivalent to "%02d".

- **-si_timing { leading_edge | trailing_edge | any_edge }**

An optional string and literal pair that provides the ability to control the capture edge of the first scan cell in a chain. The tool inserts a lockup (re-timing) cell between the scan chain input pin and the first scan cell in chain to control the capture edge of the first cell as leading or trailing edge. No lockup cell is inserted if "any_edge" is used as the argument. The default edge type is "leading_edge".

- **-so_timing { leading_edge | trailing_edge | any_edge }**

An optional string and literal pair that provides the ability to control the change edge of the last scan cell in a chain for this scan mode. The tool inserts a lockup (re-timing) cell between the scan chain output pin and the last scan cell in chain to control the change edge of the last cell as leading or trailing edge. No lockup cell is inserted if "any_edge" is used as the argument. The default edge type is "trailing_edge".

- **-lockup_cell_type { flop | latch }**

An optional switch and string that controls the type of lockup (re-timing) cell to use between timing-constrained scan elements of new scan chains. The default cell type is latch.

- **-si_lockup_cell_type { flop | latch }**

An optional switch and string that controls the type of lockup (re-timing) cell to use between the scan chain input pin and the first scan cell. The default cell type is latch.

- **-so_lockup_cell_type { flop | latch }**

An optional switch and string that controls the type of lockup (re-timing) cell to use between the scan chain output pin and the last scan cell. The default cell type is latch.

Note

 By default, the tool adds a pipeline flop in front of the wrapper chains to facilitate launching a transition from the first scan cells in the wrapper chains.

- **-unused_edt_pin_handling { auto | insert_pipelining_flop | tie_compactor_input }**

An optional switch that selects how to handle unused EDT chain pins. Options are:

insert_pipelining_flop — inserts scan chains composed of a single pipelining flop.

tie_compactor_input — ties-off the EDT compactor.

auto — selects "insert_pipelining_flop" for EDT controllers with bypass chains, and "tie_compactor_input" for all other EDT controllers. This is the default.

- **-si_pipelining { all_chains | off | wrapper_chains_only }**

An optional switch and string that controls whether a pipelining flop gets inserted at the beginning of chains. When set to all, then all scan chains get a pipelining flop. When set to

wrapper_chains_only, then only chains of internal or external mode types and composed of wrapper scan elements get a pipelining flop. The default is wrapper_chains_only.

- **-si_pipelining_type { non_scan_flop | holding_scan_flop }**

An optional switch and string that controls whether to implement pipelining using a simple non-scan data flop or a holding flop constructed using a scan flop with its output connected to its data input. The default is holding_scan_flop.

- **-enable_scan_cell_mapping { on | off }**

An optional switch and literal pair that controls the mapping from non-scan to scan cells. The default is on.

- **-enable_retiming { on | off | skip_synchronous_clocks }**

An optional string and literal pair that provides the ability to control the insertion of lockup (re-timing) cells between the scan chain elements. skip_synchronous_clocks omits the insertion of retiming between synchronized clock domains. Use the [add_synchronous_clock_group](#) command to define the synchronous clocks. The default edge type is on.

- **-port_bus_range { ascending | descending }**

An optional switch and literal pair that determines whether created bus ports are created with ascending range (for example, [0:31]) or descending range (for example,[31:0]). The default is descending.

Examples

The following example demonstrates using the set_scan_insertion_options command to disable restricting a scan chain to a single power domain using the attribute “power_domain_name” and set the type of lockup (re-timing) cell between the scan chain output pin and the last scan cell to a flop:

```
set_scan_insertion_options -single_power_domain_chains off -lockup_cell_type flop
```

set_scan_signals

Context: dft -scan, dft -test_points

Mode: setup

Specifies the input control signals' drivers used by the [insert_test_logic](#) command.

Usage

```
set_scan_signals [-TEn pathname] [-int_test_enable pathname][-ext_test_enable pathname]
                 [-TClk pathname] [-SET pathname] [-RESet pathname]
                 [-READ pathname] [-Write pathname]
                 [-Muxed | -Disabled] [-Active {High | Low}]
```

Description

Specifies the input control signals' drivers used by the [insert_test_logic](#) command.

Additional control pins are specified with [set_scan_enable](#), [set_bidi_gating](#), and [set_tristate_gating](#) commands.

The tool uses the write control and read control pins when inserting test logic for RAMs. DRC verifies whether the RAMs can be held off when the write control pin is off. No test logic is inserted for RAMs that can be held off.

If the new scan design is intended for Tessent FastScan/Tessent TestKompress, and the write clock input of the RAM is not controllable, it is multiplexed out by a new write clock. The selector to the mux is the test enable pin.

You can use instance pin pathnames to define the test enable and clock pin names. The instance pathnames must trace back through a simple path (inverters or buffers only) to a primary input/output of the design, or you must manually develop the test procedure file and the dofile before running ATPG.

Arguments

- **-TEn pathname**

An optional switch and string pair that specifies a name for the test enable pin. By default, the test enable pin is named `test_en`.

Use the `-Active` switch to specify the active state of the Test enable signal.

- **-int_test_enable pathname**

An optional switch and string pair that specifies a name for the test enable pin in the INTEST mode. By default, the test enable pin is named `int_ltest_en`.

- **-ext_test_enable pathname**

An optional switch and string pair that specifies a name for the test enable pin in the EXTEST mode. By default, the test enable pin is named `ext_ltest_en`.

- **-TClk *pathname***

An optional switch and string pair that specifies a pathname for the test clock pin for all scan types. If no test clock pin exists, one is created using the specified name. By default, the new test clock pin is named `test_clk`.

If no test clock pin is specified, an existing clock pin from the design is used. Eligible clock pins must be defined with the `add_clocks` command and are capable of capturing data in a sequential cell without test logic in the clock path. The clock pin is selected at random. If no clock pins are found, a new one is created and named `test_clk`.

If an internal pin is specified as the test clock pin, it is traced back to a predefined scan clock. If a predefined scan clock is found, the off-state value is used for test logic insertion. This tracing can only be performed along a single path that consists of only straight wire, inverters, and buffers.

- **-SET *pathname***

An optional switch and string pair that specifies a pathname for the set pin used for the flip-flop or latch when inserting test logic. By default, the set pin is named `scan_set`.

Use the `-Active` switch to specify the active state of the Set signal.

- **-RESet *pathname***

An optional switch and string pair that specifies a pathname for the reset pin used for the flip-flop or latch when inserting test logic. By default, the set pin is named `scan_reset`.

Use the `-Active` switch to specify the active state of the Reset signal.

- **-READ *pathname***

An optional switch and string pair that specifies a pathname for the read control pin used for RAM when inserting test logic. By default, the read control pin is named `read_clk`.

- **-WRITE *pathname***

An optional switch and string pair that specifies a pathname for the write control pin used for RAM when inserting test logic. By default, the write control pin is named `write_clk`.

- **-Muxed | -Disabled**

An optional switch that determines how the specified set, reset, write control, or read control lines are gated. These options can only be used with `-Set`, `-Reset`, `-Write`, and `-Read` switches specified in the same command.

Options include:

-Muxed — Multiplexes all set and reset pins with the original signal. Only set and reset pins defined as clocks are affected. Default setting.

-Disabled — Uses an AND gate with the test enable signal to disable the set and reset inputs of flip-flops and the SEN type scan enable signal to disable the write and read clocks.

- -Active High | Low

An optional switch and literal pair that specifies the active state of the Test enable, Set or Reset signals. Within a single command, you can only use the -Active switch once.

The -Active switch applies to any of the above signals that are specified in the command with the -Ten, -Set, and -Reset switches. By default, all these signals are active on high. The -Active switch is not applicable to any of the other signals specified in this command.

Examples

Example 1

The following example specifies an internal pin, **modxyz/nand02/test_en_L**, as the driver of the Test enable signal to be used during the scan insertion.

```
add_clocks 0 clock
set_scan_signals -ten modxyz/nand02/test_en_L -active low
set_system_mode analysis
insert_test_logic
```

Example 2

The following example shows how to set different controls with successive `set_scan_signals` commands.

```
set_scan_signals -ten TEST_MODE
set_scan_signals -reset RESET_L -active low
set_scan_signals -write ATPG_WRT_INH -read ATPG_READ_INH
set_scan_signals -set ATPG_SET -disabled
```

set_screen_display

Context: unspecified, all contexts

Mode: all modes

Specifies whether the tool writes the transcript to the session window.

Usage

`set_screen_display ON | OFF`

Description

Specifies whether the tool writes the transcript to the session window.

If you create a logfile with the `set_logfile_handling` command, you may want to disable the tool from writing the same information to the session transcript window.

Arguments

- **ON**
A literal that enables the tool to write the session information to the transcript window. This is the default behavior upon invocation of the tool.
- **OFF**
A literal that disables the tool from writing any of the session information to the transcript window, including error messages.

Examples

The following example shows how to use the logfile functionality to capture the transcript in a file and then disable the tool from writing the transcript to the display.

```
set_logfile_handling /user/design/setup_file  
set_screen_display off
```

Related Topics

[set_logfile_handling](#)

set_shadow_check

Context: dft -edt, dft -scan, dft -test_points, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis (dft -scan context only)

Specifies whether the tool identifies sequential elements as “shadow” elements during scan chain tracing.

Usage

```
set_shadow_check {ON | OFF | REstricted} [-ALLOW_cross_clock_domains {ON | OFF}]
```

Description

Specifies whether the tool identifies sequential elements as “shadow” elements during scan chain tracing.

You can use the set_shadow_check command to disable the checking and avoid corresponding error messages. This prevents identification of any non-scan sequential element as a shadow element.

Arguments

- **ON**
A literal that enables shadow checking. This is the initial state upon invocation of the tool.
- **OFF**
A literal that disables shadow checking.
- **REstricted**
A literal that disables the tool’s identification of shadow cells that require independent shifts in certain pattern formats (for example, parallel Verilog format).

Note

 An independent shift results from a one-shift “apply shift” statement in the load_unload procedure. For more information, refer to the description of the [P19](#) rule.

- **-ALLOW_cross_clock_domains {**ON** | **OFF**}**

An optional switch and literal pair that enables consideration of cross-clock domain state elements as shadow cells. This option can increase test coverage, but you should turn on this switch only when you are sure that the clocks are balanced and the shift values to the cross-domain cells are reliable.

Examples

The following example disables shadow checking:

```
set_shadow_check off
```

set_shift_register_identification

Context: dft -scan, dft -test_points

Mode: setup

Enables/disables shift register identification. The default is ON.

Usage

```
set_shift_register_identification {ON | OFF}  
[-ALLOW_COMBINATIONAL_logic_between_registers {ON | OFF}]
```

Description

Enables/disables shift register identification. The default is ON.

For more information about automatic identification of shift registers, see “[Automatic Recognition of Existing Shift Registers](#)” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- **ON**

A required literal that enables shift registration identification. This is the default.

- **OFF**

A required literal that disables shift registration identification.

- **ALLOW_COMBINATIONAL_logic_between_registers {ON | OFF}**

An optional switch and literal pair that specifies for the tool to consider or ignore the use of the DRC calculated state-stability values during shift register identification. When the switch is Off, the constraint values that sensitize a data path between sequential cells are ignored. As a result, multiple-input gates (AND, OR, MUX, etc.) between sequential cells cannot be traced during shift register identification. Single-input gates (BUF and INV), on the other hand, can always be traced. When the switch is On, the constraint values that sensitize a data path between sequential cells are considered during shift register identification tracing. Multiple-input gates do not block the tracing as long as a single path is sensitized through them.

OFF

A literal that specifies ignoring the constraint values. This is the default.

ON

A literal that specifies considering the constraint values.

Examples

The following example disables automatic shift register identification.

```
set_shift_register_identification off
```

[report_scan_cells](#)

[report_shift_registers](#)

set_silicon_insight_option

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Specifies optional settings for running Tessent SiliconInsight.

Usage

```
set_silicon_insight_option [ -cdp_verification { on | off } ]  
[ -ignore_uncontacted_pin_data { on | off } ]  
[ -interactive_ijtag { on | off } ]  
[ -interactive_ijtag_pattern_type { SVF | STIL } ]  
[ -maximum_failing_cycles number ] [ -simdut_port name ]  
[ -simdut_timeout integer ]  
[ -maximum_failing_cycles max_failing_cycles ]
```

Description

The `set_silicon_insight_option` command specifies optional global settings that determine the behavior of subsequent Tessent SiliconInsight sessions. These global settings remain in effect until you change them.

Some of the options apply to particular Tessent SiliconInsight modes of operation, such as SimDUT mode, and others are general.

Arguments

- `-cdp_verification { on | off }`

An optional switch that specifies whether to automatically perform CDP verification. Set this option to “off” when you are not using a TSDB. For example, when you are running custom tests added using the `add_cdp_test` command.

In addition, this switch ensures that new test patterns added as part of a test were generated by Mentor tools (hence will contain a signature that links it to the design it was generated for). You may want to turn verification off if you are adding test patterns that were not generated by Mentor tools.

- `-ignore_uncontacted_pin_data { on | off }`

An optional switch that specifies whether to ignore uncontacted pin data on the selected_setup adaptor. You may want to set this option to “on” when, for example, you are running a custom test that uses more pins than are declared contacted in the pinmap and you know that these extra pins can safely be ignored.

- `-interactive_ijtag { on | off }`

An optional switch that specifies whether to turn on interactive IJTAG so that you can debug a device at the PDL level. See section “[PDL-Level Debugging for Tessent IJTAG-Inserted Devices](#)” in the *Tessent SiliconInsight User’s Manual for Tessent Shell* for details.

- **-maximum_failing_cycles *max_failing_cycles***

An optional switch that enables you to control the maximum number to capture failing cycles in pattern execution. By default, the tool collects and processes all failures. In cases of potential catastrophic defects, pattern execution can take a long time and result in unusable data. This option allows you to collect and process subsets of the failures.

- **-interactive_ijtag_pattern_type { SVF | STIL}**

An optional switch and string pair that specifies whether to generate SVF or STIL patterns for interactive IJTAG analysis and debugging. The default is SVF.

- **-maximum_failing_cycles *number***

An optional switch and integer pair that specifies the maximum number of raw failure cycles to collect during ATPG pattern execution. Use this option when you want to execute a subset of patterns within the STIL pattern file. The tool executes the full pattern but only collect the failing cycles for the specified subset. The default is 2000000000.

- **-simdut_port *name***

An optional switch and string pair that specifies the name of the SimDUT port.

- **-simdut_timeout *integer***

An optional switch and integer pair that controls the length of time before SimDUT mode times out. You can set this option to ensure that the tool does not time out before elaboration completes. Specify the time in seconds. The default is 600.

Examples

The following example turns on interactive IJTAG debugging.

```
set_silicon_insight_option -interactive_ijtag on
```

set_simulation_library_sources

Context: unspecified, all contexts

Modes: all modes

Defines the directories and files in which to search for the simulation Verilog library cells that are to be used by the [run_testbench_simulations](#) command.

Usage

```
set_simulation_library_sources {[-v file_path ...] [-y dir_path ... -extensions ext ...]}  
  [-sv_extensions ext ...]  
  [-logical_library_map_list name path2dir ...] }  
  [-include_directory_list dir_path ...]  
  [-f file_path ...]  
  | [-clear]
```

Description

Defines the directories and files in which to search for the simulation Verilog library cells that are to be used by the [run_testbench_simulations](#) command. The *-logical_library_map_list* is used to reference already compiled libraries.

When you use the *-logical_library_map_list* option, you must make sure to reference pre-compiled libraries that are consistent with the simulator and simulation version you are using with the [run_testbench_simulations](#) command. For example, a pre-compiled library compiled with the Questa 7.2 vlog command cannot be simulated with a different simulator nor with a newer version of vsim.

All switches for this command are interrelated. Each switch is set to their new value each time this command is issued. For example, specifying the command without the *-v* switch does not preserve the previously set *-v* values but instead clears them.

Arguments

- *-v file_path ...*
An optional repeatable switch and value pair that specifies one or more files in which to search for Verilog simulation modules. The relative order of all *-v* and *-y* switches are preserved: the library modules are searched from the first one to the last, and the *-v* files are searched from top to bottom.
- *-y dir_path ...*
An optional repeatable switch and value pair that specifies one or more directories in which to search for files matching Verilog simulation module names. Files that have a leaf name that matches a module name and have one of the extensions specified with the *-extension* switch are automatically loaded if the module does not already exist in memory. You must specify the *-extension* option when you have one or more usages of the *-y* switch. The

relative order of all -v and -y switches is preserved, and the library modules are searched from the first one to the last.

- **-extensions ext**

An optional non-repeatable switch and value pair that specifies the list of extensions that are used to search the specified -y directories for files matching the module names. You must specify the -extension switch once and only once when you specify the -y switch one or more times.

- **-sv_extensions ext**

An optional repeatable switch and value pair that specifies the list of SV extensions that are used to search the specified directories matching the module names.

- **-logical_library_map_list name path2dir**

An optional non-repeatable switch and value pair that specifies a list of logical library name and directory name pairs. Each of those pairs associates a physical directory to a pre-compiled logical library name. You can map multiple logical libraries to their respective directories by specifying multiple pairs of elements. The pre-compiled libraries must be consistent with the simulator and simulator version that you are using in the [run_testbench_simulations](#) command. For example, a pre-compiled library compiled with the Questa 7.2 vlog command cannot be simulated with a different simulator nor with a newer version of vsim.

- **-include_directory_list dir_path**

An optional switch and repeatable string that specifies one or more directory paths that contain `include files.

- **-f file_path ...**

An optional switch and Tcl list that specifies the name(s) of one or more ASCII files that contains pointers to design files. The referenced file is usually generated by another tool, so the -f option allows you to conveniently use the file rather than to reformat the contents of the file into a set_simulation_library_sources command line. The file can contain only the following elements, one per line:

- *design_path* — A string that specifies the name of a Verilog file to load.
- *-v design_path* — A string that specifies the name of a Verilog file to load.
- *-y dir_path* — A string that specifies a path to a directory that contains Verilog files to load.
- *+libext+file_extension* — A string that specifies which files in the “-y dir_path” to load. For example: “+libext+.v” loads all .v files.
- *+define+XXX[=YYY]* — A string that defines a macro called “XXX” with an optional value of “YYY”. The defined macro is used when compiling any files listed in the -f file.

- `+incdir+dir_path1+dir_path2+...` — A string that defines one or more directory paths to directories that contain files that use the ‘include directive.

If you use the `-f` switch with the `set_simulation_library_sources` command, the `file_path` can be relative; however, when specifying the `-f` switch with the [run_testbench_simulations](#) command, you must specify an absolute path for `file_path`. The `file_path` must be an absolute path to the file it references because the “compilation options” is used verbatim and not interpreted at all by the `run_testbench_simulation` command as follows:

```
run_testbench_simulations -compilation_options { -f file_path }
```

In all cases, the content of the file referenced by `file_path` must include only absolute paths to files/directories.

- `-clear`

An optional switch that clears the previously specified values for all other switches in this command as if they had never been specified before. This switch is mutually exclusive with all other switches.

Examples

The following example defines the simulation library sources to be a directory called “./mems” which contains the memory simulation files with a .v extension and a directory named “./tsmc130_questa_10.2” in which the TMSC Verilog simulation cells were pre-compiled using vlog version 10.2. The assumption is that the [run_testbench_simulations](#) command uses Questa as its `-simulator` value and that the Unix search path environment is such that it will pick the Questa commands associated with version 10.2.

```
> set_simulation_library_sources -y ./mems -extensions v \
    -logical_library_map_list tsmc130 ./tsmc130_questa_10.2
> run_testbench_simulation -simulator questa
```

Related Topics

[report_simulation_library_sources](#)

[run_testbench_simulations](#)

[set_simulation_options](#)

Context: all contexts

Mode: setup, analysis, insertion

The `set_simulation_options` command controls the behavior of the tool during pattern generation and simulation.

Usage

```
set_simulation_options [-SET_Reset_dominant_port {OFF|ON}]
[-C6_mask_races {OFF|ON}]
[-MULTIcycle_fault_simulation {ON|OFF}]
[-MUX_Select_x_sim_x {OFF|ON}]
[-FEEDback_buffer_x_init_value {ON|OFF}]
[-REPORT_X_capturing_cells {OFF|ON}]
[-REPORT_Race_masking {OFF|ON|VERbose}]
[-SIMULATE_LEARNED_SEQuential_tie_gates {OFF|ON}]
```

Arguments

- [-SET_Reset_dominant_port OFF|ON](#)

An optional switch and literal pair that enables or disables setting the Set/Reset port as the dominate synchronous port for both flip-flops and latches when multiple ports are on simultaneously. When the switch is on, and either Set or Reset port is on (but not both on), the evaluation value of the state element is dependent on the Set or Reset port. When the switch is off and multiple ports are on simultaneously, the evaluation value is dependent on all enabled ports. When enabled ports agree on the same value, the state element is set to the agreed value. Otherwise, the state element is set to X. Also, the state element is set to X when Set and Reset port are both on simultaneously despite this switch setting.

[OFF](#)

A literal that specifies disabling set/reset as the dominate port.

[ON](#)

A literal that specifies enabling set/reset as the dominate port. This is the default.

- [-C6_mask_races OFF|ON](#)

An optional switch to turn on pessimistic simulation on C6 violated state elements and mask the capture values only when the data port transitions at the same frame the clock port captures. This option allows you to change the handling of C6 violated cells when data and clock ports have a race transition. By default, `create_patterns` will turn on `clock_off` simulation and the tool assumes that the clock ports transition is earlier than the data ports. If this assumption is not true, this option is recommended to mask the C6 violated cells to prevent mismatches due to races. This functionality is less pessimistic than the command “`add_cell_constraints -DRC C6`” as the latter command will mask C6 violated cells even when no races happen.

OFF

A literal that disables this functionality. This is the default.

ON

A literal that enables this functionality.

- **-MULTIcycle_fault_simulation ON|OFF**

An optional switch and literal pair that determines whether or not the tool runs multicycle path ATPG and fault simulation. The default is ON. When this switch is ON, ATPG creates patterns to detect faults on the multicycle paths and fault simulation allows the fault delay on the multicycle path to be $(n+1)$ cycles, where n is the cycle multiplier of the multicycle path. When a fault pin is included in multiple multicycle path cones, the fault delay is determined by the smallest cycle multiplier.

- **-MUX_Select_x_sim_x OFF|ON**

An optional switch and literal pair that specifies to model _mux primitives in the design as either consensus or non-consensus. By default, the tool always models _mux as consensus (evaluates _mux with a known value as long as both data ports are the same known value).

You can use the ON argument to model the _mux primitive as non-consensus (output X for every _mux instance whose select line is X). Note that changing _mux primitives to non-consensus can reduce the test coverage. Also, you can use this switch in any mode, but when you use it in setup mode, the tool evaluates _mux instances as non-consensus mux instances, which can result in additional DRC violations.

- **-FEEDback_buffer_x_init_value ON|OFF**

An optional switch and literal pair that allows the FB_BUF primitive to carry over its value from the previous cycle instead of being initialized to X. The default is ON, which means that the FB_BUF is still initialized with X value at the beginning of a simulation cycle. You can choose to turn off X initialization to get less pessimistic simulation results. Note that turning off this option increases the chance of pattern simulation mismatches if all FB_BUF primitives in the design cannot be safely simulated in this manner.

- **-REPORT_X_capturing_cells {OFF|ON}**

An optional switch and literal pair that reports scan cells that capture X during simulation. When you set this option to ON, the tool displays this message when detecting a parallel pattern that captures X:

```
// 10 scan cells capture X
```

You use “[report_patterns -unload_x](#)” to find the patterns that capture X on scan cells. In addition, when you specify the -pattern_index switch with -unload_x, the report_patterns command reports the scan cells that capture X on the specified pattern.

- **-REPORT_Race_masking {OFF|ON|VERbose}**

An optional switch and literal pair that enables the tool to report when races or glitches are detected that cause sequential element capture values to be masked. These are reasons for races or glitches that can cause the sequential elements to be masked:

- C6 races — The sequential element is masked due to C6 port races, where the C6 data port value is changing in the same frame as the clock port capture frame.
- Glitches on set/reset port in the scan cell loading frame — The set or reset port has potential glitches and the sequential value can be different depending on the glitch value.
- Set or reset port race with the clock port — The set or reset port is de-asserted in the same frame as the clock port capture frame and the capture value can be different if the de-assert happens before or after the clock port capture event.

This message is reported during the good machine simulation when this switch is set to “on”:

```
// Warning: Forcing gate '/cm0507/cm2304/' (7956) to X due to
// glitch at set or reset port for pattern 7.
```

Note

 To prevent excessive messages, only the first ten masked cell are reported for by this tool for race and glitch masking cases (except C6 races). If there are more than ten masked cells, this message is reported:

```
// Only the first 10 have been reported.
// Use 'report_gates -glitch_masked_cells' to report all masked
// cells.
```

- **-SIMULATE_LEARNED_SEQuential_tie_gates {OFF|ON}**

An optional switch and literal pair used to change the ATPG simulator behavior for sequential gates learned as tied during DRC. When you specify off, the switch default, the tool will maintain such sequential tie gates at the learned tie values during simulation.

When you specify on, the tool will not use the learned tie values and evaluate all such sequential gates during simulation.

One possible use for this switch would be to resolve Verilog simulation differences due to X handling on a control port, where the Verilog simulator pessimistically evaluates the gate as X, even though a constant value can be preserved in silicon.

Examples

Example 1

The following example demonstrates disabling setting set/reset as the dominate synchronous port:

```
set_simulation_options -set_reset_dominant_port off
```

Example 2

The following example illustrates how to change the tool to model all _mux instances as non-consensus for both DRC checking and ATPG:

```
SETUP> set_simulation_options -mux_select_x_sim_x on
SETUP> set_system_mode analysis
// Flattening process completed, cell instances=28234, gates=45400,
// PIs=110, POs=103, CPU time=93.00 sec.
// -----
// Begin circuit learning analyses.
// -----
// Equivalent gates=54    classes=0    CPU time=9.00 sec.
...
ATPG> create_patterns
```

[get_simulation_option](#)
[report_patterns](#)
[set_clock_off_simulation](#)

set_skewed_load

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies whether the tool includes a skewed load in the patterns.

Usage

`set_skewed_load OFF | ON`

Description

Specifies whether the tool includes a skewed load in the patterns.

The `set_skewed_load` command either allows patterns to include a skewed load or restricts patterns from including a skewed load. You can use this command in any system mode, but if you use it outside the Setup mode, you must provide a `skew_load` procedure in the test procedure file. If the `skew_load` procedure does not exist, Tesson FastScan issues an error.

You use the `skew_load` procedure in LSSD designs to place different data in the master and slave of a scan cell by applying an additional clock pulse to the master shift clock.

Arguments

- **OFF**

A literal that specifies to not include a skewed load in the patterns. This is the default behavior upon invocation of Tesson FastScan.

- **ON**

A literal that specifies to include a skewed load in the patterns.

Examples

The following example specifies for patterns to include the skewed load:

```
set_skewed_load on
set_system_mode analysis
create_patterns
```

set_split_capture_cycle

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Controls whether the tool updates simulation data between clock edges.

Usage

set_split_capture_cycle ON | OFF

Description

Controls whether the tool updates simulation data between clock edges.

Tip

i If you use ATPG Expert (via the [create_patterns](#) command), you do not need to issue this command. ATPG Expert will automatically enable this command when it is needed. You may get the best results by letting ATPG Expert decide when to use this command.

The `set_split_capture_cycle` command enables or disables the simulation of level-sensitive and leading edge state elements updating as a result of applied clocks. When set to on, the tool updates simulation data between clock edges. This “split capture cycling” of data allows the tool to determine correct capture values for trailing edge and level-sensitive state elements, even in the presence of C3 and C4 violations. When set to “off”, simulation data is updated once each clock cycle.

Note that the `set_split_capture_cycle` command affects ATPG (subsequent [create_patterns](#) commands) but not logic simulation (subsequent [simulate_patterns](#) commands).

Arguments

- **ON**
A literal that specifies to update ATPG data between clock edges. This is referred to as split-capture cycling.
- **OFF**
A literal that specifies to not update ATPG data between clock edges. This is the default behavior upon invocation of the tool.

Examples

The following example enables split capture cycling:

set_split_capture_cycle on

Related Topics

[set_clock_off_simulation](#)

[set_pattern_type](#)

set_stability_check

Context: dft -edt, dft -scan, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies whether the tool checks the effect of applying the main shift procedure on non-scan cells.

Usage

For dft -scan or when EDT is Off

```
set_stability_check {ON | OFF | All_shift}
    [-SIM_Static_atpg_constraints {OFF|ON}]
    [-MAX_shift_cycles {max_number | DEfault | LOngest_chain_length}]
    [-SIM_Capture_procedures
        {ON | Off | ON_Exclude_empty_capture_cycle_for_chain_test}]
```

When EDT is On

```
set_stability_check {ON | OFF}
    [-SIM_Static_atpg_constraints {OFF|ON}]
    [-MAX_shift_cycles {max_number | DEfault | LOngest_chain_length}]
    [-SIM_Capture_procedures
        {ON | Off | ON_Exclude_empty_capture_cycle_for_chain_test}]
```

Description

Specifies whether the tool checks the effect of applying the main shift procedure on non-scan cells.

In order to perform scan chain tracing, design rules checking (DRC) sometimes requires values to be present from non-scan state elements. For example, a control register in a test controller, such as a JTAG TAP, needs to be checked to see that the TAP register holds state during the shift procedure. By default, this checking is performed. This command controls the level of checking.

For detailed information about the use and reporting of state stability, refer to the “[State Stability Issues](#)” appendix in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- **ON**

A literal that enables the tool to perform a fast check of the effect of applying the main shift procedure on non-scan cells. This is the default behavior upon invocation of the tool.

- **Off**

A literal that disables the tool from performing any checks on the effect of applying the main shift procedure on non-scan cells.

- **All_shift**

A literal that enables the tool to perform the most detailed level of checking. The main shift procedure is simulated for as many applications as the procedures call for. When you specify this option, it can significantly increase your run time.

Note

 This option is primarily for logic BIST applications where the contents of shift registers need to be known at the end of scan loading, at the beginning of the capture cycle.

- **-SIM_Static_atpg_constraints OFF | ON**

An optional switch and literal pair that enables or disables the simulation of static ATPG constraints during DRC's state stability analysis. Static ATPG constraints are those you specify using the -Static switch with the add_atpg_constraints command.

When you enable simulation of static ATPG constraints, the tool will assume the constraints are satisfied and will simulate their values during DRC's state stability analysis of nonscan memory elements. This simulation is useful in some clock gating situations.

The invocation default is for DRC not to perform this simulation. The argument choices are as follows:

OFF — A literal that disables the simulation of static ATPG constraints during DRC.
This is the invocation default.

ON — A literal that enables the simulation of static ATPG constraints during DRC.

- **-MAX_shift_cycles max_number | DEfault | LOngest_chain_length**

An optional switch and integer or literal pair that limits the number of shift cycles. You can only use this switch when stability check is set to ON (set_stability_check ON).

- The *max_number* is an integer greater than or equal to 1 (one) that limits the maximum number of shift cycles the state stability analysis can simulate. When setting *max_number*, you should follow the guidance of the **D12** DRC warning message for the number of shift cycles; the tool automatically considers existing independent shift cycles when calculating this recommended number.
- Use the **DEfault** option with this switch to revert to the default behavior of state stability analysis without imposing a specific shift cycle limit using the following syntax:

```
set_stability_check ON -MAX_shift_cycles default
```

- The **LOngest_chain_length** option instructs the tool to use the full-chain length as the iteration limit instead of the default. Using this option can significantly increase runtime.

- **-SIM_Capture_procedures {ON | OFF| ON_Exclude_empty_capture_cycle_for_chain_test}**
(setup mode only)

An optional switch and literal pair that enables a more accurate stability analysis for the NCP (named capture procedure) flow. The two “ON” options are useful when all capture sequences are using predefined NCPs. These options are needed only if the events applied in the NCP matter to state stability and the tool's ability to pass DRC. When performing state stability in preparation for DRC, the tool usually simulates the clocks as *off_value-X-off_value*. However, if the exact capture sequence to be applied during capture needs to be simulated accurately so the state of a clock or shift controller is in the right state, then you can use this option for that purpose.

By default, the more accurate stability analysis for NCPs is turned OFF. The argument choices are as follows:

ON — A literal that enables a more accurate stability analysis for the NCP flow. During state stability analysis for capture windows, the tool simulates every NCP, plus a virtual NCP that includes an empty cycle that does nothing (in order to mimic a chain test).

For each gate, the tool takes the common simulation values at the end of all NCPs (and includes the empty cycle NCP) as the end value of capture window. That is, the gate's final stability value at the end of capture is 1 or 0 if and only if its simulation value at the end of all NCPs is 1 or 0; otherwise, the final stability value is X. This is still pessimistic in the sense that only the common values of all NCPs are preserved, but it is more accurate because the simulation of the capture is exactly as specified by those NCPs.

For the case of an NCP with multiple loads, the tool splits the NCP during simulation, so there is an NCP for each individual load.

OFF — A literal that disables the more accurate stability analysis for the NCP flow. This is the default.

ON_Exclude_empty_capture_cycle_for_chain_test — A literal that enables the more accurate stability analysis, but specifies that the tool not include the virtual NCP with an empty cycle in the stability analysis (as with the ON option). Also, the tool does not save chain test patterns if the stable values at the beginning and end of the capture window for all NCPs are not the same.

Note that once the tool has performed DRC stability analysis based on the NCPs, you must only run subsequent ATPG operations using those NCPs.

For more information about the effect of using this switch on gate reporting, refer to “[Example 12 — Basic with Enhanced Stability Check for NCPs](#)” in the *Tessent Scan and ATPG User's Manual*.

Examples

Example 1

The following example enables fast stability checking of the effect of applying the main shift procedure on non-scan cells:

```
set_stability_check on
```

Example 2

The following example enables fast stability checking as well as the simulation of static ATPG constraints during DRC. Notice the use of the report_environment command to confirm the resultant changes in tool settings:

```
report_environment
```

```
...
split capture cycle =      OFF
stability check =         OFF
...
```

```
set_stability_check on -sim_static_atpg_constraints on
report_environment
```

```
...
split capture cycle =      ON
stability check =          ON
...
```

Related Topics

[set_gate_report](#)

set_static_dft_signal_values

Context: dft patterns

Mode: setup

Prerequisites: ICL is elaborated.

Sets the static DFT signal that exists in the design such that the signal can be used as part of a test_setup.

Usage

```
set_static_dft_signal_values
[-all | -current_design | -icl_instances icl_instances | -instances instances]
dft_signal_value_pairs
```

Description

Sets the static DFT signals that exist in the design such that the signals can be used as part of a test_setup. All static DFT signals implemented with IJTAG can be set using this command. See the [add_dft_signals](#) command for information on adding the DFT signals. The DFT signals are grouped by each module in which you added the DFT signals and ran the [process_dft_specification](#) command. These modules have the tesson_design_level attribute equal to “chip”, “physical_block”, and “sub_block” in their extracted ICL module view.

When setting a static DFT signal within an instance, the other DFT signals without an explicit setting are assigned an implicit value from the following using the heuristic described below. An implicit value will result in an iWrite command in the iCall when the implicit value is different than the reset value. Explicit value always results in an iWrite even if the value matches the reset value of the signal. Use the [report_static_dft_signal_settings](#) command to see the effect of the set command. A - in the value column means the value will be kept to its reset value:

- When setting a DFT signal of usage “scan_mode”:
 - All other DFT signals within the same instance with usage scan_mode are set to 0 unless the signal had a previous explicit setting.
 - All DFT signals within the same instance with usage “logic_test_control” are set to their “value_in_pre_scan_drc” values unless the signal had a previous explicit setting. If the “value_in_pre_scan_drc” value is an X, it is converted to a 0.
 - If the scan_mode_type is “internal”, the int_ltest_en DFT signal within the same instance is set to 1 unless the signal had a previous explicit setting.
 - If the scan_mode_type is “external”, the ext_ltest_en DFT signal within the same instance is set to 1 unless the signal had a previous explicit setting.
 - All DFT signals within the same instance with usage “global_dft_control” are set to their “default_value_in_all_test” values unless the signal had a previous explicit setting.

- When setting a DFT signal of usage “logic_test_control”:
 - All DFT signals within the same instance with usage “logic_test_control” are set to their “value_in_pre_scan_drc” values unless the signal had a previous explicit setting. If the “value_in_pre_scan_drc” value is an X, it is converted to a 0.
 - All DFT signals within the same instance with usage “global_dft_control” are set to their “default_value_in_all_test” values unless the signal had a previous explicit setting.
- When setting a DFT signal of usage “global_dft_control”:
 - All DFT signals within the same instance with usage “global_dft_control” are set to their “default_value_in_all_test” values unless the signal had a previous explicit setting.

To remove a previous explicit setting, use the [reset_static_dft_signal_values](#) command.

Arguments

- **-all**

An optional switch that applies the setting to the specified DFT signals found within all ICL instances having the `tessent_design_level` attribute set to “chip”, “physical_block”, and “sub_block” within their ICL module definition. The DFT signals found within the top module are also set.

The `-all`, `-current_design`, `-icl_instances`, and `-instances` switches are mutually exclusive. When unspecified, the `-current_design` switch is the default.

- **-current_design**

An optional switch that applies the setting to the specified DFT signals found within top module. The top-level module must have the `tessent_design_level` attribute set to “chip”, “physical_block”, and “sub_block” within their ICL module definition.

The `-all`, `-current_design`, `-icl_instances`, and `-instances` switches are mutually exclusive. When unspecified, the `-current_design` switch is the default.

- **-icl_instances *icl_instances***

An optional switch that applies the setting to the specified DFT signals found within the specified ICL instances. The specified ICL instances must have the `tessent_design_level` attribute set to “chip”, “physical_block”, and “sub_block” within their ICL module definition.

The `-all`, `-current_design`, `-icl_instances`, and `-instances` switches are mutually exclusive. When unspecified, the `-current_design` switch is the default.

- **-instances *instances***

An optional switch that applies the setting to the specified DFT signals found within the specified design instances. The specified design instances must match the value of the “`hierarchical_design_instance`” attribute found on an ICL instance with the

tessent_design_level attribute set to “chip”, “physical_block”, and “sub_block” within their ICL module definition.

The -all, -current_design, -icl_instances, and -instances switches are mutually exclusive. When unspecified, the -current_design switch is the default.

- *dft_signal_value_pairs*

A repeatable set of string pairs used to specify DFT signal name and value pairs. The string list must include an even amount of elements where the odd elements correspond to DFT signal names and the even values correspond to 0 or 1. The string can also be a single well-formatted Tcl list containing an even number of element where the odd elements correspond to DFT signal names and the even values corresponds to 0 or 1.

Examples

The following example shows the use of the `set_static_dft_signal_values` followed by `report_static_dft_signal_settings` and the `get_static_dft_signal_icall` inside an `open_pattern_set`.

Notice how the DFT signals start with no explicit nor implicit setting. You can use the `reset_static_dft_signal_values` to return to this state after you have specified the settings. In the example, the “int_edt” DFT signal is set to 1. Consistent with the algorithm described above, the other DFT signals of usage “scan_mode” are left to stay in their reset state. The DFT signals of usage “logic_test_control” are set to their “value_in_pre_scan_drc” values. Because “int_edt” is a scan_mode of type “internal”, the int_ltest_en is also asserted high. The DFT signals of usage “global_dft_control” are automatically set to the “default_value_in_all_test” values. Remember that implicit values matching the reset values are shown as -. No iWrite commands are issued for them as their reset states are already the needed values.

To reuse this scan mode in an unwrapped manner, you explicitly set int_ltest_en to 0 to prevent the signal from being implicitly set. Similarly, you can explicitly set DFT signals of usage “global_dft_control” to a value that is different than their “default_value_in_all_test” values.

As described in the `get_static_dft_signal_icall` command description section, the `get_static_dft_signal_icall` command is automatically invoked to configure the test_setup when in a context that supports `set_test_setup_icall`.

set_static_learning

Context: unspecified, all contexts

Mode: setup

Specifies whether the tool performs the learning analysis to make the ATPG process more efficient.

Usage

```
set_static_learning [ON | OFF] [-Limit integer] [-Verbose {ON | OFF}]
```

Description

Specifies whether the tool performs the learning analysis to make the ATPG process more efficient.

The `set_static_learning` command controls whether the tool performs the learning analysis immediately after design flattening. The tools use the learned behavior for intelligent decision making in later processes, such as ATPG and DRC.

When static learning analysis is on, the additional learned behavior focuses primarily on bus gates. Static learning analysis also allows the test pattern generation process to immediately recognize conflicts and restricted decisions on ATPG constraints that result from the gate assignments. By enabling static learning, you prevent the tools from unnecessarily remaking many decisions, thereby improving the ATPG performance.

For more information about the learning analysis, refer to “[Learning Analysis](#)” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- ON|OFF

An optional literal that disables additional static learning analysis. The default enables the tool to perform additional learning analysis, but you may want to disable to save time if you are not going to be running ATPG.

- -Limit *integer*

An optional switch and integer pair that specifies a single gate simulation activity threshold. When the tool reaches that threshold, it discontinues learning on gates in that design region. You would use the `-Limit` switch for performance reasons. The default value for the *integer* option is 1000.

Caution

 While changing the learning limit increases performance for some designs, it significantly decreases performance for a vast majority of designs. It is very unusual to need to change the learning limit and is therefore not recommended.

- **-Verbose {ON | OFF}**

An optional switch and literal pair that enables additional detailed reporting of analysis results, including the numbers of equivalent gates, classes, implications, and tied gates.

Examples

The following example first enables access to the learned information and then enables the tool to perform additional learning analysis before design flattening:

```
set_learn_report on
set_static_learning on -limit 500
set_system_mode analysis
```

Related Topics

[set_learn_report](#)

set_system_mode

Context: all contexts

Mode: all modes

Specifies the operational state you want the tool to enter.

Usage

```
set_system_mode {setup|insertion | analysis} [-force]
```

Description

Specifies the operational state you want the tool to enter.

The default system mode after tool invocation is setup. The context the tool is in determines which system mode you can specify with the set_system_mode command. See the *Tessent Shell User's Manual* for more information about [contexts and system modes](#).

If you attempt to change back to setup mode and have generated patterns, the tool prompts you to save the patterns with an error message similar to the following:

```
// Error: Current test pattern set has not been saved. Save the  
// patterns or use the -force switch.
```

Arguments

- **setup**

A required literal that specifies to enter Tessent Shell setup mode. This is the default.

- **insertion**

A required literal that specifies to enter Tessent Shell insertion mode.

- **analysis**

A required literal that specifies to enter Tessent Shell analysis mode.

- **-Force**

An optional switch that suppresses the errors that are normally generated when exiting analysis or insertion system modes with unsaved data. Instead of issuing an error, the tool silently deletes unsaved data.

You can also use the -force switch in the following situations:

- When you are in the “patterns -ijtag” context and try to move out of analysis system mode without saving your pattern sets, you cannot change the system mode until you either save the pattern sets or use the -force switch to discard all unsaved pattern sets.
- When you are in insertion system mode and in the rtl context, if you try to change to setup system mode without first saving edited or created modules, you cannot

change the system mode until you either save the modules or use the -force switch to discard the unsaved modules.

Examples

Example 1

The following example changes the system mode so you can perform an ATPG run:

```
add_scan_groups group1 scanfile
add_scan_chains chain1 indata2 outdata4
set_system_mode analysis
create_patterns
```

Example 2

The following example changes the system mode so that you can perform scan stitching:

```
add_tied_signals 1 vcc
add_tied_signals 0 vss
add_clocks 0 clock
set_system_mode analysis
report_scan_elements
insert_test_logic
```

Example 3

The following example changes the system mode so that you can perform an insertion run:

```
set_context dft -no_rtl
read_verilog mydesign.v
read_cell_library tessent_cell.tcellib
set_current_design
set_system_mode insertion
create_instance u1/myInst -of_module myModule
```

Related Topics

[get_system_mode](#)

set_tcl_shell_options

Context: all contexts

Mode: setup

Specifies options for the Tcl shell.

Usage

```
set_tcl_shell_options [-abort_dofile_on_error {off | on | exit}]  
                      [-legacy_dofile_comments {off | on}]  
                      [-legacy_commands_with_spaces {off | on}]  
                      [-minimum_command_typing {off | on}]  
                      [-change_no_result_warnings_to_errors {off | on}]
```

Description

Specifies options for the Tcl shell. You can use this command to control features that provide backward compatibility to old dofiles.

Arguments

- **-abort_dofile_on_error {off | on | exit}**

An optional argument that controls whether the tool aborts or continues dofile execution if it detects an error condition. This switch supersedes the set_dofile_abort command and only affects how the error is handled when it propagates up the nested command stack and reaches the dofile level.

Caution

 Use caution when specifying “-abort_dofile_on_error off” because it traps all potential error conditions. Preferably, you should trap error conditions of specific commands by using the Tcl built-in catch command or the Tesseract catch_output command.

- **-legacy_dofile_comments {off | on}**

An optional argument that controls the treatment of “//” as a comment prefix. If treating “//” as a comment prefix causes issues use “set_tcl_shell_options -legacy_dofile_comments off” to disable it. For new dofiles, you should always use the “#” as a comment prefix.

- **-legacy_commands_with_spaces {off | on}**

An optional argument that controls whether the tool accepts legacy, space-separated commands or not.

- **-minimum_command_typing {off | on}**

An optional argument that controls whether the tool accepts abbreviated commands or not. Using abbreviated commands in your dofile carries the risk that future tool versions will not accept the abbreviations anymore because of ambiguities with new commands.

Specify off for this option to ensure that you always type the full name of a command. The scripts can also run faster when commands are typed in full.

- **-change_no_result_warnings_to_errors {off | on}**

An optional argument that controls whether the tool flags a no result returned from an introspection command as an error or a warning.

The default setting is on, which means that the tool flags as an error a no result returned from an introspection command, unless you specify the -silent switch.

Setting this switch to off instructs the tool to flag with a warning a returned no result list or collection from an introspection command. However, this option introduces a risk if your scripts cannot deal with empty collections correctly. As this may result in incorrect/unintended behavior, it is not recommended.

It is recommended that you ensure your scripts can properly handle an empty collection when it is possible that a get_* introspection command finds nothing. For example, if you use the following, then it must be guaranteed that “[get_instances XXX](#)” command will find an instance:

```
get_modules -of_instance [get_instances XXX]
```

If it is possible for the get_instances command to return an empty collection, use the -silent switch and determine the size of the returned collection before passing it to other procedures or Tesseract Shell commands:

```
set inst [get_instances XXX -silent]
if {[sizeof_collection $inst] > 0} {
    my_procedure $inst
    set mods [get_modules -of_instances $inst]
    ...
}
```

The additional check eliminates any risk of unexpected behavior if the procedure or the command processing the collection cannot correctly handle an empty collection.

Do not use the -silent switch if you expect a command to always return a non-empty collection, and your script does not check the size of the returned collection as shown above.

Using the -silent switch in such cases can cause a valid error message to go unnoticed and result in undesired behavior.

[get_tcl_shell_option](#)

[report_tcl_shell_options](#)

set_test_end_icall

Context: dft, patterns -scan, patterns -scan_diagnosis, patterns -scan_retargeting

Mode: all modes

Adds an iCall to the start of the test_end procedure.

Usage

```
set_test_end_icall {[icl_instance_path.]iproc_name [arguments ...]} [[-merge] -append]  
[-non_retargetable]
```

Description

Adds an iCall to the start of the test_end procedure. The set_test_end_icall command adds an iCall to the start of the test_end procedure.

The command accepts a Tcl list consisting of the three components that normally follow an iCall: the name of the iProc; preceded by the optional ICL instance path and separated by a period; and one or more optional arguments to the iProc.

If you specify the -append switch, the new iCall is appended to the iCalls in memory. Each iCall with its arguments is called in the order the iCall was appended.

If you issue the command without the -append switch, the tool overwrites the previous values. To clear the list, assign an empty string or empty list without the -append switch.

The -merge switch provides support for iMerge in the test procedure file. It can only be used if the -append switch is also specified.

Arguments

- {[icl_instance_path.]**iproc_name** [arguments ...]}

The name of the iProc, preceded by the optional ICL instance path and separated by a dot, and one or more optional arguments to the iProc.

- -append

An optional switch that appends the specified list of iCalls to the accumulated list of iCall commands. Note that if you issue the command without the -append switch, the accumulated iCalls are cleared and only the current specified iCall command is stored.

- -merge

An optional switch to merge iCall commands together. The -merge option can only be used with the -append switch to merge the specified iCall with the previous iCall. All the merged iCall commands infer the -error_on_conflict option of the [iMerge](#) command and cannot be unspecified.

Refer to “[iMerge Conflict Reporting](#)” in the *Tessent IJTAG User’s Manual* for more information on the -error_on_conflict option.

The merged iCall commands can be specified in the test_setup/test_end procedures using the tesson shell commands set_test_setup_icall/set_test_end_icall. Later, when you use the [report_procedures](#) command, the merged iCall commands of the test_setup/test_end procedures will appear as follows:

```
iMerge  
  iCall iProcName iProcArgs  
  ....  
iMerge -end;
```

The -error_on_conflict option is always enabled, so it is not necessary to specify it explicitly.

- [-non_retargetable](#)

An optional switch that allows adding iCalls that will not be retargeted at the next level. Use this switch to apply the iCall at the current (core) level and so it is not forwarded when the core is embedded in a design.

Examples

In the following example, the iCall commands specified using the -merge option in the test_end file merge iProc2, iProc3 and iProc4 into iProc1:

```
set_test_end_icall iProc1 -append  
set_test_end_icall iProc2 -append  
set_test_end_icall iProc3 -merge -append  
set_test_end_icall iProc4 -merge -append
```

These commands are equivalent to the sequence of the iCall commands in the test procedure file:

```
Procedure test_end =  
  iCall iProc1;  
  iMerge =  
    iCall iProc2;  
    iCall iProc3;  
    iCall iProc4;  
  end;  
end;
```

set_test_logic

Context: dft -scan, dft -test_points

Mode: setup

Inserts test logic to control the set, reset, clock, enable, or write control signals to make them scannable when scan chains are inserted.

Usage

```
set_test_logic {-Set {ON | Off} | -REset {ON | Off} | -Clock {ON | Off}  
| -RAm {ON | Off} | -C6 {ON | Off}}...
```

Description

Inserts test logic to control the set, reset, clock, enable, or write control signals to make them scannable when scan chains are inserted.

Before inserting scan chains, you must specify the cell models with the [add_cell_models](#) command.

By default, no test logic is inserted on control signals. You can use the [report_environment](#) command to display the current test logic settings.

If all enable signals of a bus are driven purely by combinational logic, no additional test logic is needed to prevent contention due to scan shifting.

Arguments

- **-Set ON | Off**

A switch and literal pair that enables the insertion of test logic to make set signals controllable. The default setting is off.

- **-REset ON | Off**

A switch and literal pair that enables the insertion of test logic to make reset signals controllable. The default setting is off.

- **-Clock ON | Off**

A switch and literal pair that enables the insertion of test logic to make clock signals controllable. The default setting is off.

- **-RAm ON | Off**

A switch and literal pair that enables the insertion of test logic to make read and write signals controllable. The default setting is off.

This option does not affect the set and reset signals of the RAM. You should use the `edge_trigger` attribute in the library definition of the RAM to specify inserting test logic to control these signals. For more information, see the “[Attributes of RAM/ROM Primitives](#)” section of the *Tessent Cell Library Manual*.

- **-C6 {ON | OFF}**

A switch and literal pair that, when enabled, instructs the tool to add hardware to *fix* identified C6 violations. The tool fixes a C6 violation by inserting a multiplexer into the data path that feeds the flip-flop generating the violation. The test mode input of the multiplexer is driven by a nearby scan flip-flop. When a top-level clock feeds the data input of many flip-flops (which results in multiple C6 violations), the multiplexer is inserted at the highest possible level of hierarchy. The driving scan cells are selected to be in the same clock domain as the flip-flops generating the C6 violations. This setting is off by default.

Note

This option cannot be used when the “`set_drc_handling -Conservative`” switch is enabled.

Examples

The following example checks the set and clock signals of uncontrollable memory elements and makes them controllable with the addition of test logic:

```
add_clocks 0 clk
set_test_logic -set on -clock on
set_system_mode analysis
add_cell_models and2 -type and
add_cell_models or2 -type or
add_cell_models mux21h -type mux s a b
add_cell_models nor2 -type nor
report_cell_models
insert_test_logic
```

Related Topics

set_test_point_analysis_options

Context: dft -test_points

Mode: setup, analysis

Sets the maximum number of test points, the breakdown in control and observe points, the target fault coverage and the number of pseudo random patterns to be applied and some other parameters that are taken into account during test point analysis.

Usage

For VersaPoint test points when test point type is set to lbist_test_coverage:

```
set_test_point_analysis_options
  [-total_number integer / integer%] |
  [-control_points_number integer / integer% -observe_points_number integer / integer%] |
  [-test_coverage_target percentage] |
  [-pattern_count_target integer] |
  [-max_control_points_per_path integer] |
  [-exclude_cross_domain_paths on | off] |
  [-observe_primary_outputs on | off] |
  [-exclude_clock_domains off | object_spec] |
  [-allow_in_xbounding_regions on | off]
```

For VersaPoint test points when test point type is set to edt_pattern_count:

```
set_test_point_analysis_options
  [-total_number integer | integer%] |
  [-control_points_number integer / integer% -observe_points_number integer / integer%] |
  [-max_control_points_per_path integer] |
  [-exclude_cross_domain_paths on | off] |
  [-exclude_clock_domains off | object_spec] |
  [-allow_in_xbounding_regions on | off]
```

For VersaPoint test points when test point type is set to {edt_pattern_count lbist_test_coverage}:

```
set_test_point_analysis_options
  [-total_number integer / integer%] |
  [-control_points_number integer / integer% -observe_points_number integer / integer%] |
  [-test_coverage_target percentage] |
  [-pattern_count_target integer] |
  [-max_control_points_per_path integer] |
  [-exclude_cross_domain_paths on | off] |
  [-observe_primary_outputs on | off] |
  [-exclude_clock_domains off | object_spec] |
  [-allow_in_xbounding_regions on | off]
```

Description

Sets the maximum number of test points, the breakdown in control and observe points, the target fault coverage and the number of pseudo random patterns to be applied and some other parameters that are taken into account during test point analysis.

Not all gates in the design will be considered by the tool for inserting test points. For various reasons, test points will not be inserted on gates in the clock tree or in the scan path, gates in protected blocks or gates where the user has explicitly requested that no test points should be inserted. If there are many locations where test points cannot be inserted the tool may not be able to find the best locations for test points. This may increase the number of test points that are needed to reach the fault coverage target. Therefore, if test points cannot be inserted at more than 20% of the gate-pins the tool will generate a warning. The warning specifies the number of these locations as well as the main reason(s) why test points cannot be inserted at these locations.

By default, if you do not specify the maximum number of test points using the `-total_number`, `-control_points_number` or `-observe_points_number` switches, the tool will assume the total number of test points to be 1% of the identified memory elements in the design for EDT test points. When the test point type `lbist_test_coverage` is used, the tool will assume the number of `test_points` to be 10000000.

Please refer to the “[Test Points for Improving the Test Coverage of Deterministic Patterns](#)” in the *Tessent Scan and ATPG User’s Manual* for generating test points that improve the testability of a subset of faults.

Arguments

- `-total_number integer / integer%`

An optional switch and integer or integer percentage that specifies the maximum number of test points to be inserted as an integer or integer percentage of the total number of flops in the design, with no maximum as default. This maximum only applies to the test points automatically generated by the tool using the command `analyze_test_points`.

Note

The integer percentage must be specified as an integer followed by %.

- `-control_points_number integer / integer%`

An optional switch and integer or integer percentage that specifies the maximum number of control points to be inserted as an integer or integer percentage of the total number of flops in the design, with no maximum as default.

This maximum only applies to the control points automatically generated by the tool using the `analyze_test_points` command. Issuing these two commands is sub-optimal; the preferred flow is to let the tool automatically decide the test point distribution.

- **-observe_points_number integer / integer%**

An optional switch and integer or integer percentage that specifies the maximum number of observe points to be inserted as an integer or integer percentage of the total number of flops in the design, with no maximum as default.

This maximum only applies to the observe points automatically generated by the tool using the analyze_test_points command. Issuing these two commands is suboptimal; the preferred flow is to let the tool automatically decide the test point distribution.

Note

The number of control points and the number of observe points must both be specified in the same manner, that is, as an integer or integer percentage.

- **-test_coverage_target percentage**

An optional switch and integer that specifies the target fault coverage to be achieved by the number of random patterns. The tool will insert test points until either the maximum number of test points is reached or the desired fault coverage with the target number of random patterns is achieved. The default is 99%.

When you perform test point analysis for a set of target faults (instead of all faults), the default value is 100%.

Note

This option is not relevant when test point type is set to edt_pattern_count.

- **-pattern_count_target integer**

An optional switch and integer that specifies the number of random patterns to be applied to the design. Fault coverage estimations will be done using this parameter as reference. Default is 100,000.

When you perform test point analysis for a set of target faults (instead of all faults), the default value is 1000.

Note

This option is not relevant when test point type is set to edt_pattern_count.

- **-max_control_points_per_path integer**

An optional switch and integer that specifies the maximum number of control points to be inserted on a single path. The default maximum number of control points per path is five.

- **-exclude_cross_domain_paths on | off**

An optional switch and literal that prevents the tool from inserting test points in inter-clock domains. The default is off.

- **-observe_primary_outputs on | off**

An optional switch and literal pair that allows you to control the insertion of observe points at primary outputs. The default is off - no observe points are inserted at primary outputs.

Note

 This option is not relevant when test point type is set to edt_pattern_count.

If you set this switch to on, an observe point is inserted at each primary output where at least three previously unobserved cells can be observed.

If you have specified a target set of faults, the tool will by default insert an observe point at each primary output where at least ten user-specified faults are observed by the inserted observe point that would otherwise not be observable.

When you are in Analysis mode and have selected test points with the analyze_test_points command, if you try to change the setting of the -observe_primary_outputs switch from on to off, you will get an error message that you need to first delete all test points before the -observe_primary_outputs switch can be changed. If you try to change the setting of the -observe_primary_outputs switch from off to on, however, and test points have already been selected, you will get a warning that some of the test points may no longer be optimal after adding test points to primary outputs, and for best results you should delete all test points before proceeding with the analyze_test_points command.

Note

 The number of observe points inserted on primary outputs is independent of the total number of test points or the number of observe points that you may specify with the -total_number or -observe_point options of the set_test_point_analysis_options command. The total number of test points that are reported by report_test_points will include test points inserted at the primary outputs because the -observe_primary_outputs option was used, as well as those identified using our standard algorithm. Therefore, the total number may exceed the user specified threshold.

- **-exclude_clock_domains off | object_spec**

An optional switch and literal that prevents the tool from inserting test points at any gate within a specified clock domain. The default is off.

The value of object_spec can be a Tcl list of one or more object names or a collection of one or more objects. Typically, these objects are primary input pins that have been specified as clocks by the add_clocks command. The default test_clock or the test clock specified with the set_scan_signals command is also an acceptable clock object.

When you use the “set_test_point_analysis_options -exclude_clock_domains” command multiple times, the latest specification of the “-exclude_clock_domains” switch overrides all previous specifications. Using the “exclude_clock_domains” switch with the “off” argument (“-exclude_clock_domains off”) deletes all excluded clock domains.

By using this switch, you can prevent test points from the following locations:

- Any gate that receives data that is launched from a flip-flop that is clocked by an excluded clock.
- Any gate whose output value is captured at the data port of a flip-flop that is clocked by an excluded clock.

If you want to allow test points at some gates in the excluded clock domains, set the “no_control_point”/“no_observe_point” attributes to false or use the delete_notest_point command to overwrite the “-exclude_clock_domain” switch. The set_attribute_value and delete_notest_point commands have a higher priority than the “-exclude_clock_domains” switch. These specifications (delete_notest_points command, “no_control_point”/“no_observe_point” attribute value, “-exclude_clock_domains” switch) can be entered in any order and can be entered in setup mode or analysis mode. The locations where no test points are allowed will be consistent irrespective of the order of the commands and the time (setup or analysis mode) when they are entered.

In both setup and analysis modes, the set_test_point_analysis_options command with no options will report the excluded clock domains along with the settings of the other switches. In analysis mode the “no_control_point”/“no_observe_point” attributes of the gates in the excluded clock domains are set to true. Therefore, the actual gates that are in these excluded clock domains can be reported or introspected in analysis mode. For example, in analysis mode the “report_notest_points” command can be used to show where test points are not allowed, including the locations in the excluded clock domains.

In analysis mode, if you have selected test points with the analyze_test_points command and then want to change the excluded clock domains, an error will be reported and you will be advised that all test points must be deleted before the excluded clock domains can be changed.

When you specify an excluded clock domain, the tool will first check whether the specified pin is indeed a clock. That is, it will verify that the excluded clock domain has previously been specified as a clock with the add_clocks command (the default test_clk or the test clock that is specified with the set_scan_signals command will also be accepted). An error will be reported if the pin is not a clock. In analysis mode (or during the transition to analysis mode) the tool will also verify whether the excluded clock is actually clocking any flip-flops. A warning will be reported if an excluded clock pin connects to the set/reset inputs of one or more flops. The warning will mention the clock pins that connect to a set/reset pin, but the flops with a set/reset pin that is connected to an excluded clock will not be listed. The connections to set/reset inputs will be ignored. Only flip-flops that are actually clocked by an excluded clock pin will be used to identify gates in the excluded clock domains.

Note

 When you exclude a top clock domain, the clock domains derived from it are not automatically excluded. This gives you the flexibility to exclude the top clock domain without excluding all derived clock domains. However, the tool will issue a warning when a top clock domain is excluded but one or more of the derived clock domains are not excluded.

- -allow_in_xbounding_regions on | off

An optional switch and literal that specifies whether or not to allow the insertion of test points in the X-bounding regions identified during X-bounding analysis. Set this switch to **on** to allow the tool to insert test points in the X-bounding regions. The default value is **off**.

when the test point type is set to only lbist_test_coverage, and **on** any time the test point type edt_pattern_count is used.

Note

 During X-bounding, the tool adds muxes or other logic to block X-sources at specific nets within the design. This blocking logic is placed as close to the X-source as possible, but may not be directly at the source. X-bounding regions are defined as any nets or pins that are in the path of the X-source prior to reaching the X-bounding hardware. These nets and pins may attain an X state even after the X-bounding hardware has been added.

Examples

Example 1

The following example specifies that enough test points should be generated to achieve 99.5 percent fault coverage, but not more than a maximum number of 3000 test points, for a design that will be tested with a set of 131072 random patterns:

```
set_test_point_analysis_options -test_coverage_target 99.5 -total 3000 \
-patterncount_target 131072
```

The following is a snippet from the log file that shows the test coverage reporting before and after selecting test points:

```

// command: analyze_test_points
// Identifying locations of x-bounding muxes prior to test point analysis
//
// Test Coverage Report before Test Point Analysis
// -----
// Target number of random patterns          131072
//
// Total Number of Faults                  15577
//   Testable Faults                      15063  ( 96.70%)
//     Logic Bist Testable                14970  ( 96.10%)
//     Blocked by xbounding               0      ( 0.00%)
//     Uncontrollable/Unobservable       93     ( 0.60%)
//
// Estimated Maximum Test Coverage        99.38%
// Estimated Test Coverage (pre test points) 96.19%
// Estimated Relevant Test Coverage (pre test points) 96.24%
//
// Warning: Test points cannot be inserted at 4033 (33.6%) gate-pins.
// This may increase the number of test points that is needed to reach the
// fault coverage target.
// 3929 (32.7%) gate-pins are located on clock lines or on the scan path.
//
// Incremental Relevant Test Coverage Report
// -----
// TPs 50 =    21 (CP) +    29 (OP), TC 99.41
// TPs 100 =   42 (CP) +   58 (OP), TC 99.41
// TPs 150 =   62 (CP) +   88 (OP), TC 99.42
// (snipped)
// TPs 1150 = 128 (CP) + 1022 (OP), TC 99.49
// TPs 1200 = 135 (CP) + 1065 (OP), TC 99.49
// TPs 1250 = 148 (CP) + 1102 (OP), TC 99.50
//
// Test point analysis completed: target estimated test coverage has been
// achieved.
// Inserted Test Points                 1297
// Control Points                      157
// Observe Points                      1140
//
// Test Coverage Report after Test Point Analysis
// -----
// Target number of random patterns          131072
//
// Total Number of Faults                  18042
//   Testable Faults                      17528  ( 97.15%)
//     Logic Bist Testable                17435  ( 96.64%)
//     Blocked by xbounding               0      ( 0.00%)
//     Uncontrollable/Unobservable       93     ( 0.52%)
//
// Estimated Test Coverage (post test points) 99.03%
// Estimated Relevant Test Coverage (post test points) 99.50%
```

Note

- The “Total Number of Faults”, the number of “Testable Faults” and the number of “Logic Bist Testable” faults are larger after test point insertion as these numbers include the (testable) faults at the new test point logic.
-

Example 2

The following example specifies that enough test points should be generated to achieve 99 percent fault coverage (default), but not more than a maximum number of 3000 control points, and a maximum of 2000 observe points:

```
set_system_mode analysis
set_test_point_analysis_options -control_points 3000 -observe_points 2000
analyze_test_points
report_test_points
insert_test_logic
```

Example 3

The following example specifies excluded clock domains and uses the **set_test_point_analysis_options** command to display the excluded clock domains. Then it adds a few more clock domains and displays the excluded clock domains again. The example uses a collection named \$some_clocks which is comprised of two clock pins and a collection named \$more_clocks which is comprised of four clock pins:

```
set_test_point_analysis_options -exclude_clock_domains $some_clocks
set_test_point_analysis_options

// Maximum Number of Test Points      :      50
// Maximum Number of Control Points   :      50
// Maximum Number of Observe Points  :      50
// Target Test Coverage               :    99.00
// Target Pattern Count              :    1000
// Maximum Control Points per Path   : 65535
// Exclude Cross Domain Paths       :    off
// Excluded_Clock_Domains           : fast_clock1
//                                         fast_clock2
//                                        

set_test_point_analysis_options -exclude_clock_domains $more_clocks
set_test_point_analysis_options

// Maximum Number of Test Points      :      50
// Maximum Number of Control Points   :      50
// Maximum Number of Observe Points  :      50
// Target Test Coverage               :    99.00
// Target Pattern Count              :    1000
// Maximum Control Points per Path   : 65535
// Exclude Cross Domain Paths       :    off
// Excluded_Clock_Domains           : fast_clock1
//                                         fast_clock2
//                                         fast_clock3
//                                         fast_clock4
```

Example 4

This example specifies that no control points can be inserted in clock domain fast_clock1. The report_notest_points command shows the locations in the excluded clock domain (gates U10 to U90). Next the no_control_point attributes for the pins on gate U10 are reset to false. After that the report_notest_points command shows all gates in the excluded clock domain. Note that gate U10 is no longer excluded:

```
set_test_point_analysis_options -exclude_clock_domains fast_clock1
set_system_mode analysis
report_notest_points

/U10/A
/U10/B
/U10/Z
/U11/A
/U11/B
/U11/Z
...
/U90/Z

set_attribute_value U10 -name no_control_point -value false
{U10}

report_notest_points

/U11/A
/U11/B
/U11/Z
...
/U90/Z
```

Example 5

In this example, you specify an excluded clock domain after test points have been inserted. An error is reported as this is not allowed until all test points have been deleted:

```
set_system_mode analysis
analyze_test_points

// ...
// Test point analysis completed: target estimated test coverage has been
achieved.
// Inserted Test Points 2
// Control Points 2
// Observe Points 0
// ...

set_test_point_analysis_options -exclude_clock_domains fast_clock1

// Error: Excluded clock domains cannot be specified when test points
have already been inserted.
// Please delete all test points before proceeding with specifying
(an) excluded clock domain(s).
```

Example 6

The number of control points and observe points must both be specified as an integer or as an integer percentage. The following command will result in an error.

```
set_test_point_analysis_options -control_points 30 -observe_points 5%
```

[write_scan_setup](#)

set_test_point_insertion_options

Context: dft -test_points

Mode: setup, analysis

Prerequisites: None

Sets parameters related to test point insertion.

Usage

```
set_test_point_insertion_options
  [-control_point_enable pin_path_name]
  [-observe_point_enable pin_path_name]
  [-observe_point_share integer]
  [-test_point_clock system_clocks | always_tclk | tclk_as_needed ]
  [-prefer_scan_cells on | off]
```

Description

Sets parameters related to test point insertion.

These parameters will impact the structure of the test logic that is generated when the [insert_test_logic](#) command is issued.

Arguments

- **-control_point_enable *pin_path_name***

An optional switch and string pair that specifies the pin and path name of the enable signal for control points. In its absence, the name lbist_en will be used at the top level.

- **-observe_point_enable *pin_path_name***

An optional switch and string pair that specifies the pin and path name of the enable for observe points. In its absence, the name lbist_en will be used at the top level.

- **-observe_point_share *integer***

An optional switch and integer pair that specifies how many observe points will be observed by one scan cell. The default is one observe point to one destination scan cell.

Note

Mentor Graphics recommends not to share multiple observe points per scan cell when test point type is set to atpg, even though it is supported by the tool. The reason is that it impacts the pattern count reduction during ATPG.

-
- **-test_point_clock *system_clocks* | *always_tclk* | *tclk_as_needed***

An optional switch and literal pair that specifies what clock to use to drive scan cells for test points.

The valid literals are as follows:

system_clocks — A literal that specifies that all test points should be controlled by system clocks. Normally, the test point clock is selected based on analysis of the fanin/fanout cone. Instead of using `test_clock`, when this analysis fails to identify a suitable clock, the tool will select the system clock that drives the most scannable cells within the design. This is the default.

Note

 When selecting an existing system clock, the tool will give preference to clocks that do not drive the set or reset port of any scannable flops. The test clock must pulse during shift, so we do not want to choose a clock that is also connected to the set/reset port of scannable flops since this would cause S2 violations for those flops.

always_tclk — A literal that specifies to use the user_defined `test_clock` signal for all sequential elements that are inserted during test point insertion. When this option is specified, the tool takes the global clock name from the `-tclk` option of the `set_scan_signals` command.

tclk_as_needed — A literal that specifies to use the user_defined `test_clock` when no other option is found in the fanin or fanout cone, or for observe points, when both the fanin and fanout cone connect to multiple clock domains and false or multicycle paths have been defined.

- **-prefer_scan_cells on | off**

An optional switch and literal that controls the search order that is used to identify a scan cell that will be inserted to control or observe a test point. The default is on. The tool will first look for a scan cell, and will only use a non-scan cell if a scan cell is not found. The scan cell can be automatically identified by the tool and reported by “`report_cell_models`” or manually specified by the “`add_cell_models`” command.

When `-prefer_scan_cells` is off, the tool will first look for a non_scan cell, and will use a scan cell only when the “`report_cell_models`” command reports that all available cell models are scan cells.

Note

 Prior to the v2014.4 release, the tool would insert a non-scan cell by default.

Examples

Example 1

The following example uses the “`-observe_point_share`” switch to determine the size of the XOR tree that is generated when the tool merges several observe points together before capturing the value into either a new or existing scan cell. This example XOR’s together no more than 7 observe points before feeding the output of the XOR tree into a scan cell.

```
set_test_point_insertion_options -observe_point_share 7
```

Example 2

The following example specifies the names of enables for control points and observe points respectively. It also specifies that the global clock that was specified with the `set_scan_signals` command ('`test_clk`') is to be used to drive the scan cells for the test points:

```
set_scan_signals -tclk test_clk
...
set_test_point_insertion_options -control_point_enable control_enable
set_test_point_insertion_options -observe_point_enable observe_enable
set_test_point_insertion_options -test_point_clock always_tclk
```

Example 3

The following example generates a maximum of 5000 test points. Then it specifies the names of enables for control points and observe points respectively, and it inserts the test points into the netlist:

```
set_system_mode analysis
set_test_point_analysis -total_number 5000
analyze_test_points
report_test_points
set_test_point_insertion_options -control_point_enable cp_enable \
-observe_point_enable op_enable
insert_test_logic
```

[set_test_point_analysis_options](#)
[set_test_point_types](#)
[write_scan_setup](#)

[set_test_point_types](#)

Context: dft -test_points

Mode: setup

Specifies the type of test points to insert in the design.

Usage

```
set_test_point_types [lbist_test_coverage | edt_pattern_count |  
 {lbist_test_coverage edt_pattern_count}]
```

Description

Specifies the type of test points to insert in the design. If no argument is specified, the default is edt_pattern_count test points.

Arguments

- lbist_test_coverage

An optional switch that specifies that the test points inserted will be for improving random pattern test coverage.

When you specify this switch:

- The tool will perform X-bounding analysis by default. Any node with an Xsource will be assumed to be bounded and therefore will be fully controllable.
- All the faults behind X-bounding logic will be ignored during analysis. Both incremental test coverage and test coverage estimates will be written out before and after test point analysis.
- The targeted pattern counts and test coverage thresholds will be taken into account.
- The default pattern count is 10000 and test coverage is 99.

If you provide a fault list, test point analysis will try to improve ATPG test coverage for the fault list provided. In this case, X-bounding analysis will not be done by default. The default pattern count will be 1000 and default coverage will be 100.

- edt_pattern_count

An optional switch that specifies that the test points inserted will be for reducing deterministic pattern count.

When you specify this switch:

- The tool will not perform X-bounding analysis by default.
- No incremental test coverage and test coverage estimates are written out.
- If a fault list is provided in conjunction with this option, this will be the fault list used to insert the specified number of test points for ATPG pattern count reduction, instead of the full fault list, which may result in non-ideal results.

- **lbist_test_coverage edt_pattern_count**

If you specify both types of test points, the tool identifies test points to reduce both pattern count reduction and improve random pattern testability.

- The tool will not perform X-bounding analysis by default.
- Both incremental test coverage and test coverage estimates will be written out before and after test point analysis.
- The targeted pattern counts and test coverage thresholds will be taken into account.
- If a fault list is provided in conjunction with both these options specified together, this will be the fault list used to insert the specified number of test points for ATPG pattern count reduction and LBIST coverage improvement, instead of the full fault list which may result in non-ideal results. Coverage improvement may not be as good as it could be when using just the **lbist_test_coverage** option alone.
- The default pattern count is 10000 and test coverage is 99.

Examples

The following example sets the test points type for test coverage improvement, performs test point analysis and then reports the test points for your design:

```
set_context dft -test_points -no_rtl
set_test_point_types lbist_test_coverage
set_system_mode analysis
set_test_point_analysis_options -total_number 1000
analyze_test_points
report_test_points
```

[write_scan_setup](#)

[set_test_setup_icall](#)

Context: dft, patterns -scan, patterns -scan_diagnosis, patterns -scan_retargeting

Mode: all modes

Adds an iCall to the end of the test_setup procedure.

Usage

```
set_test_setup_icall {[icl_instance_path.]iproc_name [arguments ...]}  
  [[-merge] -append] {[[-front] | [-end] [-non_retargetable]}}
```

Description

The set_test_setup_icall command adds an iCall to the end of the test_setup procedure.

The command accepts a Tcl list consisting of the three components that normally follow an iCall: the name of the iProc, preceded by the optional ICL instance path and separated by a dot, and one or more optional arguments to the iProc.

If you specify the –append switch, the new iCall is appended to the iCalls in memory. Each iCall with its arguments is called in the order they were appended.

If you issue the command without the -append switch, it overwrites the previous values. To clear the list, assign an empty string or empty list without the -append switch.

The -merge switch provides support for iMerge in the test procedure file. It can only be used if the -append switch is also specified.

If the test_setup procedure contains iCalls, then Tesson Shell infers input constraints on the ports with ICL port function DataInPort. For more details, see the description of the [add_input_constraints](#) command.

To keep the iCalls of the set_test_setup_icall command in the correct order, the iCall can be added to the front, middle, or end list.

The iCalls from the front list will be executed first. The iCalls from the middle list will be executed second. The iCalls from the end list will be executed last.

By default, the targeted list that the new iCall is added to is the middle list, but you can override this default with the following options:

- -front — This option adds the iCall to the front list.
- -end — This option adds the iCall to the end list.

The -append switch adds the iCall to the end of the targeted list. If you add an iCall without using the -append switch, then all the previous iCalls of the targeted list will be cleared. Note: This only clears all the iCalls of the targeted list, not all the iCalls of all three lists. When you

add an iCall with the -merge switch, then this iCall will be merge with the previous iCall on the same targeted list if a previous iCall exists.

Additionally, you can add [report_test_setup_icall](#) and [report_test_end_icall](#) commands to report iCalls configuration in test_setup and test_end procedures.

If you need to clear the test_setup_icall list, specify either quotes ("") or braces ({{}}) as an argument to the set_test_setup_icall command. Both arguments work the same and will clear the list.

Arguments

- {[*icl_instance_path.*]**iProc_name** [*arguments ...*]}

The name of the iProc, preceded by the optional ICL instance path and separated by a dot, and one or more optional arguments to the iProc.

- **-append**

An optional switch that appends the specified list of iCalls to the accumulated list of iCall commands. Note that if you issue the command without the -append switch, the accumulated iCalls are cleared and only the current specified iCall command is stored.
- **-merge**

An optional switch to merge iCall commands together. The -merge option can only be used with the -append switch to merge the specified iCall with the previous iCall. All the merged iCall commands infer the -error_on_conflict option of the [iMerge](#) command and cannot be unspecified.

Refer to “[iMerge Conflict Reporting](#)” in the *Tessent IJTAG User’s Manual* for more information on the -error_on_conflict option.

The merged iCall commands can be specified in the test_setup/test_end procedures using the tessent shell commands [set_test_setup_icall](#)/[set_test_end_icall](#). Later, when you use the tessent shell command [report_procedures](#) (available in analysis mode), the merged iCall commands of the test_setup/test_end procedures will appear as follows:

```
iMerge
    iCall iProcName iProcArgs
    ...
iMerge -end;
```

The -error_on_conflict option is always enabled, so it is not necessary to specify it explicitly.

- **-front**

An optional switch that instructs the tool to add the specified iCall to the first list which will cause it to run first.

- **-end**
An optional switch that instructs the tool to add the specified iCall to the first list which will cause it to execute last.
- **-non_retargetable**
An optional switch that allows adding iCalls that will not be retargeted at the next level. Use this switch to apply the iCall at the current (core) level and so it is not forwarded when the core is embedded in a design. This is especially needed to handle BISR programming when memories are used during scan test.

Examples

Example 1

The following example adds an iCall to the end of the test_setup procedure, then appends and merges a second iCall. The get_test_setup_icall_list command displays the added iCalls.

```
set_test_setup_icall "m8051_m8051_B1_edt_i.setup edt_low_power_shift_en on
                     edt_bypass off"

set_test_setup_icall "m8051_m8051_B2_edt_i.setup edt_low_power_shift_en on
                     edt_bypass off" -append -merge

get_test_setup_icall_list

{m8051_m8051_B1_edt_i.setup edt_low_power_shift_en on edt_bypass off}
{m8051_m8051_B2_edt_i.setup edt_low_power_shift_en on edt_bypass off}
```

Example 2

In the following example, the iCall commands specified using the -merge option in the test_setup file merge iProc2, iProc3 and iProc4 into iProc1:

```
set_test_setup_icall iProc1 -append
set_test_setup_icall iProc2 -append
set_test_setup_icall iProc3 -merge -append
set_test_setup_icall iProc4 -merge -append
```

These commands are equivalent to the sequence of the iCall commands in the test procedure file:

```
Procedure test_setup =
  iCall iProc1;
  iMerge =
    iCall iProc2;
    iCall iProc3;
    iCall iProc4;
  end;
end;
```

Example 3

The following command sequence constructs three lists of iCalls. The report_test_setup_icall command is then used to report all of the existing iCalls that were specified with set_test_setup_icall:

```
set_test_setup_icall userProc_1 -front
set_test_setup_icall userProc_2 -front -append
set_test_setup_icall userProc_3 -append
set_test_setup_icall userProc_4 -append -merge
set_test_setup_icall userProc_5 -append -end
set_test_setup_icall userProc_6 -append -end
set_test_setup_icall toolProc_1 -front -append
set_test_setup_icall toolProc_2 -append
set_test_setup_icall toolProc_3 -append -merge

// first list of iCalls with -front:
// userProc_1
// userProc_2
// toolProc_1

// second list of iCalls without -front and -end
// userProc_3
// userProc_4 -merge
// toolProc_2
// toolProc_3 -merge

// third list of iCalls with -end
// userProc_5
// userProc_6
report_test_setup_icall

iCall userProc_1
iCall userProc_2
iCall toolProc_1
iMerge -begin
    iCall userProc_3
    iCall userProc_4
iMerge -end
iMerge -begin
    iCall toolProc_2
    iCall toolProc_3
iMerge -end
iCall userProc_5
iCall userProc_6
```

set_test_end_icall

set_testbench_simulation_options

Context: unspecified, all contexts

Mode: all modes

Specifies the default values for a set of options that exist in the [run_testbench_simulations](#) command.

Usage

```
set_testbench_simulation_options [-default_simulator {questa | vcs | incisive}]  
[-simulation_output_directory directory]  
[-parallel_simulations {1 | 2...MAX_INT | maxcpu}]  
[-keep_simulation_data {on | off | on_failure}]  
[-store_simulation_waveforms {on | off}]  
[-simulation_timeout {time | unlimited}]  
[-compilation_options option_list]  
[{questa | vcs | incisive} [-simulator_options option_list] ]  
[-simulation_run_commands simulator_commands]  
[-waveform_configuration_commands simulator_commands] ]
```

Description

Specifies the default values for a set of options that exist in the [run_testbench_simulations](#) command.

This command also configures the default value of the `-simulation_output_directory` list of the [check_testbench_simulations](#) command.

Arguments

- `-default_simulator questa | vcs | incisive`
An optional switch and value pair that, when specified, sets the default value for the [run_testbench_simulations](#) option of the same name.
- `-simulation_output_directory simulation_output_directory`
An optional switch and value pair that, when specified, sets the default value for the [run_testbench_simulations](#) option of the same name. It also sets the default value of the [check_testbench_simulations](#) `-simulation_output_directory` list option.
- `-parallel_simulations {1 | 2...MAX_INT | maxcpu}`
An optional switch and value pair that, when specified, sets the default value for the [run_testbench_simulations](#) option of the same name. *MAX_INT* is the maximum integer value that the host machine allows. The *maxcpu* literal specifies using all available CPUs on the host machine.
- `-keep_simulation_data on | off | on_failure`
An optional switch and value pair that, when specified, sets the default value for the [run_testbench_simulations](#) option of the same name.

- **-store_simulation_waveforms on | off**

An optional switch and value pair that, when specified, sets the default value for the [run_testbench_simulations](#) option of the same name.

- **-simulation_timeout time | unlimited**

An optional switch and value pair that, when specified, sets the default value for the [run_testbench_simulations](#) option of the same name.

- **-compilation_options *option_list***

An optional switch and value pair that specifies a list of compilation options (for example, +initreg) that modify the compilation script during runtime. The *option_list* uses the following syntax:

```
-compilation_options {[global_options] [verilog verilog_options] [vhdl {vhdl_options}]}
```

- The verilog options are passed only to the command that compiles Verilog source files.
- The vhdl options are be passed only to the command that compiles the VHDL source files.
- The *global_options* can also be expressed as “global {*global_options*}”.

The braces are mandatory in order to identify the options preceded by the language or “global”.

See [Example 4](#).

- **questa | vcs | incisive**

A simulator literal that allows you to specify default values for options that pertain to the specified simulator.

- **-simulator_options {-timescale *value* ...}**

An optional simulator-specific switch and value pair that, when specified, sets the default value for the [run_testbench_simulations](#) option of the same name. This can only be specified with one simulator literal.

The -timescale *value* option overrides the default timescale for a specific simulator for the following default values:

- incisive — Default timescale is 1ns/1ps

- **-simulation_run_commands *simulator_commands***

An optional simulator-specific switch and value pair that, when specified, sets the default value for the [run_testbench_simulations](#) option of the same name. This can only be specified with one simulator literal.

- **-waveform_configuration_commands simulator_command_list**

An optional simulator-specific switch and value pair that, when specified, sets the default value for the [run_testbench_simulations](#) option of the same name. This can only be specified with one simulator literal.

Examples

Example 1

The following command sets the default value of the run_testbench_simulation -keep_simulation_data option to on. It demonstrates using a simulator-independent option.

```
set_testbench_simulation_options -keep_simulation_data on
```

Example 2

The following command sets the default value of the run_testbench_simulation -simulator_options passing the simulator-specific option of -novopt. This is a simulator-specific option so the simulator literal (questa) is specified. The options take effect when you use run_testbench_simulations -simulator questa, or when the default simulator is questa and you specify run_testbench_simulations without the “-simulator” argument.

```
set_testbench_simulation_options questa -simulator_options {-novopt}
```

Example 3

In the following example, the options take effect when you use run_testbench_simulations -simulator incisive, or when the default simulator is incisive and you specify run_testbench_simulations without the “-simulator” argument.

```
set_testbench_simulation_options incisive -simulator_options \  
 {+nctimescale+1ns/100ps +access+rwc+nowarn+CUVWSP +nowarn+CUVWSI  
 +nowarn+CUVWSP}
```

Example 4

The following example demonstrates using the -compilation_options switch. In this example, the [run_testbench_simulations](#) command uses the vcs simulator and the -compilation_options value is set by the [set_testbench_simulation_options](#) command.

```
set_testbench_simulation_options vcs \  
 -compilation_options { global { -kdb } vhdl { -skip_translate_body }  
 verilog { -timescale=1ns/1ps } } -default_simulator vcs  
  
run_testbench_simulations
```

set_tied_signals

Context: all contexts

Mode: setup

Changes the default value for floating pins and floating nets which do not have assigned values.

Usage

`set_tied_signals X | 1 | 0 | Z`

Description

Changes the default value for floating pins and floating nets which do not have assigned values.

The `set_tied_signals` command specifies the default value that the tool ties to all floating nets and floating pins that you do not specify with the `add_tied_signals` command. Upon invocation of the tool, if you do not assign a specific value, the tool assumes the default value is unknown (X).

If the model is already flattened and then you use this command, you must delete and recreate the flat model.

Arguments

- **X**
A literal that ties the floating nets or pins to unknown. This is the default upon invocation of the tool.
- **0**
A literal that ties the floating nets or pins to logic 0 (low to ground).
- **1**
A literal that ties the floating nets or pins to logic 1 (high to voltage source).
- **Z**
A literal that ties the floating nets or pins to high-impedance.

Examples

The following example ties floating net vcc to logic 1, ties the remaining unspecified floating nets and pins to logic 0, then performs an ATPG run:

```
set_tied_signals 0
add_tied_signals 1 vcc
set_system_mode analysis
create_patterns
```

[delete_tied_signals](#)

[report_tied_signals](#)

set_timing_exceptions_handling

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Changes the default handling of timing exception paths (false paths and multicycle paths) read by the [read_sdc](#) command.

Usage

```
set_timing_exceptions_handling [ON | OFF] [-CLOCK_groups {ON | OFF}]
[-ADD_Hold_time_when_no_settings_in_sdc {ON | OFF}] [-LIne_no {ON | OFF}]
[-SETUp {ON | OFF}]
[-MAX_Skew {HALf_cycle | ONE_cycle | MULtiple_cycles}]
[-APPLY_Clock_scaling {WIthin_each_source_clock | ACross_all_source_clocks | OFF}]
[-DERIVE_Fault_detection_cycles_from_SDC_generated_clocks {ON | OFF}]
[-X_Statistics {ON | OFF}]
[-SLOW_Cycle_mask {ON | OFF}]
[-ALLOW_Invalid_pin_names {ON | OFF}]
[-MERGE_compatible_paths {ON | OFF}]
```

Description

Changes the default handling of timing exception paths (false paths and multicycle paths) read by the [read_sdc](#) command.

When you issue the `set_timing_exceptions_handling` command without options, the command reports the current settings.

Arguments

- **ON | OFF**
A literal that enables or disables handling of timing exceptions on false paths and multicycle paths. This capability is enabled by default upon invocation of the tool. Turning off this switch is useful for debugging low coverage or simulation mismatch because you can quickly verify if the masking values or test coverage loss is due to timing exceptions. Turning off this switch can result in pattern mismatches, so you should not turn off this switch other than for debugging purposes.
- **-CLOCK_groups {ON | OFF}**
A switch and literal pair that allows you to change the clock groups handling in SDC. By default, the tool expands timing exceptions for the clocks in asynchronous clock groups as both setup and hold timing exceptions only when the clocks can be pulsed by ATPG concurrently. If you are not generating any patterns that could pulse asynchronous clocks concurrently during ATPG for the ones defined in the SDC files, you can disable this path expansion by specifying OFF.

If -clock_groups -on is used and there are already false paths derived from existing clock groups, the following message will be reported:

```
// Warning: The clock groups have been expanded into false paths.  
You must delete SDC to remove false paths derived from clock groups.
```

To avoid this issue, use the “set_timing_exceptions_handling -clock_groups -off” command prior to running read_sdc.

- **-ADD_Hold_time_when_no_settings_in_sdc {ON | OFF}**

A switch and literal pair that allows you to treat the timing exceptions to include both setup and hold-time violations when the SDC files specifies neither -setup nor -hold. By default, the tool matches the SDC file used by your static timing analyzer, which is useful if your design must include hold timing exceptions during stuck-at ATPG. When you turn off this switch, the tool assumes that all false paths without -setup or -hold options have only setup timing exceptions.

[Table 6-20](#) further explains how the tool treats timing exception paths based on the setting in the SDC file and the -ADD_Hold_time_when_no_settings_in_sdc switch.

Table 6-20. SDC File and -ADD_Hold_time_when_no_settings_in_sdc switch

SDC file switches	Default tool behavior	Tool behavior with switch OFF
none	setup & hold	setup *
-setup	setup	setup
-hold	hold	hold
-setup -hold	setup & hold	setup & hold

* True unless the timing exception path is added across clock domains, in which case the path is treated as both setup & hold. As an example, the following SDC commands are equivalent:

```
set_false_path -from {get_clocks {CLK1}} -to {get_clocks {CLK2}}
set_false_path -from {get_clocks {CLK1}} -to {get_clocks {CLK2}} -setup -hold
```

- **-LIne_no {ON | OFF}**

An optional switch and literal pair that allows you to turn on reporting of SDC filename and line numbers for timing violations when using the [report_false_paths](#) or the [report_multicycle_paths](#) command. By default, the tool does not report the SDC filename and line numbers.

- **-SETUp {ON | OFF}**

An optional switch and literal pair that disables setup time simulation without having to modify the SDC file. By default, setup time simulation is enabled.

Note that the tool automatically reclassifies AU faults when you change this option, so there is no need to issue a “reset_au_faults -reclassify” command.

- **-MAX_Skew**

An optional switch that specifies the maximum clock skew allowed when simulating the hold time exception. This option impacts the masking effect of most hold time exceptions defined using either the add_false_path command or the hold time exceptions from read_sdc. This option does not impact false paths added with the “add_false_paths -cross_clock_domains” command and the false paths derived from the asynchronous clock groups in SDC files.

HALf_cycle

Specifies half cycle as the maximum clock skew. This is the default value for this option, unless -cross_clock_domains is specified, in which case, the max skew is multiple cycle.

ONE_cycle

Specifies one cycle as the maximum clock skew.

MULtiple_cycles

Specifies multiple cycles as the maximum clock skew.

- **-APPLY_Clock_scaling {WIthin_each_source_clock | ACross_all_source_clocks | OFF}**

An optional switch and literal pair that specifies the behavior of multicycle path (MCP) cycle scaling.

The following text explains the concept of cycle scaling. For synchronous clock domains with different frequencies (either within each source clock or across all source clocks), the tool scales the clocks according to their frequency information provided in the SDC file. In cases when the driving clock of a multicycle path has a different frequency source clock, this switch defines how the tool should determine their relationship. For example, consider a multicycle path with 2 cycles defined with -end in the SDC file. If the frequency of the endpoint driving clock is twice as slow as its source clock, the tool scales the clocking so that the path is treated as a multicycle path with 4 cycles.

This switch has the following options:

WIthin_each_source_clock — Applies the cycle scaling only for the generated clocks defined in SDC using the create_generated_clock command with the same source clock. Treats different source clocks independently, and treats all generated clocks with the same source clock as synchronous clocks. This is the default.

ACross_all_source_clocks — Applies the cycle scaling across all source clocks. This option is applicable when treating all source clocks as synchronous.

OFF — Does not apply the cycle scaling, so the tool uses the cycle count as defined in SDC set_multicycle_path commands.

- **-DERIVE_Fault_detection_cycles_from_SDC_generated_clocks {ON | OFF}**

An optional switch and literal pair that allows the tool to ignore SDC-generated clocks from which to derive the fault detection cycles. By default, the tool allows ATPG and the fault simulator to consider the transition faults in slower clock domains to be detected with multiple activation cycles without needing to define multicycle paths. For example, if a

transition fault is on a divide-by-2 clock domain, the fault can be activated for up to 2 cycles before capture. The switch default is ON, which instructs ATPG and the fault simulator to consider the transition faults activated up to n cycles for divide-by- n clock domains unless explicitly specified using multicycle paths. Note that the tool takes into account the SDC command “create_generated_clock -divide_by” but only in the absence of the -multiply_by switch. The SDC command “create_generated_clock -multiply_by” is unsupported.

Tip

 You can use the [report_clocks](#) command to list all of the SDC-defined clocks.

- **-X_Statistics {ON | OFF}**

An optional switch and literal pair that enables the tool to collect statistics on masking that result from timing exceptions when running the [create_patterns](#) or [simulate_patterns](#) commands. When you enable this option before pattern generation or simulation, the tool collects statistics about the number of Xs captured into each to-point of timing exception paths. This option is useful to identify the timing exception paths with the most masking effect that could impact the test coverage. Collection of masking statistics is disabled by default. For an example of using this switch, refer to “[Example 7](#)” on page 1544.

- **-SLOW_Cycle_mask {ON | OFF}**

An optional switch and literal pair that specifies that the slow cycles defined in named capture procedure are treated as at-speed cycles and to apply all timing exceptions during pattern simulation. By default, the slow cycles are not considered as at-speed cycles and setup timing exceptions are not considered.

- **-ALLOW_Invalid_pin_names {ON | OFF}**

An optional switch and literal pair that specifies how the tool reports undefined SDC command objects. When set to on, the [read_sdc](#) and [add_false_paths](#) commands will report warnings when defined objects are not found. The default is off, indicating that the commands will issue error messages.

- **-MERGE_compatible_paths {ON | OFF}**

An optional switch and literal pair that specifies whether or not the tool merges compatible false paths. To enhance performance in static false path analysis and dynamic false path simulation, by default (the switch set to ON) the tool merges simple, compatible false paths into a single path.

The tool can only merge false paths if they are error free, if they have exactly the same “setup time” and/or “hold time” properties, and they meet any of these criteria:

- All the false paths that contain from-points only, and no through-points, to-points or any other conditions can be merged into a single false paths that combines all the from-points.
- All the false paths that contain to-points, and no from-points, through-points, or any other conditions, can be merged into a single false path that combines all the to-points.

- All the false paths that contain one-level through points only, and no from-points, to-points, or any other conditions can be merged into a single false path that combines all the through-points.

By default the tool merges compatible false paths and issues a summary message. For example:

```
// Note: N false paths have been merged into M paths to speed up
      timing exception analysis.
//       To disable merging for debug, you may invoke
      'set_timing_exceptions_handling -merge_compatible_paths
       off'.
```

When reporting false paths, the tool reports the merged paths and includes their original paths, as annotated with the “|+” symbol. For example:

```
// command: report_false_paths
// False path -from clk4 -through /u7 -setup (id=0)
// False path -from clk5 -through /u8 -setup (id=1)
// False Path -from clk1 clk2 clk3 -setup -hold (id=2) (merged)
// |+ False Path -from clk1 -setup -hold
// |+ False Path -from clk2 -setup -hold
// |+ False Path -from clk3 -setup -hold
```

You cannot add or delete merged paths directly. You can only add or delete the original paths and allow the tool to re-merge them. All the original false paths are preserved in the flat model. You can disable this feature by using the -off option for this switch.

Also, when you invoke switches such as “`set_timing_exceptions_handling -x_statistics on`”, the tool assumes you are debugging based upon original paths and will turn off the “`merge_compatible_paths`” feature, unless you specify it as on in the same command line.

Examples

Example 1

The following example specifies that the tool not expand timing exception paths for the clocks in asynchronous clock groups as both setup and hold timing exception paths.

`set_timing_exceptions_handling -clock_groups off`

Example 2

The following example shows how to specify reporting of SDC filename and line numbers for timing violations:

```
set_timing_exceptions_handling -line_no on
read_sdc timing.sdc
report_false_paths
```

```
// False Path -from_clock cmem_fclk1 cmem_fclk1n -to_clock p_clk
spm_pci_clk -setup (filename = \
    timing.sdc, line 406)
// False Path -from_clock p_clk spm_pci_clk -to_clock cmem_fclk1
cmem_fclk1n -setup (filename = \
    timing.sdc, line 408)
...
// Total reported false paths = 177
```

Example 3

This example shows how to specify reporting merged false paths:

```
set_timing_exceptions_handling -merge_compatible_paths on
report_false_paths -all

// Note: 2 false paths have been merged into 1
// path to speed up timing exception analysis.
// To disable merging for debug, you may invoke
// 'set_timing_exceptions_handling -merge_compatible_paths off'.

// False Path -from_clock U1/CP U2/CP -setup -hold
// False Path -from_clock U3/CP -to U8/CP -hold
// False Path -from nclk6 -setup -hold
// False Path -through G7/B G3/A nclk7 G3/A -setup -hold (merged)
// |+ False Path -through G7/B G3/A -setup -hold
// |+ False Path -through nclk7 G3/A -setup -hold
```

[set_tla_loop_handling](#)

Context: all contexts

Mode: setup

Specifies how to simulate feedback loops that contain transparent latches (TLAs).

Usage

`set_tla_loop_handling [ON | OFF]`

Description

Specifies how to simulate feedback loops that contain transparent latches (TLAs).

By default, TLAs in feedback loops are simulated using the same iterative algorithm used to simulate loops through combinational logic. This can increase test coverage; however, it requires feedback loop analysis to be performed whenever DRC is run, which may result in a slightly longer DRC run time. When this command is disabled, feedback loop analysis is performed only after flattening; however, TLAs that are in feedback loops are treated as TIEX gates during simulation, which can reduce test coverage.

Note

 Be aware that extra processing time is required to support loop simulation through TLAs. In some circumstances, the improved fault detection yields sufficient reduction in ATPG effort that overall runtimes decrease, but you should anticipate an increase in runtimes in most cases.

Any TLA that is in a feedback loop is treated as a place to break the loop (similar to the FB buffer gate used for combinational loops). Strongly connected sets of gates are identified as feedback networks. You can display feedback networks by using the [report_feedback_paths](#) command.

You can use the -Environment switch of the [write_patterns](#) command to save the value of the -Iteration switch. You can use the [report_environment](#) command to see the current value of the `set_tla_loop_handling` command.

Arguments

- [ON](#)
An optional literal that enables TLA loop simulation. This is the default.
- [OFF](#)
An optional literal that disables TLA loop simulation.

[set_loop_handling](#)

set_tool_options

Context: all contexts

Mode: all modes

Sets certain options for Tessent Shell.

Usage

```
set_tool_options [-reapply_settings_after_reelaboration {on | off}]  
                  [-allow_vhdl_2008 {on | off}]  
                  [-instantiate_unconnected_pins_in_written_design {on | off}]
```

Description

This command sets certain options in Tessent Shell.

Arguments

- **-reapply_settings_after_reelaboration on | off**

When using [set_current_design](#) on the current design again the design will be re-elaborated.

When this setting is set to “on” Tessent Shell will preserve certain settings, if possible.

These are the settings done with the following commands:

- [add_clocks](#)
- [add_black_boxes](#)
- [add_output_masks](#)
- [add_primary_inputs](#)
- [add_primary_outputs](#)
- [add_input_constraints](#)
- [add_tied_signals](#)
- [set_output_masks](#)

Note that all settings are removed independent of this setting if you set a different current design.

- **-allow_vhdl_2008 on | off**

VHDL 2008 has a different set of IEEE STD packages compared to previous VHDL formats. You must specify to Tessent Shell if any blocks contain VHDL 2008 constructs in order to load 2008 packages. This has to be done before issuing any [read_verilog/read_vhdl](#) commands.

- **-instantiate_unconnected_pins_in_written_design on | off**

An optional switch and Boolean that specifies how the tool instantiates unconnected pins. The default is on, meaning that the tool instantiates pins even if they have no connection.

When this switch is set to off and the tool is in -no_rtl mode, the unconnected pins are not used in the following:

- Read in instances
- Created instances
- For additional pins that are created by a [replace_instances](#) command

When this switch is set to off and the tool is in -rtl mode, the unconnected pins are not used in the following:

- Created instances
- For additional pins that are created by a [replace_instances](#) command

In -rtl mode, read in instances are not changed because of format preservation.

Related Topics

[get_tool_option](#)

[set_tcl_shell_options](#)

set_trace_flat_model_options

Context: all contexts

Mode: setup, analysis

Modifies the default behavior of the trace_flat_model command.

Usage

```
set_trace_flat_model_options [-tag_condition tag_attribute_expression]
    [-stop_condition stop_attribute_expression]
    [-controllability {controlling | constant | unblocked | connected}]
    [-stop_at_first_tag {ON | OFF}] [-max_levels {unlimited | number}]
    [-latch {normal | transparent}] [-map_tag_to_design_module_boundary {ON | OFF}]
```

Description

Modifies the default behavior of the [trace_flat_model](#) command.

This command sets options as global defaults. These defaults will always be applied if they are not specified in the current trace_flat_model execution.

This command removes the requirement for you to repeatedly specify trace configuration information for each call to the trace_flat_model command.

Arguments

- **-tag_condition *tag_attribute_expression***

An optional switch and string pair that specifies the tag condition for the trace. All of the reached design objects fulfilling the defined tag condition are returned. The default is an empty string; in this case, the trace stop points are returned. In a non-default case, the trace stop points are not returned if the tag condition expression is not true for these objects. The format for the *tag_attribute_expression* is identical to the -filter option used for the [get_pins](#) command.

- **-stop_condition *stop_attribute_expression***

An optional switch and string pair that defines the stop condition for the trace. The default is an empty string; in this case, the trace is stopped at the gate_pin failing the specified controllability requirements. The pins of memory or dff primitives are always stop points even when not explicitly specified.

- **-controllability {controlling | constant | unblocked | connected}**

An optional switch and literal pair that defines the controllability requirements before traversing a gate.

controlling—Gates are only traversed if the other inputs have simulated constant values making a single input directly controlling the output without an inversion,

constant—Only pins with a constant value are traversed. This mode is useful to find the source of a constant value.

unblocked—Gates are only traversed if the other inputs do not have simulated constant values making the input blocked from the output pin. Only unblocked combinational paths are traversed.

connected—With this value, gates are always traversed when reached.

- **-stop_at_first_tag {ON | OFF}**

An optional switch and literal pair that specifies whether to interrupt tracing when the first tag object with the specified controllability is found. This is useful when checking for at least one occurrence of a given condition in the fanin or fanout of a pin without wasting time to find them all.

- **max_levels {unlimited | number}**

An optional switch and value pair that defines the maximum level of gates to trace. The default is unlimited but you can specify a positive integer to limit the level count.

- **-latch {normal| transparent}**

An optional switch and literal pair that specifies the behavior of tracing through a latch.

normal—A latch is traced through only if the simulated value in the current simulation context makes the latch satisfy the specified controllability requirements. In case of “-controllability connected” all latch input pins - including the latch enable pin - are traced through.

transparent—All latches are traced through the data input, set and reset pins regardless of the value at the latch enable pin. The latch enable pin is not traced through.

- **-map_tag_to_design_module_boundary {ON | OFF}**

An optional switch and literal pair that specifies whether to map the tag points to gate_pins outside of library cells. When this switch is ON, the trace_flat_model command maps the tag points to gate_pins outside of library cells and never inside the cells. Library cells can be either cells from a Tessent Cell library or `celldesign Verilog modules.

Examples

The following example script shows how the set_trace_flat_model_options command uses attribute expressions to constrain the trace for level 1 clock gaters.

```
set stop_condition_expr " (isClockGater == true) || (isRegister == true) "
set tag_condition_expr "isClockGater == true"

set_trace_flat_model_options -tag_condition ${tag_condition_expr} \
    -stop_condition ${stop_condition_expr}
foreach_in_collection pin [all_clocks] {
    set CGs [trace_flat_model -from $pin -direction forward]
    if {[sizeof_collection $CGs] > 0} {
        puts "Level1 clock gaters for clock ${pin} are:"
        foreach_in_collection CG ${CGs} {
            puts " ${CG}"
        }
    }
}
}
```

set_trace_report

Context: dft -edt, dft -scan, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup, analysis

Specifies whether the tool displays gates in the scan chain trace.

Usage

`set_trace_report OFF | ON`

Description

Specifies whether the tool displays gates in the scan chain trace.

The `set_trace_report` command controls whether the tool displays all of the gates in the scan chain trace during rules checking.

Arguments

- **OFF**
A literal that specifies for the tool not to display gates in the scan chain trace. This is the default behavior upon invocation of the tool.
- **ON**
A literal that specifies for the tool to display gates in the scan chain trace during rules checking.

Examples

Example 1

The following example displays the gates in the scan chain trace during rules checking:

```
add_scan_groups group1 scanfile
add_scan_chains chain1 group1 indata2 outdata4
set_trace_report on
set_system_mode analysis
```

Example 2

The following example displays the gates in the scan chain trace during rules checking:

```
add_clocks 0 clock
add_scan_groups group1 scanfile
add_scan_chains chain1 group1 indata2 outdata4
set_trace_report on
set_system_mode analysis
```

Related Topics

[add_scan_chains](#)
[report_scan_chains](#)

[set_transcript_style](#)

Context: unspecified, all contexts

Mode: all modes

Specifies the style in which the tool transcripts commands.

Usage

```
set_transcript_style {off | full | tool_commands_only | input_only}  
    [-result_collection_limit {unlimited | limit}]  
    [-argument_collection_limit {unlimited | limit}]  
    [-one_collection_entry_per_line {on | off}]
```

Description

Specifies the style in which the tool transcripts commands.

Arguments

- **off**

A keyword that turns off all command transcription so that the commands run as though included using the Tcl “source” command. This option allows you to execute scripts that do not echo the tool commands, which can be helpful running scripts that use the report commands as required for introspection.

- **full**

A keyword that transcribes all commands read from a dofile before any Tcl evaluation is done. This includes all Tcl commands and constructs.

Since the command interpreter accumulates input until receiving a complete Tcl command before sending to Tcl for evaluation, entire if/else, for, and foreach constructs will transcript as a single item. In addition, when non-introspection tool commands are embedded within another command, they transcript as they are about to execute. (Introspection commands are commands that simply return information about the design or tool state and therefore have no effect on operation of the tool. Tool commands included within the catch_output command are also considered introspection commands since they do not write to the transcript.)

As in a standard Tcl shell, any result returned from each top-level Tcl command transcripts when you run the tool in interactive mode. In batch mode, this option does not transcript command results.

- **tool_commands_only**

A keyword that transcribes tool commands, including all arguments, as the commands execute. The command string is transcribed after being evaluated by Tcl so all variable and command references are resolved. For commands in a loop or if/else construct, the tool transcripts each execution of each command plus any output produced so that the context is evident.

This option does not transcript Tcl flow control constructs, pure Tcl commands, and introspection commands nor their results. This option essentially specifies the legacy behavior of the tools.

- **input_only**

A keyword that transcripts all input from the dofile (both Tcl and tool commands) before sending to Tcl for evaluation. Since the command interpreter accumulates input until receiving a complete Tcl command before sending to Tcl for evaluation, entire if/else, for, and foreach constructs transcript as a single item. Embedded tool commands are not transcribed again when they execute.

- **-result_collection_limit** unlimited | *limit*

A switch and string or integer pair that specifies number of collection entries show in the interactive mode when a collection is returned. The default is 50.

- **-argument_collection_limit** unlimited | *limit*

A switch and string or integer pair that specifies the number of collection entries show in the listing when a collection is passed to a command as an argument. The default is 1.

- **-one_collection_entry_per_line** on | off

A switch and literal pair that show the collections on arguments and results with one entry per line. The default is off.

Examples

The following example consists of a dofile and the transcription results of the various style options.

Dofile:

```
set foo 2
set myclk(1) CLK1
set myclk(2) CLK2
set pfile mytest.proc
if { $foo == 2 } {
    add_clocks 0 $myclk(1)
    add_clocks 0 $myclk(2)
}
add_scan_groups g1 $pfile
```

Full-style transcript:

```
// command: set foo 2
// command: set myclk(1) CLK1
// command: set myclk(2) CLK2
// command: set pfile mytest.proc
// command: if { $foo == 2 } {
//             add_clocks 0 $myclk(1)
//             add_clocks 0 $myclk(2)
//         }
// sub-command: add_clocks 0 CLK1
// sub-command: add_clocks 0 CLK2
// command: add_scan_groups g1 $pfile
```

Tool_commands_only-style transcript:

```
// command: add_clocks 0 CLK1
// command: add_clocks 0 CLK2
// command: add_scan_groups g1 mytest.proc
```

Input_only-style transcript:

```
// command: set foo 2
// command: set myclk(1) CLK1
// command: set myclk(2) CLK2
// command: set pfile mytest.proc
// command: if { $foo == 2 } {
//           add_clocks 0 $myclk(1)
//           add_clocks 0 $myclk(2)
//         }
// command: add_scan_groups g1 $pfile
```

[no_transcript](#)

[set_logfile_handling](#)

set_transient_detection

Context: dft -edt, dft -scan, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis (dft -scan context only)

Specifies whether the tool detects all zero width events on the clock lines of state elements.

Usage

`set_transient_detection Off | {ON [-Verbose | -NOVerbose]}`

Description

Specifies whether the tool detects all zero width events on the clock lines of state elements.

The `set_transient_detection` command sets the simulator to detect all zero width events on the clock lines of state elements. If the zero width event causes a change of state in the state element, the tool sets that state element to X.

If Off is specified, DRC simulation treats all events on state elements as valid. Because the simulator is a zero-delay simulator, it is possible for DRC to simulate zero width, monostable circuits with ideal behavior which is rarely matched in silicon. The resulting zero width output pulse from the monostable circuit is also treated as a valid clocking event for other state elements.

Arguments

- **Off**

A literal that specifies for the tool to set transient detection off.

Caution

 This argument is only for special cases where you understand the potential hazards from transients on the clock lines and know how to handle them. Turning transient detection off without taking care of the hazards can result in bad patterns that mismatch when verified in a timing based simulator. Be sure you understand the consequences and are willing to accept the risks before turning transient detection off.

- **ON**

A literal that specifies for the tool to set transient detection on. This is the invocation default.

- **-Verbose**

An optional switch that specifies for the tool to display a message identifying each time a state element is set to X due to transient detection. This is the invocation default and is valid only when transient detection is enabled.

- **-NOVerbose**

An optional switch which specifies for the tool *not* to display a message identifying each time a state element is set to X due to transient detection. This switch is valid only when transient detection is enabled.

Examples

Transient detection is enabled in verbose mode by default. Unless you use the **set_transient_detection** command to modify the default, you will see a message similar to the following for each transition that is caused by a transient, or zero-width, pulse:

```
// Warning: 0 width pulse detected on pin 2 of  
/my_design/my_inst/my_latch/ (463228) in procedure my_procedure at time 0.
```

You can eliminate these messages, while retaining the advantages of transient detection, by issuing this command:

set_transient_detection on -noverbose

Or you can disable transient detection, causing DRC simulation to treat all events on state elements as valid.

set_transient_detection off

set_transition_holdpi

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies for the tool to freeze all primary input values other than clocks and RAM controls during multiple cycles of pattern generation.

Usage

set_transition_holdpi ON | OFF

Description

Specifies for the tool to freeze all primary input values other than clocks and RAM controls during multiple cycles of pattern generation.

The **set_transition_holdpi** command lets you turn this feature on while the fault type is in “transition”. This is useful in cases where it is not practical to maintain high data rates to the primary input pins of the device under test on a tester. Primary inputs may still change from pattern to pattern however.

Note

 Because launch off shift transition patterns require the scan enable signal (which is not a clock or RAM control) to transition within a single pattern, the tools ignore this command when generating this type of pattern.

Arguments

- **ON**

A literal that specifies for the tool to hold all primary input values (other than clocks and RAM controls) during multiple cycles of pattern generation.

- **OFF**

A literal that specifies for the tool not to hold all primary input values. This is the invocation default.

Examples

The following example holds all primary input values.

```
set_transition_holdpi on
```

Related Topics

[report_primary_inputs](#)

[set_pathdelay_holdpi](#)

[set_tristate_gating](#)

Context: dft -scan, dft -test_points

Mode: setup

Specifies how tri-state devices are controlled during scan chain shifting.

Usage

```
set_tristate_gating {OFF | ON | Busdrivers | Scan | primary_input_or_output...}  
[-Control {SEN | TEn}] [-Force_gating]
```

Description

Specifies how tri-state devices are controlled during scan chain shifting.

The set_tristate_gating command ensures tri-state devices are controlled to either prevent bus contention or be turned on during testing. If the necessary test logic already exists, none is inserted.

When enabled, test logic is inserted that controls tri-state devices as follows:

- **Multiple tri-state gates driving nets (bus net)** — One gate is turned on and the rest are turned off during testing.
- **Single tri-state gates driving nets (primary net or an internal net)** — All single tri-state gates are turned on for testing.

You can also specify which signal (SEN or TEN) controls the enable lines of tri-state devices.

By default, when the enable signal of a tri-state device is directly controlled by a primary input, by TIE0, or by TIE1, no gating is necessary and a force statement for the primary input is added to the load_unload procedure in the new procedure file. This behavior can be overridden by using the -Force_gating switch.

Arguments

- {**OFF** | **ON**| **Busdrivers**| **Scan**| *primary_input_or_output...*}

Required literal or repeatable string that specifies which tri-state devices to control during scan shifting. The default setting is off. Options include:

OFF — no test logic is inserted to control tri-state devices. Default setting.

ON — test logic is inserted when necessary to control all tri-state devices.

Busdrivers — test logic is inserted to control tri-state devices driving bus nets.

Scan — test logic is inserted to control tri-state devices used as scan inputs/outputs.

primary_input_or_output — specifies a primary input or output pin. Test logic is inserted to control the tri-state devices driving the specified primary output pin(s) or driven by the specified primary input pin(s).

- -Control SEn | TEn

An optional switch and literal pair that specifies the enable signal used to control tri-state devices. Literal options include:

SEn — Specifies the scan_enable signal. Default setting.

TEn — Specifies the test_enable signal.

- -Force_gating

An optional switch that adds test logic to the enable lines of tri-states devices when these lines are directly controlled by primary inputs, or by TIE1, or by TIE0. When the enable line is directly controlled by a primary input, the tool adds the force statement for this primary input to the load_unload procedure in the procedure file.

Examples

Example 1

The following example uses the set_tristate_gating command to insert test logic and make all tri-state devices driving bus nets controllable via the SEN signal.

```
add_clocks 0 clk
set_tristate_gating on
set_bidi_gating scan
set_system_mode analysis
add_scan_mode unwrapped -si_connections c1 bidi_in1/X \
    -so_connections blkB1/blkA/utri2/A
analyze_scan_chains
```

[set_bidi_gating](#)

[set_test_logic](#)

set_tsdb_output_directory

Context: unspecified, dft, patterns

Mode: setup

Sets the TSDB output directory used by the process_dft_specification command.

Usage

```
set_tsdb_output_directory directory_path
```

Description

Sets the TSDB output directory used by the [process_dft_specification](#) command.

The TSDB output directory defaults to `./tsdb_outdir` until the `set_tsdb_output_directory` command has been invoked. When either the `get_tsdb_output_directory` or `set_tsdb_output_directory` command is invoked, the tool verifies that the specified path is a writable directory if it already exists, or that the parent directory is a writable directory if it does not.

The `process_dft_specification` command is currently the only command that makes use of the TSDB directory.

Arguments

- *directory_path*

A required string value used to specify the TSDB output directory which is populated by commands such as `process_dft_specification`. The specified `directory_path` can be a relative path with respect to the current working directory or an absolute path. In either case, the directory must be a writable directory when it exists, or the effective parent directory where it is to be created must be a writable directory. The `set_tsdb_output_directory` command does not create the directory; it is created the first time a command needs to store information into it such as when the `process_dft_specification` command is invoked.

Examples

Example 1

The following example set the TSDB output directory to `“./dir1”`.

```
set_tsdb_output_directory dir1
```

Example 2

The following example shows a possible error than can be generated when setting the TSDB output directory.

```
set_tsdb_output_directory dir2/dir1
```

```
// Error: The parent directory of the specified tsdb_output_directory '/  
home/user1/dir2' does not exist.
```

Related Topics

[process_dft_specification](#)
[get_tsdb_output_directory](#)

[set_visualizer_logging](#)

Context: unspecified, all contexts

Mode: setup, analysis

Writes the commands entered into the Transcript window to the file specified by the *enhanced_dofile* argument.

Usage

```
set_visualizer_logging {{-STArt enhanced_dofile [-Replace | -Append]} | -STOp}
```

Description

Writes the commands entered into the Transcript window to the file specified by the *enhanced_dofile* argument.

Because only executable commands are written to *enhanced_dofile*, you can use the file like a normal dofile to recreate a previous view in DFTVisualizer.

Arguments

- **-Start**

A required argument that specifies to begin writing each command that is entered into the Transcript window to the *enhanced_dofile* file.

- ***enhanced_dofile***

A required string that specifies the name of the file into which you want to write the commands entered into the Transcript window. Only executable commands are written to this file.

- **-Replace**

An optional switch that specifies to replace the contents of *enhanced_dofile* if that file already exists.

- **-Append**

An optional argument that specifies to add the output of the logging operation to the *enhanced_dofile* file.

- **-Stop**

A required argument that specifies to stop writing commands to the *enhanced_dofile* file.

Examples

The following example unselects an object identified by its instance name:

```
set_visualizer_logging -start my_logfile
```

Related Topics

[open_visualizer](#)

set_visualizer_preferences

Context: unspecified, all contexts

Mode: setup, analysis

Controls a subset of DFTVisualizer preferences for the Flat Schematic and Hierarchical Schematic windows.

Usage

```
set_visualizer_preferences [-Compact | -NOCompact] [-NOQuery  
| -Query threshold_number] [-Split | -NOSplit] [-Display {FLAt_schematic |  
HIEarchical_schematic | ALL}]
```

Description

Controls a subset of DFTVisualizer preferences for the Flat and Hierarchical Schematic windows.

This command controls the following three aspects of DFTVisualizer schematic display behavior:

- Display of gates
- Whether the tool will query you for confirmation before beginning to process data to display a large schematic
- Display of schematics in multiple sheets

There are invocation defaults for all the settings. When you use this command to change any of the settings, the specified preferences (along with any window displays affected by the settings) are updated immediately.

Arguments

- -Compact

A switch that specifies to display only gates that could have a logical impact on the output results. This is the invocation default behavior.

This switch is supported in the Flat Schematic window only.

- -NOCompact

A switch that specifies to display all netlist gates, including buffers, inverters, ZVAL, and single-input bus gates. Many of these types of gates may not affect the logical output results, yet tend to clutter the display. The clutter is most noticeable when the gate level is set to primitive (set_gate_level Primitive).

This switch is supported in the Flat Schematic window only.

- **-NOQuery**

A switch that specifies for DFTVisualizer to display any netlist you request, regardless of its gate count.

- **-Query *threshold***

A switch and integer pair that specifies the maximum number of gates that may be added to the Flat and Hierarchical Schematic windows without first asking if you want to continue. Displaying netlist segments containing a relatively large number of gates can increase run time. This switch enables you to set a gate count threshold at which the tool will prompt you for confirmation that you do want to add more than the *threshold* number of gates. The default threshold is 500 gates.

- **-Split**

A switch that specifies to split the schematic into multiple schematic sheets and display just one sheet at a time. This is the invocation default behavior.

In -Split mode, an off-sheet connector on a net indicates a connection to a gate on another sheet. Double click on the off-sheet connector to change the display to the other sheet. At the bottom of the display, to the right of the message area, the tool lists the sheet currently being displayed and the total number of sheets. Entering a sheet number in the sheet number entry box is another way to change the display to another sheet.

This switch is supported in the Flat Schematic window only.

- **-NOSplit**

A switch that specifies for DFTVisualizer not to split the schematic into multiple schematic sheets.

This switch is supported in the Flat Schematic window only.

- **-Display {FLAt_schematic| HIErarchical_schematic | ALL}**

A switch and literal that specify the window(s) to which this command's settings apply. When you use the -Display switch, you have the following three choices:

FLAt_schematic — A literal that applies the settings to the Flat Schematic window only.
This is the invocation default behavior.

HIErarchical_schematic — A literal that applies the settings to the Hierarchical Schematic window only.

ALL — A literal that applies the settings to both the Debug and Design Flat and Hierarchical Schematic windows.

Examples

The following example changes the setting of the query threshold for both the Flat and Hierarchical Schematic windows. The compaction and sheet splitting options continue to use the default settings.

```
set_visualizer_preferences -query 200 -display all
```

set_wrapper_analysis_options

Context: dft -scan

Mode: setup, analysis

This command sets up parameters for the wrapper cells analysis.

Usage

```
set_wrapper_analysis_options
  [-output_fanin_flop_threshold {32 | integer | unlimited}]
  [-input_fanout_flop_threshold {32 | integer | unlimited}]
  [-output_fanin_libcell_levels_threshold {32 | integer | unlimited}]
  [-input_fanout_libcell_levels_threshold {32 | integer | unlimited}]
  [-non_scan_depth_threshold {2 | unlimited | integer}]
  [-register_ports_exceeding_non_scan_depth on | off]
  [-register_undriven_output on | off]
  [-allow_internal_segments_as_wrapper on | off]
  [-pipeline_start_of_wrapper_chains on | off]
  [-dedicated_wrapper_cells_location inside_power_isolation | outside_power_isolation]
  [-exclude_ports port_spec]
  [-clear_excluded_ports]
  [-register_ports_reaching_blackboxes {blackbox_instances_list | all | off}]
```

Description

This command sets up parameters for the wrapper cells analysis.

Arguments

- `-output_fanin_flop_threshold {32 | integer | unlimited}`

An optional switch and integer or literal pair that specifies the maximum number of sequential elements allowed to be reached during the backward tracing from a PO. The default is 32.

For the scan segments (sub-chains) encountered during the backward tracing from POs, there is a special cost function to average the number of the backward hit flops between the total number of POs reaching this sub-chain and the length of this sub-chain.

- `-input_fanout_flop_threshold {32 | integer | unlimited}`

An optional switch and integer or literal pair that specifies the maximum number of sequential elements allowed to be reached during the forward tracing from a PI. The default is 32.

For the scan segments (sub-chains) encountered during the forward tracing from PIs, there is a special cost function to average the number of the forward hit and the backward flops (feedback flops) between the total number of PIs reaching this sub-chain and the length of this sub-chain.

- **-output_fanin_libcell_levels_threshold {32 | integer | unlimited}**

An optional switch and integer or literal pair that specifies the maximum number of levels of library cells to be traversed during the backward tracing from a PO until the first sequential element is reached. The default is 32.

- **-input_fanout_libcell_levels_threshold {32 | integer | unlimited}**

An optional switch and integer or literal pair that specifies the maximum number of levels of library cells to be traversed during the forward tracing from a PI until the first sequential element is reached. The default is 32.

- **-non_scan_depth_threshold {2 | integer}**

An optional switch and integer or literal pair that controls the depth of non_scan sequential elements traced by the tool. When the threshold is exceeded, the behavior depends on the **-register_ports_exceeding_non_scan_depth** switch. The default is 2.

- **-register_ports_exceeding_non_scan_depth on | off**

An optional switch and literal pair that controls the behavior of the tool when the non-scan depth threshold is exceeded. If it is set to on, a dedicated wrapper cell will be added to the port that is being traced. If it is off, the branch that exceeds the threshold will be ignored and the tracing will continue to search for shared wrapper cell candidates.

- **-register_undriven_output on | off**

An optional switch and literal pair that specifies whether an output port having no functional source should receive a dedicated wrapper cell.

- on — undriven outputs will receive dedicated wrapper cells except for specific ports that are configured with “**set_dedicated_wrapper_cell_options off –ports {...}**”.
- off — undriven output ports will not receive any wrapper cells except for specific ports that are configured with “**set_dedicated_wrapper_cell_options on –ports {...}**”. This is the default.

- **-allow_internal_segments_as_wrapper on | off**

An optional switch and literal pair that specifies whether to identify the defined sub-chains as Input or Output wrapper elements during the forward and backward tracing from the Primary IOs.

- on — identify encountered sub-chains as Input or Output wrapper elements. This is the default.
- off — do not identify encountered sub-chains as wrapper elements. Ports which reach sub-chains will have a dedicated wrapper cell inferred unless these ports are specified to not allow inferring dedicated wrapper cells for them (see **set_dedicated_wrapper_cell_options**)

- **-pipeline_start_of_wrapper_chains on | off**

An optional switch and literal pair that specifies whether to automatically insert an at-speed test flop at the beginning of each wrapper chain. When multiple clock domains are allowed

per chain, the tool breaks the scan path with SE and adds a pipelining at the beginning of each domain so as not to create domain interaction through the scan path. The default is on.

- **-dedicated_wrapper_cells_location inside_power_isolation | outside_power_isolation**
An optional switch and literal pair that specifies where to insert the Input and Output dedicated wrapper cells with relation to the encountered power isolation cells.
 - inside_power_isolation — insert Input dedicated wrapper cells after the encountered power isolation cells and the Output dedicated wrapper cells before the encountered power isolation cells. This is the default.
 - outside_power_isolation — insert Input wrapper cells immediately after the PI ports being registered and insert the dedicated Output wrapper cells immediately before the PO ports being registered.
- **-exclude_ports *port_spec***
An optional switch and string that specifies that all ports in *port_spec* will be excluded from wrapper analysis without regard to their previous state (off/on/auto). Ports can only be removed from exclusion with **-clear_excluded_ports** switch.
port_spec can be a Tcl list of one or more ports or a collection of one or more port objects.

If one or more ports in the port spec has already been set with
“**set_dedicated_wrapper_cell_options on|off –ports {...}**” a note will alert you that this setting has been overridden.

```
// Note: Excluding and overriding set_dedicated_wrapper_cell
configurations for the following port(s):
<port1>, <port2>, <port3> ...
```

- **-clear_excluded_ports**
An optional switch that clears the list of ports that have been excluded from wrapper analysis. These ports are now included in wrapper analysis and will receive shared, dedicated, or no wrapper cells based on future and/or global “**set_dedicated_wrapper_cell_options [on|off|auto]**” configurations.
- **-register_ports_reaching_blackboxes {*blackbox_instances_list* | all | off}**
An optional switch and a list of blackbox instances or a literal that directs the tool to add a dedicated wapper cell to ports connected to the specified blackbox instances. The argument choices are as follows:
 - *blackbox_instances_list* — Adds dedicated wrapper cells to ports connected to any blackbox instance in the list.
 - all — Adds dedicated wrapper cells to ports connected to any blackbox instance.
 - off — A literal that disables this feature. This is the default.

Note

 This command switch is cumulative, and every invocation adds to the list of blackbox instances. Using the off literal clears the list.

Examples

Example 1

In the following example, all Primary IOs except for excluded_1 will receive dedicated wrapper cells, including undriven IOs.

```
set_wrapper_analysis_options --exclude_ports excluded_1
set_dedicated_wrapper_cells on
set_wrapper_analysis_options --register_undriven_output on
```

Example 2

In the following example:

Ports A, B, C, D, excluded_1 are driven.

Ports undriven_1, undriven_2 are undriven.

Ports C, D, undriven_1 will receive dedicated wrapper cells

Ports A, B, undriven_2, excluded_1 will not receive dedicated wrapper cells.

```
set_wrapper_analysis_options --exclude_ports excluded_1
set_wrapper_analysis_options --register_undriven_output on
set_dedicated_wrapper_cells off --ports {A B undriven_2}
```

```

Description

Creates the subset of ports or vector callbacks to use with the [write_patterns](#) commands. See “[Vector Creation and Modification](#)” in the *Tessent Scan and ATPG User's Manual* for additional information.

Port List Usage

This command is used to create the subset of ports to use in the subsequent write_patterns commands.

The add_port_name argument is a tcl list of object names or a collection of objects. The valid object types are ports , pseudo-port, pin, or gate_pin. A pin must map to a pseudo-port and a gate pin must map to a pseudo-port or port. The action is to add port names to the used subset, assuming that we are starting from an empty subset. Multiple instances of this command are not cumulative. Each command first removes any existing subset, and starts over from the full port list. Issuing the –existing_used_ports option with an empty *obj_spec* such as {} creates an empty subset. To add ports to the port list that do not exist in the original design data, use the –additional_port switch to specify a list of lists of strings which specify the name to add and its port direction. Port directions can be one of input, output, or inout. Optionally, the clock attribute and an optional off state for a clock can also be specified. If no off state is specified, an off state of 0 is assumed. If “clock” is not specified, the additional port is not treated as a clock and the P state value cannot be assigned to it. If “clock” is specified, the additional port is treated as a clock, the P state value can be used, and the timing for the port is taken from the “pulse_clock” statement in the timeplate instead of “force_pi” statement. Issuing the command with only –additional_ports will only add ports to the default port list supplied by the design and setup information. If any additional ports are added that match the name of an existing port, an error will be issued. This example instructs the write_patterns commands to only include the ports starting with ijtag_ and two new ports called myNewInput and myNewOutput[1:0].

```
set_write_pattern_options -existing_used_ports [get_ports iJtag_*] \
    -additional_port_list {[list myNewInput input myNewOutput[1:0] output]}
```

Vector Callback Usage

This command adds a vector callback proc name to the list of vector callback procs that will be used in the subsequent write_patterns commands. The switch –vector_callback must specify the name of a defined tcl proc that will be passed a vector set and will return a vector set. An optional trigger can be specified as an activation criterion for this Tcl proc. If no trigger is specified, the every_cycle trigger is the default and this callback is used for all vectors. Only one callback can be specified with each trigger. If another callback is specified with the same trigger as a previously specified callback, this new callback replaces the older one if -replace is used otherwise an error is issued. If a new callback is added with the same name as a previous one, it replaces the previous one if –replace is used, otherwise an error is issued.

When using vector_callback procs and writing patterns, the data fed to the vector callback procs must be the internal view pattern data, and therefore, any external_mode cycles from a named capture, or external_mode cycles from PLL_cycles or external_capture are not used. When you enable vector callbacks, the tool issues the following warnings:

```
// Warning: The set_write_pattern_options -vector_callback command causes
// write_patterns to use the internal_mode view of the pattern data.
// Set_external_capture_options -PLL_cycles is ignored in that case.
```

Or:

```
// Warning: The set_write_pattern_options -vector_callback command causes
// write_patterns to use the internal_mode view of the pattern data.
// Set_external_capture_options -capture_proc is ignored in that case.
```

Arguments

- **-additional_port_list *add_port_name***

An optional switch and value pair that specifies a list of lists of strings which specify the name to add and its port direction using the following syntax:

```
-additional_port_list {{port_name input | output | inout [clock <0|1>]} ...}
```

- **-existing_used_ports *used_port_name***

An optional switch and value pair that specifies an absolute list of the subset of existing design ports to use when writing patterns. Refer to “[Controlling Ports Used in Pattern and Testbench Generation](#)” on page 1182 in the [process_patterns_specification](#) command description for additional information and usage notes.

- **-reset_used_ports**

An optional switch used to reset the port list back to the original port list supplied by the design and setup information contained in the tool.

- **-vector_callback** *vector_callback* [-received_ports *received_ports*] [-returned_ports *returned_ports*] [-replace]

An optional switch and value pair that adds a vector callback proc name to the list of vector callback procs that will be used in subsequent write_patterns commands.

-received_ports *received_ports* — Specifies a Tcl list of port names or gate_id or a collection of ports or gate that is used as the callback port list when passing a vector set to the callback.

-returned_ports *returned_ports* — Specifies a Tcl list of port names or gate_id or a collection of ports or gate that is used as the callback port list when returning a vector set from the callback.

- **-delete_vector_callbacks**

An optional switch that removes all existing vector callbacks.

set_xbounding_options

Context: dft -scan, dft -test_points

Mode: setup

Sets up the parameters for X bounding insertion. The analysis is triggered by the analyze_xbounding command.

Usage

```
set_xbounding_options [-xbounding_enable xbounding_enable_name]
                      [-connect_to {existing_scan_cell | new_scan_cell | constant_value}]
                      [-scan_drive_limit integer]
                      [-mcp_bounding_enable mcp_enable_name]
                      [-exclude_sdc_cross_domain_paths {off | on}]
                      [-test_clock {off | on}] [-exclude pin_or_port]
                      [-use_scan_cells {off | on}] [-bound_clock_gater_enables {on | off}]
```

Description

Sets up the parameters for X bounding insertion. The analysis is triggered by the [analyze_xbounding](#) command.

You use this command to set various options that control how the tool performs X-bounding analysis. These options include:

- The name of the enable signals that activate the bounding logic.
- The type of bounding (new scan cells, existing scan cells, or constant values) that is used to block the X source.
- Activate (or disable) bounding of cross-clock domain paths as specified by the SDC file.

The actual analysis must be triggered by issuing the [analyze_xbounding](#) command.

If you issue this command without any arguments, all the defined and default settings are reported.

Arguments

- **-xbounding_enable *xbounding_enable_name***
An optional switch and literal pair used to specify the name of the of the X-bounding enable signal.
- **-connect_to {existing_scan_cell | new_scan_cell | constant_value}**
An optional switch and literal pair used to specify whether the X sources are controlled by existing or new scan cells or whether the X source is blocked with a constant value.
Choose from one of the following:
 - existing_scan_cell* — Specifies using existing scan cells to control the X sources.

new_scan_cell — Specifies using new scan cells to control the X sources. When using new scan cells for X bounding, the scan cell model specified either by the [add_cell_models](#) command or the **cell_type** Tessent Cell library attribute is used.

constant_value — Specifies using either an AND gate to block the X source with a constant 0 or an OR gate to block the X source with a constant 1. The specific bounding value (0 or 1) is determined by performing a simple analysis of the logic that will be forced to the constant value.

- **-scan_drive_limit *integer***

An optional switch and integer pair that specifies a limit on how many Mux-type control points one scan cell can drive for bounding. Having one scan cell drive a large number of Mux control points can reduce test coverage, due to structural dependency. 0 means there is no limit. The invocation default is 1.

- **-mcp_bounding_enable *mcp_enable_name***

An optional switch and string pair that specifies the name of an alternate enable signal for bounding at-speed paths. This provides independent control of these bounding muxes as the tool must bound multicycle paths during at-speed testing.

- **-exclude_sdc_cross_domain_paths {off | on}**

An optional switch and literal that specifies whether the tool bounds cross clock-domain paths that are specified in the SDC file.

A cross clock-domain path occurs when memory elements driven by one clock domain, feed logic that is observed (captured) by memory elements that are operated by a different clock.

Cross clock-domain paths are typically specified as false paths in the SDC file. In that case, these paths are identified as potential X sources and bounding muxes are inserted near the capture point.

In some cases, this might constrain the clock sequences that are applied during Logic BIST such that these paths will never be sensitized. However, if your hardware is designed such that certain cross clock_domain interactions are not tested during Logic BIST, and you choose to not test these the cross clock_domain paths by constraining the capture sequences, then there is no need to insert bounding muxes.

The **-exclude_sdc_cross_domain_paths** switch instructs the tool to ignore false paths that are specified in the SDC file during analysis.

Note

 In order to guarantee that all cross clock domains are targeted for x-bounding, you must specify all cross clock domain paths as false paths in the SDC file. This can be done indirectly by using the **set_clock_groups** command to assign each clock to a separate group.

- **-test_clock {off|on}**

An optional switch and literal pair that determines the clock signal for the newly inserted scan cells that will drive the test_mode input of the x-bounding muxes. This option must be used in conjunction with the -connect_to new_scan_cell option.

off — A literal that specifies that the clock signal for the newly created scan cells will be chosen to match the clock domain of the flops in the fanout cone of the x-bounding mux.

on — A literal that specifies that the newly created scan cells will be driven by the test clock signal as defined with the “set_scan_signals -tclk” command.

- **-exclude *pin_or_port***

An optional switch and string pair that specifies the pins/ports that are guaranteed to have a known value during fault simulation and will never propagate an X value to the MISR.

The value of *pin_or_port* can be a Tcl list of one or more pins/ports, or a collection of one or more pin/port objects.

Note

 The tool will not insert X-bounding muxes at the specified pins/ports, or at the logic that is driven by these pins. During fault simulation the X-sources will not be ignored, which means you must manually apply the appropriate initialization and constraints in order to avoid X's reaching the MISR during fault simulation.

- **-use_scan_cells {off|on}**

An optional switch and literal pair that controls the tool behavior for the following specific scenario:

- x-bounding is done on a pre-scan netlist.
- the “-connect_to new_scan_cells” option was used.
- you do not issue the “analyze_scan_chains” command after analyze_xbounding.

When this switch is off (this is the default) the tool will insert non-scan flops to drive the test_mode input of the x-bounding muxes.

When the switch is on, the tool will insert scan_cells. However, since analyze_scan_chains was not called, these new scan flops will NOT be stitched into chains.

- **-bound_clock_gater_enables {on|off}**

An optional switch and literal pair that controls x-bounding of false or multi-cycle paths that reach the functional enable input of clock gaters that drive scannable cells.

When set to on (this is the default), the tool will add x-bounding logic at the test_enable input of the clock gater to force it to always be enabled such that the potential x at the functional enable will not have any impact.

When set to off, the tool does not perform any bounding of such paths.

Examples

Example 1

In the following example, when you issue this command without any arguments, it reports the current settings:

set_xbounding_options

```
Xbounding enable name      : lbist_en
Connect to                 : existing scan cell
Scan drive limit          : 1
Exclude sdc cross domain paths : OFF
MCP bounding enable name   : lbist_en
Use test clock             : OFF
Exclude pin or port list  : DataOut_i[0]
                           : DataOut_i[1]
                           : DataOut_i[2]
```

Example 2

The following command specifies non-default enable names for the primary enable signal as well as the false and multicycle path enable prior to performing the x-bounding analysis:

```
set_xbounding_options -xbounding_enable lbist_en \
-mcp_bounding_enable mcp_path_enable
analyze_xbounding
```

set_xclock_handling

Context: all contexts

Mode: setup, analysis

Specifies whether the sequential element model outputs X when any of its clock inputs become X.

Usage

```
set_xclock_handling {Retain | X} [-Pessimistic_simulation {ON | OFF}]
```

Description

Specifies whether the sequential element model outputs X when any of its clock inputs become X.

By default, the flip-flop and latch default models are used for sequential elements. These default models retain their output values when their clock value becomes X so long as the other input values do not cause the stored output value to change, regardless of whether the clock was at a 0 or 1. The set_xclock_handling command lets you override this behavior during pattern simulation, causing the stored output value to become X.

[Table 6-21](#) lists the Q capture value of the level-sensitive sequential element models based on the X values on input pins, the Q value, and on the set_xclock_handling arguments. [Table 6-22](#) lists the outputs of edge-triggered sequential element models based on the clock transition, the D value, and on the set_xclock_handling arguments.

This command has no effect during DRC simulation. The default flip-flop and latch behavior is used during DRC simulation.

Table 6-21. X Handling for Level-Sensitive Ports

Level-Sensitive Sequential Element Ports		Q capture value when using the Retain argument	Q capture value when using the X argument
latch enable = X	Q=D	Q	X
	Q≠D	X	X
set = X	Q=0	X	X
	Q=1	1	X
reset = X	Q=0	0	X
	Q=1	X	X

Table 6-22. X Handling for Edge-Triggered Ports

Edge-triggered Sequential Element Inputs		Output when using “Retain -pessimistic_simulation OFF / ON”		Output when using “X -pessimistic_simulation OFF / ON”	
Clock event	D value before clock event	OFF	ON	OFF	ON
X→X X→1 0→X	D=Q	Q	Q	X	X
	D≠Q	X	X	X	X
1→X	D=Q	Q	Q	Q	X
	D≠Q	Q	X	Q	X
X→0	D=Q	Q	Q	Q	Q
	D≠Q	Q	Q	Q	Q

Arguments

- **Retain | X**
A required literal that uses the default sequential element model (by default) or uses a modified sequential element model. For information about the effect of using these arguments, refer to [Table 6-21](#) and [Table 6-22](#).
- **-Pessimistic_simulation {ON | OFF}**
An optional switch that affects the output of the edge-triggered sequential element model when the clock port becomes X, as shown in [Table 6-22](#).

Examples

The following example sets the outputs of edge-triggered sequential elements to X unless any of their clock inputs transition from X to 0 during pattern simulation:

```
set_xclock_handling x -pessimistic_simulation on
```

[get_xclock_handling](#)

set_z_handling

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup

Specifies the simulation handling for high impedance signals on internal and external tri-state nets.

Usage

set_z_handling {Internal state} | {External state}

Description

Specifies the simulation handling for high impedance signals on internal and external tri-state nets.

The set_z_handling command specifies how to handle the high impedance state for internal and external tri-state nets during pattern simulation. If the high impedance value can be made to behave as a binary value, certain faults may become detectable. If you do not use this command to set the Z handling, the default value is X.

This command does not impact expected values on tri-state and bidirectional pins in the final saved patterns. The command changes the behavior of how Z values are simulated on internal nets. By default, Z values are treated as X values when fed into another internal gate, such as an AND gate. However, a Z value on a tri-state output pin is not converted to an X by default.

Arguments

- **Internal state**

A literal pair that specifies how the tool simulates high impedance values for internal tri-state nets. The literal choices for the *state* option are as follows:

X — A literal that specifies to treat high impedance states as an unknown state. This is the default behavior upon invocation of the tool.

0 — A literal that specifies to treat high impedance states as a 0 state.

1 — A literal that specifies to treat high impedance states as a 1 state.

- **External state**

A literal pair that specifies how the tool simulates high impedance values for external tri-state nets. The literal choices for the *state* option are as follows:

X — A literal that specifies not to measure high impedance states; they cannot be distinguished from a 0 or 1 state. This is the default behavior upon invocation of the tool.

0 — A literal that specifies to treat high impedance states as a 0 state that can be distinguished from a 1 state.

- 1** — A literal that specifies to treat high impedance states as a 1 state that can be distinguished from a 0 state.
- Z** — A literal that specifies to uniquely measure the high impedance states; they can be distinguished from both a 0 or 1 state.

Examples

The following example specifies to treat high impedance values as 1 states when they feed into logic gates, and as 0 states at the output of the circuit, then performs a pattern simulation run:

```
set_z_handling internal 1
set_z_handling external 0
set_system_mode analysis
create_patterns
```

Related Topics

[write_patterns](#)

[set_zhold_behavior](#)

Context: dft -edt, patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Specifies whether ZHOLD gates retain their state values.

Usage

`set_zhold_behavior OFF | ON`

Description

Specifies whether ZHOLD gates retain their state values.

The ZHOLD gate allows the tool to model tri-state nets so that they can retain the previous state value when the net goes to a high impedance (Z) value. ZHOLD gates normally require clock sequential patterns to utilize this capability. But, if a ZHOLD gate is set to a fixed binary value when the clocks are off, the ZHOLD gate can retain that value for combinational patterns. The combinational fault simulation does not consider the fault effect on the retained value.

By invocation default, the tool assumes the retained value is always the `clock off_state` value for both the good machine and the faulty machine simulation.

The tool cannot assume a state from a previous scan pattern or from a load operation. The amount of time the ZHOLD gate can hold its value is limited to the number of sequential clock cycles.

Arguments

- **OFF**

A literal that specifies not to allow ZHOLD gates to retain values.

- **ON**

A literal that specifies for the tool to use ZHOLD gates to retain values subject to restrictions that the rules checker identified. This is the default behavior upon invocation of the tool.

Examples

The following example specifies that the ZHOLD gates are not allowed to retain their previous values:

```
set_zhold_behavior off
```

setenv

Context: unspecified, all contexts

Mode: all modes

Sets a shell environment variable within the tool environment.

Usage

`setenv variable_name [value]`

Description

Sets a shell environment variable within the tool environment.

The setenv command sets or changes the value of a shell environment variable within the current tool environment, enabling the tool to access the variable for the rest of the session just as if the variable had been set from the shell. This command is useful if you ever find that the tool requires an environment variable that was not set prior to invocation.

Note

 A shell variable you set with this command is set only with respect to the current tool session. The command does not alter the value of the variable in the invocation shell.

To unset the variable before you exit, use the [unsetenv](#) command. To view the value of the variable, use the command to pass an appropriate shell command ([echo](#) or [env](#) for example) to the operating system for execution.

Arguments

- ***variable_name***
A required string that specifies the name of the variable.
- ***value***
An optional string that specifies the value of the variable.

Examples

The following example assigns a value to the environment variable `SSH_AGENT_PID`, then displays its value:

```
setenv SSH_AGENT_PID 66216
system {echo $SSH_AGENT_PID}
66216
```

shutdown_sid_tester

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Terminates the currently active SID tester process that was created by executing the [launch_sid_tester](#) command.

Usage

`shutdown_sid_tester`

Description

Terminates the currently active SID tester process that was created by executing the [launch_sid_tester](#) command.

Arguments

None

Examples

The following example shuts down the SID tester process.

`shutdown_sid_tester`

Related Topics

[launch_sid_tester](#)

[simulate_clock_pulses](#)

Context: all contexts

Mode: setup, analysis

Prerequisites: The flat model must already exist, and you must have previously used the add_clocks command to define specified gate_pin objects as clocks.

Pulses one or more clocks within the current simulation context.

Usage

`simulate_clock_pulses obj_spec [-repetitions number]`

Description

Pulses one or more clocks within the current simulation context.

The simulate_clock_pulses command pulses the specified clock(s) within the current simulation context. Before issuing this command, you must previously use the add_clocks command to define the specified gate_pin objects as clocks.

The default number of clock pulses is 1 unless you specify a different number with the -repetitions switch. If any forces have been queued with previous add_simulation_forces commands, the tool automatically simulates these forces before pulsing the clocks.

Arguments

- *obj_spec*
A required value that specifies one or more gate_pin objects.
- -repetitions *number*
An optional switch and integer pair that specifies the number of clock pulses to simulate. If you do not use this switch, the default number of clock pulses is 1.

Examples

The following example shows the use of the simulate_clock_pulses command:

```
SETUP> add_clocks myInst1/OUT
SETUP> add_clocks myInst2/OUT -pseudo_port_name myClk
SETUP> simulate_clock_pulses [get_gate_pins {myInst1/OUT myClk} ] -repetitions 2
```

[simulate_forces](#)

Context: all contexts

Mode: setup, analysis

Prerequisite: The flat model must already exist

Simulates the queued forces in the current simulation context.

Usage

```
simulate_forces [-latch {normal | transparent}]
```

Description

Simulates the queued forces in the current simulation context.

The simulate_forces command simulates all the queued simulation forces previously added with the add_simulation_forces command. This command operates only within the current simulation context.

Arguments

- **-latch {normal | transparent}**

An optional switch and value pair that controls how latches are to be handled when propagating simulation values.

A value on the D input of a latch will propagate to the Q output of the latch when the enable pin of the latch is simulated to its active value. When the enable pins of the latch is simulated to its inactive value, the Q pin retains its value. The -latch switch controls the behavior when the enable pin of the latch simulates to an X.

Choose one from the following literals:

normal — The output of the latch will go X if the D and Q values are different.

transparent — The output of the latch will be updated to match the value on the D pin.

This switch is needed when you are trying to extract clock paths from the destination back to the source. Because there are often clock gaters along the clock paths and those clock gaters have latches along the enable paths, you have to let the enable values propagate through the latches to be able to disable the clock gaters and trace through the clock gaters.

Note

 When using this option, it is important that you later come and verify the proper connection and polarity of the latches along the enable paths to make sure they were implemented correctly.

Examples

The following example shows the effect of adding a force on a particular gate_pin object, and then issuing the simulate_forces command to trigger the tool to simulate that force:

```
ANALYSIS> set_current_simulation_context myContext  
ANALYSIS> add_simulation_forces [get_gate_pins I1] -value 1  
ANALYSIS> report_simulation_forces
```

Value	Object
-----	-----
1	I1

```
ANALYSIS> get_simulation_value_list [get_gate_pins I1]  
{ X }
```

```
ANALYSIS> simulate_forces  
ANALYSIS> get_simulation_value_list [get_gate_pins I1]  
{ 1 }
```

[simulate_patterns](#)

Context: patterns -scan, patterns -scan_diagnosis

Mode: analysis

Performs simulation by applying the specified pattern source.

Usage

```
simulate_patterns [-source {external | bist | random}]  
[-store_patterns {all | effective | none}]
```

Description

Performs simulation by applying the specified pattern source.

The simulate_patterns command performs a good-machine simulation, and also performs a fault simulation only when there is a current fault list. By default, the command simulates the external patterns previously loaded with the [read_patterns](#) command, and the tool retains the pattern order (disables pattern classification) after simulation. The command optionally stores the patterns to the internal pattern set.

The command issues a warning before performing a good-machine simulation when no patterns are stored.

When executing the simulate_patterns command, the tool analyzes the design to determine if split capture cycle or clock_off simulation is needed. If so, the tool turns these functions on automatically. When the pattern source is set to BIST and an NCP (named capture procedure) is used, the tool checks the NCP to determine the necessary sequential depth and other environment settings (such as multi-load or hold_pi) before starting fault simulation. For more information, refer to “[Example 2](#)” on page 2476.

Arguments

- `-source {external | bist | random}`

An optional switch and literal pair that specifies which pattern source to simulate. By default, the command simulates the external patterns previously loaded with the [read_patterns](#) command.

The “bist” option specifies that the tool simulate only BIST patterns. Note that when running from BIST mode (LFSR is defined or in EDT_LBIST mode) and no external patterns are loaded, the default pattern source is BIST. There must be at least one defined LFSR. The existence of such an LFSR means that the design successfully passed the BIST rules checking when leaving Setup.

You can use the `-store_patterns` switch to store the BIST patterns when performing good simulation; however, the “`-store_patterns effective`” option is not allowed. These patterns are different from normal patterns in that they specify the excess values that occur on short

scan chains during the load and unload process. Also, the last pattern does not contain an unload of the scan chains.

The “random” option specifies the random patterns, capture clock, and observation point specified previously. You can use this option to create patterns for random pattern testable faults. For fault simulation, you can use this option to evaluate the expected random pattern test coverage.

- **-store_patterns {all | effective | none}**

An optional switch and literal pair that specifies if the simulated patterns should be added to the internal pattern set. By default, the command stores no patterns. However, you can optionally store all patterns or store only the patterns that were effective at detecting additional faults.

Examples

Example 1

The following example performs a good-machine simulation using the current BIST patterns and then adds those patterns to the internal pattern set:

```
simulate_patterns -source bist -store_patterns all
```

Example 2

The following example applies an NCP named “cap_depth3” and then initiates a BIST pattern fault simulation. Note that before running the simulation, the tool first analyzes the NCP and then automatically changes the sequential depth to 3 and also issues a “set_split_capture_cycle on” command.

```
add_bist_capture_range cap_depth3 0 511
simulate_patterns -source bist
```

```
// Warning: Current sequential depth is not large enough to apply named capture procedures.  
//           Automatically increase the sequential depth to be 3.  
// largest sequential test depth = 1, largest controllability depth = 1,  
// largest observability depth = 1

sizeof_collection

Context: unspecified, all contexts

Mode: all modes

Returns the number of objects in a collection.

Usage

`sizeof_collection collection`

Description

Returns the number of objects in a collection.

The `sizeof_collection` command is an efficient way to determine how many objects are in a collection.

Arguments

- *collection*

A required string that specifies the collection for which to get the number of objects. The returned size for an empty collection is 0.

Examples

Example 1

The following example shows a simple way to find out how many instances of cell module the current design has.

```
puts [sizeof_collection [get_instances -filter {type == "cell"}]]
```

```
56781
```

Example 2

The following example shows the size of a collection as it gets appended to.

```
set a ""
puts [sizeof_collection $a]
0

append_to_collection a b[7]
{b [7] }

puts [sizeof_collection $a]
1

append_to_collection a {b c d}
{b [7] b c d}
```

puts [sizeof_collection \$a]

4

[remove_from_collection](#)
[sort_collection](#)

sort_collection

Context: unspecified, all contexts

Mode: all modes

Sorts a collection based on the value of one or more attributes, resulting in a new sorted collection.

Usage

`sort_collection collection criteria [-descending] [-numerical_sort]`

Description

Sorts a collection based on the value of one or more attributes, resulting in a new sorted collection.

The sort is in ascending order by default. In an ascending sort, objects that have Boolean attributes set to false are first followed by Boolean objects that have attributes set to true. The sorting considers the default values of the attributes when the attribute has never been set on the object.

To sort the objects in reverse order, specify the `-descending` option. To sort the objects numerically, instead of lexically, specify the `-numerical_sort` option.

Arguments

- ***collection***

A required string that specifies the collection to be sorted.

- ***criteria***

A required value that specifies an attribute name or a Tcl list of attribute names to use as sort keys. The order of the attribute name in the list controls the order of priority while sorting.

- `-descending`

An optional switch that sorts the collection in reverse order. By default, the sort proceeds in ascending order.

- `-numerical_sort`

An optional switch that sorts the collection numerically.

This is the sorted collection with the switch:

```
core1_28x16/a[1]
core1_28x16/a[2]
core1_28x16/a[3]
core1_28x16/a[10]
core1_28x16/a[20]
```

By default, the sort proceeds lexically. This is the sorted collection without the switch:

```
core1_28x16/a[10]
core1_28x16/a[1]
core1_28x16/a[20]
core1_28x16/a[2]
core1_28x16/a[3]
```

Examples

The following example illustrates the use of two attributes to sort a collection. Notice how the first attribute has higher priority than the second attribute in the sorting.

```
register_attribute -name att2 -value_type string -default a
register_attribute -name att1 -value_type string -default a

set_attribute_value {ba bb} -name att1 -value b
{ba bb}

set_attribute_value {ab bb} -name att2 -value b
{ab bb}

sort_collection [get_inst {aa ab ba bb}] {att1 att2}
{aa ab ba bb}

sort_collection [get_inst {aa ab ba bb}] {att2 att1}
{aa ba ab bb}

sort_collection [get_inst {aa ab ba bb}] {att2 att1} -descending
{bb ab ba aa}
```

start_silicon_insight

Context: patterns -silicon_insight, patterns -ijtag -silicon_insight, patterns -scan -silicon_insight

Mode: setup, analysis

Starts Tesson SiliconInsight and initializes the data structures.

Usage

`start_silicon_insight [-gui]`

Arguments

- `-gui`

Starts the Tesson SiliconInsight GUI.

stop_silicon_insight

Context: patterns -silicon_insight

Mode: setup

Stops Tesson SiliconInsight.

Usage

`stop_silicon_insight`

Description

Closes the CDP and exits the sid_tester process when you are running Tesson SiliconInsight Desktop, SimDUT or “NoTester.” When you are running on an ATE, this command closes the connection to the test program.

Arguments

None

system

Context: unspecified, all contexts

Mode: all modes

Passes the specified command to the operating system for execution.

Usage

`system os_command`

Description

Passes the specified command to the operating system for execution.

The system command executes one operating system command without exiting the currently running application.

Note

 There have been isolated incidents in which the “system echo” command resulted in memory overrun. If this occurs, the recommendation is to use the TCL “puts” command instead.

Arguments

- *os_command*

A required string that specifies any legal operating system command.

Examples

Example 1

The following example invokes a synthesis script to synthesize generated RTL, and reloads the synthesized view:

```
write_design -output_file rtl/my_module.v
system "cd synth_work; ./synth_script"
read_verilog gate/my_modul.v -force
set_current_design mytop
```

Example 2

The following example performs an ATPG run, then displays the current working directory without exiting the tool:

```
set_system_mode analysis
create_patterns
system pwd
```

Related Topics

[setenv](#)

unsetenv

trace_flat_model

Context: all contexts

Mode: setup, analysis

Prerequisites: This command can only be used after the design is flattened to the simulation model; this occurs when you first exit setup mode to enter analysis mode, or when you issue the [create_flat_model](#) command.

Traces the flat model taking into account the current simulation context.

Usage

```
trace_flat_model -from from_obj_spec [-to to_obj_spec] -direction {forward | backward}
[-tag_condition tag_attribute_expression] [-stop_condition stop_attribute_expression]
[-controllability {controlling | controlling_allow_reconvergence | constant | unblocked
| connected}] [-stop_at_first_tag {On | Off}] [-max_levels {unlimited | number}]
[-max_combinational_cells {unlimited | number}] [-max_tags {unlimited | number}]
[-latch {normal | transparent}] [-map_tag_to_design_module_boundary {ON | OFF}]
[-store_polarity_to_tagged_objects polarity_var_name]
[-store_polarity_along_paths_to_tagged_objects path_polarity_var_name]
[-store_paths_to_tagged_objects tag_path_var_name]
[-store_path_to_stop_point stop_path_var_name]
[-store_starts_to_tagged_objects starts_to_tagged_objects_var_name]
```

Description

Traces the flat model taking into account the current simulation context.

For information about simulation contexts, refer to the [set_current_simulation_context](#) command description.

The tool begins tracing at the objects specified by the -from option. The direction is either forward or backward. You can use equations based on attributes found on gate_pin objects to specify the gate_pins that you want the tracing to stop on, or the gate_pin objects you want to tag when reached.

This command returns a collection of reached gate_pins for which the tag condition evaluates to true. When the -tag_condition argument is specified, this command returns a collection of all gate_pin objects the trace stopped on. You can also provide a Tcl variable in which to store the path between the start object and the tagged objects so that you can display them in DFTVisualizer as shown in two of the following examples.

Note

 This command only returns the start point when it is reached again during the trace, that is, when there is a feedback path.

When using this command in setup mode, you may see the following error message because no simulation data is available:

```
Error: Controllability 'unblocked' is the default, but no simulation  
data exists in the current simulation context ...
```

To avoid this error, you must specify the “-controllability connected” trace option.

Arguments

- **-from *from_obj_spec***

A required option that specifies a Tcl list of one or more names of gate_pin, pin, or port objects, or a collection of one or more gate_pin, pin, or port objects. When using pin names or objects, these pins must have been preserved in the flat model.

Pins that are preserved in the flat model are either all pins on instances of type cell, or pins on instances of type design on which an attribute is set to a non-default value and the set_attribute_option -preserve_boundary_in_flat_model option of that attribute is set to true. These attributes must have been defined on the pin in setup mode prior to creating the flat model.

Note

 By default, when the tool flattens the design, hierarchical pins are not kept as gate_pin elements. If you need to work with a hierarchical pin, you need to instruct the tool to keep it as part of the flat model by using the “preserve_boundary” option as shown here: set_attribute_value *object_spec* -name preserve_boundary

The tracing is performed starting from each object specified in the *from_obj_spec* argument.

When the direction is forward and the start object has no fanout, a null collection is returned. When the direction is backward and the start object has no fanin or is tied to a constant, a null collection is returned when the -map_tag_to_design_module_boundary switch is set to on as the tieX or tie0 or tie1 gate in the fanin does not correspond to a design module boundary.

- **-to *to_obj_spec***

An optional switch and value pair that directs the trace operation to stop at the objects specified by *to_obj_spec* and to tag them, if reached. The *to_obj_spec* argument can be a Tcl list of one or more names of gate_pin, pin, or port objects, or a collection of one or more gate_pin, pin, or port objects. When using pin names or objects, these pins must have been preserved in the flat model.

You can use this switch to specify objects as stop points in addition to the objects specified with the -stop_condition switch, and to specify which objects will be tagged in addition to the objects specified with the -tag_condition switch.

- **-direction {forward | backward}**

A required string that specifies whether tracing should be performed forward or backward from the defined start object(s).

- **-tag_condition tag_attribute_expression**

An optional switch and string pair that specifies the tag condition for the trace. All of the reached design objects fulfilling the defined tag condition are returned. The default is an empty string; in this case, the trace stop points are returned. In a non-default case, the trace stop points are not returned if the tag condition expression is not true for these objects. The format for the *tag_attribute_expression* is identical to the *-filter* option used for the [get_pins](#) command.

- **-stop_condition stop_attribute_expression**

An optional switch and string pair that defines the stop condition for the trace. The default is an empty string; in this case, the trace is stopped at the *gate_pin* failing the specified controllability requirements. The pins of memory or dff primitives are always stop points even when not explicitly specified.

- **-controllability {controlling | controlling_allow_reconvergence | constant | unblocked | connected}**

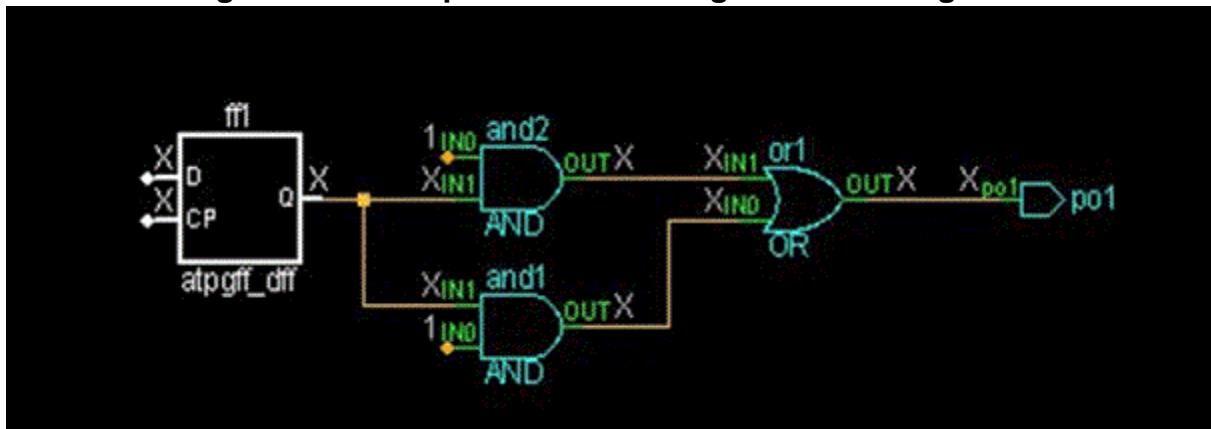

An optional switch and literal pair that defines the controllability requirements before traversing a gate.

controlling— Gates are only traversed if the other inputs have simulated constant values making a single input directly controlling the output. Inversions are possible and information about them is stored in the variable specified by the *-store_polarity_to_tagged_objects* argument.

controlling_allow_reconvergence — Supports tracing reconvergent controlling paths. When this option is specified, the tool first tries to perform the trace with controllability 'controlling' (see description above). If this trace succeeds, the tool behavior is identical with a trace performed with the controllability controlling. If this trace fails, an unblocked backward trace from the target is internally performed to find all the possible controlling source candidates. These candidates are then investigated by simulating 0 and 1 to them and observing the effect on the destination.

In [Figure 6-6](#) on page 2488, you can see one example of a reconvergent controlling path from ff1/Q to po1.

Figure 6-6. Example of a Reconvergent Controlling Path

Information about inversions is stored in the variable specified by the -store_polarity_to_tagged_objects switch. In case the reconvergence analysis was necessary to find the controlling source, the variable specified by the -store_paths_to_tagged_objects switch returns an empty collection.

Unnecessarily specifying controllability controlling_allow_reconvergence instead of controlling has negative impact on tool's performance.

constant — Only pins with a constant value are traversed. This mode is useful to find the source of a constant value.

unblocked — Gates are only traversed if the other inputs do not have simulated constant values making the input blocked from the output pin. Only unblocked combinational paths are traversed.

connected — With this value, gates are always traversed when reached. You should use this option when this command is used in setup mode because no simulation data exists yet.

- **-stop_at_first_tag {On | Off}**

An optional switch and literal pair that specifies whether to interrupt tracing when the first tag object with the specified controllability is found. This is useful when checking for at least one occurrence of a given condition in the fanin or fanout of a pin without wasting time to find them all.

- **-max_levels {unlimited | number}**

An optional switch and value pair that defines the maximum levels of gates to trace. The default is unlimited but you can specify a positive integer to limit the level count. The gates are the primitive gates as seen in the flat model. An AND-OR gate will have two levels of primitive gates in the flat model and will count as two levels of gates for this limit. If you want to only count cells irrespective of their complexity, use the -max_combinational_cells switch instead.

- **-max_combinational_cells {unlimited | number}**

An optional switch and value pair that defines the maximum number of combinational cells to trace. The default is unlimited. Each combinational cell is counted as one cell except for inverters and buffers which do not count at all. Even if a cell has several levels of primitives inside it, it is not counted as more than one cell. To limit the search to a maximum number of primitive gates, use the -max_levels switch instead.

- **-max_tags {unlimited | number}**

An optional switch and value pair that directs the trace operation to stop when the number of tagged objects reaches the specified limit. The default is unlimited. This is useful when you are coding your own custom DRC using the [register_drc](#) register_drc command and you only want detect the first 100 violations. There is no point tagging all violations if you only want to show the first 100.

- **-latch {normal | transparent}**

An optional switch and literal pair that specifies the behavior of tracing through a latch.

normal — A latch is traced through only if the simulated value in the current simulation context makes the latch satisfy the specified controllability requirements. In case of “-controllability connected” all latch input pins - including the latch enable pin - are traced through.

transparent — All latches are traced through the data input, set and reset pins regardless of the value at the latch enable pin. The latch enable pin is not traced through.

- **-map_tag_to_design_module_boundary {ON | OFF}**

An optional switch and literal pair that specifies whether to map the tag points to `gate_pins` outside of library cells. When this switch is ON, the command maps the tag points to `gate_pins` outside of library cells and never inside the cells. Library cells can be either cells from a Tesson Cell library or `celldefine Verilog modules.

- **-store_polarity_to_tagged_objects *polarity_var_name***

An optional switch and string pair that specifies the name of a Tcl variable in which to store a list of 0 or 1 values to reflect the presence of an inversion between the start object and the tag object(s). If an inversion exists between the start and tag object(s), the value 1 is stored in the list; otherwise, the value 0 is stored. This option can only be used with the -controllability controlling option; inversion is meaningless in all other cases.

- **-store_polarity_along_paths_to_tagged_objects *path_polarity_var_name***

An optional switch and string pair that specifies the name of a Tcl variable in which to store a list of 0 or 1 values to reflect the presence of inversions between the start object and the tag object(s). If an inversion exists between the start and tag object(s), the value 1 is stored in the list; otherwise, the value 0 is stored. This switch provides a list of 0 and 1 values representing the local polarity of each node that the corresponding collection found by the -store_paths_to_tagged_objects switch. This option can only be used with the -controllability controlling option; inversion is meaningless in all other cases.

- **-store_paths_to_tagged_objects *tag_path_var_name***

An optional switch and string pair that specifies to store a list of paths in the variable `tag_path_var_name`. Each path holds a collection containing all of the traversed `gate_pins` between the start object and the tagged object(s). The list is in the order specified by the -direction option and includes the start object and the reached tagged object.

- **-store_path_to_stop_point *stop_path_var_name***

An optional switch and string pair that specifies to store the path between the start object and the `gate_pin` where the trace stopped independent of whether the stop point is a tagged object. This switch is only valid when -direction is specified as backward and -controllability is specified as controlling or constant. In this case, only one start object is supported and only one stop point can ever be found. This mode is useful to trace a clock source and display the path to the stop point if an appropriate source is not reached.

- **-store_starts_to_tagged_objects *starts_to_tagged_objects_var_name***

An optional switch and string pair that specifies to store the start point from which all tagged objects were reached from. The return value is a single collection containing the start points from which the tagged objects were seen from.

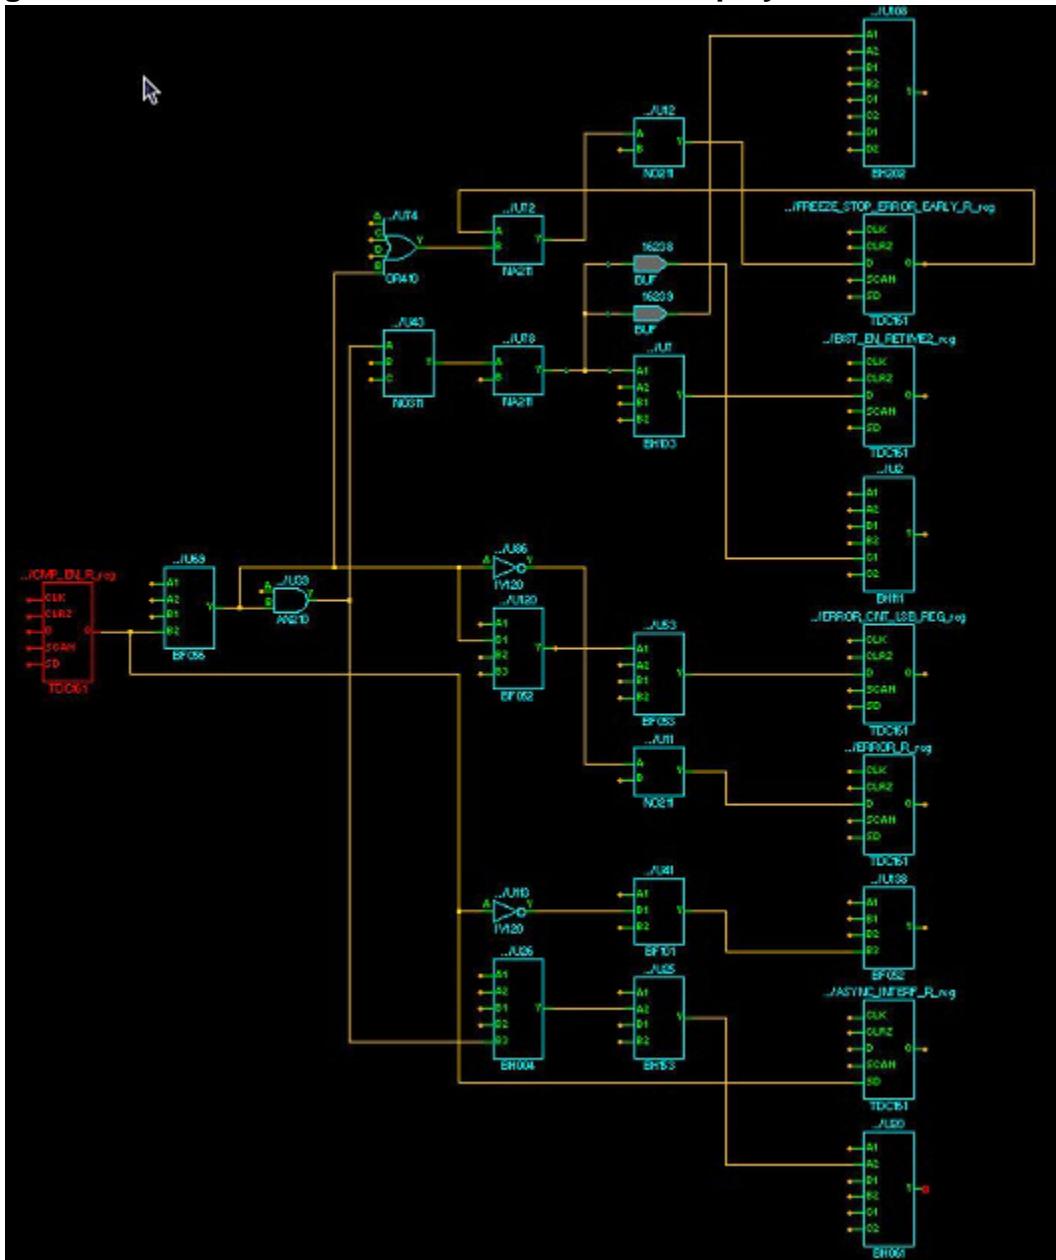

Examples

Example 1

The following example traces the unblocked fanout of a pin. Because no `-tag_condition` is specified, the tool automatically tags every node with no unblocked fanout. The paths to the tag elements are stored in the Tcl variable `tag_paths`. The `foreach` command iterates on the list of paths and the `add_display_instance` command displays the paths in the DFTVisualizer Flat Schematic window. [Figure 6-7](#) shows the resulting schematic drawn in the Flat Schematic window.

```
set start_pin [get_pins BOB_CKB2_1_MBIST1_MBIST_I1/CMP_EN_R_reg/Q]
trace_flat_model -from $start_pin -direction forward \
    -store_paths_to_tagged_objects tag_paths
add_display_instance $tag_paths
mark_display_instances $start_pin -marking_index 5
```

Figure 6-7. Flat Schematic Window After add_display_instance Command

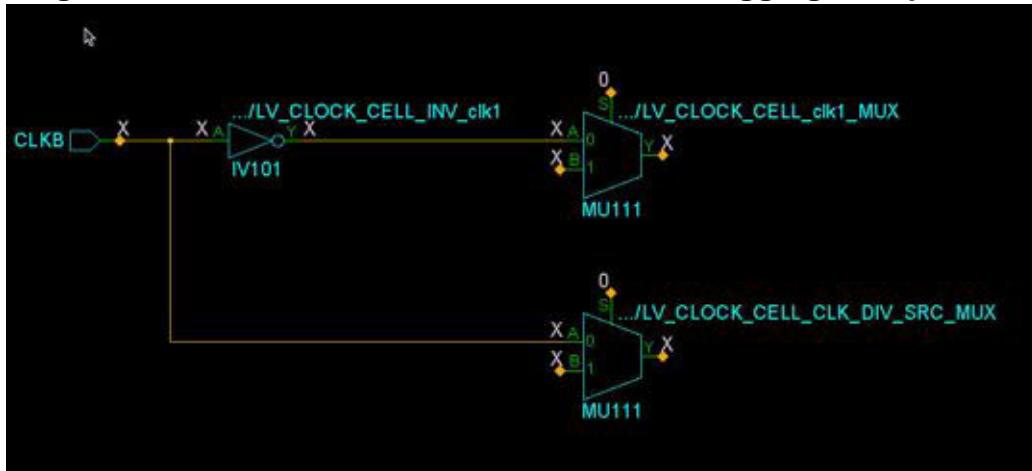

Example 2

The following example performs a controlling walk forward from a clock source and collects any MU111 multiplexers traversed along the way. The paths from the start point to all tag elements are displayed in the Flat Schematic window as shown in [Figure 6-8](#). Notice how the set_gate_report drc command is set to stable_after_setup; this corresponds to the simulation conditions used by the trace_flat_model command. You can see that the two muxes have a controlling value on the select pin. Multiplexers without a controlling value on the select pin were not traversed and therefore their output pins were not tagged.

```
trace_flat_model -from CLKB \
    -tag_condition {module_name == MU111 && direction == output} \
    -direction forward \
    -store_paths_to_tagged_objects tag_paths -controllability controlling
set_gate_report drc stable_after_setup
add_display_instance $tag_paths
```

Figure 6-8. Result of trace_flat_model While Tagging Multiplexers

Example 3

The following example uses the trace_flat_model command to find paths between output and inout pins of modb to pins of modd. Notice how the -stop_at_first_tag option is set to on, ensuring that only one path from each modb pin is reported.

```
set_system_mode setup
set_attribute_value [get_instances -of_module {modb modd}] -name preserve_boundary
set_system_mode analysis
trace_flat_model -from [get_pins u4/* -direction {output inout}] -direction forward \
    -stop_condition preserve_boundary \
    -tag_condition {module_name == modd} \
    -stop_at_first_tag on \
    -store_paths_to_tagged_objects paths
if {[llength $paths] > 0} {
    puts "pins of modb fanning out to modd:"
    foreach path $paths {
        puts [get_single_name [index_collection $path 0]]
    }
}
```

uncompress_layout

Context: patterns -scan_diagnosis

Mode: analysis

Uncompresses a Layout Database.

Usage

LDBs created after v2013.2: `uncompress_layout`

LDBs created with v2013.2 and before: `uncompress_layout layout_database_name`

Description

Uncompresses a Layout Database.

You must open the Layout Database using the [open_layout](#) command before performing the uncompress operation.

See “[Layout Database Compression and Decompression](#)” in the *Tessent Diagnosis User's Manual* for complete information.

Arguments

- *layout_database_name*

A required string that specifies the location to and the name of the Layout Database to be created during the uncompress operation.

Related Topics

[compress_layout](#)

[create_layout](#)

[open_layout](#)

uniquify_instances

Context: all contexts

Mode: insertion

Uniquifies the module definition of the specified instance objects found in *obj_spec*.

Usage

```
uniquify_instances obj_spec [-module_uniquification_suffix module_uniquification_suffix]  
[-silent]
```

Description

Uniquifies the module definition of the specified instance objects found in *obj_spec*.

If the instances specified by *obj_spec* have a module definition that is used more than once below the current design, the module name is made unique by appending the specified -module_uniquification_suffix value to its name.

This command returns a collection of all modules associated with the instances in the *obj_spec* irrespective of whether the module name was uniquified or not.

Arguments

- *obj_spec*
A required value that specifies the instances whose module name is to be uniquified. The *obj_spec* value must be a Tcl list of one or more instance names, or a collection of one or more instances as generated by the get_instances command
- -module_uniquification_suffix *module_uniquification_suffix*
An optional switch and value pair that specify a string to append to the module name if the instance's module definition is used more than once below the current design. The default module_uniquification_suffix is “_#” where # begins at 1 and increments by one until a unique module name is found.
- -silent
An optional argument that specifies to ignore specified instance objects that do not exist or instances that are not of type design, and to not generate error messages.

Examples

Example 1

The following example requests all instances found within u2 to be uniquified. All instances of design modules in this example are instances of module moda and modb. From the result of the command, you can see that there are only three instances of moda within the current design and they are all within the u2 instance. Once the first two instances were uniquified to moda_1 and moda_2, the third instance was not changed as it was now unique. Because modb was uniquified, this means that it is used in other instances of the current design.

```
uniquify_instances [get_instances u2/* -of_type design ]
{moda moda_1 moda_2 modb_1}
```

Example 2

The following example overwrites the default module_uniquification_suffix of “_#” to “_uniq#” so that it is easier to identify which modules were uniquified:

```
uniquify_instances [get_instances u2/* -of_type design] -module_unification_suffix _uniq#
{moda moda_uniq1 moda_uniq2 modb_uniq1}
```

Example 3

The following example appends to the my_design_modules collection the collection of modules returned by the uniquify operation. Note that by definition, uniquify_instances will return a collection with a different module object for each instances object because uniquified modules are only ever instantiated once.

```
append_to_collection my_design_modules \
[uniquify_instances [get_instances u2/* -of_type design]]
```

unmark_display_instances

DFTVisualizer windows: Debug, Design

Context: all contexts

Mode: setup, analysis

Returns the specified marked instances to their original color. Color marking occurs with the [mark_display_instances](#) command.

Usage

```
unmark_display_instances {gate_id# | instance_name | pin.pathname}... | -All | -Selected  
[-Display {FLAt_schematic | HIHierarchical_schematic}]
```

Description

Returns the specified marked instances to their original color. Color marking occurs with the [mark_display_instances](#) command.

Tip

 If a gate is selected, any highlighting or marking applied to the gate is not visible until the gate is unselected.

Arguments

- ***gate_id#***

A repeatable integer that specifies the gate identification number of instances to unmark display instances. The value of the *gate_id#* argument is the unique identification number that the tool automatically assigns to every gate within the design during the model flattening process.

- ***instance_name***

A repeatable string that specifies the name of an instance to unmark display instances.

- ***pin.pathname***

A repeatable string that specifies the name of a pin whose gate you want to unmark display instances.

- **-All**

A switch that specifies to unmark all the gates in the design.

- **-Select**

A switch that specifies to unmark currently selected gates.

- -Display {FLAt_schematic| HIEarchical_schematic}

A switch and literal pair that specifies the window for which to apply the unmark_display_instances command. The following literals can be used with the -Display switch:

FLAt_schematic — Applies the settings to the Flat Schematic window. This is the default behavior.

HIEarchical_schematic — Applies the settings to the Hierarchical Schematic window.

Examples

The following example unmarks two instances by specifying the instance name of one and the gate identification number (85) of the other:

unmark_display_instances /i\$142 85

unregister_attribute

Context: unspecified, all contexts

Mode: all modes

Unregisters a user-defined attribute that was registered using the register_attribute command.

Usage

```
unregister_attribute -name attribute_name [-object_types type_list] [-silent]
```

Description

Unregisters a user-defined attribute that was registered using the register_attribute command.

Following de-registration, the attribute is unavailable for use.

Pre-defined attributes cannot be de-registered.

If attribute_name does not exist, or if a design object type in type_list does not exist, an error message displays unless the -silent is specified.

Arguments

- **-name *attribute_name***

A required switch and value pair that specifies the name of the attribute to de-register.

- **-object_types *type_list***

An optional switch and value pair that specifies the object type to which the new attribute can be assigned. The type_list string is a Tcl list that contains one or more of the following object types: module, instance, port, pin, or net. If an object type is not included in the type_list, the new attribute cannot be assigned to that object_type.

If this argument is not specified, by default, the new attribute is de-registered for all object types.

- **-silent**

An optional switch that suppresses error messages if the given attribute_name is not registered.

Examples

The following example de-registers the attribute added_by for only the net object type.

```
unregister_attribute -name added_by -object_type net
```

[unregister_static_dft_signal_names](#)

Context: unspecified, all context

Mode: all modes

Prerequisites: You cannot unregister static dft signal names after the [add_dft_signals](#) command is run.

Registers previously registered static DFT signal names.

Usage

```
unregister_static_dft_signal_names {name ...} | -all_user_defined
```

Description

Registers previously registered static DFT signal names. After you have run the [add_dft_signals](#) command, it is no longer possible to unregister a static DFT signal. Only DFT signal previously registered with the [register_static_dft_signal_names](#) command can be unregistered. The built-in names as well as the logic test control signals registered using the [tcd_scan](#) metadata cannot be unregistered.

Arguments

- ***name***

A repeatable string value that specifies the names of the DFT signals to unregister. The string can also be a well-formatted Tcl list of names. These names must correspond to DFT signal names that were registered using the [register_static_dft_signal_names](#) command.

- **-all_user_defined**

A Boolean switch specifying that all DFT signal names previously registered using the [register_static_dft_signal_names](#) command are to be unregistered.

Examples

The following example registers a DFT signal name then unregisters it:

```
register_static_dft_signal_names clockb_select  
unregister_static_dft_signal_names clockb_select
```

unregister_tcl_command

Context: unspecified, all contexts

Mode: all modes

Unregisters a command that was previously registered using the register_tcl_command.

Usage

`unregister_tcl_command command_name`

Description

Unregisters the command that was previously registered using the register_tcl_command.

An error is generated if the command was registered before the last lock_current_registration command invocation. Commands loaded as part of a plugin are automatically locked.

Arguments

- *command_name*

A required string that specifies the command to unregister.

Examples

The following example unregisters the commands ABC and DEF. The command ABC was registered prior to the last lock_current_registration command so it cannot be unregistered:

```
unregister_tcl_command ABC
// Error: Command locked and can't be un-registered

unregister_tcl_command DEF
```

unselect_display_instances

Context: all contexts

Mode: setup, analysis

Unselects the specified objects in the Flat and Hierarchical Schematic window(s).

Usage

```
unselect_display_instances {{gate_id# | instance_name | pin.pathname}} ... | -All  
[-Display {FLAt_schematic | HIErarchical_schematic}]
```

Description

Unselects the specified objects in the Flat and Hierarchical Schematic window(s).

Arguments

- ***gate_id#***

A repeatable integer that specifies the gate identification number of a gate to unselect. The value of the *gate_id#* argument is the unique identification number that the tool automatically assigns to every gate within the design during the model flattening process.

- ***instance_name***

A repeatable string that specifies the name of an instance to unselect.

- ***pin.pathname***

A repeatable string that specifies the name of a pin associated with a gate you want to unselect.

- **-ALL**

A switch that unselects all currently displayed gates.

- -Display {FLAt_schematic | HIErarchical_schematic}

A switch and literal pair that specifies the window in which this command selects objects. The following literals can be used with the -Display switch:

FLAt_schematic — Unselects the specified objects in the Flat Schematic window. This is the default behavior.

HIErarchical_schematic — Unselects the specified objects in the Hierarchical Schematic window.

Examples

The following example unselects an object identified by its instance name in the Flat Schematic window:

```
unselect_display_instances /i_top/i144
```

unsetenv

Context: unspecified, all contexts

Mode: all modes

Unsets a shell environment variable within the tool environment.

Usage

`unsetenv variable_name`

Description

Unsets a shell environment variable within the tool environment.

The unsetenv command unsets a shell environment variable within the current tool environment. When you only need a variable unset within the tool, this command saves you the time and trouble of exiting, issuing the UNIX unsetenv command in the shell, and re-invoking.

Note

 A shell variable you unset with this command is unset only with respect to the current tool session. The command does not alter the value of the variable in the invocation shell.

To set or change the value of a variable, use the [setenv](#) command. To view the value of the variable, use the [system](#) command to pass an appropriate shell command ([echo](#) or [env](#) for example) to the operating system for execution.

Arguments

- *variable_name*

A required string that specifies the name of the variable.

Examples

The following example unsets the SSH_AGENT_PID environment variable within the current tool environment, then confirms that it is unset:

```
system {echo $SSH_AGENT_PID}  
66216  
  
unsetenv SSH_AGENT_PID  
system {echo $SSH_AGENT_PID}
```

update_implicit_detections

Context: dft -edt, patterns -scan

Mode: analysis

Performs an analysis on the undetected and possibly detected faults to determine if any of those faults can be classified as detected-by-implication.

Usage

```
update_implicit_detections
```

Description

Performs an analysis on the undetected and possibly detected faults to determine if any of those faults can be classified as detected-by-implication.

The update_implicit_detections command is automatically issued after the simulate_patterns command executes a fault simulation when using external patterns or when using internal patterns in non-Atpg. The update_implicit_detections command is also automatically issued as part of the create_patterns command.

By invocation default, only scan-path-associated faults for the detected-by-implication classification are analyzed. The following faults are classified as detected-by-implication when the update_implicit_detections command is issued:

- A stuck-at-1 fault on the set input line of a transparent latch, scan latch, scan D flip-flop, shadow, copy, or sequential cell when the tool detects the stuck-at-1 fault on the output.
- A stuck-at-1 fault on the reset input line of a transparent latch, scan latch, scan D flip-flop, shadow, copy, or sequential cell when the tool detects the stuck-at-0 fault on the output.
- A stuck-at-0 fault on a clock input line of a transparent latch, scan latch, scan flip flop, shadow, copy, or sequential cell when the tool detects both the stuck-at-0 and stuck-at-1 faults for the associated data line.
- A stuck-at-0 fault on a data input line of a transparent latch, scan latch, scan D flip-flop, shadow, copy or sequential cell when the tool detects the stuck-at-0 fault and no other ports can capture a 1.
- A stuck-at-1 fault on a data input line of a transparent latch, scan latch, scan D flip-flop, shadow, copy, or sequential cell when the tool detects the stuck-at-1 fault on the data output and no other port can capture a 0.

Arguments

None

Related Topics

[report_faults](#)

verify_patterns

Context: patterns -scan_diagnosis

Mode: analysis

Performs pattern verification for diagnosis, and creates, updates, or loads the Diagnosis Startup Cache for use with the diagnosis tool.

Usage

```
verify_patterns {-Diagnosis |
  -Create_startup_cache startup_cache_name [-Force_open] |
  -Update_startup_cache startup_cache_name [-Force_open] |
  -Load_startup_cache startup_cache_name}
```

Description

Performs pattern verification for diagnosis, and creates, updates, or loads the Diagnosis Startup Cache for use with the diagnosis tool.

See “[Pattern Verification and the Diagnosis Startup Cache](#)” in the *Tessent Diagnosis User’s Manual* for complete information.

Arguments

- **-Diagnosis**

A required switch that only runs pattern verification without storing the pattern verification results into Diagnosis Startup Cache. The diagnosis tool outputs the pattern verification results to stdout and in the tool’s transcript.

If the pattern verification passes, then Tessent Diagnosis does not re-run pattern verification following the [diagnose_failures](#) command, unless there changes to the current pattern set.

- **-Create_startup_cache *startup_cache_name***

A required switch and string pair that runs pattern verification and creates a new Diagnosis Startup Cache. If *startup_cache_name* already exists, then the tool produces an error.

If the pattern verification passes, then the tool creates a new Diagnosis Startup Cache with the given filename. If the pattern verification does not pass, then the tool outputs the pattern verification results to stdout and does not create the Diagnosis Startup Cache.

- **-Update_startup_cache *startup_cache_name***

A required switch and string pair that loads an existing Diagnosis Startup Cache and compares the contents of the Diagnosis Startup Cache (netlist, patterns, and so on) to this information in the current Tessent Diagnosis session. If *startup_cache_name* does not exist, then the tool produces an error.

If the specified Diagnosis Startup Cache does not contain the current pattern sets or does not match the current tool version, then the tool runs pattern verification.

If the pattern verification passes, then the tool updates the specified Diagnosis Startup Cache. If the pattern verification does not pass, then the tool outputs the pattern verification results to stdout and does not update the Diagnosis Startup Cache.

- **-Load_startup_cache *startup_cache_name***

A required switch and string pair that loads an existing Diagnosis Startup Cache. If *startup_cache_name* does not exist, then the tool produces an error and exits.

If the specified Diagnosis Startup Cache contains the current pattern sets and matches the current tool version, then the tool loads the Diagnosis Startup Cache. Otherwise, the tool produces an error.

- **-Force_open**

An optional switch used with either -Create_startup_cache or -Update_startup_cache that unlocks a locked Diagnosis Startup Cache.

Examples

Example 1

This example demonstrates creating a Diagnosis Startup Cache for future use in diagnosis with Tessian Diagnosis.

In the Tessian Diagnosis scan diagnosis point tool, the following command sequence loads the test patterns, performs the pattern verification, and creates a Diagnosis Startup Cache named *my_startup_cache*:

```
read_patterns pat1
read_patterns pat2 -append
verify_patterns -create_startup_cache ./my_startup_cache
exit
```

Subsequently, you re-invoke Tessian Diagnosis, load the patterns and newly created Diagnosis Startup Cache (*my_startup_cache*), and perform diagnosis using the following command sequence:

```
read_patterns pat1
read_patterns pat2 -append
verify_patterns -load_startup_cache ./my_startup_cache
diagnose_failures log1
diagnose_failures log2
.....
exit
```

Example 2

This example command sequence illustrates updating an existing Diagnosis Startup Cache (*my_startup_cache*) for future use by Tessian Diagnosis:

```
read_patterns pat1
read_patterns pat2 -append
read_patterns pat3 -append
verify_patterns -update_startup_cache ./my_startup_cache
exit
```

Subsequently, you re-invoke Tessian Diagnosis, load the patterns and updated Diagnosis Startup Cache (*my_startup_cache*), and perform diagnosis using the following command sequence:

```
read_patterns pat1
read_patterns pat2 -append
read_patterns pat3 -append
verify_patterns -load_startup_cache ./my_startup_cache
diagnose_failures log1
diagnose_failures log2
.....
exit
```

Example 3

The following example provides the command sequence you would perform to use an existing Diagnosis Startup Cache with the Tessian Diagnosis Server:

1. Create the Diagnosis Startup Cache (*my_startup_cache*) with the following commands using the Tessian Diagnosis scan diagnosis point tool:

```
read_patterns pat1
read_patterns pat2 -append
verify_patterns -create_startup_cache ./my_startup_cache
exit
```

2. In the Tessian Diagnosis Server, add the patterns and load the Diagnosis Startup Cache (*my_startup_cache*) using the following command sequence:

```
add_pattern monitor1 pat1
add_pattern monitor1 pat2
