add_startup_cache monitor1 ./my_startup_cache
...
```

Example 4

In this example, Tesson Diagnosis does not create a Diagnosis Startup Cache or re-run pattern verification during diagnosis:

```
read_patterns pat1
read_patterns pat2 -append
verify_patterns --diagnosis // assume pattern verification passed
diagnose_failures log1 // will not re-run pattern verification
```

write_atpg_setup

Context: dft -scan

Mode: analysis, insertion

Prerequisites: Scan chains must be inserted.

Writes a test procedure file and a dofile that describes the chains that were created during scan insertion. In addition, for multi-mode scan insertion, the tool also generates a dofile that can be used to verify all of the defined scan modes.

Usage

```
write_atpg_setup basename [-Replace] [-NO_merge] [-NO_Edt] [-All_internal_clocks]
```

Description

Writes a test procedure file and a dofile that describes the chains that were created during scan insertion. In addition, for multi-mode scan insertion, the tool also generates a dofile that can be used to verify all of the defined scan modes.

You can use these files to identify the scan chains when loading the scan design into Tessent FastScan. By default, the test procedure and the dofile for newly inserted scan chains are merged with those for existing scan chains.

The order of the commands in the test procedure file determine the different levels of test procedure file information produced by this command.

- If you execute write_atpg_setup without first using the [read_procfle](#) command, a test procedure file that contains default timeplates and the procedures needed for ATPG setup (for example, shift, load_unload, and test_setup) are created.
- If you run [read_procfle](#) and load a test procedure file that contains timeplate definitions, non-scan procedure definitions (capture, ram_sequential, and others), and empty or template scan procedures, and then execute the write_atpg_setup command, a more complete test procedure file is created.

Note

 If the test procedure file loaded with the [read_procfle](#) command contains scan procedures (for example, shift and load_unload), they are replaced by ones generated with the write_atpg_setup command based on test logic inserted during the current session. The tool issues a W14 warning each time it replaces a procedure. However, it uses timeplates specified in the original procedure file for the newly-generated procedures. The only exceptions are for the test_setup procedure. Instead of being replaced, the events created by the write_atpg_setup command are appended to the end of the test_setup procedure.

By default, the tool automatically detects a SoC DFT flow and writes out EDT-specific commands to the ATPG setup files.

The dofile defines a Tcl procedure named “tessent_scan_setup” that accepts a parameter that is used to specify the name of the scan mode that you want to set up. For example, to define the scan chains that are accessible in “unwrapped” mode, you must add a call to tessent_scan_setup with the parameter set to “unwrapped”, as shown below:

```
dofile setup.dofile
tessent_scan_setup unwrapped
```

Finally, for designs that had pre-inserted scan chains, the default is that these scan chains will not be defined regardless of the selected mode. However, there is an optional argument to the tessent_scan_setup procedure that can be set to “1” if you want to also define these chains for the subsequent step. The example for this is shown below:

```
dofile setup.dofile
tessent_scan_setup unwrapped 1
```

In addition to generating the setup dofile, the tool will also generate a verification dofile that will enter the patterns -scan context, and will set up each scan mode, and trigger a system mode transition to verify that the inserted scan chains can be traced in that mode. By default, this procedure does not include any pre-defined chains. For designs with pre-existing chains, two additional procedures are created: verify_all_scan_modes_with_existing_chains and verify_all_scan_modes_without_existing_chains. You can choose the desired procedure after sourcing the verification dofile.

Hybrid TK/LBIST Flow Specifics

The regular scan insertion dofile includes additional commands that specify the pin names for scan enable and BIST enable signals. The tool automatically includes logicBIST-related commands either X-bounding or bounding of timing exceptions paths is implemented. Refer to the [Hybrid TK/LBIST Flow User’s Manual](#) for complete information.

Arguments

- ***basename***
A required string that specifies the root name for the test procedure and dofile. The files produced are *basename*.testproc and *basename*.dofile.
- **-Replace**
An optional switch that replaces the contents of a file that already exists. By default, files are not replaced.
- **-No_merge**
An optional switch that prevents merging the test procedure and the dofile of the newly inserted scan chains with those of the existing scan chains. By default, the test procedures and dofiles are merged.
- **-NO-Edt**
An optional switch that specifies that EDT-specific commands are *not* written to the ATPG setup files. By default, the tool automatically detects a SoC DFT flow and writes out EDT-

specific commands to the ATPG setup files. For more information, see the [set_edt_options](#) command.

- **-All_internal_clocks**

An optional switch that specifies to write all internally defined clocks to the timeplate, to the ATPG dofile, and to the shift procedure.

Examples

The following example writes the test procedure, the dofile, and the new netlist for the inserted scan chains to the specified filenames:

```
add_clocks 1 clk1
add_clocks 0 clk0
set_system_mode analysis
insert_test_logic

write_atpg_setup scan -replace
write_design -output_file scan.v
```

write_cell_library

Tools Supported: Tessent Scan, Tessent FastScan, and Tessent TestKompress

Mode: all modes

Writes out a single library file of all library files loaded by the `read_cell_library` command.

Usage

```
write_cell_library new_lib_filename [-replace]
    [-INCLUDE_CREATED_dft_cell_selections | -ONLY_DFT_cell_selections ]
```

Description

Writes out a single library file of all library files loaded by the `read_cell_library` command, or alternately (if not using Tessent Shell) loaded at tool invocation with the `-library` switch; this single library file can subsequently be loaded by the `read_cell_library` command or at tool invocation with the `-library` switch to reproduce the internal library state that would exist if the same set of original files was loaded.

Note

 Library cells that were read into the tool using the `read_verilog` command with associated Verilog compiler directives like ``celldesign` and ``endcelldesign` are not included in the output of the `write_cell_library` command.

A `dft_cell_selection` wrapper is optional information that can be in the same file as the tessent cell library models, or in a separate file. A `dft_cell_selection` wrapper allows you to specify the cells (which are also models in the cell library) to use for DFT test logic applications such as scan insertion. Also, the `get_dft_cell` command accesses information from the `dft_cell_selection`. For example, if you need a 2-input AND cell, and one is specified in the `dft_cell_selection` wrapper, then that referenced model is used when you need such a cell for the test logic being inserted into your netlist, or when the “`get_dft_cell` and `--inputs 2`” command is issued. For more information, refer to the `get_dft_cell` command description in this manual.

If no `dft_cell_selection` wrapper is provided, a default will be created when a command is issued which causes elaboration, such as `get_dft_cell` or `set_current_design`, and will be given the name “`default`”. A model will be selected with an appropriate learned `simulation_function` (“`and`” in the example described above), and an attempt is made to determine which of those models (if any) is best. Note that there is no need to provide the `simulation_function` which is written out for informational purposes when you issue `write_cell_library`, as it is discarded when the file is parsed. Models with a `cell_type` specified in the model in the tessent cell library file (such as “`cell_type = and`”) are preferred over models with no `cell_type` specified when the file is parsed. Also, any model already instantiated in the current design netlist is preferred over a model which has no instances in the current design.

If both the default `dft_cell_selection` wrapper and models are written out, the learned `cell_type` is also written in appropriate models. These should also be checked and corrected if the file is to

be read back in for use in subsequent runs of some test tool requiring a tessent cell library. You can find these cells by searching for the string “// Learned cell_type”, as illustrated next.

Note

 All parsed input is considered to be user input, regardless of comments or names. If you do not change the default dft_cell_selection name from “default”, then that is the name for your selected dft cells. If you do not check and edit the default dft_cell_selection wrapper, but instead read it back as written, all the learned cell_type will be considered as user-provided and approved cell_type, not learned. This is true despite any comment in the parsed library file saying a cell_type was learned – that is ignored because when parsed, the cell_type is now user-specified, not learned. These cells will no longer defer to other cells whose cell_type was originally specified in the library models.

The following examples illustrate the output resulting from a model having its cell_type learned rather than specified when the model was parsed, combined with -include_default_dft_cell_selection. Note that the simulation_function is always learned and is always written out, but it is informative only and is discarded and recalculated each time the file is parsed. A cell_type must have a compatible simulation_function (for example, simulation_function should be mux for cell_type mux or cell_type clock_mux) to be used for test logic, even if you set the cell_type.

If the -include_default_dft_cell_selection switch is specified, and a default dft_cell_selection wrapper exists:

```
model TC4MUX2XC
  (Y, D0, D1, S0)
(
  cell_type = mux; // Learned cell_type
  simulation_function = mux;
  ....
```

If the -include_default_dft_cell_selection switch is not specified, or a default dft_cell_selection wrapper does not exist:

```
model TC4MUX2XC
  (Y, D0, D1, S0)
(
  simulation_function = mux;
```

Arguments

- *new_lib_filename*

A required string that specifies the location of the file to which the library contents are written in cell/model format. If this file is subsequently loaded using “read_cell_library new_lib_filename” or alternately (if not using tessent shell) using “-library new_lib_filename” at invocation, the internal library state that existed when the file was written will be effectively restored.

- **-replace**
An optional switch that specifies to replace the contents of the file specified by the new_lib_filename argument if the file already exists.
- **-INCLUDE_CREATED_dft_cell_selections**
An optional switch that writes out the created dft_cell_selection information. If no dft_cell_selection is parsed, the default dft_cell_selection will be written at the top of the tesson cell library file, before the models are written. Otherwise, the parsed dft_cell_selections will be written including the augmented dft_cell_selection information. Models with a learned cell_type will also have the cell_type written in the model. If this switch is not specified, only user specified cell_type are written in the model.
- **-ONLY_DFT_cell_selections**
An optional switch that allows you to write out only the dft_cell_selections to a file. If no parsed dft_cell_selection exists, in which case a default dft_cell_selection will be written, it is recommended that you change the name from “default” and adjust the default dft_cell_selection to reference the cells that you prefer, and then use the result in future tool invocations to achieve deterministic selection of the cells used for test logic. The file containing the edited dft_cell_selection wrapper can then be given to the read_cell_library command as a tesson cell library filename.

Examples

Example 1

The following example assumes the tool is invoked with the -library switch and the library files are loaded. The write_cell_library command writes the cells/models contained in those files to the new library file new_library.tcelllib. If the new_library.tcelllib file already exists the file is not written.

```
$ fastscan -library mylib.tcelllib
SETUP> write_cell_library new_library.tcelllib
```

Example 2

The following example assumes the tool is invoked without the -library switch and the library files are loaded after invocation with the read_cell_library command. The write_cell_library command writes the cells/models contained in those files to the new library file new_library.tcelllib. If the new_library.tcelllib file already exists, its contents are replaced with the new library data.

```
$ tessent -shell
SETUP> read_cell_library pad_lib.tcelllib
SETUP> read_cell_library standard_lib.tcelllib
SETUP> read_cell_library my_lib.tcelllib
SETUP> write_cell_library new_library.tcelllib -rep
```

[delete_cell_library](#)

[read_cell_library](#)

[write_config_data](#)

Context: unspecified, all contexts

Mode: all modes

Writes the configuration data presently in memory into a file. When using the -wrappers option, the data written to the file can be limited to some specific wrappers.

Usage

```
write_config_data filename [-wrappers wrapper_spec] [-specify_all] [-indent integer]  
[-replace] [-original_hierarchy] [-no_banner]
```

Description

Writes the configuration data presently in memory into a file. When using the -wrappers option, the data written to the file can be limited to some specific wrappers.

Arguments

- ***filename***

A required string option that specifies the name of the file into which to write the configuration data.

- **-wrappers *wrapper_spec***

An optional switch and value pair that specifies a Tcl list of one or more names of configuration wrappers, or a collection containing one or many configuration wrapper objects. Only the specified wrapper elements are written to the file.

Just like with the [report_config_data](#) command, if *wrapper_spec* only contains a single wrapper of type CSV, the format of the file will be changed such that a true CSV file is written out and ready to be read in to tools that support the CSV format such as Excel. This behavior is disabled if you use the -original_hierarchy option. A true CSV file has no wrapper and the line termination character is the carriage return instead of the semicolon, as is the case in a normal configuration data file.

- **-specify_all**

An optional switch that specifies that unspecified properties and singular wrappers all show up in the written file with the unspecified properties specified to their default values. By default, unspecified properties and singular wrappers do not appear in the output file.

- **-indent *integer***

An optional switch and value pair that specifies to change the amount of white spaces used for indentation. By default, sub-elements are indented by two characters with respect to their parent wrapper.

- **-replace**

An optional Boolean switch that suppresses the error that normally is issued if the filename already exists. When the -replace option is used, the tool silently deletes the existing file before creating the new one.

- **-original_hierarchy**

By default, the wrappers specified with the -wrappers options become root wrappers in the output file. You can use this option to preserve their original hierarchy and include all parent wrappers above them. When you write out a sub-wrapper without preserving the original hierarchy, you can then read it back into any valid parent wrapper using the “[report_config_data -in_wrapper](#)” command and option.

- **-no_banner**

An optional Boolean option that suppresses the banner that is normally written at the top of the file. The banner format is the following:

```
-----  
// File created by: Tesseract Shell  
// Version: 2014.1  
// Created on: Mon Jan 20 12:12:28 PST 2014  
-----
```

Notice that the banner is also removed when the file is output in the true CSV format. See the description of the -wrappers option for more info about the CSV format.

Examples

The following example shows the effect of all options.

```
#shows the configuration data currently in memory  
report_config_data  
  
tmp(1) {  
    subWrapper1 {  
        prop1 : v1;  
    }  
    subWrapper2 {  
        prop1 : v1;  
    }  
}  
  
# Standard write to a file  
write_config_data file1  
cat file1
```

```

//-----
// File created by: Tessent Shell
// Version: 2014.1-prerelease
// Created on: Mon Jan 20 12:47:09 PST 2014
//-----
tmp(1) {
    subWrapper1 {
        prop1 : v1;
    }
    subWrapper2 {
        prop1 : v1;
    }
}

# Limit write to one sub wrappers
write_config_data file2 -wrappers tmp(1)/subWrapper1
cat file2

//-----
// File created by: Tessent Shell
// Version: 2014.1-prerelease
// Created on: Mon Jan 20 12:47:09 PST 2014
//-----
subWrapper1 {
    prop1 : v1;
}

# Preserve the original hierarchy
write_config_data file3 -wrappers tmp(1)/subWrapper1 -original_hierarchy
cat file3

//-----
// File created by: Tessent Shell
// Version: 2014.1-prerelease
// Created on: Mon Jan 20 12:47:09 PST 2014
//-----
tmp(1) {
    subWrapper1 {
        prop1 : v1;
    }
}

#Remove the banner. Show error when file exist and -replace is not used.
catch {write_config_data file3 -no_banner}

// Error: File file3 cannot be overwritten unless you use the option -replace.

write_config_data file3 -no_banner -replace
cat file3

tmp(1) {
    subWrapper1 {
        prop1 : v1;
    }
    subWrapper2 {
        prop1 : v1;
    }
}

```

[report_config_data](#)

[write_core_description](#)

Context: patterns -scan, patterns -scan_retargeting

Mode: analysis

Prerequisites: Retargetable pattern generation is enabled in patterns -scan_retargeting context ([set_current_mode](#) -type internal).

Writes out the core description corresponding to the current chip level.

Usage

`write_core_description file_name [-replace]`

Description

Writes out the core description corresponding to the current design.

The tool only writes out the current mode of the current core. It also writes out the core descriptions of any of its core instances so that the definition of the current core's current mode is self-contained.

The core description file can be generated in the following cases:

- After ATPG for the internal mode of a core, so that information can be fed forward for pattern retargeting.
- For the top level during pattern retargeting, so it can be used for reverse-mapping of chip-level failures back to the core level for diagnosis.
- For logicBIST in the patterns -ijtag context when generating chip-level patterns.

This command works in the -scan_retargeting context because this file is required as input for failure mapping.

Hybrid TK/LBIST Flow Specifics

Writes the description of the core for the logicBIST mode of operation. This includes description of the core pins, scan chain information, and EDT/logicBIST hardware registers (essentially, all information to capture the core-level logicBIST mode operation). Refer to the [Hybrid TK/LBIST Flow User's Manual](#) for complete information.

Arguments

- *file_name*

A required switch that specifies the pathname of the file to which the core description is written.

- *-replace*

An optional switch that specifies to overwrite the existing file *file_name*.

Examples

The “[Retargeting Example](#)” in the *Tessent Scan and ATPG User’s Manual* demonstrates the use of this command in a design context.

[report_core_instances](#)

write_core_timing_constraints

Context: dft -edt, patterns -scan

Mode: analysis

Creates timing (SDC) files that provide the constraints related to the scan path and ATPG settings in the core design.

Usage

`write_core_timing_constraints filename_prefix [-Replace]`

Description

Creates timing (SDC) files that provide the constraints related to the scan path and ATPG settings in the core design.

If launch-off capture (broadside) transition patterns are used, fast capture constraints are generated, otherwise slow capture constraints are generated.

For more information on the timing files, see “[SDC Timing File Generation](#)” in the *Tessent TestKompress User’s Manual*.

Arguments

- ***filename_prefix***
A required string that specifies the naming prefix for the timing files.
- **-Replace**
An optional switch that replaces the contents of the file if the *filename* already exists.

Examples

The following example outputs timing files for the scan path and ATPG settings in the core design, using *atpgm* as the filename prefix:

```
write_core_timing_constraints atpgm
// Writing atpgm_core_shift_sdc.tcl
// Writing atpgm_slow_capture_sdc.tcl
```

Related Topics

[write_edt_files](#)

write_design

Context: all contexts

Mode: all modes

Writes the current design in Verilog netlist format to the specified file.

Usage

Usage 1: Creating interface modules

```
write_design -output_file filename [-banner banner] [-modules modules_list]
    [-interface] [-verbose] [-replace]
```

Usage 2: Writing out created modules in rtl context

```
write_design -output_file filename [-banner banner] [-created | -modules modules_list]
    [-hierarchical]] [-exclude_modules exclude_modules] [-verbose] [-replace]
```

Usage 3: Writing out read-in modules in rtl context

```
write_design {-output_directory directory | -original_location [-extension_suffix suffix]}
    [-modified | -all_read | -modules modules_list [-hierarchical]]
    [-exclude_modules exclude_modules] [-write_out_updated_f_files] [-verbose]
    [-file_map file_map_var] [-replace]
```

Usage 4: Writing out read-in or created modules in no_rtl context

```
write_design -output_file filename [-banner banner]
    [-modified | -created | -modules modules_list
    [-hierarchical]] [-exclude_modules exclude_modules] [-verbose] [-replace]
```

Usage 5: Writing out the graybox view of the current design

```
write_design -output_file filename [-banner banner] [-graybox] [-verbose] [-replace]
```

Usage 6: Writing out the modified design in the dft_inserted_designs directory of the TSDB

```
write_design -tsdb [-verbose]
```

Usage 7: Writing out the graybox view of the current design in the dft_inserted_designs directory

```
write_design -tsdb -graybox [-verbose]
```

Usage 8: Creating a dft_inserted_designs directory in the TSDB with a softlink to the read-in concatenated netlist

```
write_design -tsdb -softlink_netlist [-verbose]
```

Description

Writes the current design in Verilog netlist format to the specified file.

Use the -modules switch to write only specific modules. The default is to write the top module with all the modules in the hierarchy below except the created modules and the modules below them. The file organization of the read in files is never changed when using the -rtl mode of the [set_context](#) command. See the section “[Difference Between -rtl and -no_rtl Mode](#)” for the

difference between `-rtl` and `-no_rtl` mode when it comes times to write out the design using the `write_design` command.

Note

 You cannot use the `write_design` command to overwrite files containing RTL modules that were read in with the `read_verilog` command. See the section “[Difference Between -rtl and -no_rtl Mode](#)” below for an explanation why.

Note

 The `write_design` command is disabled if you read in a flat model using the `read_flat_model` command.

Note

 Verilog modules originally defined inside `'celldefine` and `'endcelldefine` directives are not included in the output netlist. For more information about using `'celldefine` to define cell boundaries, refer to the “[Fault Locations](#)” discussion in the *Tessent Scan and ATPG User’s Manual*.

Usage 1 — This usage case writes out the interface definition of the specified modules only. The port and parameter definitions are saved but everything else is deleted from the module; this has no impact on the module definition in memory and only affects the content of the file being written out. If you do not specify the `-modules` option, the interface of the current design is written out.

Usage 2 — This usage case writes out the created modules in the `rtl` context. Created modules are modules created using the `create_module` command; these modules do not have a source file associated with them so you must specify one using the `-output_file` option. You can write all created modules into a single file using the `-created` option; this only works if all of your created modules have a common language because modules from different languages (VHDL versus Verilog) must be written into different files.

If you do not specify either `-modules` or `-created` options, the tool infers the following: “`-modules [get_current_design] -hierarchical`.” In this case, the tool generates an error if the current design is a created module and you did not specify the `-output_file` switch. When you specify the `-modules` option, you can only specify created modules; otherwise, an error is generated.

When you specify the `-hierarchical` option, read-in modules are automatically skipped.

Usage 3 — This usage case writes out read-in modules in the `rtl` context. Because RTL can contain many directives that affect how things are later compiled, the tool preserves the content and ordering of the RTL files when writing them out. For this reason, you can only write out read-in modules using either the `-output_directory` or the `-original_location` switch. The use of the `-output_file` option is not allowed for read-in modules in the `rtl` context.

By default, the tool does not write out the read-in -f files. You must specify the optional -write_out_updated_f_files switch to write out the -f files in addition to the read-in RTL files.

You can use the -all_read option to decompile and write all files previously read with read_verilog or read_vhdl, even if they contain no module definitions such as files containing only the definitions of System Verilog interfaces, `define statements, or files containing no modules instantiated below the current design.

You can use the -modified option to quickly write out only the modified modules, but if you also specify created modules, the tool does not write those out. However, you can write out the created modules using a separate write_design command invocation with the -output_file option specified.

If the -modules or -modified options are not specified, the tool infers the following: “-modules [get_current_design] -hierarchical.” In this case, the tool generates an error if the current design is a created module and you used the -output_directory or the -original_location switches. When you specify the -modules option, you can only specify read-in modules in this usage.

For more explanation about how read-in modules are written out in the RTL context, see the “[Difference Between -rtl and -no_rtl Mode](#)” section below.

Usage 4 — This usage case writes out read-in or created modules in the no_rtl context. In the no_rtl context, the design modules are written out with all compiler directives removed. The dependencies on the file order is thus removed, allowing the concatenation of any modules into common files. You can merge both read-in and created modules into the same file.

In the no_rtl context, the recommended use model is to write out the entire design hierarchically into a single file which is the default behavior when the -modules, -created or -modified option are not specified.

Usage 5 — This usage case writes out the graybox view of the current design into a single file. Only those instances and nets that have the in_graybox attribute set to true are kept in this file. All other nets and instances are removed. You can set this attribute using the [set_attribute_value](#) command but this attribute is normally populated using the [analyze_graybox](#) command. See Usage 7 below for how to get the graybox model saved into the TSDB.

Usage 6 — This usage case creates a [dft_inserted_designs](#) directory with the modified design that you created using a custom script. If ICL is elaborated, it is written out to the new dft_inserted_designs directory with the [tessent_design_id](#) attribute updated to match the new *design_id* define with the [set_context](#) command. The concatenated PDL file is also copied and the .tcd file and the .tsdb_info files are also created. You use this case when you want to run a custom editing script. Saving it using “write_design -tsdb” will store it inside the TSDB such that you can read it back later in using the [read_design](#) command.

Usage 7 — This usage case writes out the graybox view in the `dft_inserted_designs` directory. When using the `-graybox` switch, an error is generated if the `analyze_graybox` command was not called prior. The graybox view can be saved in a `dft_inserted_designs` directory that was previously created using the “`write_design -tsdb`” or “`insert_test_logic -write_in_tsdb on`” command. If the current “`set_context -design_identifier`” value does not match an existing `dft_inserted_designs` directory, a new one is created with all the associated files: the ICL, PDL, TCD, and the TSDB info files.

Usage 8 — The `-softlink_netlist` usage case is only usable in the `-no_rtl` mode right after the design was elaborated in the setup mode. It creates a `dft_inserted_designs` directory for the read-in netlist such that it can be easily loaded with `read_design` or by the `run_testbench_simulations` commands. This option is typically used to create a TSDB entry for the post synthesis netlist when scan insertion is not done in Tessent Shell. The post synthesis TSDB view is created by “`insert_test_logic -write_in_tsdb on`” when the scan insertion is done in Tessent Shell. It is also used to create a TSDB entry for the post layout netlist such that the `read_design` command can be used in ATPG to load this netlist, create a graybox view when it is a wrapped core and automate the design loading in `run_testbench_simulations`.

Difference Between `-rtl` and `-no_rtl` Mode

There are many differences that exist between `rtl` and `netlist` files. Those differences are listed and contrasted in [Table 6-23](#). Because of the characteristics of the `rtl` files mentioned in the table, the module organization of `RTL` files cannot be changed.

[Figure 6-9](#) shows the differences that exist inside the tool when reading `rtl` vs `netlist` files. In both cases, the data model inside the tool only consists of the structural elements found inside the modules, instances, ports, pins, and nets. The different color used for the input files of the `rtl` mode are meant to illustrate the various languages and formats the files may have in `rtl` mode. In the `netlist` mode, the files are always with language Verilog and format 2001. When it comes time to write out the modified `netlist`, all the information is in the data model and a new `netlist` is reconstructed from scratch using the information inside the tool. In the `rtl` mode, only the edits made to the structural objects (module, instances, pin, port, net) are present in the internal data model. The effects on the `rtl` files are only reflected when the `write_design` command is used. The original files containing the modified modules are used and the edits are patched in a surgical fashion such that all white spaces, comments and carriage returns in the original files are preserved. Only the pins, ports, and nets affected by the edits show modifications. Because each file came in with a unique language and format, all written out files preserve the unique language and format as illustrated with the coloring of the files. [Figure 6-10](#) shows the effect of doing two insertion passes on the same design. Some files were never modified. Some files were only modified by the first insertion pass. Some files were only modified by the second insertion pass. Finally, some files were modified by both insertion passes. The design view that represents the design as it exists after the second insertion pass has files located in the original location, in the `dft_inserted_designs` directory of the first insertion pass and in the `dft_inserted_designs` directory of the second insertion pass. Refer to the `read_design`, `run_testbench_simulations` and the `write_design_import_script` command descriptions to see how the tool provides powerful commands to help reload the edited `rtl` design files.

Table 6-23. Difference between rtl and Netlist files

RTL	Netlist
9 distinct formats, no superset parser Verilog (1995 2001 sv31a sv2005 sv2009) VHDL (1987 1993 2002 2008)	1 format Verilog 2001
Content of read-in file affects the files read afterward. Ex :`define, packages, SV definitions,...	Read order has no effect
File structure and read order must be preserved one format per file read order cannot be changed	Support concatenating all modules into one file
Typically one file per module or functional block manually edited and maintained revision control system like CVS or Git	One file per physical block
One module name can have multiple implementations parameters, generate blocks, logical libraries, ...	One module name, one implementation

Figure 6-9. Writing Out the Modified Design in rtl vs no rtl Modes

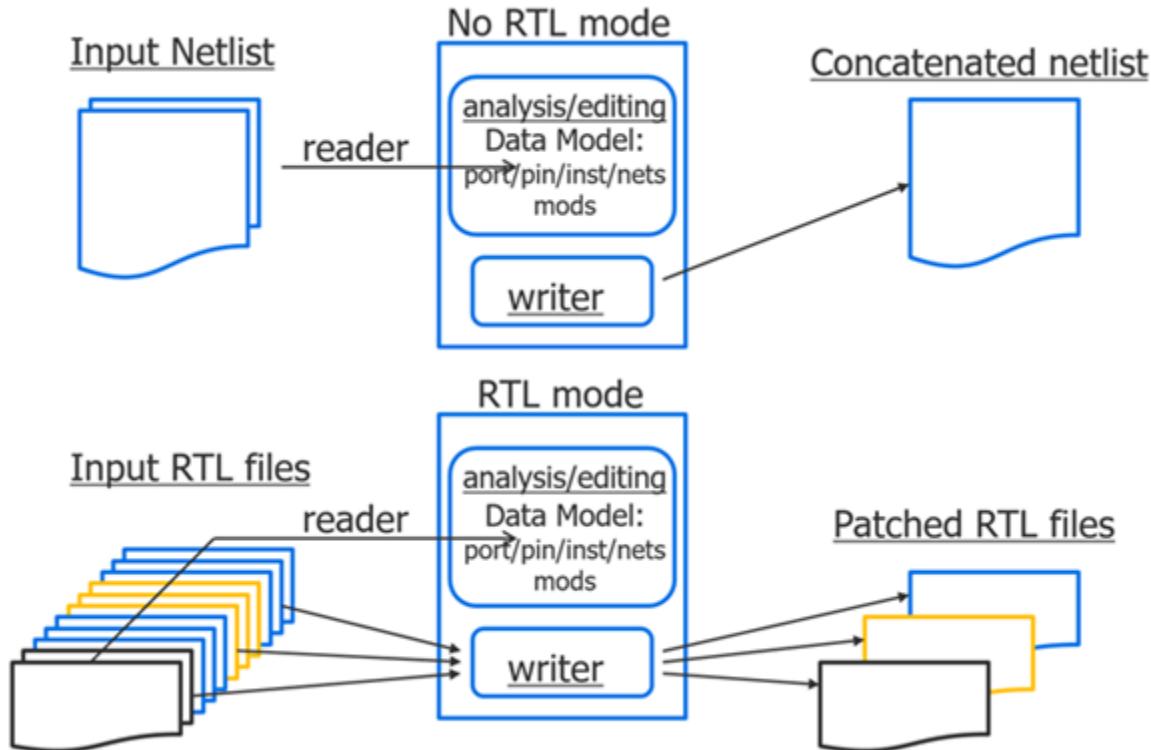

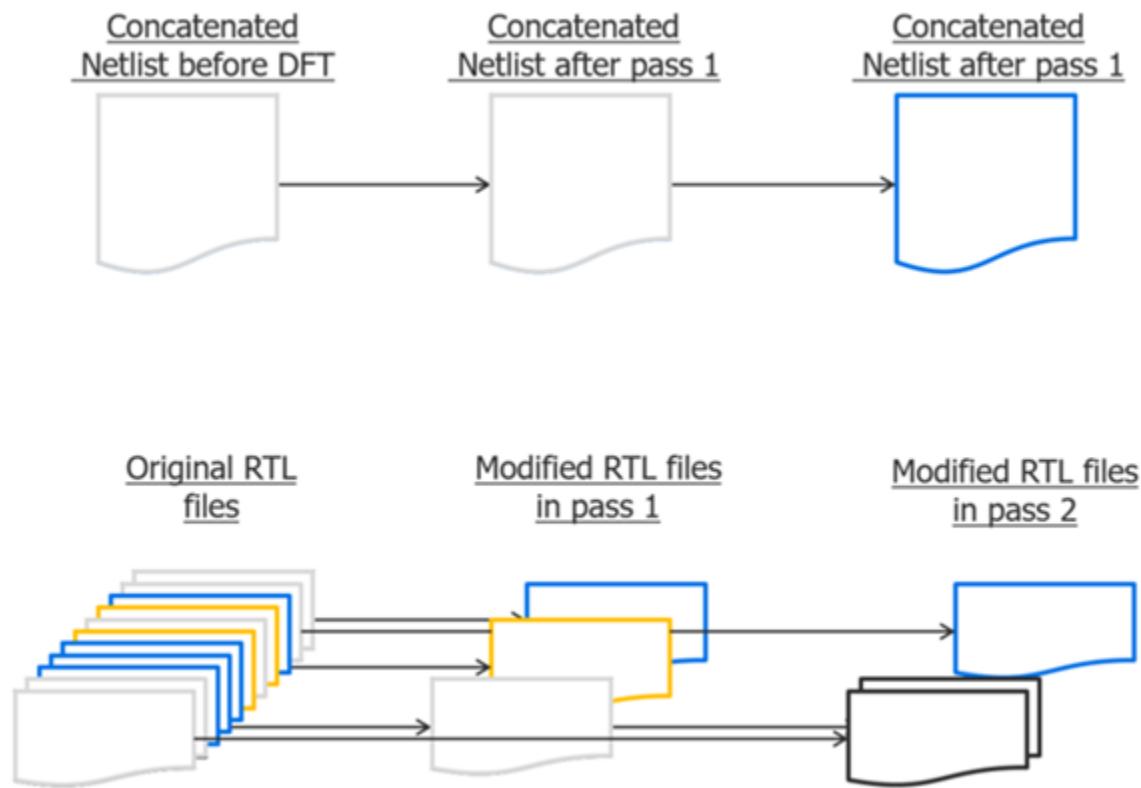

Figure 6-10. Effect of Successive Design Editing Passes on the Design View

Arguments

- **-output_file *filename***

A switch and string pair that specifies the name of the file in which to write all specified modules. This switch can only be used in the rtl context when writing created modules as described in Usage 2 above. It can be used for any modules in the no_rtl context.

- **-banner *banner***

An optional switch and string pair that specifies a header comment to be written as the first line of the output file.

- **-output_directory *directory***

A switch and string pair that specifies the directory in which to write all specified modules. All files containing at least one of the specified modules will be written out. Subdirectories within the specified output directory will be created if the read-in files were stored in separate directories in order to avoid file name collisions. This switch is only allowed in -rtl mode and defines Usage 3 described above. See the “[Difference Between -rtl and -no_rtl Mode](#)” section for an explanation why the file structure is not modified when using the rtl context.

- **-original_location**

A switch that specifies to write out the specified modules in the same directory that they were read in from. All files containing at least one of the specified modules in the -modules

switch value will be written out. The file name and directory location of the source file will be used except that the default or specified -extension_suffix value will be appended to the file extension.

This option preserves the same file and directory structure as the original rtl description. The modified rtl files can be loaded into the next tool using the original -y options by simply modifying the extension search list. You must, however, have write access in the source directories. The source file can be write protected but not the source directory.

The commands [process_dft_specification](#), “[insert_test_logic -write_in_tsdb on](#)”, and “[write_design -tsdb](#)” all create a “[dft_inserted_designs](#)” TSDB container for the new design view. The modified rtl files are stored inside that directory and the [.design_source_dictionary](#) file contains the information to load that design view within the [read_design](#), [write_design_import_script](#), and the [run_testbench_simulations](#) commands. If you want the modified rtl files to be stored back beside the original file locations as it was done in the LV Flow, then issue the following command before leaving the insertion mode (for example, after having called the [process_dft_specification](#) command but before calling [extract_icl](#)):

```
write_design -modified -original_location -extension_suffix _et
```

The file dictionary will be written into the TSDB when exiting the insertion pointing to the modified rtl files written back into their original location.

- **-modules *module_list***

An optional switch and value pair that specifies the names of the modules to write out. The *module_list* value is a Tcl list of module names, or a collection of modules as returned by the [get_modules](#) command.

In the rtl context when using multiple logical libraries and vhdl architectures, use the [get_modules](#) commands to select modules from a specific library or architecture. A module name in the *module_list* is only looked for in the default library with the default architecture.

In the rtl context, you cannot use the -output_file switch when writing out read-in modules. The written out file always contain the exact same modules list that existed in the read-in file. If you use the -modules switch to refer to a module, the source file that contains the read-in module will be written out containing all modules that existed when it was read-in. See the “[Difference Between -rtl and -no_rtl Mode](#)” section for an explanation of why the file structure cannot be modified for read-in files in rtl mode.

- **-hierarchical**

An optional switch that writes out all child modules below the specified modules. This switch can only be used with the -modules switch. If the -modules switch includes created modules, read-in modules found below those modules are ignored. If the -modules switch includes read-in modules, created modules found below those modules are ignored. An error is generated if the -modules switch contains both read-in and created modules as those consist of different usage. See Usage 2 and 3 above for an explanation of the difference. See the “[Difference Between -rtl and -no_rtl Mode](#)” section for more details.

- **-exclude_modules** *exclude_modules*

An optional switch and value pair that excludes modules from being written out. This argument is useful only when the -hierarchical option is inferred or specified. All modules below these excluded modules are also excluded if they are not specified in the -modules list or found below other non-excluded modules.

In the rtl context, when using multiple logical libraries and vhdl architectures, use the [get_modules](#) command to select modules from specific libraries or architectures. A module name in the module_list is only looked for in the default library with the default architecture.

In the rtl context, all modules found in a read-in file are always included in the written out file even if the -exclude_modules switch specifies to exclude some of those module. As soon as one module in the file is in the -module switch, the entire file is written out with all modules found in the read-in file. See the “[Difference Between -rtl and -no_rtl Mode](#)” section for more details.

- **-write_out_updated_f_files**

An optional switch to add the read-in -f files to the written rtl files. The -f files are modified to point to the new location of the written directories and files. This may change the directory structure of the written files if the -f files were located higher in the directory tree as the rtl files.

- **-all_read**

An optional switch that decompiles and writes out all files previously read with [read_verilog](#) or [read_vhdl](#), even if they contain no modules. This switch is available only in the rtl context.

- **-created**

An optional switch that specifies to limit the written modules to only those *created*. Specifying this option is equivalent to using “-modules [[get_modules](#) -filter is_created].”

- **-tsdb**

An optional switch that specifies to write the design and all its associated files in the [Tessent Shell Data Base \(TSDB\)](#). See the Usage 6, 7, and 8 above for more details.

- **-graybox**

An optional switch and string pair that specifies that the content of the output files will not contain the complete module descriptions but only those nets and instances having the in_graybox attribute set to true. You can set this attribute using the [set_attribute_value](#) command but is normally populated using the [analyze_graybox](#) command.

This switch is available only in the no_rtl context.

- **-softlink_netlist**

An optional switch that is only usable in the -no_rtl mode right after the design was elaborated in the setup mode. It must be used with the -tsdb switch to create a [dft_inserted_designs](#) directory containing a softlink to the read-in netlist such that it can be

easily loaded with [read_design](#) or by the [run_testbench_simulations](#) command. For more information about this switch, see Usage 8 described above.

- **-interface**

An optional switch that specifies to write out only the interface of the current design or the interfaces of the modules specified by the **-modules** option.

- **-extension_suffix *suffix***

An optional switch and string pair that specifies the suffix to use to distinguish the written-out file names from the read-in file names when the **-original_location** option is used. The **-extension_suffix** defaults to “**_ts**.”

- **-verbose**

An optional switch that specifies to print the name of each written file, one per line.

- **-file_map *file_map_var***

An optional switch and string pair that creates a list of files the tool modifies during the design writing operation. Use this switch when doing flows that require the generation and use of context views for designs requiring uniquification. The *file_map_var* will show which files got modified, enabling you to update your design load script.

- **-replace**

An optional switch that specifies to overwrite an existing file. When you use this switch, the error message that is normally generated if the file being written out already exists is suppressed.

Examples

Example 1

The following example writes out the current design and every other design module instantiated below it into a common file.

```
write_design -output_file design_out.v
```

Example 2

The following example generates an interface module description for the current design inside the file called mod.shell.

```
write_design -output_file mod.shell -interface
```

Example 3

The following example writes out all modules within the current design but stops on CoreA and CoreB. Separate commands are used to write out all modules within CoreA and CoreB. Notice how the first command does not specify the **-modules** option which means the current design is to be written out and the **-hierarchical** switch is inferred.

```
write_design -output_file myTop.v -exclude_modules {CoreA CoreB}
write_design -output_file CoreA.v -modules CoreA -hierarchical
write_design -output_file CoreB.v -modules CoreB -hierarchical
```

Example 4

The following example uses the `-no_hdl` option of the `read_design` command to load the information about `my_design` from the pre-synthesis TSDB directory and combine it with the post-synthesis netlist to create a complete gate level TSDB directory. This will later allow using “`read_design my_design -design gate`” to create patterns.

```
set_context dft -design_id gate -no_rtl
read_cell_library cell_library
read_verilog path/my_design.vg
read_design my_design -design_id rtl -no_hdl -verbose
set_current_design my_design
write_design -tsdb -softlink_netlist -verbose
```

Refer to [Example 2 in run_testbench_simulations](#) for a usage example about how to use the `write_design -tsdb -softlink_netlist` command to create a TSDB `dft_inserted_designs` container for a netlist generated from synthesis or layout, and on which you want to use the `run_testbench_simulations` command to simulate the patterns described in your PatternsSpecification.

write_design_import_script

Context: dft, patterns

Mode: setup, analysis

Generates a script that can be processed by a synthesis tool to synthesize an RTL design that has been DFT inserted.

Usage

```
write_design_import_script [file_name] [-replace] [-module module_spec]
[-design_id design_id] [-use_relative_path_to directory]
[-exclude_sub_blocks]
```

Description

This command generates a script that can be processed by a synthesis tool to synthesize an RTL design that has been DFT inserted. The script analyzes all the source files that were read into Tessent Shell and reported into the *design_name.design_source_dictionary* for the current design that is generated into the [Tessent Shell Data Base \(TSDB\)](#). By default, all the sub-blocks of the design are also analyzed by the script, unless the option `-exclude_sub_blocks` is specified. When the *design_name.design_source_dictionary* has not been generated for the current design, the generated script uses the information in memory about the source files that were read into Tessent Shell when the command is issued.

Arguments

- *file_name*

An optional string that specifies the script file name. When *file_name* is not specified, the name defaults to:

design_name.tool_name_import_script

- `-replace`

An optional switch that specifies overwriting *file_name* when the file exists.

- `-module module_spec`

An optional switch and string pair that specifies a specific module name in an opened TSDB that has been DFT inserted. The default is to use the current design and current design identifier.

- `-design_id design_id`

An optional switch and value pair that specifies a specific *design_id* when a module has been DFT inserted more than once.

- `-use_relative_path_to directory`

An optional switch and value pair that specifies a directory from which the generated script is processed. The files being referenced are relative to this directory. By default, the generated script includes the full paths to the files to process.

- [-exclude_sub_blocks](#)

An optional switch that specifies to ignore the analysis of the sub-blocks instantiated in the main module in the generated script. By default and if this switch is not specified, the generated script considers the design source dictionary for the selected DFT inserted design and all the sub-blocks that are included in the selected design. The inclusion stops and does not include any module that is a physical block. All the TSDBs used to assemble the selected module must be opened in order for the sub-block information to be accessible.

Examples

Example 1

The following produces the report for the current design in memory, with full paths and including all the sub-blocks. The resulting script is displayed when in interactive mode and is reported in the Tesson Shell log file.

[write_design_import_script](#)

Example 2

The following produces the report for the design *my_core* with paths relative to the subdirectory *synth/my_core* and without the sub-blocks. The generated script is saved in the file *synth/my_core/analyze.tcl*.

```
file mkdir synth/my_core
write_design_import_script analyze.tcl -replace -module my_core \
    -exclude_sub_blocks -use_relative_path_to ./synth/my_core
```

[run_synthesis](#)

write_design_source_dictionary

Context: dft, patterns

Mode: setup, analysis, insertion

Writes a design-source dictionary into a file. This file contains the file and directory paths relative to the output file location.

Usage

`write_design_source_dictionary output_file [-dictionary dictionary] [-replace]`

Description

Writes a design-source dictionary into a file. This file contains the file and directory paths relative to the output file location. You can subsequently source this written-out design-source dictionary to reload the design using the “[read_design -from_dictionary \\$design_source_dictionary](#)” command. Refer to the [example](#) to see how you use this command to package an RTL test case into a single directory. If you omit the -dictionary switch, then the design-source dictionary returned by the “[get_design_sources -file_dictionary](#)” command is written out. You can also choose to store the design-source dictionary returned by the “[get_design_sources -file_dictionary](#)” command into a variable, make edits to the dictionary stored into the variable using the Tcl “dict” command, and then write out the modified dictionary using the “-dictionary \$var” switch, where “var” is the Tcl variable that holds the dictionary you modified.

Note

 If you want to write out a design-source dictionary that reflects the state of the RTL design after you have edited the design in insertion mode, then you must first go to setup mode to synchronize the design in order for the file dictionary to reflect the files with your edits.

Arguments

- ***output_file***

A required string argument that specifies the name of the file into which the tool will write the design-source dictionary. All of the file and directory paths contained in the design-source dictionary file are relative to the location of the output file.

- **-dictionary *dictionary***

An optional switch-string pair that specifies a Tcl dictionary the tool will write out. Typically, you do not use this switch. When unspecified, the tool writes the design-source dictionary that is returned by the “[get_design_sources -file_dictionary](#)” command. You can choose to store the design-source dictionary returned by the “[get_design_sources -file_dictionary](#)” command into a variable, make edits to the dictionary stored into the variable using the Tcl “dict” command, and then write out the modified dictionary using the -dictionary \$var switch, where “var” is the Tcl variable that holds the dictionary you modified.

- **-replace**

An optional Boolean switch that suppresses the error the tool normally issues when the specified ***output_file*** already exists. Instead of issuing an error, the tool silently replaces the file.

Examples

The following example demonstrates writing out the complete RTL source files into a single directory with an associated design-source dictionary.

You can subsequently tar the dictionary file and the RTL directory as a test case. When the dictionary file and the RTL directory are untarred at the destination, the file dictionary is sourced into the tool using the **read_design -from_dictionary \$design_source_dictionary** command, which reads the design from the RTL directory. Use the **-skip_existence_checks** switch to suppress the error that the tool issues if the design you are loading uses the **-y** and/or **-v** libraries, or **+incdir** specifications. The design-source dictionary will contain paths to the original path as well as the new path found within the RTL directory:

```
# To store the complete RTL file, use those commands:  
set current_design_name [get_single_name [get_current_design]]  
write_design -output_directory ${current_design_name}_rtl_files -all_read  
write_design_source_dictionary ${current_design_name}.design_source_dictionary  
  
# Tar up the file and the directory and untar it at the destination  
# To reload the design, use those commands:  
set current_design_name my_design  
source ${current_design_name}.design_source_dictionary  
read_design -from_dictionary $design_source_dictionary -skip_existence_checks  
set_current_design $current_design_name
```

write_diagnosis

Context: patterns -scan_diagnosis

Mode: analysis

Writes diagnosis reports in text, comma separated values (CSV), and layout (physical) marker location formats.

Usage

```
write_diagnosis [-SHORT] [-ENCoded] [-FORmat {TEXT | LAYout_marker | CSV}...] [-FILE name [-REPlace]] [-XMAP {V2LVS | CELL_HIERarchy}...]
```

Description

Writes diagnosis reports in text, comma-separated values (CSV), and layout (physical) marker location formats.

If you specify write_diagnosis with no arguments, Tessent Diagnosis creates an ASCII text diagnosis report and names the file using the *failure_filename* from the diagnose_failures command and puts the results file where *failure_filename* is located.

Arguments

- **-SHORT**

An optional switch that changes the diagnosis report from the layout-aware diagnosis report format to the traditional diagnosis report. Allows for backward compatibility with other tools for reading in the diagnosis report.

Using this option does not change the computed diagnosis result including layout-aware diagnosis information, but rather suppresses the display of the layout-aware information.

Note

This option performs the layout-aware diagnosis, but suppresses the display of this information.

- **-ENCoded**

An optional switch specifying encoding a suspect's pin pathname, net name, and cell name in the diagnosis output file.

- **-FORmat {TEXT | LAYout_marker | CSV}**

An optional switch and single or multiple literals specifying the report's output format. By default, the write_diagnosis command creates an ASCII text version of the report if you specify no arguments.

Note

To produce the location tables (XMAP tables), you must select the default ASCII text report format (-format TEXT) for the write_diagnosis command.

If you use the -FORmat switch, then you must specify at least one of the following options:

- TEXT — Specifies ASCII text format.
- LAYout_marker — Specifies layout coordinate format.
- CSV — Specifies comma separated value (CSV) format.

You can specify any combination of these literals. For example, the following syntax creates both text (*example.diag*) and CSV (*example.csv*) reports:

```
write_diagnosis -format text csv -file example
```

- **-FILE *name***

An optional switch and string pair specifying the filename (*name*) of the report. The tool uses the *name* value for the report filename, regardless of format, and identifies the format using the following filename suffixes:

- *name.csv* — CSV format diagnosis report.
- *name.diag* — ASCII text format diagnosis report.
- *name.lay* — Layout markers.
- *name.enc.csv* — Encoded CSV diagnosis report.
- *name.enc.diag* — Encoded ASCII text diagnosis report.
- *name.enc.lay* — Encoded layout markers.

- **-REPlace**

An optional switch for overwriting an existing file.

- **-XMAP {V2LVS | CELL_HIERarchy}**

An optional switch and single or multiple literals specifying the outputting of SPICE-mapped nets, Verilog module hierarchy, or both in the diagnosis report.

If you use the -XMAP switch, then you must specify at least one of the following options:

- V2LVS — Specifies outputting the SPICE-mapped nets.
- CELL_HIERarchy — Specifies outputting Verilog module hierarchy.

You can specify any combination of these switches. For example, the following syntax creates both the SPICE-mapped nets and the Verilog module hierarchy in the diagnosis report:

```
write_diagnosis -XMAP V2LVS CELL_HIERarchy
```

Examples

Example 1

The following example creates a CSV and ASCII text diagnosis report with the filename *foo* in the *bar* directory, which must exist:

```
write_diagnosis -format text csv -file bar/foo
```

If you list the *bar* directory, then the following information is displayed:

```
% ls -l bar  
...  
-rwxrwxr-x    1 user account 1339 Aug 10 09:53 foo.csv  
-rwxrwxr-x    1 user account 1768 Aug 10 09:53 foo.diag
```

Example 2

The following example creates encoded CSV, ASCII text, and layout markers with the filename *foo* in the *bar* directory, which must exist:

```
write_diagnosis -encoded -format text csv layout_marker -file bar/foo -replace
```

If you list the *bar* directory, the following information is displays:

```
% ls -l bar  
...  
-rwxrwxr-x    1 user account 1241 Aug 10 09:53 foo.enc.csv  
-rwxrwxr-x    1 user account 1502 Aug 10 09:53 foo.enc.diag  
-rwxrwxr-x    1 user account 40495 Aug 10 09:53 foo.enc.lay
```

Related Topics

[report_diagnosis](#)

[diagnose_failures](#)

write_edt_files

Context: dft -edt

Mode: analysis

Creates the files that implement the EDT logic.

Usage

```
write_edt_files filename_prefix [-Replace]
  [-VErilog | -VHdl [-Signal_type STD_Logic | STD_Ulogic]]
  [-SYnthesis_script {DC_Tcl | DC_Shell | RTL_Compiler}]
  [-NO_Timing_constraints | -Timing_constraints]
  [-Nortl_prefix | -RTI_prefix prefix_string]
  [-REDuced_netlist]
  [-Insertion Ts | Dc]
  [-Single_module_per_file]
  [-UNIque_bypass_lockup_clock]
  [-EXClude_modules list_of_modules]
  [-NO_SYNOpssyse_pragma]
  [-NO_WRITE_Design]
  [-IJtag {Off | data_ports}]
  [-TSdb [-DESIGN_Id design_id]]
```

Description

Creates the files that implement the EDT logic.

For more information, see “[Creation of the EDT Logic](#)” in the *Tessent TestKompress User’s Manual*. By default, if no other switches are specified, the following files are written:

- EDT logic RTL (**_edt.v*)
- Tessent Core Description (TCD) file (**_edt.tcd*)
- ICL file (*_edt.icl*)
- PDL file (*_edt.pdl*)
- Test procedure file (**_edt.testproc*)
- Dofile (**_edt.dofile*)
- Design Compiler (DC) synthesis script (**_dc_script.scr*)
- Bypass dofile (**_bypass.dofile*)
- Bypass test procedure file (**_bypass.testproc*)

The following additional files are written out for the external flow:

- Core top file (**_edt_top.v*)

-
- Core blackbox file (**_core_blackbox.v*)

If the [set_lpct_controller](#) command is enabled and issued, then the tool writes out the following additional file:

- LPCT TCD file (**_edt_lpct.tcd*)

When the EDT logic is configured for multiple compression configurations, a separate test procedure and dofile are written for each configuration. For more information, see “[Defining Dual Compression Configurations](#)” in the *Tessent TestKompress User’s Manual*.

By default, the language of the netlist read in is the format used for the EDT logic.

If you execute this command and you are using the internal IP location flow with Tessent Shell EDT insertion, the tool writes out all EDT files, inserts EDT IP into the design, and automatically changes the system mode from analysis to insertion.

If you execute this command and you are using the external IP location flow, the tool writes out all EDT files including the wrapper that instantiates the core design and EDT logic and remains in analysis mode. You can explicitly go to insertion mode, at which time you can further edit the core design and save the modifications. However, saving the design in insertion mode is only necessary if you have modified the design in insertion mode.

If you execute this command and you are using the internal IP location flow with DC-based EDT insertion, the tool writes out all EDT files and the DC insertion script and remains in analysis mode. If you change to insertion mode and modify the design, make sure the modifications are compatible with the DC synthesis script that was already generated.

Arguments

- *filename_prefix*

A required string that specifies a name prefix for the EDT logic files. The filenames are composed of this prefix followed by an underscore (_) and a descriptive file-specific suffix. You can include the pathname to an existing directory as a component of the *filename_prefix*, and the files are written to that location. This option is mutually exclusive with the use of the -tsdb option.

- -Replace

An optional switch that replaces the contents of each file that already exists.

- -VERilog

An optional switch that writes the EDT logic in Verilog format.

- -VHdl

An optional switch that writes the EDT logic in VHDL 93 format.

- **-SYnthesis_script DC_Tcl | DC_Shell | RTL_Compiler**

An optional switch and set of literals that specify to generate a synthesis script:

DC_Tcl —

DC_Shell —

RTL_Compiler —

- **-SIGNAL_type STD_Logic | STD_Ulogic**

An optional switch and literal pair that specifies the type of signals and ports to use (std_logic or std_ulogic) when writing out the EDT logic in VHDL format.

Note

 When writing out the top-level wrapper (*_edt_top.vhd) and the black box description of the core (*_core_blackbox.vhd), the std_logic and std_ulogic declaration of signals and ports in the original netlist are preserved.

- **-REDuced_netlist (internal flow only)**

An optional switch that writes out the input netlist into two files as follows:

- <naming_prefix>_reduced_netlist.v (or .vhd) — Reduced netlist containing only the part of the original netlist required for making necessary connections between pad terminals and EDT logic pins during synthesis. Use this file instead of the original input netlist with the synthesis script. Then use the output netlist from the synthesis run along with the _rest_of_netlist.v file to generate test patterns.
- <naming_prefix>_rest_of_netlist.v (or .vhd) — Netlist file containing everything in the original netlist read into the tool except the modules written out in the _reduced_netlist.v file. Use the _rest_of_netlist.v file and the output netlist from the synthesis run to generate test patterns.

Use this switch to create a reduced input netlist to save time during synthesis. For more information, see “[Creation of a Reduced Netlist for Synthesis](#)” in the *Tessent TestKompress User’s Manual*.

Note

 This switch can only be used with the *-Insertion Dc* command.

- **-Single_module_per_file**

An optional switch that writes the EDT logic into multiple files with one Verilog module (or VHDL entity/architecture pair) in each file. Use this switch only if your synthesis flow requires the RTL files to be organized this way.

The number of files written depends on the EDT logic setup. When the EDT logic is located outside the core, the top-level wrapper file may be split up if any pins share channel outputs. The DC synthesis script is modified to read in each of the RTL files individually.

Note

-  If set up to use the internal flow (“set_edt_options -location internal”), the tool ignores the -Single_module_per_file switch for the gate-level core netlist when you include the -Reduced_netlist switch.

The -Single_module_per_file switch causes the tool to use a different naming convention for the output files as described in [Table 6-24](#).

Table 6-24. Single Module Per File Naming Convention

Old Name	New Name	Output File
<filename_prefix> _edt_top.v (or .vhd)	{<top_module_name> <rtl_prefix>} _edt_top.v (or .vhd)	Top-level wrapper (external flow only)
<filename_prefix> _edt.v (or .vhd)	{<top_module_name> <rtl_prefix>} _edt.v (or .vhd)	EDT circuitry
<filename_prefix> _core_blackbox.v (or .vhd)	<top_module_name> _blackbox.v (or .vhd)	Blackbox description of core (external flow only)

The additional *single module* files are named as follows:

- {<top_module_name> | <rtl_prefix>}_edt_<module_name>.v (or .vhd)
- {<top_module_name> | <rtl_prefix>}_edt_pinshare_logic.v (or .vhd)
(external flow only)

The RTL prefix string is used when constructing the preceding names only if you include the -Rtl_prefix switch; otherwise it uses the top-module name. If the command’s *filename_prefix* argument includes a pathname component, the tool still writes all files to that location even though the filename prefix may not appear in all filenames.

- **-Nrtl_prefix**

An optional switch that disables the default internal RTL naming feature. By default,

- **-RTl_prefix *prefix_string***

An optional switch and string pair that specifies a *prefix_string* to prepend to the module and instance names in the EDT logic RTL. The specified *prefix_string* must follow the normal naming rules for Verilog or VHDL identifiers.

- **-Insertion *Ts* | Dc (internal flow only)**

Optional switch and literal pair that determines the method used to insert the EDT logic inside the design core. Options include:

[Ts — Inserting EDT Logic During Synthesis](#)” in the *Tessent TestKompress User’s Manual*.

Note

 You must enter all commands for determining configuration, test coverage, and data volume before saving out the EDT logic files. After the composite netlist is written, . For more information, see “[ATPG Baseline Generation](#)” in the *Tessent TestKompress User’s Manual*.

Dc — Writes a Synopsys Design Compiler script to insert and synthesize the EDT logic inside the core netlist. For more information, see “[Synthesizing the EDT Logic](#)” in the *Tessent TestKompress User’s Manual*.

- **-NO_Timing_constraints | -Timing_constraints**

An optional switch that determines if SDC timing files are output. By default, no timing files are output. When you specify -timing_constraints, the tool reports both the fast capture and slow capture constraints. For more information, see “[SDC Timing File Generation](#)” in the *Tessent TestKompress User’s Manual*.

- **-UNIque_bypass_lockup_clock**

An optional switch that individually routes the clock pin of all scan cells involved with bypass lockup cells to the EDT logic. The clock pins created on the EDT logic boundary are named *edt_bypass_clk<n>* instead of top-level clock names.

- **-EXClude_modules *list_of_modules* (DC-based insertion only)**

An optional switch and string pair that specifies to exclude from the complete EDT logic-inserted netlist, those modules specified by the *list_of_modules* argument; *list_of_modules* and any sub-module used by one of the specified modules, unless the sub-module is also used by another module that is to be written out. The *list_of_modules* is a list of strings that are separated by spaces.

In the internal IP location flow with DC-based insertion, the tool writes out a Synopsys Design Compiler script to make EDT connections and to write out the modified design. Without the -EXClude_modules switch, the netlist is complete and contains a description of all the modules present in the input netlist. This switch excludes from the netlist the descriptions of the modules specified by the *list_of_modules* argument.

During pattern generation, you need to provide the complete view of the EDT-inserted design including the module descriptions you excluded from the IP-creation output netlist with this command.

Note

 If any of the modules excluded by this switch need to be modified during IP insertion, a warning message is issued but the modified modules are written out.

- **-NO_SYNopsys_pragma**

An optional switch that specifies to *not* write out pragmas when the tool writes out the RTL description of EDT logic in either Verilog or VHDL. By default, when synthesis targets Synopsys Design Compiler (-SYnthesis_script DC_Tcl | DC_Shell), a pragma is written

indicating to the synthesis tool that it is a reset signal and should not be merged with other signals.

- **-NO_WRITE_Design**

An optional switch that directs the tool to not write out an EDT-inserted netlist when this command is executed. In insertion mode, you can edit the netlist further and save the design. You must save the design using the [write_design](#) command, and you must name the file using the naming convention *<filename_prefix>_ edt_top_rtl.v* which is referenced by the synthesis script.

- **-Ijtag Off | Data_ports**

An optional switch and value pair that directs the tool to use IJTAG in the generated dofiles to describe the static configuration inputs of the TestKompress IP. Use this option if you are using a dofile to pass IP information from the IP creation phase to the pattern generation phase. These static configuration inputs set, enable, or disable certain features of the TestKompress IP: edt bypass, single chain bypass, low power and edt configuration.

Note

 If you are using the Tessent Core Description (TCD) EDT flow, then you do not need to specify this option. See “[IJTAG and the EDT IP TCD Flow](#)” in the *Tessent TestKompress User’s Manual* for more information. By default, the tool performs the IJTAG mapping automatically and writes out the ICL and PDL files.

For the TCD EDT flow, you can disable the IJTAG mapping using the following command:

```
set_procedure_retargeting_options -ijtag off
```

For details on how to use the IJTAG files for TestKompress ATPG, see section “Setting up EDT IP for IJTAG Integration” in the “[IJTAG Features of ATPG in Tessent Shell](#)” section of the *Tessent IJTAG User’s Manual*.

- **-TSdb [-DESIGN_Id *design_id*]**

An optional and optional switch and string pair that specifies to write the EDT files into the [instruments](#) directory of the [Tessent Shell Data Base \(TSDB\)](#). The name of the TSDB directory defaults to *tsdb_outdir* and is specified using the [set_tsdb_output_directory](#) command.

The optional **-DESIGN_Id *design_id*** switch and string pair specifies the *design_id* value when creating the TSDB directory. Refer to “[Tessent Shell Data Base \(TSDB\)](#)” on page 3763 for complete information. The default *design_id* is that specified by the [set_context](#) command, or the default of that command if “[set_context -design_identifier](#)” is not used. In general, it is not recommended to specify **-DESIGN_id** as part of [write_edt_files](#) since this option overrides the value used by other TSDB-related commands used in that context.

Exporting your instruments using this method during post-scan insertion also enables the [run_synthesis](#) command to synthesize the generated IP.

The EDT Tesson Core Descriptions are also written out. See “[Tesson Core Description \(TCD\)](#)” in the *Tesson TestKompress User’s Manual* for more information. EDT TCDs created using this switch will be automatically loaded into the tool and do not need to be explicitly read.

This option is mutually exclusive with the use of *filename_prefix*. See [Example 12](#) for a usage example.

Examples

Example 1

The following external flow example writes the files for EDT logic including bypass circuitry, and uses the filename prefix, *my_design* to name the output files:

```
write_edt_files my_design -verilog -replace -nortl_prefix

// Writing my_design_edt.v
// Writing my_design_edt_top.v
// Writing my_design_core_blackbox.v
// Writing my_design_dc_script.scr
// Writing my_design_edt.dofile
// Writing my_design_edt.testproc
// Writing my_design_bypass.dofile
// Writing my_design_bypass.testproc
// Writing my_design_edt.icl
// Writing my_design_edt.pdl
// Writing my_design_edt.tcd
```

The module and instance names in the RTL generated by the preceding example all begin with the *edt_* prefix.

Example 2

The following internal flow example shows the files written when the EDT logic is placed inside the core netlist including a reduced version of the input netlist for synthesis. The files resulting from the *-Reduced_netlist* switch are in bold.

```
write_edt_files my_design -verilog -replace -nortl_prefix -reduced_netlist -insertion dc

// Writing my_design_edt.v
// Writing my_design_dc_script.scr
// Writing my_design_reduced_netlist.v
// Writing my_design_rest_of_netlist.v
// Writing my_design_edt.dofile
// Writing my_design_edt.testproc
// Writing my_design_bypass.dofile
// Writing my_design_bypass.testproc
// Writing my_design_edt.icl
// Writing my_design_edt.pdl
// Writing my_design_edt.tcd

write_design -output_file my_design_new.v
```

Example 3

Assume the output file resulting from synthesis of *my_design_reduced_netlist.v* is named *my_design_edt_top_gate.v*. The following example shows how to invoke the tool, set the context for pattern generation, and load the Verilog files:

```
tessent -shell <other arguments>
SETUP> set_context patterns -scan
SETUP> read_verilog my_design_edt_top_gate.v my_design_rest_of_netlist.v
SETUP> read_cell_library tessent_cell.tcellib
SETUP> set_current_design
```

Example 4

The following internal flow example writes out EDT logic in multiple files, one Verilog module per file. The EDT logic is placed internal to the design core, and the top-module name in the design is *core1*:

```
write_edt_files results/created -single_module_per_file -verilog

// Writing results/core1_edt_decompressor.v
// Writing results/core1_edt_spatial_compactor_8.v
// Writing results/core1_edt_controlled_decoder_3_to_8.v
// Writing results/core1_edt_compactor.v
// Writing results/core1_edt_bypass_logic.v
// Writing results/core1_edt.v
// Writing results/core1_edt_mux_2_to_1.v
// Writing results/created_dc_script.scr
// Writing results/created_edt.dofile
// Writing results/created_edt.testproc
// Writing results/created_bypass.dofile
// Writing results/created_bypass.testproc
// Writing results/created_edt.icl
// Writing results/created_edt.pdl
// Writing results/created_edt.tcd

write_design -output_file results/created_new.v
```

Example 5

The following external flow example shows how the *-Rtl_prefix* switch affects the filenames when the EDT logic is placed external to the design core, the EDT logic is written in multiple files, and the design has a top module named *mtm2*:

```
write_edt_files multiple -single_module_per_file -verilog -rtl_prefix designX_blockY
```

```
// Writing designX_blockY_edt_decompressor.v
// Writing designX_blockY_edt_spatial_compactor_8.v
// Writing designX_blockY_edt_controlled_decoder_3_to_8.v
// Writing designX_blockY_edt_compactor.v
// Writing designX_blockY_edt.v
// Writing designX_blockY_edt_pinshare_logic.v
// Writing designX_blockY_edt_top.v
// Writing mtm2_blackbox.v
// Writing multiple_dc_script.scr
// Writing multiple_edt.dofile
// Writing multiple_edt.testproc
// Writing designX_blockY_edt.icl
// Writing designX_blockY_edt.pdl
// Writing designX_blockY_edt.tcd
```

Example 6

The following internal flow example shows the files created when the tool inserts EDT logic into the design core with the *-Insertions* switch:

write_edt_files results/created -verilog -rep -insertions

```
// Writing results/created_edt.v
// Writing results/created_dc_script.scr
// Writing results/created_edt.dofile
// Writing results/created_edt.testproc
// Writing results/created_bypass.dofile
// Writing results/created_bypass.testproc
// Writing results/created_edt.icl
// Writing results/created_edt.pdl
// Writing results/created_edt.tcd
// -----
// Begin EDT logic insertion
// -----
// Inserting EDT logic in the design.
// EDT logic insertion completed.
```

write_design -output_file results/created_new.v

The output file *created_edt_top_rtl.v* contains the EDT logic inserted design without the EDT logic description.

Example 7

The following external flow example writes out timing files in addition to the default EDT files and specifies *created* for the naming prefix:

write_edt_files created -timing_constraints

write_edt_files

```
// Writing created_edt.v
// Writing created_edt_top.v
// Writing created_core_blackbox.v
// Writing created_dc_script.scr
// Writing created_edt.dofile
// Writing created_edt.testproc
// Writing created_bypass.dofile
// Writing created_bypass.testproc
// Writing created_edt_shift_sdc.tcl
// Writing created_bypass_shift_sdc.tcl
// Writing created_edt_slow_capture_sdc.tcl
// Writing created_edt.icl
// Writing created_edt.pdl
// Writing created_edt.tcd
```

Example 8

The following internal flow example shows the files created when the tool inserts EDT logic into the design core and the *-synthesis_script* switch is specified with the *rtl_compiler* option. The file resulting from the *-synthesis_script rtl_compiler* switch and option is in **bold**.

```
write_edt_files created -verilog -synthesis_script rtl_compiler -replace

// Writing created_edt.v
// Writing created_rtlc_script.scr
// Writing created_edt.dofile
// Writing created_edt.testproc
// Writing created_bypass.dofile
// Writing created_bypass.testproc
// Writing created_edt.icl
// Writing created_edt.pdl
// Writing created_edt.tcd

// -----
// Begin EDT logic insertion
// -----
// Inserting EDT logic in the design.
// EDT logic insertion completed.
// Note: The synthesis script assumes the modified design will be saved
// in file 'created_edt_top_rtl.v'.
// Update the synthesis script when saving to a different file.
```

write_design -output_file created_new.v

Example 9

In this example, assume the top level of the design has the three modules *cpu_core*, *clkblk*, and *padring* instantiated. The following commands write out the top-level module of the design but exclude the *cpu_core*, *clkblk*, and *padring* modules. After executing these commands, the output netlist contains only the top module description with the instances of these three modules:

```
write_edt_files created -replace
write_design -output_file created_edt_top_rtl.v -exclude_modules {cpu_core clkblk padring}
```

Assume the input design for this example is contained in two files: *top.v*, which contains only the top-level module, and *chip.v*, which contains the other three modules. The following

example invokes the tool, sets the context for IP creation, loads the Verilog files, and runs the dofile, which is assumed to include the above write_edt_files and write_design commands:

```
tessent -shell
SETUP> set_context dft -edt
SETUP> read_verilog top.v chip.v
SETUP> read_cell_library tessent_cell.tcellib
SETUP> set_current_design
SETUP> dofile ip_creation.do
```

After performing logic synthesis of the EDT logic, the output file is *created_edt_top_gate.v*. The command-line invocation for pattern generation uses the synthesized EDT logic file *created_edt_top_gate.v* as well as the file *chip.v* that contains the description of the modules excluded during IP creation.

```
tessent -shell
SETUP> set_context patterns -scan
SETUP> read_verilog created_edt_top_gate.v chip.v
SETUP> read_cell_library tessent_cell.tcellib
SETUP> set_current_design
SETUP> dofile pattern_gen.do
```

Example 10

In this example, the write_edt_file command writes out RTL with synopsys pragma:

write_edt_files created -replace

In Verilog, the pragma is included as a comment near the *always* block that describes the target registers as shown here:

```
*****  
** Module: m8051_edt_decompressor  
** Tessent TestKompress version: v9.1  
** IP version: 5  
** Date: Thu Aug 19 14:58:39 2010  
***** /
```

```

module m8051_edt_decompressor (edt_clock, edt_update, edt_channels_in,
    edt_scan_in);
    input edt_clock;
    input edt_update;
    input [ 1:0] edt_channels_in;
    output [15:0] edt_scan_in;
    reg      [15:0] edt_scan_in;
    reg      [11:0] lfsm_vec;
    reg      [11:0] lfsm_vec_lockup;
    // synopsys sync_set_reset edt_update
    always @(posedge edt_clock)
    begin : lfsm
        if (edt_update == 1'b1) begin
            lfsm_vec <= 12'b00000000000000;
        end
        else begin
            lfsm_vec[ 0] <= lfsm_vec[ 1];
            lfsm_vec[ 1] <= lfsm_vec[ 2] ^ edt_channels_in[1];
            lfsm_vec[ 2] <= lfsm_vec[ 3];
            lfsm_vec[ 3] <= lfsm_vec[ 4] ^ edt_channels_in[1];
            lfsm_vec[ 4] <= lfsm_vec[ 5];
            lfsm_vec[ 5] <= lfsm_vec[ 6] ^ edt_channels_in[1];
            lfsm_vec[ 6] <= lfsm_vec[ 7] ^ lfsm_vec[ 3];
            lfsm_vec[ 7] <= lfsm_vec[ 8] ^ edt_channels_in[0];
            lfsm_vec[ 8] <= lfsm_vec[ 9] ^ lfsm_vec[ 4];
            lfsm_vec[ 9] <= lfsm_vec[10] ^ edt_channels_in[0];
            lfsm_vec[10] <= lfsm_vec[11] ^ lfsm_vec[ 1];
            lfsm_vec[11] <= lfsm_vec[ 0] ^ edt_channels_in[0];
        end
    end
    ...

```

In VHDL, the pragma is specified as an attribute from the Synopsys library in the declarations section of the architecture description as shown here:

```
-----  
-- Module: m8051_edt_decompressor  
-- Tesson TestKompress version: v9.1  
-- IP version: 5  
-- Date: Thu Aug 19 15:01:15 2010

```

Example 11

The following example shows two commands that do not include the synopsys pragma:

`write_edt_files noprag1 -synthesis_script rtl_compiler`

write_edt_files noprag2 -no_synopsys_pragma

Example 12

The following example uses the -tsdb option and default value of the [set_tsdb_output_directory](#) command. The module name prefix is “*current_design_design_id_tessent_*”. See the [set_context](#) -design_identifier command for more information about the design identifier. See the [instruments](#) directory section for details about the instrument container directory.

write_edt_files -tsdb -replace

```
// Writing ./tsdb_outdir/instruments/m8051_gate_edt.instrument/
m8051_gate_tessent_edt.v
// Writing ./tsdb_outdir/instruments/m8051_gate_edt.instrument/
m8051_gate_edt.synthesis_dictionary
// Writing ./tsdb_outdir/instruments/m8051_gate_edt.instrument/
m8051_gate_tessent_edt.icl
// Writing ./tsdb_outdir/instruments/m8051_gate_edt.instrument/
m8051_gate_tessent_edt.pdl
// Writing ./tsdb_outdir/instruments/m8051_gate_edt.instrument/
m8051_gate_tessent_edt.tcd
// -----
// Begin EDT logic insertion
// -----
// Inserting EDT logic in the design.
// EDT logic insertion completed.
// Writing modified netlist ./tsdb_outdir/dft_inserted_designs/
m8051_gate.dft_inserted_design/m8051.vg_no_instruments.
// Writing interface netlist ./tsdb_outdir/dft_inserted_designs/
m8051_gate.dft_inserted_design/m8051.v_interface
```

write_failing_paths

Context: patterns -scan_diagnosis

Mode: analysis

Reports, for each diagnosed symptom from a failure log, the scan pattern number, suspect(s) and paths.

Usage

```
write_failing_paths [-DIAGnosis_report diagnosis_report_file_name]  
[-Pattern number] [-ENDpoints [Cell_Ins_Name1 PO_Pin_Name1 ...]]  
[-OUTput name [-REPlace]]
```

Description

Reports, for each diagnosed symptom from a failure log, the scan pattern number, suspect(s) and paths.

You must specify performing at-speed diagnosis using the “set_diagnosis_options -at_speed on” command before using the write_failing_paths command. The write_failing_paths command issues a warning message if at-speed diagnosis is off. If you use the following commands:

```
read_patterns pat.file  
set_diagnosis_options -at_speed on  
write_failing_paths -diagnosis_report report.diag
```

Then you don't have to use the diagnose_failures command at all.

Arguments

- **-DIAGnosis_report *diagnosis_report_file_name***
An optional switch and string pair specifying the diagnosis report filename from which failure diagnosis is processed.
- **-Pattern *number***
An optional switch and integer pair specifying the failing pattern number for which failing paths are reported.
- **-ENDpoints *Cell_Ins_Name1 PO_Pin_Name1 ...***
An optional switch and report failing paths that end at the given cell instance names or PO pin names. The end cell instances are the state elements where at-speed failures are captured. Default: report failing paths for all cells or POs.
- **-OUTput *name***
An optional switch and string pair specifying the filename (*name*) where failing paths are reported. The tool will report failing paths to the screen and log file.

Examples

Example Failing Path Report

```
// Symptom = 1
// Scan pattern: 42
// Suspect = 1
PATH "path1" =
PIN /CORE/TP004/P1001/PC00W33_0/Q;
PIN /CORE/TM00T/AL011/U117/B1 ;
PIN /CORE/TM00T/AL011/U117/OEQ ;
PIN /CORE/TM00T/AL011/U39/I1 ;
PIN /CORE/TM00T/AL011/U39/O ;
PIN /CORE/TM00T/AL011/AP00A00_0/D ;
END ;
— skipping paths "path2-4" in this example —
PATH "path5" =
PIN /CORE/TP004/P1001/PC00W55_0/Q ;
PIN /CORE/TM00T/AL011/U116/B2 ;
PIN /CORE/TM00T/AL011/U116/OEQ ;
PIN /CORE/TM00T/AL011/U54/B ;
PIN /CORE/TM00T/AL011/U54/OB ;
PIN /CORE/TM00T/AL011/AP00A00_0/D ;
END ;
// Suspect = 2
// "path5"
// Scan pattern: 121
// Suspect = 1
// "path1"
// "path2"
// Suspect = 2
// "path5"
```

The above example shows 5 failing paths for *symptom 1, suspect 1* at scan pattern 42. Detailed description of the PATH definition can be found in the FastScan manual. Also shown is that for same scan pattern, 42, there is only one failing path for *symptom 1, suspect 2*, which is equivalent to *path5* that was defined earlier. For scan pattern 121, there are two patterns for *suspect 1 of symptom 1*, and they are path1 and path2 which are defined earlier; there is one path, path5 for *suspect 2 of symptom 1*.

Example 1

This example reports warning message because this command can only used for at-speed diagnosis.

```
set_diagnosis_options -at_speed off
diagnose_failures chip1.fail
write_failing_paths
```

Example 2

This example reports the at-speed failing paths for the diagnosis result of *chip1.fail* on the screen.

```
set_diagnosis_options -at_speed on
```

diagnose_failures chip1.fail

write_failing_paths

Example 3

In this example at-speed failing paths of scan pattern 5 for *chip1.fail* and the failing paths of scan pattern 10 for *chip2.fail* are printed on the screen.

set_diagnosis_options -at_speed on

diagnose_failures chip1.fail -output chip1.diag

write_failing_paths -pattern 5

diagnose_failures chip2.fail -output chip2.diag

write_failing_paths -pattern 10

Example 4

The at-speed failing paths of diagnosis *chip1.diag* are printed on the screen. The *-end_cell* switch reports only failing paths ending at cell “/cpu/exu/pmi/ix926,” where “/cpu/exu/pmi/ix926” is the name of the cell where at-speed failures are captured.

set_diagnosis_options -at_speed on

diagnose_failures chip1.fail -output results/chip1.diag

write_failing_paths -end_cell /cpu/exu/pmi/ix926

Example 5

The critical paths of diagnosis results for *chip1.fail* are written to file named *chip1.path*.

set_diagnosis_options -at_speed on

diagnose_failures chip1.fail -output results/chip1.diag

write_failing_paths -output chip1.path

[set_design_sources](#)

write_failures

Context: dft -edt, patterns -scan, patterns -scan_diagnosis,
patterns -failure_mapping

Mode: analysis

Injects faults and/or writes failing pattern results to a file.

Usage

```
write_failures failure_filename [-Replace]
[[{pin.pathname -Stuck_at {0 | 1}}...] |
[pin.pathname {-SLOW_TO_RISE | -SLOW_TO_FALL}] ]
[-Pdet | -Exact] [-Max max_failed_scan_pat_num] [-CYCle]
[-Faulty_chain faulty_chain_name faulty_chain_type {-Cell faulty_cell_id...}...]
```

Description

Injects faults and/or writes failing pattern results to a file.

The resulting file can be used to perform a diagnosis of the failures with Tesson Diagnosis

By default, the write_failures command performs a good simulation of the current design and test pattern source and writes the failing pattern information to the display. write_failures also does not produce the cell paths by default.

You can also use this command to inject faults into the design, simulate them, and write the resultant failures into the failure file for diagnosis. When faults are injected, a fault simulation is run with those values. The fault is injected with respect to the scan cell that is closest to the scan output.

For failure mapping, the tool creates core-level failure files by reverse mapping the top-level failures that were obtained by applying the top-level patterns generated with scan pattern retargeting. After reading a valid top-level failure file, the command extracts core-level failures for all failing cores and saves them into separate files that are named based on *failure_filename* and the naming convention as described below. The command strips the Verilog escaped characters too.

The tool names the core-level failure file for a failing core by appending its adjusted core instance name, its core module name, and its core test mode to the given failure file basename. A triple underscore ("___") is used to separate the core failure file basename from the other appended names, which are separated by double underscores ("__"). To convert the hierarchical instance name to a valid file name, the tool replaces "/" characters in the core instance name with a period character (".").

For example, the tool would save the core-level failure file for core instance core_10 of core module MyCore, tested in internal mode, to the name *./core_flogs/fail1.top___core_10__MyCore__internal*. Likewise, the tool would save the core-level failure

file for the core instance A/B/core1 of core module “MyCore, tested in internal mode, to the name *./core_flogs/fail1.top__A.B.core1__MyCore_internal*.

Arguments

- ***failure_filename***
A required string that specifies the name of a file to write the failing pattern information to.
- **-Replace**
An optional switch that directs the tool to overwrite an existing *failure_file*. Use this if the specified *failure_file* already exists, and you want to update the contents.
- ***pin.pathname* -Stuck_at {0 | 1}**
An optional, repeatable string, switch, and literal triplet that specifies the location and the value of a logic failure to inject into the design as follows:
 - pin.pathname* — A string that specifies the pin pathname of the location to inject the fault.
 - Stuck_at 0 | 1 — A switch and literal that specifies the stuck-at value for the fault. The stuck-at options include:
 - 0 — *stuck-at-0* fault
 - 1 — *stuck-at-1* fault
- ***pin.pathname* {-SLOW_TO_RISE | -SLOW_TO_FALL}**
An optional repeatable string and switch pair that injects single transition fault to support at-speed diagnosis using the following criteria:
 - pin.pathname* — A string that specifies the pin pathname of the location to inject the transition fault.
 - SLOW_TO_RISE — A literal that specifies failure at the 0->1 transition.
 - SLOW_TO_FALL — A literal that specifies failure at the 1->0 transition.
 This argument supports injecting a single transition fault. Additionally, when the transition fault is injected, other faults (for example, stuck-at logic faults or chain faults) cannot be injected together, specifically this argument does not support a mixture of a transition fault with other faults.
- **-Pdet**
An optional switch that directs the tool to output a failure when it simulates an X value where a binary value is expected for a specified fault. By default, only the binary detections are output to the file.
- **-Exact**
An optional switch that directs the tool to output a failure when it simulates an X value where a binary value is expected or a binary value where an X value is expected for a specified fault. By default, only the binary detections are output to the file.

- **-Max** *max_failed_scan_pat_num*

An optional switch and integer pair that specifies a maximum number of failing patterns to write for the specified faults. When the maximum number is reached, the simulation stops. By default, all failing patterns are written.

- **-CYCle**

An optional switch that writes the failure file in a cycle-based format. By default, a pattern-based format is output. For more format information, see the “[Input File Requirements](#)” chapter in the *Tessent Diagnosis User’s Manual*.

- **-Faulty_chain** *faulty_chain_name* *faulty_chain_type*

An optional repeatable switch and argument pair that specifies the names and fault types of the chain faults to inject into a design and simulate. Argument options include:

faulty_chain_name — String that specifies the name of the faulty chain.

fault_type — literal that specifies the fault type associated with the chain. Argument options include:

STUCK_AT_1

STUCK_AT_0

SLOW_TO_FALL

SLOW_TO_RISE

FAST_TO_RISE

FAST_TO_FALL

FAST

- **-Cell** *faulty_cell_id*

An optional switch and repeatable integer that specifies the faulty cells within the specified faulty chain.

Examples

Example 1

The following example switches to analysis system mode, loads a test pattern source, injects a stuck-at 1 failure at the i_1006/o logic in the specified a pattern-based failure file.

```
set_system_mode analysis
read_patterns file1
write_failures fail1 i_1006/o -stuck_at 1
// failing_patterns=8 simulated_patterns=36 simulation_time=0.00 sec
```

The output file looks like:

```

4 chain1 3 L H //uINTR/ix476
6 /D_OUT(0) L H //uINTR/ix446
7 chain1 3 L H //uINTR/ix356
...
29 /D_OUT(1) L H //uINTR/ix358
29 chain1 3 L H //uINTR/ix362
31 /D_OUT(1) L H //uINTR/ix601
31 /D_OUT(2) L H //uINTR/ix602
last_pattern_tested 35

```

Example 2

The following example shows a pattern-based output file written from Tesson TestKompress (4X compression).

```

0 edt_channel1 2 H L // chain1---2---DFF_reg0
// chain2---2---DFF_reg1
// chain3---2---DFF_reg2
// chain4---2---DFF_reg3
1 edt_channel1 2 L H // chain1---2---DFF_reg0
2 output[1] H L // PO
.....

```

Example 3

The following example shows the cycle-based output file written from Tesson TestKompress (4X compression).

```

20 ch_out1 H L //pat 0 channel1 2 chain1---2---DFF_reg0
// chain2---2---DFF_reg1
// chain3---2---DFF_reg2
// chain4---2---DFF_reg3
.....

```

Example 4

The following example reverse maps a top-level failure file into core-level failure files and saves them to the `./core_flogs` directory based on the naming convention described above.

```

write_failures ./core_flogs/top_flog1 -rep
// command: write_failures ./core_flogs/top_flog1 -rep
// Note: Core level faillog
//      (./core_flogs/top_flog1__logic_die_BOT_inst_logic_die_internal)
//      is created for core ( logic_die_BOT_inst_logic_die_internal ).
// Note: Extract 1 core faillog for 1 failing core from top level
//      faillog ( top_flogs/top_flog1 ).
```

write_fault_sites

Context: dft -edt, patterns -scan

Mode: analysis

Writes path definitions or bridge entries from the internal list to a file.

Usage

Path Delay Faults Usage:

```
write_fault_sites filename [-Replace] [-All | {-Path gate_id_begin gate_id_end}]
```

Bridge Faults Usage:

```
write_fault_sites filename [-Replace] [-All | net.pathname_pair / bridge_name... |  
 net.pathname... | instance_name...] [-NAME | -SINGLE]  
 [-NET.pathname | -PIN.pathname] [-NOEQ]
```

Description

Writes path definitions or bridge entries from the internal list to a file.

The write_fault_sites command writes the specified fault sites from the internal list to a file. Depending on the active fault model, fault sites may be defined with path definitions or bridge entries. Fault sites are loaded into the internal list with the read_fault_sites command.

For more information on bridge faults and the bridge fault definition file, refer to “[The Static Bridge Fault Model](#)” in the *Tessent Scan and ATPG User’s Manual*.

For more information on path delay faults and the path definition file, refer to “[Path Delay Test Set Creation](#)” in the *Tessent Scan and ATPG User’s Manual*.

By default, this command writes out the loaded fault attributes.

Path Delay Specifics

The write_fault_sites command also writes unambiguous paths that you previously added to the internal path list using the [add_ambiguous_paths](#) command. When writing derived unambiguous paths, write_fault_sites cannot list a gate if it does not have a pin pathname associated with it. For some designs, gates without associated pin pathnames could be fairly common. Therefore, refer to the written unambiguous paths for launch and capture points, but be aware the listing may not show all the gates in between.

Note

 If you get ambiguous path warnings, then add_ambiguous_paths, those paths when written out lose the information about which of the ambiguous paths they were. Consequently, you cannot reload them and get back to the same set of paths.

Arguments

- ***filename***
A required string that specifies the name of the file to which the tool should write the path definition or bridge entry information.
- **-Replace**
An optional switch that replaces the contents of the file, *filename*, if it already exists.
- **-All**
An optional switch that displays all fault definitions for the currently loaded path definitions or bridge entries. This is the default.
- **-Path *gate_id_begin* *gate_id_end***
An optional switch and two-integer triplet that specifies a particular path or portion of a path whose definition you want to write. Use this argument to write_paths that were not defined in a path definition file and, therefore, were not loaded using the `read_fault_sites` command.
The two integers specify two gate identification numbers that indicate the beginning and end of the path. The path begins at *gate_id_begin* and ends at *gate_id_end*.
The value of *gate_id_begin* or *gate_id_end* is the unique gate identification number that the tool automatically assigns to every gate within the design during the model flattening process.
- ***net_pathname_pair***
A string pair that specifies the net or pin pathname to bridge fault site. The first string specifies NET1, and the second string specifies NET2.
- ***bridge_name***
A repeatable string that specifies the name of a specific bridge entry.
- ***net_pathname***
A repeatable string that specifies a single net or pin pathname contained in a bridge entry.
- ***instance_name***
A repeatable string that specifies an instance pathname contained in a bridge entry.
- **-NAME**
An optional switch that specifies all entered strings are bridge names.
- **-SINGLe**
An optional switch that specifies all the entered strings are either a single net pathname or instance pathname. The tool searches for a net first. If a corresponding net cannot be found, the tool searches for a corresponding instance.
- **-NET_pathname**
An optional switch that specifies to write net pathnames for bridge entries. This is the default.

- **-PIN.pathname**
 An optional switch that specifies to write pin names for bridge entries instead of net pathnames.
- **-NOEQ**
 An optional switch that writes only the representative fault information: net pair and fault categories.

Examples

Example 1

The following path delay example writes to the file my_path_definitions using the path definition file format, the pins in the specified path:

write_fault_sites /user/design/my_path_definitions -path 180 178

The following shows an example of the contents of a path definition file:

```
PATH "path0" =
PIN /I$6/Q + ;
PIN /I$35/B0 + ;
PIN /I$35/C0 + ;
PIN /I$1/I$650/IN + ;
PIN /I$1/I$650/OUT - ;
PIN /A_EQ_B + ;
END ;
```

Example 2

The following bridge example reports all bridge entries in the current fault site list, then writes one entry (including its attributes) to the file my_bridge_definitions using the bridge fault definition file format:

```
report_fault_sites

BRIDGE {
  NET1 = "/G5";
  NET2 = "/G10";
  FAULTS = {DS, DS, DS, DS};
  NAME = "U7.BRIDGE";
}
BRIDGE {
  NET1 = "/G4";
  NET2 = "/G10";
  FAULTS = {DS, DS, DS, DS};
  NAME = "U5.BRIDGE";
}
BRIDGE {
  NET1 = "/G11";
  NET2 = "/G10";
  FAULTS = {DS, DS, DS, DS};
  NAME = "U0.BRIDGE";
}
```

write_fault_sites /user/design/my_bridge_definitions U5.BRIDGE -name

The following shows the contents of the resultant *my_bridge_definitions* file:

```
VERSION      1.1

FAULT_TYPE="BRIDGE_STATIC_4WAY_DOM"

BRIDGE {
    NET1  = "/G4";
    NET2  = "/G10";
    FAULTS = {DS, DS, DS, DS};
    WEIGHT = 1.0000;
    DISTANCE = 4.96575000e-06 um;
    PARALLEL_run = 7.30000000e-05 um;
    X_COORDINATE = 174500;
    Y_COORDINATE = 570000;
    LAYER = "1";
    NAME = "U5.BRIDGE";
}
```

 [-INstance *name*] [-MModule *name*]}} | {-UNlisted}
 [-FRom pin...] [-THrough pin...] [-TO pin...]
 [-STOP_at {sequential_elements | scan_cells | ports_only}]}

Description

Writes fault information from the current fault list to a file.

For more information about the MTFI file format, refer to the [Tessent Scan and ATPG User's Manual](#).

The write_faults command is similar to the report_faults command, except that the data is written into a file. You can review or modify the file and later load the information into the fault list with the read_faults command. You can use the optional arguments to narrow the focus of the report to only specific stuck-at or transition faults that occur on a specific object in a specific class. If you do not specify any of the optional arguments, write_faults writes information on all the known faults to the file.

The file contains the following columns of information for each fault:

- fault value—The fault value may be either 0 (for stuck-at-0 or slow-to-rise transition faults) or 1 (for stuck-at-1 or slow-to-fall transition faults).
- fault code—A code name that indicates the lowest-level fault class assigned to the fault.
- fault site—The pin pathname of the fault site.
- cell name (optional)—The name of the cell corresponding to the fault (included only if you used the -Cell_name argument).

You can use the -Hierarchy option to write a hierarchical summary of the selected faults. The summary identifies the number of faults in each level of hierarchy whose level does not exceed the specified level number. You can further specify the hierarchical summary by using the -Min_count option which specifies the minimum number of faults that must be in a hierarchical level before writing.

You can choose to display either collapsed or uncollapsed faults by using the set_fault_mode command.

Note that this command can write specific AU.TC and AU.PC faults when you previously issue the “[report_statistics](#) -detailed_analysis” command. If you want to report specific AU.TC faults, you must specify gate IDs instead of the full pin pathname. If you want to report specific AU.PC

faults, you must specify the full pin pathname. See [Example 5](#) for an example of writing specific AU.TC and AU.PC faults.

Arguments

- ***file_name***

A required string that specifies the name of the file where the tool is to write the fault information. The *file_name* must be the first argument.

- **-Replace**

An optional switch that replaces the contents of *file_name* if the file already exists.

- **-Class *fault_class*[.*fault_subclass*]**

An optional switch and literal pair that specifies the fault class or fault class/sub-class to write. You should use the code when specifying a fault class or sub-class. If you do not use this switch, the default is to write all fault classes.

This command can write specific AU.TC and AU.PC faults when you previously issue the “[report_statistics -detailed_analysis](#)” command. For AU.TC faults you must specify gate IDs rather than the full pin pathname. For AU.PC faults, you must specify the full pin pathname. For more information, refer to “[Example 5](#)” on page 2578.

- **-change_classification_to *fault_class*[.*subclass*]**

By default, the tool writes the fault class (and subclass) of the faults learned by the tools (for example, AU.TI or DS). This option allows you to select the faults and force these faults to be written as the specified class (and subclass). For a list of fault classes and subclasses refer to “[Fault Sub-classes](#)” in the *Tessent Scan and ATPG User’s Manual*.

- **-FORmat [Basic | Mtfi]**

An optional switch and literal pair that specifies the format of the fault file. By default, the command writes out in MTFI format. For more information about MTFI, refer to the “[MTFI File Format](#)” chapter in the *Tessent Scan and ATPG User’s Manual*.

- **-FRom pin...**

This option sets the start pin(s) of the cone of logic used to select faults to write. When specified, the tool performs forward cone tracing from the specified pin(s) until it encounters a stop point. You can specify one or more instance names, rather than pin names. When you specify an instance name with -from, its output pins are used when defining the cone.

- **-TThrough pin...**

This option sets the through pin(s) of the cone of logic used to select faults to write. When specified, the tool performs forward and backward cone tracing from the specified pin(s) until it encounters a stop point in both directions. You can specify one or more instance names, rather than pin names. When you specify an instance name with -through, its output pins are used when defining the cone.

- **-TO pin...**

This option sets the end pin(s) of the cone of logic used to select faults to write. When specified, the tool performs backward cone tracing from the specified pin(s) until it encounters a stop point. You can specify one or more instance names, rather than pin names. When you specify an instance name with **-to**, its input pins are used when defining the cone.

Note

 When **-from**, **-to**, and **-through** are used with other switches, the selected faults will be the intersection of the cones traced for all specified switches.

- **-STOP_at {sequential_elements | scan_cells | ports_only}**

This option sets the stop condition for tracing of the cone of logic used to select faults to write. By default, the traced logic cone includes only combinational logic, so cone tracing stops at any sequential elements. When you specify “**scan_cells**”, the cone includes non-scan cells and tracing stops only at scan cells. When you specify “**ports_only**”, the cone includes any sequential elements and tracing stops only at primary inputs and outputs.

- **-UNlisted**

Writes only the unlisted fault data. If there are multiple grayboxed instances in the design, this switch writes accumulated fault numbers.

- **-NO_Subclass**

Prevents the display of fault sub-classes after the fault code. The default is to display fault sub-classes when available.

- **-Stuck_at 01 | 0 | 1**

An optional switch and literal pair that specifies the stuck-at or transition faults you want to write. The choices are as follows:

01 — A literal that specifies for the tool to write both stuck-at-0 and stuck-at-1 faults for stuck-at faults; or to write both slow-to-rise and slow-to-fall faults for transition faults. This is the default.

0 — A literal that specifies to write only the stuck-at-0 faults (slow-to-rise faults for transition faults).

1 — A literal that specifies to write only the stuck-at-1 faults (slow-to-fall faults for transition faults).

- **object_pathname**

An optional repeatable string that specifies the list of pins, instances, or delay paths whose faults you want to write.

- **-Hierarchy integer**

An optional switch and integer pair that specifies the maximum fault class hierarchy level for which you want to write a hierarchical summary of the faults.

- **-Min_count *integer***
 An optional switch and integer pair that you can use with the -Hierarchy option and that specifies the minimum number of faults that must be in a hierarchical level to write a hierarchical summary of the faults. The default is 1.
- **-NOEQ**
 - For stuck-at, transition, toggle, iddq, and udfm faults only, an optional switch that turns off the display of “EQ” as the fault class for any equivalent faults; the fault class displayed is then that of the representative fault. When you do not specify this switch, the tool displays an “EQ” as the fault class for any equivalent faults. This switch is meaningful only when the [set_fault_mode](#) command is set to Uncollapsed. For more information about representative and equivalent faults, see “[Fault Collapsing](#)” in the *Tessent Scan and ATPG User’s Manual*.
 - For bridge faults only, an optional switch that writes only the representative bridge fault information: the net pair and fault classes of each corresponding dominant net. The tool does not report physical data.
- **-Both | -Rise | -Fall**
 An optional switch that specifies which faults to write for each path already added via the [read_fault_sites](#) command. Use these switches only for path delay faults.
 - Both - An optional switch that specifies to write both the slow-to-rise and slow-to-fall faults. This is the default.
 - Rise - An optional switch that specifies to write only the slow-to-rise faults.
 - Fall - An optional switch that specifies to write only the slow-to-fall faults.
- **-VERilog | -VHdl**
 An optional switch pair that output the fault paths in either Verilog or VHDL syntax, rather than using the existing netlist independent format.
- **-CELL_name**
 An optional switch that specifies to list, for each reported fault, the corresponding circuit element (Tessent Cell library cell, Verilog primitive, primary input, or primary output) as summarized in [Table 6-25](#). Cell names displayed for equivalent faults are based on the cells associated with the equivalent faults, not the cells associated with the representative faults. This switch is valid for the stuck-at, transition, toggle and IDDQ fault models only.

Table 6-25. Name Conventions Used by `write_faults -Cell_name`

Corresponding Circuit Element	Listed Cell Name
Tessent Cell library cell	Name of the Tessent Cell library cell
Supported Verilog primitive (for a list, see the <i>Tessent Cell Library Manual</i>)	Name of the Verilog primitive
Primary input or output	“primary_input” or “primary_output”

- ***net.pathname_pair***

A string pair that specifies the net or pin pathname to bridge fault site. The first string specifies NET1, and the second string specifies NET2.

- ***bridge_name***

A repeatable string that specifies the name of a specific bridge entry.

- ***net.pathname***

A repeatable string that specifies a single net or pin pathname contained in a bridge entry.

- ***instance.name***

A repeatable string that specifies an instance pathname contained in a bridge entry.

- **-NAME**

An optional switch that specifies all entered strings are bridge names.

- **-SINGle**

An optional switch that specifies all the entered strings are either a single net pathname or instance pathname. The tool searches for a net first. If a corresponding net cannot be found, the tool searches for a corresponding instance.

- **-NET.pathname**

An optional switch that reports net pathnames for bridge entries. This is the default.

- **-PIN.pathname**

An optional switch that reports pin pathnames for bridge entries instead of net pathnames.

- **-CLOCK.Domains {ALL | clock.pathname...}**

An optional switch and literal or repeatable string pair that specifies a list of clocks and directs the tool to write only faults that are potentially detectable using any of the specified clocks (or equivalent clocks). For a transition fault to be potentially detectable, it must be detectable when the same clock (one of the specified clocks or an equivalent) is used for launch and capture. Any other type of fault must be detectable when one of the specified clocks or equivalents is used as the capture clock. The argument choices are as follows:

ALL — A literal that specifies all the clocks in the design.

clock.pathname — A repeatable string that specifies a particular clock.

Be aware that a fault written using this switch might also be detectable by an unspecified clock.

The tool takes user-defined non-race clocks and faults between synchronous clock groups into account when adding or deleting faults by clock domain.

- **-NO_EQUIvalent_clocks**

An optional switch that prevents the -Clock_domains switch from writing faults in equivalent clock domains. When specified, only faults within clock domains are considered when adding or deleting faults by clock domain.

- **-EXCLUDE_FAULTS_BETWEEN_SYNC_clock_domains**

The tool takes user-defined non-race clocks and faults between synchronous clock groups into account when deleting faults in the clock domain.

- **-CAPture_procedures {ALL | *capture_procedure_name*...}**

An optional switch and literal or repeatable string pair that specifies a list of enabled named capture procedures and directs the tool to write_faults that are potentially detectable by any of the specified procedures. The argument choices are as follows:

ALL — A literal that specifies all enabled named capture procedures.

capture_procedure_name — A repeatable string that specifies a particular enabled named capture procedure.

See the [set_capture_procedures](#) command description for information about enabling or disabling named capture procedures.

- **-DElay_data**

An optional switch that saves the delay faults including the slacks of the faulty site.

- **-TIMING_CRITICAL**

An optional switch that saves the timing critical faults identified by the tool. Before issuing the write_faults command with this switch, you must issue the [set_atpg_timing](#) command with the -TIMING_CRITICAL switch and *timing_margin%* value.

Note

 In order to use the -DElay_data or -TIMING_CRITICAL switches, you must have previously loaded an SDF file containing timing information. See “[Timing-Aware ATPG](#)” in the *Tessent Scan and ATPG User’s Manual* for complete information.

- **-SCAN_Enable**

An optional switch that specifies to only write faults that fan out to the select lines of multiplexers in the scan path. For this switch, a multiplexer is either a MUX simulation primitive or a nonprimitive type multiplexer composed of AND and OR gates. Basically, this switch writes all faults that are in the fanin cone of local scan enable signals and are dominated by them.

- **-CLOCK_Cones**

An optional switch that deletes all faults in the clock cone. The clock cone is the intersection of the fan-in of the sequential element clock ports and the fan-out of the clock sources. This switch considers any sequential elements, such as flops, latches, RAMs, and ROMs, not just scan cells.

- **-IO**

An optional switch that specifies to write faults that are:

- Only controlled by PIs — To be acted on by the -IO switch, a PI either must not be defined as a clock or, if defined as clock (or read/write control), must be constrained off during capture.
- Only observed by POs

- **-ASYnchronous_controls**

An optional switch that specifies to only write faults that fan out to Set/Reset ports of state elements and RAMs. This switch applies to a subset of the faults the -CLOCK_Cones switch writes.

- **-Udfm_type *name***

An optional switch and string that specifies a name of a UDFM fault type. Use this option to write the faults associated with a specified UDFM fault type to the file. The name string may include any number of asterisk (*) and/or question mark (?) wildcard characters.

- **-Cell *name***

An optional switch and string pair that specifies the name of a library cell. Use this option to write all faults associated with a specified library cell to the file. The name string may include any number of asterisk (*) and/or question mark (?) wildcard characters.

- **-MOdule *name***

An optional switch and string pair that specifies the name of a module. Use this option to write all faults associated with a specified module to the file. The name string may include any number of asterisk (*) and/or question mark (?) wildcard characters.

- **-INSTance *name***

An optional switch and string pair that specifies the name of an instance. Use this option to display all faults associated with a specified instance. The name string may include any number of asterisk (*) and/or question mark (?) wildcard characters.

Examples

Example 1

The following example performs an ATPG run, then writes all the untestable faults to a file for review:

```
set_fault_type stuck
set_system_mode analysis
create_patterns
write_faults faultlist -class ut -format basic
```

The content of the *faultlist* file will look similar to the following:

```

0      UU    /ip_scan_clk
1      UU    /ip_scan_clk
0      UU    /ipt_scan_tf_en
1      UU    /ipt_scan_tf_en
0      UU    /ff0/qb
1      UU    /ff0/qb
...

```

Example 2

The following example rewrites all the untestable faults to the file, but includes the name of the cell associated with each fault in the written information:

```
write_faults faultlist -class ut -cell_name -format basic -replace
```

The file now contains an additional column with the cell information:

```

0      UU    /ip_scan_clk  primary_input
1      UU    /ip_scan_clk  primary_input
0      UU    /ipt_scan_tf_en  primary_input
1      UU    /ipt_scan_tf_en  primary_input
0      UU    /ff0/qb  dsffd
1      UU    /ff0/qb  dsffd

```

Example 3

The following command writes out a fault file in MTFI format that contains all faults:

```
write_faults fault_file1 -format mtfi
```

This is an example of a small MTFI file that could result from the previous command:

```

FaultInformation {
    version : 1;
    FaultType Stuck {
        FaultList {
            Format : Identifier, Class, Location;
            Instance ("") {
                1, UC, "in1";
                0, DS, "in1";
                0, DS, "i1/IN0";
                1, DS, "i1/OUT";
                1, DS, "i1/IN0";
                1, AU, "i1/IN1";
                0, UC, "i5/Z";
                1, DS, "out";
                1, DI , "i5/Z";
            }
        }
    }
}

```

Example 4

The following example displays the fault data for *ds* class faults associated with library cells that start with *mux* or *an* to the *my_fault_list* file:

```
write_faults my_fault_list -class ds -cell mux* -cell an*

// Command output
FaultInformation {
    version : 1;
    FaultType (UDFM) {
        FaultList {
            Format : Identifier, Class;
            UdfmType ("intra-cell-bridges_1") {
                Cell ("MUX2") {
                    Instance ("/top/i1/i4") {
                        "F2", DS;
                    }
                }
                Cell ("AND3") {
                    Instance ("/top/i1/i456") {
                        "F2", DS;
                        "F4", DS;
                        "F5", DS;
                        "F7", DS;
                    }
                }
            }
        }
    }
}
```

Example 5

The following example shows how to write specific AU.TC and AU.PC faults:

```
report_statistics -detailed_analysis
# you must first run this command

write_faults fltlist_au.tc -class au.tc 1195
# you must supply a gate ID rather than pin pathname

write_faults fltlist_au.pc -class au.pc mode[3]
# you must supply a pin pathname
```

Example 6

The following example writes out bridge faults in the full format (no *-noeq* switch):

```
write_faults exa.flt
```

```
FaultInformation {
version : 1;
FaultType (Bridge) {
  FaultList {
    Format : Identifier, Class, LocationA, LocationB, BridgeName;
    Instance ("") {
      A0, DS, "/G13", "/G12", "C506";
      A1, DS, -, -, -;
      B0, DS, -, -, -;
      B1, DS, -, -, -;
      A0, DS, "/G13", "/G12", "C505";
      A1, DS, -, -, -;
      B0, DS, -, -, -;
      B1, DS, -, -, -;
      A0, DS, "/G13", "/G12", "C504";
      A1, DS, -, -, -;
      B0, DS, -, -, -;
      B1, DS, -, -, -;
      A0, DS, "/G2", "/G4", "C478";
      A1, DS, -, -, -;
      B0, DS, -, -, -;
      B1, DS, -, -, -;
    }
  }
}
```

Example 7

The following example writes out bridge faults in an abbreviated format that lists only the net pair and fault classes of each corresponding dominant net:

```
write_faults exa.flt -noeq
```

```
FaultInformation {
version : 1;
FaultType (Bridge) {
  FaultList {
    Format : Identifier, Class, LocationA, LocationB, BridgeName;
    Instance ("") {
      A0, DS, "/G13", "/G12", "";
      A1, DS, -, -, -;
      B0, DS, -, -, -;
      B1, DS, -, -, -;
      A0, DS, "/G2", "/G4", "";
      A1, DS, -, -, -;
      B0, DS, -, -, -;
      B1, DS, -, -, -;
    }
  }
}
```

write_flat_model

Context: patterns -scan, patterns -scan_diagnosis

Mode: setup, analysis

Saves the flattened circuit model, the scan trace, and all DRC-related information to a specific binary file.

Usage

```
write_flat_model filename
  [-Password password] [-Command_file command_file] [-Replace]
  [-INCLUDE_Proc_simulation_data {Exclude_test_setup_and_test_end | All}]
```

Description

Saves the flattened circuit model, the scan trace, and all DRC-related information to a specific binary file.

Note

 After saving the flat model, you cannot add primary inputs to the model. This includes using the “[add_scan_chains -internal](#)” command.

This command enables you to quickly restore a new session to the state of a previous session based on saved check point data. This command lets you enter into analysis mode without reading the netlist, flattening, and performing DRC.

The write_flat_model command does not save pattern or fault list information in the flat model file. However, you can use the set_checkpointing_options command to save the pattern set and the fault list periodically.

Note

 If you are preparing a flat model for later use in Tessent Diagnosis, save the flat model immediately after performing ATPG (issuing the create_patterns command) and saving final patterns. For more information, refer to “[Preparing the Design Netlist](#)” in the *Tessent Diagnosis User's Manual*.

When reading in a previously-stored flat model, the tool defaults to the same system mode as when the model was saved. It is also possible to save only the flat model (no scan chain or DRC data) to be restored into setup mode from any system mode.

Arguments

- *filename*

A required string that specifies the name of the file to which you want to write the flattened circuit model.

- -Password *password*

An optional switch and replaceable string pair that directs the tool to embed the specified *password* in the saved file. The *password* is case sensitive and there are no restrictions on its content. Before reading in a flat model that was saved using the -Password switch, the tool will require you to enter the password that was provided with the switch when the model was saved.

For batch runs, you can set the MGC_DFT_FLAT_MODEL_PASSWORD environment variable to the specified password; the tool will then obtain the password from the environment variable instead of querying you for it. If the password setting of this variable is incorrect, however, the tool will revert to querying you for it.

Caution

 Be sure to write down the password and store this copy in a readily accessible, secure location. This will ensure that a forgotten password is only a minor inconvenience.

- -Command_file *command_file*

An optional switch and string pair that specifies the pathname of an ASCII file you previously created that lists commands you want the tool to permanently disable for this flat model. You can create this file with any ASCII text editor.

Choose one of the two keywords, **disable** or **enable**, to place by itself on the first line of the command file. On subsequent lines, list the commands to which the keyword applies, one command or command group per line. The keywords have the following meaning:

- **disable**—Disables the commands listed after the keyword. If the design is one you read into the tool as a flat model, any commands already disabled as a result of the previous flattening will remain disabled; omitting them from the current “disable” list will not re-enable them. All other commands the tool normally supports will be available.
- **enable**—Disables all normally supported commands *except* those listed after the keyword. If the design is one you read into the tool as a flat model, commands already disabled as a result of the previous flattening will remain disabled; listing them after the “enable” keyword will not re-enable them.

Note

 The dofile, exit, and help commands are immune to the command file and are always available.

You specify a command group by listing just the first word or words that all commands in the group have in common. For example, you could list “set” on one line in order to specify the group of all commands that start with the word, “set.”

- -Replace

An optional argument that lets you overwrite an existing circuit model file.

- **-INCLUDE_Proc_simulation_data {Exclude_test_setup_and_test_end | All}**

An optional argument and keyword pair that allows you to save all of the DRC simulation data with the flat model. By default, the tool saves DRC simulation data for everything except for the test_setup and test_end procedures with the flat model. Note that saving all DRC simulation data can save time if you need to debug your test_setup or test_end procedures; however, saving this data can result in a much larger flat model file, especially when the test_setup or test_end procedures contain a large number of cycles.

Examples

Example 1

The following example creates a flat model and saves the model along with all DRC simulation data:

```
create_flat_model
write_flat_model file1 -include_proc_simulation_data all
```

Example 2

The following example uses an external command file to ensure the saved flat model only works with the following commands:

- dofile
- exit
- help
- any command that starts with “set”
- any command that starts with “write_primary”

```
create_flat_model
write_flat_model file1 -command_file commands_for_file1
exit

shell> cat commands_for_file1
enable
set
write primary
```

write_icl

Context: all contexts

Mode: setup, analysis

Prerequisite: ICL modules must be available. You use the [read_icl](#) command to create ICL modules.

Writes out ICL modules created and/or read in with the [read_icl](#) command to the specified file.

Usage

```
write_icl filename [-modules modules_list [-hierarchical]]  
[-exclude_modules exclude_modules] [-created]  
[-modified] [-replace]
```

Description

Writes out ICL modules created and/or read in with the [read_icl](#) command to the specified file.

This command writes out read-in and/or created ICL modules. You can merge both read-in and created ICL modules into the same file. The recommended use model is to write out the ICL hierarchically into a single file which is the default behavior when neither the -modules or -created option are specified.

Use the -modules switch to write only specific ICL modules. The default is to write the top module with all of the modules in the hierarchy below including the read-in modules and the modules below them. Use the -created option if you only want to write out the ICL modules created by ICL extraction and omit those that were read-in

Arguments

- *filename*

A required string that specifies the name of the file to which to write all specified modules.

Note

 For backward compatibility with v2014.4 and earlier releases, you can use the -output_file switch to specify the name of the file. For example:
write_icl -output_file icl_out.icl

- -modules *module_list*

An optional switch and value pair that specifies the names of the modules to write out. The *module_list* value is a Tcl list of one or more ICL module names, or a collection of one or more ICL modules as returned by the [get_icl_modules](#) command.

- -hierarchical

An optional switch that specifies to write out all child modules below the specified ICL modules. This switch can only be used with the -modules switch.

- **-exclude_modules** *exclude_modules*

An optional switch and value pair that excludes ICL modules from being written out. This argument is only useful when the -hierarchical option is inferred or specified. All ICL modules below these excluded ICL modules are also excluded if they are not specified in the -modules list or found below other non-excluded ICL modules.

- **-created**

An optional switch that specifies to limit the written ICL modules to only those *created*.

Specifying this option is equivalent to using the following:

“-modules [get_icl_modules -filter is_created].”

- **-modified**

An optional switch that verifies whether a module has the *is_modified* attribute set to true; if it does, the tool writes out the module.

- **-replace**

An optional switch that specifies to overwrite an existing file. When you use this switch, the error message that is normally generated if the file being written out already exists is suppressed.

Examples

The following example writes out the current design and every other ICL module instantiated below it into a common file.

write_icl icl_out.icl

Related Topics

[read_icl](#)

[set_current_design](#)

write_loops

Context: dft -edt, dft -scan, patterns -scan

Mode: analysis

Writes a list of all the current feedback loops to a file.

Usage

`write_loops filename [-Replace]`

Description

The write_loops command writes all feedback loops in the circuit to a file. For each loop, the file contents show whether the loop was broken by duplication. The file shows loops unbroken by duplication as being broken by a constant value, which means the loop is either a coupling loop or has a single, multiple-fanout gate. The report also includes the pin pathname and gate type of each gate in each loop.

Arguments

- *filename*
A required string that specifies the name of the file to which you want to write the loops.
- -Replace
An optional switch that replaces the contents of the file if the *filename* already exists.

Examples

The following example writes a list of all the loops in the circuit to a file:

```
set_system_mode analysis
write_loops loop.info -replace
```

Related Topics

[report_loops](#)

write_memory_repair_dictionary

Context: patterns -ijtag

Mode: analysis

Writes the CompressBisrChain configuration file.

Usage

```
write_memory_repair_dictionary [-file_name file_name]  
    [-return_dictionary]  
    [-fuse_box_controller_icl_instance fuse_box_controller_icl_instance ]  
    [-replace]
```

Description

Writes the configuration file, as a Tcl dictionary, that is required to run the CompressBisrChain script. The resulting file contains all the fuse box controller parameters, as well as the ordered list of BISR register ICL instances listed per power domain group. The CompressBisrChain script is used to program the fuse box using the [FuseBox Access](#) mode, which uses the IJTAG interface instead of using the fuse box controller's autonomous self-fusebox programming mode. For more information, refer to “[Top-Level Verification and Pattern Generation](#)” in *Tessent MemoryBIST User’s Manual For Use with Tessent Shell*.

Arguments

- **-file_name *file_name***
An optional switch and string pair that specifies the name of the file to which you want to write the CompressBisr configuration contents. If this property is not specified, the default output file will be named “BisrCtrlParams.tcl”.
- **-return_dictionary**
An optional switch that instructs the command to return the content as a Tcl dictionary rather than saving it to a file.
- **-fuse_box_controller_icl_instance *fuse_box_controller_icl_instance***
An optional switch and string pair that specifies the fuse box controller ICL instance to use.
- **-replace**
An optional switch that replaces the contents of *file_name* if the file already exists.

write_modelfile

Context: dft -edt, patterns -scan

Mode: analysis

Writes all internal states for a RAM or ROM gate into the file that you specify.

Usage

`write_modelfile filename RAM/ROM_instance_name [-Replace]`

Description

Writes all internal states for a RAM or ROM gate into the file that you specify.

The write_modelfile command writes, in the Mentor Graphics modelfile format, all the internal states for a RAM or ROM gate into a file.

The RAM and ROM internal states are identical to the initial values. If no initial values exist, the command reports an error condition.

Arguments

- ***filename***

A required string that specifies the name of the file to which you want to write the internal states for the RAM or ROM gate. The information is written in Mentor Graphics modelfile format.

- ***RAM/ROM_instance_name***

A required string that specifies the instance name of the RAM or ROM gate whose internal states you want to write. The command reports an error condition if the instance contains multiple RAM/ROM gates.

- **-Replace**

An optional switch that replaces the contents of the file if the *filename* already exists.

Examples

The following example writes all the internal states of a RAM gate into a file for review:

```
add_write_controls 0 w1
set_system_mode analysis
create_patterns
write_modelfile model.ram /p1.ram
```

write_patterns

Context: patterns -ijtag, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: analysis

Saves the current test pattern set to a file in a specified format.

Usage

For patterns -scan and EDT Off

```
write_patterns pattern_filename
[-pattern_sets [chain] [scan]]
[format_switch]
[-Replace]
[-PROcfile procedure_filename]
[-PARAMeter_file parameter_filename]
[-PARAMETER_List {keyword_value_pair...}]

[-VERBose]
```

For Writing Out Hybrid TK/LBIST Flow Parallel Patterns

```
write_patterns pattern_filename -Verilog -PARALLEL -MODE_Internal [-Replace]
```

For Writing Out Hybrid TK/LBIST Flow PatDB Files

```
write_patterns pattern_filename -PATDB
    [-max_scan_load_unload_size integer] [-Replace]
```

For Writing Out User-Defined Broadside Vector Data

```
write_patterns -vector_set vector_set
```

Description

Saves the current test pattern set to a file in a specified format.

By default, the module name created for Verilog test benches consist of the specified design name followed by an underscore, followed by the name of the specified test procedure file followed by _ctl. All periods are converted to underscores. For example:

design_name_test_proc_file_name_ctl

Note that you can type Ctrl-C on the command line to cancel the write_patterns operation without creating any files.

Note

 The tool issues an AG11 DRC error if you attempt to write patterns in a parallel format other than Verilog or STIL using a multiple cycle shift procedure. Any serial format is fine.

By default and when writing patterns, any signal that is classified as unused for the pattern being written is removed from the pattern file, reducing the size of the pattern file or of the Verilog testbench. To disable this behavior, set the [ALL_EXCLUDE_UNUSED](#) keyword to 0.

For techniques to handle slow scan enable transitions, see “[Delaying Clock Pulses in Shift and Capture to Handle Slow Scan Enable Transitions](#)” in the *Tessent Scan and ATPG User's Manual*.

Multiple Processors Use for Writing EDT External Retargeted Patterns

For EDT external patterns, you can use multiple threads to speed-up calculation of output channel values. The supported pattern formats are ASCII, STIL, WGL and Verilog. You must use the [add_processors](#) command and the appropriate number of licenses.

Hybrid TK/LBIST Flow Specifics

Writes out parallel patterns and PatDB files—refer to the [Hybrid TK/LBIST Flow User's Manual](#) for complete information.

IDDQ Fault Type and External Capture Options

When you are using external capture options with IDDQ faults for use with multiple fault types, the tool issues a warning under the following circumstances:

1. You issue the [set_external_capture_options](#) command.
2. You then set the fault type to IDDQ.

Under these circumstances, the tool issues the following warning:

```
// Warning: The set_external_capture_options <option> command is not
// compatible with IDDQ patterns.
// Set_external_capture_options <option> is being ignored while writing
// these patterns.
```

The tool writes the external_mode IDDQ patterns and ignores the external capture options.

Arguments

- *pattern_filename*

A required string that specifies a name for the saved test pattern file. If the filename ends with .gz or .Z, the file is automatically compressed with the GNU gzip utility.

Note

 When you write patterns in the pattern database (PatDB) format, do not end the pattern filename with .gz or .Z, because the PatDB format is already compressed to a size smaller than achievable with the GNU gzip utility. The [read_patterns](#) command does not support .gz or .Z files for the PatDB format.

- *format_switch*

An optional switch that specifies a format for the saved test patterns. You should always save simulation patterns in the same format as the design netlist.

ASIC vendor test data formats usually support only a single timing file. You can specify the test timing that each ASIC vendor requires by using different timing definition files for each format.

Any time you save the pattern set in an ASIC vendor data format, you should also save the patterns in PatDB, ASCII, binary, STIL or WGL format as backup. This is in case you want to read in the patterns from an external file using the [read_patterns](#) command. Only PatDB, ASCII, binary, STIL or WGL formatted test patterns can be read by the [read_patterns](#) command.

Options include:

-Ascii — A switch that writes test patterns in the standard ASCII format. The ASCII format includes the statistics report, environment settings, scan structure definition, scan chain functional test, scan test patterns, and the scan cell information. This is the default.

Excess load and unload values are padded with Xs. You can override this behavior with the **-Nopadding** switch.

If you use the **-External** or the **-Begin** and **-End** switches, test coverage and fault information is omitted from the ASCII pattern set.

-PATDB — An optional switch that directs the tool to write out patterns in a pattern database (PatDB) format.

Use this switch for Hybrid TK/LBIST in LBIST mode, to write patterns as PatDB. The PatDB file includes the pattern information, such as PRPG and MISR values, used when you retarget the core-level PDL using IJTAG to generate top-level patterns.

In ATPG mode, you can use the PatDB format in place of the ASCII format. It is the recommended format for archival patterns. For hierarchical designs, core-level patterns in the PatDB format are the recommended source for retargeting scan patterns to the top level. You can also use them for core-level diagnosis which is performed on the fail logs generated by reverse-mapping chip-level failures.

This format is not available for use in the patterns **-ijtag** context.

-Binary — A switch that writes the test patterns in binary format. This option is not supported in the patterns **-scan_retargeting** context.

-CTI2005 — A switch that writes the patterns in CTL format. The CTL language is used, but in a more structured manner, and with the addition of CTL information. CTL is an extension to the STIL language. You can customize the output format when you utilize a parameter file. For more information, refer to the description of the **-Parameter** switch later in this section and to “[Parameter File Format and Keywords](#)” on page 3937.

-PDL — A switch that writes the pattern back out in PDL format. This format is supported only for patterns **-ijtag** context. The original PDL is converted to iRead and iWrite commands on ScanRegisters and Primary input/output pins. The scan operations needed to perform the ICL network reconfiguration are also explicitly described with iWrite and iApply commands. All PDL events associated with each

pattern set are grouped into individual iProc wrappers and each iProc is named with the name of the corresponding pattern set.

- STIL2005 — A switch that writes the patterns in STIL format that conforms to IEEE Std. 1450.0 and 1450.1. You can customize the output format with a parameter file. For more information, see the description of the -Parameter switch later in this section and to “[Parameter File Format and Keywords](#)” on page 3937. Note that minimum typing for this switch is -STIL2.
- STil1999 — A switch that writes the patterns in STIL format that conforms to IEEE Std. 1450.0. You can customize the output format with a parameter file. For more information, see the description of the -Parameter switch later in this section and to “[Parameter File Format and Keywords](#)” on page 3937.
- Verilog — A switch that writes the patterns in Verilog format. The Verilog format contains pattern information and timing information from the timing file as a sequence of events. Saving patterns in Verilog format also causes the tool to write out a configuration (.cfg) file along with the test bench and .vec files. For example:

```
Patterns.v
Patterns.v.0.vec
Patterns.v.1.vec
Patterns.v.cfg
Patterns.v.po.name
Patterns.v.chain.name
```

For information specific to the chain name file see the description of the [SIM_NO_CHAINNAME_FILE](#) parameter keyword.

The configuration file contains the following lines:

```
Patterns.v.0.vec    740
Patterns.v.1.vec    820
```

(The number after the filename is the number of data lines to read from the .vec file.)

Even though the test bench is created with each `write_patterns` command, you only have to compile the design and test bench .v files once. You can use additional patterns just by copying the .vec and .cfg file to the location of the compiled simulation files.

All timeplates that are currently loaded into the tool are also saved in the Verilog test bench, not just the timeplates used by the current set of patterns. If a new procedure file with different timeplates or if the netlist information is modified in any way, you have to compile the new test bench before simulating.

The default Verilog test bench supports the following Verilog plusargs: STARTPAT, ENDPAT, CHAINTEST, END_AFTER_SETUP, SKIP_SETUP, and CONFIG. For more information, refer to “[The Verilog Test Bench](#)” in the *Tessent Scan and ATPG User’s Manual*.

You can use the Verilog patterns to interface to a Verilog simulator such as ModelSim. You can customize the output format with a parameter file. For more information, see the description of the -Parameter switch later in this section and to “[Parameter File Format and Keywords](#)” on page 3937.

-Wgl — A switch that writes the patterns in the WGL format. The WGL format contains the waveform pattern information and any timing information from the timing file. You can use the WGL format patterns to generate test patterns in a variety of tester and simulator formats.

-Fjtdl — A switch that writes the test patterns in the Fujitsu ASIC format: FTDL-E.

-MItdl — A switch that writes the test patterns in the Mitsubishi ASIC format: MITDL.

For MITDL format there is restriction that multiple pulse timing must be a cyclical repetition of the first pulse. Consequently, multi-pulse and double-pulse timing in the procedure file only works in the MITDL output without an error if the timing fits the restrictions of the MITDL syntax. See “[Timeplate Definition](#)” in the *Tessent Shell User’s Manual*.

-Mode Lsi — A switch that changes the functionality of the Verilog and WGL output formats so that the saved pattern files meet LSI Logic requirements. This switch is valid only with the -Verilog and -Wgl switches.

-TItdl — A switch that writes the test patterns in the Texas Instruments ASIC format: TDL91. You can customize the output format with the parameter file. For more information on the format of the parameter file, refer to “[Parameter File Format and Keywords](#)” on page 3937.

Note If the design uses a single timeplate the TDL version 4.3 format is used. This removes the TIMING, END_TIMING, and SET_TIMING statements from the test pattern file. Also, the VERSION statement changes from 6.0 to 4.3. However, if the design uses multiple timeplates, then the TDL version output is 6.0.

-TSTL2 — A switch that writes the patterns in Toshiba ASIC format: TSTL2.

-SVf — A switch that writes out the IJTAG patterns in Serial Vector Format. This switch is supported only for “patterns -ijtag” context and can only be used to write IJTAG pattern sets to files.

If the IJTAG patterns make use of more than one TAP interface or of non-TAP scan interfaces, the SVF file will be generated automatically with series of PIO commands instead of SDR, SIR, STATE or TRST commands.

The TCK ratio of the pattern set(s) must be 1 (the TCK ratio is set by means of the -tck_ratio switch of the [open_pattern_set](#) command).

The –test_setup and –test_end switches of the [write_patterns](#) command are taken into account. If requested, the test setup procedure and the test end procedure are also converted to SVF and placed at the beginning/at the end of the pattern file.

- -Replace

An optional switch that replaces the contents of an existing *pattern_filename*.

-
- **-PROcfile procedure_filename**

An optional switch and string that specifies the name of the test procedure file to retrieve non-scan event timing information from. This option saves test patterns using the enhanced pattern output that includes timing information from the test procedure file.

You can specify the procedure filename with this argument or specify it before using this command by issuing the `read_procfile` command. You cannot use this argument with the `-Ascii` or `-Binary` formats.

For more details about the test procedure file, including which output format switches are valid in conjunction with the `-Procfile` switch, refer to “[Test Procedure File](#)” in the *Tessent Shell User’s Manual*.

- **-pattern_sets [chain] [scan] (patterns -scan only)**

An optional switch and keyword pair that specifies which pattern type (scan or chain) to write from the current session. By default, the tool writes both scan and chain patterns. Note that when you specify both chain and scan patterns, the tool writes chain patterns first regardless of the order of specification.

- **-pattern_sets pattern_set_list (patterns -ijtag only)**

An optional switch and string that specifies a Tcl list of pattern set names that were created using the `open_pattern_set` command. The tool writes patterns in the order specified in the `pattern_set_list`. When you do not use the `-pattern_sets` switch, the command writes all pattern sets in the order specified by the `open_pattern_set` command.

- **-PARAMeter_file parameter_filename**

An optional switch and string pair that specifies an external parameter file to retrieve field names for use in certain pattern output formats. For more information about the format of the parameter file, refer to “[Parameter File Format and Keywords](#)” on page 3937.

- **-PARAMETER_List {keyword_value_pair...}**

An optional switch and keyword/value pair that specifies one or more parameter file keywords and their values for use in certain pattern output formats. The keywords and values are delimited by spaces, and you must enclose the list in braces { }. For more information about parameter file keywords, refer to “[Parameter File Format and Keywords](#)” on page 3937.

Note

The `-PARAMETER_List` switch is not supported for ASCII and Binary Pattern formats.

- **-PARAllel**

An optional switch that saves all scan cells in parallel. This is the default.

In designs with scan cells, only scan pins are active during the scan shift cycles. If the tool tries to represent the state of each pin during each shift cycle, it may produce very large pattern files. Simulating the shift operations of these patterns might require a considerable

amount of time if you use a different simulator. You can avoid these problems by saving all scan cells in parallel. The -Parallel switch is compatible with all formats.

Note

 When EDT is On and you save parallel Verilog patterns, the data is saved with respect to the internal scan chains. These patterns are for simulation and cannot be saved as serial. But when you write patterns in parallel tester formats (for example, WGL), the tool saves the data with respect to the external scan channels. These patterns are meant to be saved in serial and cannot be used for parallel simulation.

- -Serial

An optional switch that saves all scan cells in series. You can only use this switch with the -STil1999, -STIL2005, -TItdl (enhanced pattern output only), -Wgl, and -Verilog format type switches.

Note

 You cannot use the -Serial switch and the -Scan_memory_size switch in the same command.

When you use this switch together with the -Verilog switch and the -Parameter switch in the same command, the tool checks the specified parameter file for the SIM_SHIFT_DEBUG keyword. If this keyword exists and is set to 1, every scan chain in the Verilog patterns contain a parallel observe of the entire scan chain for *every shift*, while serially shifting the test patterns. If this keyword is set to 2 or more, the parallel observe occurs for that many shifts, not all. This format is particularly useful for debugging scan chain problems because it allows you to locate the exact scan element causing a problem in a scan chain.

Tip

 Use SIM_SHIFT_DEBUG serial Verilog patterns only for debugging scan chain problems. They typically take more time to create than other kinds of patterns and contain large amounts of data (so file sizes tend to be large). Also, because they simulate serially, the patterns take more time to simulate. Consider using the “-pattern_sets chain,” -Begin, and -End switches to limit the size of the pattern file.

For more information about the parameter file and the SIM_SHIFT_DEBUG keyword, refer to “[Parameter File Format and Keywords](#)” on page 3937.

- -NOInitialization

A switch that writes patterns without creating the initialization cycle in the pattern file. The -Noinitiation switch is valid with the following output formats:

- STil
- SVF
- Verilog
- WG1 (Ascii)

The **-Noinitiation** switch is valid with all enhanced pattern output formats. For more information on the enhanced pattern output, see “[Test Procedure File](#)” in the *Tessent Shell User’s Manual*.

Note

 If DRC was run with initialization enabled ([set_drc_handling](#) -Initialization_cycle On), which is the default, using the **-Noinitiation** switch when saving patterns may result in simulation mismatches when you verify the patterns in a timing-based simulator.

- **-B**Egin {*pattern_number* | *pattern_name*}

An optional switch and integer (*pattern_number*) or string (*pattern_name*) that specify the pattern to begin storing test patterns. This switch is usually used to specify the first pattern in a range to include in the test patterns. The default *pattern_number* is 0. There is no default *pattern_name*.

For Tessent FastScan and Tessent TestKompress, *pattern_number* integer is assigned to each pattern by the tool during pattern creation. You can use the *pattern_name* string with **-begin** when the patterns have been previously written using the “[write_patterns](#) *pattern_filename* -tag *tag_name*” command in the current session or when you read external patterns with tag names.

After ATPG or pattern retargeting, tag based pattern names are not yet available and you must use **-begin** *pattern_number* to write patterns without tag names or together with the **-tag** *tag_name* to create the *pattern_name*.

When used together with “**-pattern_sets chain**” in the same command, the **-begin** switch applies to chain test patterns only. When used together with “**-pattern_sets -scan**” in the same command, the **-begin** switch applies to scan patterns only.

Only one **-begin** argument can be used per [write_patterns](#) command. To save multiple ranges of patterns, for example patterns 11 through 20 and 81 through 100, use the [set_pattern_filtering](#) command with the **-Range** and/or **-Norange** switches before you issue the [write_patterns](#) command.

If you save only a portion of the internal patterns in the **-Ascii** format, test coverage and fault information is not included.

In this example, the [write_patterns](#) command, using **-begin** *pattern_number*, creates an ASCII format pattern file beginning at pattern 25:

```
create_patterns
write_patterns pat1.ascii -ascii -begin 25
```

This example demonstrates using **-begin** *pattern_name*. The [write_patterns](#) command is used with **-tag** to create the tag name for the patterns and then another [write_patterns](#)

command uses the -begin and -end switches with the tag name to write a subset of the patterns:

```
create_patterns
write_patterns tagged_patterns.ascii -tag my_tag -ascii
write_patterns tagged_pat1.ascii -begin my_tag_25 -end my_tag_49
```

- **-END {pattern_number | pattern_name}**

An optional switch that specifies the last pattern of a range to include in the test patterns. This argument is inclusive; therefore, the tool stores the pattern identified by the pattern_number or pattern_name you specify. The default pattern is the last pattern of the pattern set.

For Tesson FastScan and Tesson TestKompress, pattern_number integer is assigned to each pattern by the tool during pattern creation. You can use the pattern_name string with -begin when the patterns have been previously written using the “write_patterns pattern_filename -tag tag_name” command in the current session or when you read external patterns with tag names.

After ATPG or pattern retargeting, tag based pattern names are not yet available and you must use -end pattern_number to write patterns without tag names or together with the -tag tag_name to create the pattern_name.

When used together with “-pattern_sets chain” in the same command, the -end switch applies to chain test patterns only. When used together with “-pattern_sets -scan in the same command, the -end switch applies to scan patterns only.

If you save only a portion of the internal patterns in the -Ascii format, the tool does not include test coverage and fault information.

In this example, the write_patterns command, using -end pattern_number, creates an ASCII format pattern file ending at pattern 25:

```
create_patterns
write_patterns pat1.ascii -ascii -end 25
```

This example demonstrates using -end pattern_name. The write_patterns command is used with -tag to create the tag name for the patterns and then another write_patterns command uses the -begin and -end switches with the tag name to write a subset of the patterns:

```
create_patterns
write_patterns tagged_patterns.ascii -tag my_tag -ascii
write_patterns tagged_pat1.ascii -begin my_tag_25 -end my_tag_49
```

- **-TAg tag_name**

An optional switch that adds a unique user-specified label, tag_name, to each pattern. All chain tests automatically have “chain as the tag_name” regardless of the tag_name given in the -Tag switch. Since all tag names must be unique, “chain” is not a valid tag_name. If the tag_name supplied is not unique, an error message is issued and the run aborts.

If the tool reads in patterns using the Set Pattern External command, the patterns must also be unique. The run aborts if the tool attempts to make two identically named patterns co-

resident by any method. This uniqueness extends across both the internal and external pattern sets. It is not possible to have the same pattern_name in the internal and external sets.

- **-CELL_placement** Bottom | Top | None

An optional switch and literal pair that controls the placement of the scan cell data in the ASCII pattern file. The literal choices are as follows.

Bottom — A literal that places the scan data after the patterns, at the end of the file. This is the default.

Top — A literal that places the scan data before the patterns, at the top of the file.

None — A literal that excludes the scan data from the file.

- **-ENVironment**

An optional switch that adds information about the current Tesson FastScan or Tesson TestKompress environment to the pattern file as comments. The information includes the identification stamp number, the environment settings, and the DRC rules. The information is the same as the report_environment and report_id_stamp commands display.

- **-TEST_Setup** {ONE_Per_file | OFF | ONLY | ONE}

An optional switch and literal pair that specifies how the command saves the test_setup procedure. If you do not use this switch, the command writes one test_setup procedure at the start of each pattern file.

The literal choices are as follows.

ONE_Per_file — A literal that places one test_setup procedure at the start of each pattern file, even when multiple pattern files are saved with one command using the -maxloads, -memory_size, or -scan_memory_size switches. This is the default option.

OFF — A literal that saves patterns without including the test_setup vectors. Using this option infers the use of the -NOInitialization switch as well. This is because the init vector is not needed in the pattern file when the test_setup vectors are not present.

Note that using this option might produce vectors that do not simulate correctly or might produce failures if used on a tester.

ONLY — A literal that saves the test_setup procedure as a separate file. This option does not work if you specify any of the following switches:

- maxloads
- test_end only
- pattern_sets
- begin
- end

ONE — A literal that applies only one test_setup procedure when both chain and scan test patterns are saved in one pattern file. When saving patterns in formats other than

ASCII and binary, a single test_setup procedure is saved in the first file generated when the -Maxloads switch is used with this “One” option.

- **-TEST_End {ONE | ONLY | OFF}**

An optional switch and literal pair that specifies how the command saves the test_end procedure. If you do not use this switch, one test_end procedure is applied at the end of the pattern file. The literal choices are as follows.

ONE — A literal that applies one test_end procedure at the end of the pattern file after all pattern sets are done. This is the default option. When you also use -maxloads, then the tool saves a test_end procedure at the end of each generated pattern file.

ONLY — A literal that saves the test_end procedure as a separate file. This option does not work if you specify any of the following switches:

- maxloads
- test_end only
- pattern_sets
- begin
- end

OFF — A literal that saves patterns without including the test_end vectors. For ASCII and Binary patterns, this switch has no effect. Note that using this switch might produce vectors that do not simulate correctly or might produce failures if used on a tester.

- **-EXternal**

An optional switch that saves the current external pattern set to the specified *pattern_filename*. By default, internal test patterns are saved.

External patterns saved in ASCII format do not include test coverage and fault information.

- **-SAMple [integer]**

Tip

 This switch has been superseded by the [set_pattern_filtering](#) command, which has multiple sampling options.

An optional switch that specifies to save a sample of patterns for each pattern type instead of saving all the patterns. This can be useful for serial pattern simulation to shorten the simulation time. In Tessent FastScan, the different types are those reported by the [report_statistics](#) command. In Tessent TestKompress, the types are additionally based on whether or not the tool used masking in a pattern. For example, in Tessent TestKompress, a clock-sequential pattern with scan chain masking is considered a different type than a clock-sequential pattern without scan chain masking.

The optional integer specifies the number of patterns contained in each sample. If you do not include an integer, the default is to sample one pattern per type.

This switch is not supported in the patterns -scan_retargeting context.

- **-IDQ_file**

An optional switch that creates an ASCII file that lists the cycle number, vector number, and measure time for each saved pattern that has an IDQ measurement point. This IDQ information file has the same name as the pattern file, with “.IDQ” appended to the end and is created for all enhanced pattern output formats. This switch does not support ASCII or binary output formats.

- **-MODE_Internal**

An optional switch that saves test patterns using the internal mode of the named capture procedures. Test patterns saved with this switch treat all internal clocks and internal primary inputs as directly controllable pins. This is the default when you write patterns in ASCII or binary format, or when you are in LBIST mode in the TK/LBIST hybrid flow.

- **-MODE_External**

An optional switch that specifies to write patterns using the external mode of the named capture procedures and no user-defined internal pins. When setting up for ATPG, if you used the [add_clocks](#) or [add_primary_inputs](#) command to define one or more internal pins, then you need to use this switch when saving patterns. This is the default when you write patterns in tester formats (for example, WGL) and Verilog format.

LBIST mode in the TK/LBIST hybrid flow does not support external mode patterns.

Note

If a capture procedure does not contain an external mode, the -Mode_external switch uses the internal mode cycle information, but ignores internal PI events. The switch also ignores internal pin events in scan procedures (shift, load_unload, and so on).

- **-Lib *work_dir* (EDT Off)**

An optional switch and string pair that specifies the working directory containing the compiled top level design. The default work_dir is “work” in the current directory.

- **-NAmE_match (EDT Off)**

An optional switch that instantiates the device under test in the test bench using the name matching method. If you start with a Verilog netlist and do not restart with a flat model, the Verilog test bench uses the position matching method.

- **-POsition_match (EDT Off)**

An optional switch that places the device under test in the test bench using the position matching method.

- **-NOPadding (EDT Off)**

An optional switch that prevents the tool from padding shorter scan chains with X values for the input data in saved ASCII test patterns. When there are scan chains of differing lengths in the design, the tool pads the patterns for the shorter chains with X values to represent unknown or *don't care* bits in the input data. Use this switch to eliminate X values in the input data due to short scan chains. This switch can only be used for ASCII test patterns.

This switch cannot be used with EDT patterns.

To load unpadded test patterns into a tool, use the [read_patterns](#) command.

- **-PAD0 | -PAD1**

For EDT Off

Optional switches that replace X values, representing unknown or *don't care* bits, with either a 1 or a 0 value in the saved test patterns. Options include:

-PAD0 — Replaces X values with 0 values.

-PAD1 — Replaces X values with 1 values.

This behavior is the same for STIL, WGL, and Verilog. When you do not specify -pad0 or -pad0, an X, which is “do not care”, is used on shorter chains. For parallel load scan loading, it is also left as X. For serial loads in a Verilog test bench, the tool shifts in each bit one vector at a time so it has access to the value of the previous bit and updates the X with the force value from the previous vector. Since padding with X means “do not care”, it is correct to use the previous force value in the place of that X.

This switch is only valid for test patterns that support scan chain padding.

For EDT On

Optional switches that replace X values with binary values in the saved test patterns. This switch only affects the unload values in the test patterns. The binary value may be a 0 or 1 and cannot be specified. Both -PAD0 and -PAD1 operate the same on Tessent TestKompress test patterns.

- **-MAXloads *load_number***

An optional switch and positive integer pair that specifies the number of scan loads, *load_number*, to include in a pattern file. Much like the -Begin and -End switches, the -Maxloads switch automatically breaks up the pattern file into a series of pattern files with the specified number of scan loads in each. For example, suppose pattern creation results in 730 basic scan patterns. The following command uses -Maxloads,

```
write_patterns my_patterns -maxloads 100
```

saves the same sequence of files with the same pattern content as this series of commands:

```
write_patterns my_patterns_1 -begin 0 -end 99
write_patterns my_patterns_2 -begin 100 -end 199
...
write_patterns my_patterns_7 -begin 600 -end 699
write_patterns my_patterns_8 -begin 700
```

In either case, the first file contains 100 chain and scan patterns, every other file would contain 100 scan patterns; the last file would contain the remaining patterns.

When there are fewer chain test patterns than the specified number of maxloads, the first file may contain fewer scan patterns than the specified number.

You can also use -Maxloads to break up a pattern subset you specify with the -Begin and/or -End arguments in the same command. For example, here is the command to write patterns 50 through 99 to a sequence of files that each contain no more than 15 patterns:

```
write_patterns my_patterns -maxloads 15 -begin 50 -end 99
```

When you use -Maxloads, the tool automatically appends an underscore and sequence number to the name of each resultant pattern file, starting with number one (_1). When you have more chain test patterns than maxloads, the tool issues this warning:

```
// Warning: The number of chain test patterns, 39, exceeds the
//          number of scan loads specified for a single file,
//          the first file will have extra scan loads.
//          Use a larger value for -maxloads, -memory_size, or
//          -scan_memory_size to correct this.
```

Note

 This switch is only valid with ASCII, Binary, and enhanced pattern output and cannot be used with the -Pattern_size switch.

- **-ADD_Pattern_index_range_to_filename**

A boolean option that adds the pattern index range to the split pattern filename for the files that are generated with the -maxloads option. When specified, the tool appends an underscore and the pattern index range (_0_999, _1000_1999) to the filename, rather than an underscore and sequence number. The default for this option is false.

The filenames reflect the range of patterns in the file. The filename has this pattern: temp_0_8.stil. Each file should have a maxloads number of patterns except the last.

The first file created contains a chain test as well as the scan test.

- **-ADD_Load_range_to_filename**

A boolean option that adds the range of loads to the split pattern filename for the files that are generated with the -maxloads option. When specified, the tool appends an underscore and the load range (_0_999, _1000_1999) to the filename, rather than an underscore and sequence number. The default for this option is false.

The filenames reflect the range of loads in the file. The filename has this pattern: temp_0_8.stil.

The first file created contains a chain test as well as the scan test.

- **-PATtern_size *integer***

An optional switch and integer pair which specifies the size of the memory buffer and pattern file in which to save. *Integer* is given in kilobytes.

Note

 The -Pattern_size switch is valid only when using -Verilog output.

The default pattern size is 128MB. However, any size specified for a pattern size will be adjusted to hold a multiple of the largest pattern. For example, if the largest Tessent FastScan or Tessent TestKompress pattern requires 3MB for one pattern, then the file size will be a multiple of 3MB, which would result in a 126MB pattern size. The maximum pattern size is 2147483646KB (approximately 268GB), and the tool issues an error if this size is exceeded.

- **-MEMory_size *size_in_KB***

An optional switch and integer pair that specifies the maximum size, *size_in_KB*, of available main tester memory, and sets this number as a limit on the size of the pattern data in a pattern file. Much like the -Maxloads switch, the -Memory_size switch automatically breaks up a large pattern file into a series of smaller pattern files that each contain no more than the specified number of kilobytes (KBs) of pattern data. The tool assumes that one pattern value (0, 1, X, or Z) requires one byte on the tester.

If you specify this switch and the -Scan_memory_size switch, the -Memory_size switch specifies the KB limit for only the non-scan pattern data. In this case, the tool ends each pattern file when the size of either the scan data or the non-scan data reaches its limit.

Note that the number of vectors in each pattern file will vary. This is because each file contains the vectors from the test_setup procedure and all the vectors for each Tessent FastScan pattern it contains. Vectors for a single pattern are not split between pattern files.

- **-SCAN_Memory_size *size_in_KB***

An optional switch and integer pair that specifies the maximum size, *size_in_KB*, of tester memory available for only scan pattern data, and sets this number as a limit on the size of this data in the pattern file. Much like the -Maxloads switch, the -Scan_memory_size switch automatically breaks up a large pattern file into a series of smaller pattern files that each contain no more than the specified number of kilobytes (KBs) of scan pattern data. The tool assumes one scan pattern value (0, 1, X, or Z) requires one byte on the tester.

If you specify this switch and the -Memory_size switch, the latter specifies the KB limit for only the non-scan pattern data. In this case, the tool ends each pattern file when the size of either the scan data or the non-scan data reaches its limit.

Note

 You cannot use the -Scan_memory_size switch and the -Serial switch in the same command.

Note that the number of vectors in each pattern file varies; this difference occurs because each file contains the vectors from the test_setup procedure and the vectors for each Tessent FastScan pattern it contains. Vectors for a single pattern are not split between pattern files.

- **-VERBose (EDT Off)**

An optional switch that writes extra information messages about the files being saved to stdout or the tool's log file. These messages use the following syntax:

```
// Writing file_type file_name
```

Where *file_type* is a phrase describing what the file is, and *file_name* is the specified or generated file name. For example, *file_type* could be “STIL patterns,” “WGL patterns,” “Verilog testbench,” “Verilog vectors,” and so forth.

- [{-EDT_Bypass | - EDT_Single_bypass_chain} | -EDT_Internal | -EDT_External] (EDT On)

Optional switch that specifies how EDT test patterns are saved. By default, Tessent TestKompress (EDT on) saves ASCII test patterns that define load data with respect to the input channels of the EDT logic and unload data with respect to the core scan chains. Options include:

-EDT_Bypass — An optional switch used with the -BInary format switch to save EDT bypass test patterns in binary format. EDT bypass test patterns are the decompressed version of the EDT test patterns. These options are only valid for EDT test pattern generation. For more information, see “[Generation of Identical EDT and Bypass Test Patterns](#)” in the *Tessent TestKompress User’s Manual*.

Note

 This option cannot be used when bypass chains are inserted in the design netlist before the EDT logic is generated.

-EDT_Single_bypass_chain — An optional switch used with the -BInary format switch to save EDT bypass test patterns for the single bypass chain configuration. The test patterns are saved in binary format. These options are only valid for EDT test pattern generation. For more information, see “[Dual Bypass Configurations](#)” in the *Tessent TestKompress User’s Manual*.

-EDT_Internal — An optional switch that saves EDT test pattern data for only the internal core scan chains to an ASCII file. The test patterns contain core scan chain force and observe data except for X values observed on the output of the compactor due to X blocking or scan chain masking. For more information, see “[Understanding Scan Chain Masking in the Compactor](#)” in the *Tessent TestKompress User’s Manual*.

Note

 Test patterns saved with the -Edt_internal switch cannot be read back into the tool.

-EDT_External — An optional switch that saves EDT test pattern data with respect to the (compressed) input and output channels. These test patterns are similar to WGL and STIL tester formats and must be resimulated before they can be saved out to an external test pattern file.

- -max_scan_load_unload_size *integer*

An optional switch and value pair that specifies the number of LBIST patterns that will have their scan chain data stored in the pattern database for diagnostic purposes. This option does not affect the PRPG/MISR/low-power seeds/signatures; the pattern database continues to store them for the entire pattern range. The default is 1024.

- -vector_set *vector_set*

A switch and value pair that specifies a vector set specified as the pattern set to write.

This switch is mutually exclusive with any other write_patterns command switch or option. See “[Vector Data Callbacks](#)” in the *Tessent Scan and ATPG User’s Manual*.

By design, when using vector_callback procs and writing patterns, the data fed to the vector callback procs must be the internal view pattern data, and therefore, any external_mode cycles from a named capture, or external_mode cycles from PLL_cycles or external_capture are not used. When you enable vector callbacks, the tool issues the following warnings:

```
// Warning: The set_write_pattern_options -vector_callback command
// causes write_patterns to use the internal_mode view of the
// pattern data. Set_external_capture_options -PLL_cycles is ignored
// in that case.
```

Or:

```
// Warning: The set_write_pattern_options -vector_callback command
// causes write_patterns to use the internal_mode view of the
// pattern data. Set_external_capture_options -capture_proc is
// ignored in that case.
```

Examples

Example 1

The following example performs an ATPG run, and then saves only the first 15 test patterns to a file in the Verilog format, including the timing information contained in the timing file:

```
set_system_mode analysis
create_patterns
write_patterns file1 -verilog timefile -end 14
```

Example 2

The following example illustrates the module name created in the enhanced Verilog output when using the -Procfile switch. If the design name is MAIN, and you issue the following write_patterns command:

```
write_patterns pattern1.pat -procfile -verilog -replace
```

the module name in the test bench will be MAIN_pattern1_pat_ctl.

Example 3

The following example (in patterns -scan) saves Verilog chain test patterns that contain a parallel observe of the entire scan chain for every shift, while serially shifting the chain test patterns (for debugging scan chain problems). The example assumes the parameter file, test.param, contains a “SIM_SHIFT_DEBUG 1;” line.

```
write_patterns chain_shift_debug_patt.v -verilog -pattern_sets chain -serial \
-parameter test.param
```

Example 4

The following examples illustrate the output of the -Verbose switch:

```
write_patterns test_pat.v -verilog -replace -verbose
```

[write_patterns](#)

```
// Writing Verilog testbench test_pat.v
// Writing Verilog PO names test_pat.v.po.name
// Writing Verilog chain names test_pat.v.chain.name
// Writing Verilog vectors test_pat.v.0.vec
// Writing Verilog vectors test_pat.v.1.vec

write_patterns test_pat.stil -stil -replace -verbose -maxloads 10

// Writing STIL patterns test_pat_0.stil
// Writing STIL patterns test_pat_1.stil
```

Example 5

The following example writes the test_setup procedure as a separate STIL file:

write_patterns test_setup.stil -stil -replace -test_setup only

Example 6

This example uses the -add_pattern_index_range_to_filename switch to add the pattern range to the split pattern filename. The maxloads is 10 and the pattern count is 29. Three files are created: temp_0_8.stil, temp_9_18.stil, and temp_19_28.stil. The first file only has 9 scan patterns, instead of 10, because it contains one chain test pattern.

```
write_patterns temp.stil -stil -verbose -maxloads 10 -add_pattern_index_range -replace

// command: write_patterns temp.stil -stil -verbose -maxloads 10
//           -add_pattern_index_range_to_filename -replace
// Writing STIL pattern          temp_0_8.stil
// // Writing STIL pattern        temp_9_18.stil
// Writing STIL pattern          temp_19_28.stil
```

Vector Creation and Modification

write_primary_inputs

Context: dft -scan, dft -test_points

Mode: setup, analysis

Writes primary inputs to the specified file.

Usage

```
write_primary_inputs filename [-Replace] [-All | primary_input_pin...]
```

Description

Writes primary inputs to the specified file.

The write_primary_inputs command writes a list of either all the primary inputs of a circuit or a specific list of primary inputs that you specify into a file where it can be reviewed.

This command is identical to the [report_primary_inputs](#) command except the data is written into a file.

Arguments

- ***filename***
A required string that specifies the name of the file to which the tool writes the primary inputs.
- **-Replace**
An optional switch that specifies for the tool to replace the contents of the file, if the file already exists.
- **-All**
An optional switch that specifies to write all the primary inputs to the file. This is the default.
- ***primary_input_pin***
An optional repeatable string that specifies a list of primary input pins that you want to write to the file.

Examples

The following example writes all primary inputs to a file:

```
write_primary_inputs inputfile
```

Related Topics

[report_primary_inputs](#)

write_primary_outputs

Context: dft -scan, dft -test_points

Mode: setup, analysis

Writes primary outputs to the specified file.

Usage

`write_primary_outputs filename [-Replace] [-All | primary_output_pin...]`

Description

Writes primary outputs to the specified file.

The `write_primary_outputs` command writes a list of either all the primary outputs of a circuit or a specific list of primary outputs that you specify into a file where it can be reviewed.

This command is identical to the [report_primary_outputs](#) command except the data is written into a file.

Arguments

- ***filename***

A required string that specifies the name of the file to which the tool writes the primary outputs.

- **-Replace**

An optional switch that specifies for the tool to replace the contents of the file, if the file already exists.

- **-All**

An optional switch that specifies to write all the primary outputs to the file. This is the default.

- ***primary_input_pin***

An optional repeatable string that specifies a list of primary output pins that you want to write to the file.

Examples

The following example writes all primary outputs to a file:

`write_primary_outputs outputfile`

Related Topics

[report_primary_outputs](#)

write_procedure_testbench

Context: dft -edt, patterns -scan

Mode: analysis

Writes a test bench for verifying correct operation of internal signals used in procedures.

Usage

```
write_procedure_testbench testbench_filename [-Replace]  
[-PARAMeter parameter_filename] [-AL1] | -CApture capture_name... | -LOad_unload]
```

Description

Writes a test bench for verifying correct operation of internal signals used in procedures.

The write_procedure_testbench command writes a Verilog test bench for verifying correct operation of internal signals used in procedures, including named capture procedures. The test bench will verify that if a procedure forces or pulses an internal signal, the value forced or pulsed is actually produced by the circuit when simulated in a Verilog simulator. (The expect values in the test bench are based on the statements in the procedure file that force or pulse internal pins.)

Note

 The test bench written by this command is unrelated to the test bench written by the [write_patterns](#) command, which enables you to simulate and verify the ATPG patterns. Saving patterns is the last step of the ATPG process, whereas you should write a test bench to verify named capture procedures before you create patterns.

Determining from incorrect patterns where the mistakes are in the procedures can be difficult. This command helps you find the mistakes in the procedures, so you can correct them *before* they result in incorrect patterns.

Arguments

- ***testbench_filename***

A required string that specifies the name of the file to which you want to write the test bench.

- -Replace

An optional switch that replaces the contents of *testbench_filename* if the file already exists. By default, the command will not overwrite an existing file.

- -PARAMeter *parameter_filename*

An optional switch and string pair that specifies an external parameter file to retrieve field names for use in certain output formats. For more information on the format of the parameter file, refer to the “[Parameter File Format and Keywords](#)” on page 3937.

- **-All**

An optional switch that specifies to write a test bench that simulates the test_setup procedure, followed by all named capture procedures simulated as load_unload/capture pairs. Values forced on internal signals in all procedures are used as expected responses. Named capture procedures that do not force values on internal signals are skipped. An error message is issued if none of the procedures force values on internal signals. This is the default.

- **-CAPture *capture_name***

An optional switch and repeatable string that specifies a list of named capture procedures to verify. In this case, the command will write a test bench that simulates the test_setup procedure, followed by the load_unload procedure with shift procedure, and then the specified named capture procedure(s). If you specify more than one named capture procedure, the test bench simulates the additional ones as additional load_unload/capture pairs. Each load_unload/capture pair is simulated twice. Values forced on internal signals in the named capture procedures are used as expected responses. An error message is issued if a specified named capture procedure does not force any values on internal signals.

- **-LOAD_unload**

An optional switch that specifies to write a test bench that simulates the load_unload and shift procedures. This test bench simulates the test_setup procedure (if present), followed by the load_unload procedure with one shift. Values forced on internal signals in the load_unload and shift procedures are used as expected responses.

Examples

Example 1

The following example writes a Verilog test bench for verifying the functionality of the named capture procedure “cap1.”

```
write_procedure_testbench verilog_tb_cap1.v -capture cap1 -replace
```

Example 2

The following example assumes the pathname of the ModelSim bin directory has previously been added to the PATH variable. From the shell, the example first creates a Verilog library named “proc_test_work,” then compiles the following three elements into the library:

- Source for the top level design
- Test bench written out in the preceding example
- Parts library

With these prerequisites met, the example simulates the test bench.

```
% vlib proc_test_work
% vlog -work proc_test_work counter_syn_scan.v verilog_tb_cap1.v \
      -v my_verilog_source/verilog_lib.v
```

```

Model Technology ModelSim SE vlog 6.1 Compiler 2005.06 Jun  6 2005
-- Compiling module mux21_macro
-- Compiling module sffr_macro
-- Compiling module lmmux
...
-- Scanning library file 'my_verilog_source/verilog_lib.v
-- Compiling UDP dff_r_err
-- Compiling UDP dff_r

Top level modules:
    counter_verilog_tb_cap1_v_ctl

vsim counter_verilog_tb_cap1_v_ctl -lib proc_test_work \
    -t 100ps -c -voptargs=+acc=npr -do "run -all"

...
# //
# Loading proc_test_work.counter_verilog_tb_cap1_v_ctl
# Loading proc_test_work.counter
# Loading proc_test_work.count4
...
# Loading proc_test_work.dff_r
# Loading proc_test_work.dff_err
# Loading proc_test_work.dff_p
# run -all
#           1850: inst_0/QI_nx7 simulated 0  expected 1
#           1850: Procedure: CAPTURE1 Event: force inst_0/QI_nx7 to 1 at 0

```

The last two lines indicate the procedure named “capture1” forces a 1 on the internal pin /inst_0/QI_nx7, but the value produced on the pin when simulated in the Verilog simulator is 0. This

suggests the force statement is applying an incorrect value. The next example shows what the corresponding force statement (highlighted in bold) might look like in the test procedure file:

```
procedure capture capture1 =
    scan_group groupcnt ;
    mode internal =
        timeplate gen_tp1 ;
        cycle =
            force clear 0 ;
            force clock[0] 0 ;
            ...
            force clock[9] 0 ;
            force test_clk 0 ;
            force /inst_0/QI_nx7 1;
            force_pi ;
            measure_po ;
            pulse clock[0] ;
            ...
            pulse clock[4] ;
    end;
    mode external =
        timeplate gen_tp1_long ;
        cycle =
            force clear 0 ;
            force clock[0] 0 ;
            ...
            force clock[9] 0 ;
            force test_clk 0 ;
            force_pi ;
            measure_po ;
            pulse clock[0] ;
            ...
            pulse clock[4] ;
    end;
end; // capture1
```

Example 3

The following example shows what the message at the end of the Verilog simulation run looks like if there are no mismatches:

```
# run -all
# No error between simulated and expected patterns.
```

write_procfile

Context: dft -edt, dft -scan, dft -test_points, patterns -ijtag, patterns -scan, patterns -scan_retargeting, patterns -scan_diagnosis

Mode: setup, analysis

Writes existing procedure and timing data to the named test procedure file.

Usage

`write_procfile proc_filename [-Replace] [-Full [-EXternal]] [-EXpand_iprocs]`

Description

Writes existing procedure and timing data to the named test procedure file.

For complete information on test procedure file creation, syntax, and structure, refer to “[Test Procedure File](#)” in the *Tessent Shell User’s Manual*.

The write_procfile command writes out existing procedure and timing data to the named test procedure file.

Arguments

- ***proc_filename***

A required string that specifies the name of the file to which you want to write existing procedure and timing data.

- **-Replace**

An optional switch that replaces the contents of the file if the *proc_filename* already exists.

- **-Full**

An optional switch that causes the tool to parse the ATPG pattern list (if any) and create all needed non-scan procedures before writing the procedure file data. In Tessent FastScan and Tessent TestKompress, this option will always create a capture procedure.

Note

 The -Full option can cause the write_procfile command to take more time if there are a large number of ATPG-generated patterns in the internal pattern list.

- **-EXternal**

An optional switch that causes the -Full switch to use the external patterns specified by the read_patterns command instead of internally generated patterns. This switch behavior is similar to the -External switch behavior for the write_patterns command. The -External switch is only valid when using the -Full switch.

- **-EXpand_iprocs**

An optional switch that replaces all iCall and iMerge statements within procedures with the cycles that represent the solution to these iCall statement. For iMerges, the tool replaces the

entire iMerge with the cycles representing the solution to that iMerge. The start and end of the expanded cycles is marked by comments in the reported procedure or procedure file. Use this switch to when debugging [E14](#) DRC violations.

Examples

The following example writes the existing procedure and timing data to the specified file:

```
write_procfile myprocfile.proc
```

write_scan_order

Context: dft -scan

Mode: insertion

Writes the scan chains into the SCANCHAINS section of the ScanDEF file, where each statement describes a single scan chain. ScanDEF is a subset of the DEF language.

Usage

```
write_scan_order filename [-Replace] [-use_escaping_rule {Verilog | Lefdef}]
```

Description

The write_scan_order command writes the scan chains into the SCANCHAINS section of the ScanDEF file, where each statement describes a single scan chain. ScanDEF is a subset of the DEF language. When the tool successfully traces through a subchain, the cells that comprise that subchain are written to the FLOATING list of the corresponding scan chain's statement by default. In this case, the order of cells comprising such a subchain doesn't have to be preserved, and cells can appear in the START and STOP sections.

Modules which have the “exclude_from_concatenated_netlist” attribute specified are considered as hard macros and are not included in the concatenated netlist. Moreover, when writing the scanDEF file, any traced scan elements from existing segments on these modules are omitted between the scanIn and scanOut sections of these segments, and stop at the SI/SO boundary, as is done for a cell library.

Arguments

- ***filename***

A required string that specifies the name of the DEF file.

- **-Replace**

An optional switch that replaces the specified DEF file, if it exists.

- **-use_escaping_rule {Verilog | Lefdef}**

An optional switch and literal pair that specifies whether to use the Verilog escaping mechanism or the LEF/DEF escaping mechanism for specifying special characters in strings/identifiers. The default is Verilog.

In the Verilog escaping mechanism, you start the escaped identifier with a backslash character, “\”, and terminate the escaped identifier with a white space. Neither the leading backslash character nor the terminating white space is considered to be part of the identifier.

In the LEF/DEF escaping mechanism, you use the backslash character, “\”, in front of any character that has a special meaning in LEF/DEF, in which case the special meaning of the character is ignored.

Note

 The escape character cannot be used with the pound sign, '#', in LEF/DEF.

Examples**Example 1**

This example illustrates the information reported with the report_scan_cells command and written to the scanDEF file.

report_scan_cells

Clock	Chain	Group	ShiftReg		Library	Clock		
	CellNo	Name	Name	Pathname	ID/CellNo	ModelName	ScanOut	Pinname
	Polarity							
0	chain1	dummy	/ud5	-/-	sff	QB	clk1	(+)
1	chain1	dummy	/ud4	1/4	dff	QB	clk1	(+)
2	chain1	dummy	/ud3	1/3	dff	Q	clk1	(+)
3	chain1	dummy	/ud2	1/2	dff	Q	clk1	(+)
4	chain1	dummy	/ud1	1/1	sff	Q	clk1	(+)
5	chain1	dummy	/ud10	3/2	dff	Q	clk1	(+)
6	chain1	dummy	/ud9	3/1	sff	Q	clk1	(+)
7	chain1	dummy	/ud8	-/-	sff	QB	clk1	(+)
0	chain2	dummy	/ud11	-/-	sff	Q	clk1	(+)
1	chain2	dummy	/ud7	2/2	dff	QB	clk1	(+)
2	chain2	dummy	/ud6	2/1	sff	Q	clk1	(+)
3	chain2	dummy	/ud12	-/-	sff	Q	clk1	(+)
4	chain2	dummy	/ud13	-/-	sff	Q	clk1	(+)
5	chain2	dummy	/ud14	-/-	sff	Q	clk1	(+)
6	chain2	dummy	/ud15	-/-	sff	Q	clk1	(+)

The tool identifies three shift registers as shown in the following output generated by the report_shift_registers command.

report_shift_registers -verb

Id	Length	Path	Hierarchical	SequentialCell	Clock	Library
			InstanceName	Edge & Name	ModelName	
[1]	4	/	ud1	+ clk1	sff	
			ud2	+ clk1	dff	
			ud3	+ clk1	dff	
			ud4	+ clk1	dff	
[2]	2	/	ud6	+ clk1	sff	
			ud7	+ clk1	dff	
[3]	2	/	ud9	+ clk1	sff	

Given this input, the following command generates the scan DEF file that follows.

write_scan_order results/scandef -replace

Note that in the following file, regular flip-flops and shift register flip-flops within the same domain are separated by FLOATING and ORDERED lists, respectively. Each shift register is written out in a separate ORDERED list.

```

#
VERSION 5.7 ;
DIVIDERCHAR "/" ;
BUSBITCHARS "[]" ;
DESIGN A ;
UNITS DISTANCE MICRONS 1000 ;

SCANCHAINS 2 ;

- chain1_sub0
+ START ud8 QB
+ ORDERED
    ud9 ( IN SI ) ( OUT Q )
    ud10 ( IN D ) ( OUT Q )

    ud7 ( IN D ) ( OUT QB )
+ STOP ud11 SI

# Partition for core chain in clock clk1 (pos-edge) domain
+ PARTITION partition_1 MAXBITS 5 ;

END SCANCHAINS

END DESIGN

```

Similarly, given the same input, the following command generates the scan DEF file that follows:

`write_scan_order scan.def`

Note the following about the scan DEF file:

- sub1 and sub2 are instances of library cell libsubchmodel, which contains a subchain of length 2. The scan DEF includes this length in the BITS field. For regular cells of length 1, the BITS field is not printed.
- All flip-flops are written out in one ORDERED list because chain1 contains cells in different clock edge domains.

```

```

write_scan_setup

Context: dft -test_points

Mode: insertion

Writes out a dofile containing all necessary steps for scan insertion.

Usage

```
write_scan_setup -prefix filename_prefix [-replace] [-all_internal_clocks]
```

Description

Writes out a dofile containing all necessary steps for scan insertion.

The existing chain and sub-chain information will be carried over from previous dofiles.

When you use this command for test point insertion in a post-scan design, the tool writes out the dofile with the test point flops. The name of the new dofile is *filename_prefix_tp_flops*.

Arguments

- **-prefix *filename_prefix***

A required switch and string that specifies a name prefix for the scan setup files.

The filenames are composed of this prefix followed by an underscore (_) and a descriptive file-specific suffix. You can include the pathname to an existing directory as a component of the *filename_prefix*, and the files are written to that location.

- **-replace**

An optional switch that replaces the contents of each file that already exists.

- **-all_internal_clocks**

An optional switch that specifies to write all internally defined clocks to the timeplate, to the ATPG dofile, and to the shift procedure.

Examples

The following example writes out a dofile and test procedure file that can be used from the dft - scan context to perform x-bounding and scan insertion on the design:

```
analyze_test_points  
insert_test_logic  
write_design -output netlist_with_test_points.v -replace  
write_scan_setup -prefix scan_setup -replace
```

write_test_point_dofile

Context: dft -test_points

Mode: all modes

Writes out a dofile containing the test points.

Usage

```
write_test_point_dofile filename [-all | -control | -observe] [-tool_analyzed_only] [-replace]
```

Description

Writes out a dofile containing the test points.

Writes out a dofile consisting of [add_control_points](#) and/or [add_observe_points](#) commands that describe the currently identified test point locations. This dofile can be used to manually edit the list of test points and override the default selections prior to inserting the hardware. It can also be used to completely bypass the analysis step during a subsequent tool invocation.

Arguments

- *filename*

A required string that specifies the name of the file into which you want to write the test points information.

- -all | -control | -observe

An optional switch that specifies the type of test point to write to the dofile. Choose one from the following:

- all — Writes out both control and observe points.

- control — Writes out only the control points.

- observe — Writes out only the observe points.

- -tool_analyzed_only

An optional switch that writes out only the tool generated only test points to the dofile. If you do not specify this switch, then the tool writes out both the tool-generated and the manually-added test points.

- replace

An optional switch that directs the tool to overwrite an existing *filename*.

Examples

The following example performs test point analysis and then writes out the dofile:

```
analyze_test_points
```

```
write_test_point_dofile my_test_points.dofile -replace
```

write_tsdb_data

Context: patterns -scan, patterns -scan_retargeting

Mode: analysis

Populates the contents of the Tesson Shell Data Base (TSDB).

Usage

```
write_tsdb_data [-design_id string] [-pattern_id string]
                 [-max_scan_load_unload_size integer] [-replace]
```

Description

Writes the contents of the **Tesson Shell Data Base (TSDB)**, which is a structured directory containing subdirectories and files. The subdirectory naming is designed to group related information for each specific view of each design block. The files in the TSDB include the flat model, the Tesson Core Description file, the PatDB pattern file, and the fault list.

Note

 For different configurations, you must use different modes, that is each fault type and each configuration requires a different mode. For example, if you have high compression and low compression patterns, you must generate these patterns using different modes. Refer to the [set_current_mode](#) command.

When using this command, the fault list is not written out if pattern filtering is enabled with the [set_pattern_filtering](#) command.

LogicBIST Usage

Writes the `<design_name>.lbist_mode[<mode_name>]` directories that contain all of the files needed to enable logicBIST test mode during [PatternsSpecification](#) processing and that allow diagnosis of the failures once in the production flow. The files generated after LBIST fault simulation are used when you use IJTAG to generate the top-level patterns.

The command detects that it has to create the `<design_name>.lbist_mode[<mode_name>]` directory when the context is patterns -scan and at least one [add_lfsrs](#) command was specified in the setup mode. You can check whether the logicBIST mode is enabled using the “[get_context_logic_bist](#)” command.

ATPG and Pattern Retargeting Usage

Writes the `<design_name>.atpg_mode[<mode_name>]` or `<design_name>.atpg_retargeting_mode[<mode_name>]` directories. When performing ATPG and pattern retargeting in Tesson Shell, the following usage applies:

- If you invoke `write_tsdb_data` after core-level ATPG, the tools writes the files you specified. These files are needed for retargeting core-level patterns, as well as the

patterns and the flat model needed for core-level diagnosis after reverse-mapping of chip-level failures.

- The TCD for the core will be auto-loaded (if not already in memory) at the next level when performing pattern retargeting and [add_core_instances](#) is used to add the design core.
- For “patterns –scan_retargeting” context and performing core extraction, using `write_tsdb_data` writes out the TCD. No flat model/patterns/fault list are written out in this case. If it is chip level, this TCD will be used for reverse-mapping of fails back to the cores, or for subsequently performing pattern retargeting without rerunning core extraction. See “[Scan Pattern Retargeting](#)” in the *Tessent Scan and ATPG User's Manual*.

Arguments

- `-design_id string`

An optional switch and value pair that specifies the *design_id* value to use when creating the [logic_test_cores](#) TSDB sub-directory.

If you specify the *design_id* with the `-design_id` switch, then the tool uses this *design_id*. A *design_id* must only use a combination of the following characters:

- Alphabetic, both uppercase and lowercase. For example: “abc”, “ABC”, “AbC”, and so on.
- Numeric. For example: “123”.
- Underscore. For example: “A_1”.

If you do not specify the *design_id*, then the tool uses the value of the [design_id](#) module attribute that is set on the current design module when this attribute has a non-null value. When you load a design with the [read_design](#) command, then the tool sets the *design_id* attribute when reading the design. Additionally, the tool also sets this attribute after elaboration of the current design to the value returned by [get_context -design_id](#) when the value of the *design_id* is null (the design was not loaded with `read_design`, but, rather, with [read_verilog](#)). If the *design_id* module attribute on the current design is still null by the time you use the `write_tsdb_data` command, then the tool uses the value returned by [get_context -design_id](#).

Do not confuse *design_id* with *mode_name* and *pattern_id* when creating the [logic_test_core](#) containers. The mode name is set using the [set_current_mode](#) command while in the setup mode of the -patterns scan context. The *pattern_id* is specified using the `-pattern_id` switch and is used to differentiate different pattern sets for a given mode name of a given design view. The *design_id* defines the design view used; this is typically used to differentiate the pre-layout versus post-layout design views so that you can create your post-layout patterns without losing the pre-layout copies.

- **-pattern_id *pattern_id***

An optional switch and value pair that specifies the *pattern_id* when saving the <design_name>_<mode_name>_<fault_type>[_<pattern_id>].faults.gz file. For a specific fault type, you may have performed different simulations such as a different value of n-detect. For UDFM, you may have a different set of faults during different fault simulation runs. The optional pattern_id is a way to save the fault classification under different file names.

If you do not specify a -pattern_id string, the *pattern_id* portion of the file name is omitted.

- **-max_scan_load_unload_size *integer***

An optional switch and value pair that specifies the number of LBIST patterns that will have their scan chain data stored in the pattern database for diagnostic purposes. This option does not affect the PRPG/MISR/low-power seeds/signatures; the pattern database continues to store them for the entire pattern range. The default is 1024.

- **-replace**

An optional switch and value pair that suppresses the error that is normally generated when you rerun the command and the <design_name>[_<design_id>].logic_test_core (see “[logic_test_cores](#)” on page 3776) directory already exist. Instead of producing an error, the files inside the <design_name>[_<design_id>].logic_test_core directory are silently overwritten. Notice that if you issue the command multiple time with different pattern_id values, the files that are independent of the pattern id will exist because they were saved by the last invocation include the following:<design_name>_<mode_name>.flat.gz, <design_name>_<mode_name>.patdb, <design_name>_<mode_name>.tcd.gz files.

Multiple <design_name>_<mode_name>_<fault_type>[_<pattern_id>].faults.gz files can coexist in the directory.

Examples

In this example, the write_tsdb_data command is invoked after fault simulation is performed to store all of the files that will be needed to generate signoff and manufacturing patterns and perform diagnosis once the chip is in production. The symbol <...> represents the path “./tsdb_outdir/logic_test_cores/mychip_pre_layout.logic_test_core”. The “_pre_layout” string is appended to the design name in the “mychip_pre_layout.logic_test_core” name because the -design_id option was specified when the [set_context](#) command was issued.

```
set_context patterns -scan -design_id pre_layout
<read_verilog and setup commands here>set_current_mode normal

set_system_mode analysis
set_fault_type stuck
add_faults -all
set_random_patterns 100

simulate_patterns -source bist -store_patterns all
write_tsdb_data -replace
```

```
// Writing <...>/mychip.lbist_mode_normal/mychip1_lbist.tcd.gz  
// Writing <...>/mychip.lbist_mode_normal/mychip1_lbist.flat.gz  
// Writing <...>/mychip.lbist_mode_normal/mychip1_lbist.patdb  
// Writing <...>/mychip.lbist_mode_normal/m8051_lbist_stuck.faults.gz
```

write_visualizer_dofile

Context: unspecified, all contexts

Mode: setup, analysis

Writes a dofile containing the commands needed to recreate the current instance and data sets displayed in the DFTVisualizer windows.

Usage

`write_visualizer_dofile file_pathname [-Display window_name...] [-Replace]`

Description

Writes a dofile containing the commands needed to recreate the current instance and data sets displayed in the DFTVisualizer windows.

The commands in this dofile do not replicate the entire command sequence you have used in the tool session, but rather they simply add the instances and data sets currently present in the specified displays. For example, if you add ten instances to the Hierarchical Schematic window, delete three of them, then issue the `write_visualizer_dofile` command, the resultant dofile will contain commands that add seven instances to the Hierarchical Schematic window.

Arguments

- ***filename***

A required string that specifies the name of the dofile you are writing.

- **-Display *window_name***

An optional switch and repeatable literal that specify the DFTVisualizer windows to which the dofile should restore current instances and data sets. The valid options for the *window_name* argument, from which you can select as many as you want, are as follows:

`FLAt_schematic` — A literal that specifies the Flat Schematic window.

`HIEarchical_schematic` — A literal that specifies the Hierarchical Schematic window.

`DAta` — A literal that specifies the Data window.

`Browser` — A literal that specifies the Design Browser window.

`Signals` — A literal that specifies the Signals window.

Omit the `-Display` switch to include commands in the dofile that restore current instance and data displays in the following windows: Data, Flat and Hierarchical Schematic.

- **-Replace**

An optional switch that specifies to replace the contents of *file_pathname* if a file by that name already exists.

Examples

The following example writes a dofile that will restore instances and data sets currently displayed in the Flat and Hierarchical Schematic windows of DFTVisualizer:

```
write_visualizer_dofile debug.do -display flat_schematic hierarchical_schematic -replace
```

Related Topics

[close_visualizer](#)

[open_visualizer](#)

[set_visualizer_preferences](#)

write_visualizer_preferences

Context: unspecified, all contexts

Mode: setup, analysis

Writes the current DFTVisualizer preference settings to the specified file.

Usage

`write_visualizer_preferences filename`

Description

Writes the current DFTVisualizer preference settings to the specified file.

To read in the preference settings, use the [read_visualizer_preferences](#) command.

Arguments

- *filename*

A required string that specifies the name of the text file to which to write the current DFTVisualizer preference settings.

Examples

The following example writes the current DFTVisualizer preference settings to the file, *my_prefs.dftvis*:

```
set_system_mode analysis
write_visualizer_preferences my_prefs.dftvis
```

Related Topics

[read_visualizer_preferences](#)

write_window_contents

Context: unspecified, all contexts

Mode: setup, analysis

Saves the current content of the specified DFTVisualizer window to the specified file.

Usage

```
write_window_contents file.pathname [-Replace] -Display window_name  
[-Format file_format]
```

Description

Saves the current content of the specified DFTVisualizer window to the specified file.

The window must be visible, not minimized. You can save the file in one of several formats, both graphic and text formats.

To view a graphic file generated by this command, you can use any third-party tool that supports that particular graphic format.

Arguments

- ***file.pathname***

A required string that specifies the pathname of the screen capture file.

- **-Display *window_name***

A required switch and literal pair that specifies the DFTVisualizer window whose content you are capturing. Select the window name from the following list:

FLAt_schematic — A literal that specifies the Flat Schematic window. This is the invocation default.

HIEarchical_schematic — A literal that specifies the Hierarchical Schematic window.

Browser — A literal that specifies the Design Browser window.

Signal — A literal that specifies the Signals window.

DAta — A literal that specifies the Data window.

WAve — A literal that specifies the Wave window.

TRanscript — A literal that specifies the Transcript window.

Format — A literal that specifies the Format window.

SEarch — A literal that specifies the Global Search window.

TEst_structures — A literal that specifies the Test Structures window.

- **-Replace**

An optional switch that specifies replacement of the contents of *file.pathname*, if a file by that name already exists.

- -Format *file format*

An optional switch and literal pair that specify the format of the capture content. By default, JPEG format is used. Format options include:

schematic — A literal that specifies the Mentor Graphics Tessent schematic format.
This is the default for the Flat and Hierarchical Schematic windows.

PS — A literal that specifies the Postscript format. This format can only be used with the schematic window.

JPG (or JPEG) — A literal that specifies the JPG file interchange format. This is the default for all windows except the Flat and Hierarchical Schematic windows.

GIF — A literal that specifies the Graphics Interchange Format.

PNG — A literal that specifies the Portable Network Graphics format.

TXT — A literal that specifies ASCII text format. This option is valid for the Design Browser, Data, and Signal windows only.

CSV — A literal that specifies the CSV (comma-separated values) file format. This option is valid for the Design Browser, Data, and Global Search windows.

Examples

The following example analyzes a DRC violation (automatically invoking DFTVisualizer in the process and displaying the part of the netlist related to the violation in the Flat Schematic window), then saves a screen capture of the displayed netlist segment in GIF format:

```
analyze_drcViolation c3-1
// command: open_visualizer -display flat_schematic
// Note: Gate report now set to clock_cone (clock=/tck).
// Creating Schematic for 5 instances

write_window_contents my_c3-1.gif -display flat_schematic -format gif
// INFO: "flat schematic window" contents saved in my_c3-1.gif
// 10599 bytes) using the "gif" format.
```

Chapter 7

Design Rule Checking

Design rule checks are separated into categories based on the type of verification they perform.

Design Rule Overview	2640
Scan Insertion Checking	2640
How to Troubleshoot Rules Violations	2641
Design Rules	2653
RAM Rules (A Rules)	2666
Assertion Rules (ASSERT Rules)	2680
BIST Rules (B Rules)	2686
Clock Rules (C Rules)	2687
Scan Cell Data Rules (D Rules)	2732
Pre-DFT Clock Rules (DFT_C Rules)	2747
Extra Rules (E Rules)	2775
EDT Finder Rules (F Rules)	2796
Flattening Rules (FN, FP, and FG Rules)	2821
General Rules (G Rules)	2829
ICL Extraction Rules (I Rules)	2834
ICL Semantic Rules (ICL Rules)	2843
EDT Rules (K Rules)	2895
Procedure Rules (P Rules)	2916
Core Mapping for ATPG and Scan Pattern Retargeting Rules (R Rules)	2961
Scannability Rules (S Rules)	2984
Scan Chain Trace Rules (T Rules)	2994
Power-Aware Rules (V Rules)	3018
Timing Rules (W Rules)	3032
Other DRC Messages	3052

Design Rule Overview

The design rules are organized into functional categories.

Scan Insertion Checking	2640
How to Troubleshoot Rules Violations	2641
Rules Settings	2641
How to Turn on ATPG Analysis	2641
How to Debug DRC Violations in DFTVisualizer.....	2641
How to Set the Level of Gate Data	2646
How to Set the Gate Information Type.....	2648
How to Report Gate Data	2648
Flattening Rule Violations	2652
Design Rule Output	2652

Scan Insertion Checking

Prior to scan insertion, the tool performs limited rule checks on the design as you switch from setup to analysis mode. Part of the checking it does is scannability checking.

For more information, refer to [Scannability Rules \(S Rules\)](#).

For primary clock inputs gated by other logic, a test procedure file describes the logic conditions that permit propagation of the clock signal through these gates. For uncontrollable clock circuitry, the tool can assist you in modifying your circuit by inserting test logic circuitry at these clock nodes whenever necessary. Refer to “[Test Logic Insertion](#)” in the *Tessent Scan and ATPG User’s Manual* for details.

If you specify existing scan circuitry, or if you have a test procedure file that sets up conditions to allow some state elements to be scan candidates, the tool performs more extensive checking. After you add scan circuitry to your design and generate or write a test procedure file, you should go back to setup mode and specify this information. Then you can return to analysis mode and perform extensive rules checking *before* entering patterns -scan context.

How to Troubleshoot Rules Violations

You will need to troubleshoot your design to identify the cause of design rule violations.

Rules Settings	2641
How to Turn on ATPG Analysis	2641
How to Debug DRC Violations in DFTVisualizer	2641
How to Set the Level of Gate Data	2646
How to Set the Gate Information Type	2648
How to Report Gate Data	2648
Flattening Rule Violations.....	2652
Design Rule Output	2652

Rules Settings

Some rules allow you to specify how a violation is handled either error, warning, note, or ignore.

How to Turn on ATPG Analysis

The Atpg_analysis option to the set_drc_handling command provides full test generation analysis during rules checking for clock rules C1, C3, C4, C5, C6, some D rules and some E rules (such as E4, E5, E8, E10, E11 and E12). For the C1 rule, this analysis is enabled by default; for other rules, the tool does not perform the analysis unless you direct it to.

For example, assume that you select Atpg_analysis for clock rule C1 and the tool simulates a clock input to be X. The rule violation occurs when the analysis determines that it is, or may be, possible to turn the clock input on when all other defined clocks are off, and constrained pins are at their constrained values.

Note

 The ATPG analysis rules checking process may require additional CPU time and memory.

How to Debug DRC Violations in DFTVisualizer

When you issue the analyze_drcViolation command, the tool automatically opens the relevant DFTVisualizer schematic window (if it is not already open) and sets gate reporting to match the type of rule violation that has occurred.

In the schematic window, DFTVisualizer displays *callouts* next to failing gates or clocks associated with DRC violations. Each callout displays a summary of the DRC and potential next

steps. For more information about using callouts, see “[Flat Schematic Window](#)” in the *Tessent Shell User’s Manual*.

[Table 7-1](#) lists the DRCs that are supported by callouts in the DFTVisualizer schematic windows and their messages and appearance.

Table 7-1. DRC Violation Messages

DRC Rule	Instance or Port Callout Box is Attached To	Callout Message Displayed
A1	Failing RAM instance	Setting all write controls off failed to force off RAM write line. Trace write control lines backward to debug the issue further.
A2	Failing RAM instance	Connected to scan clock.
A3	Failing RAM instance	Read or write control line is connected to address input of RAM. Trace address input backwards to debug the issue further.
A4	Failing RAM instance	Read or write control line is connected to data input of RAM. Trace data input backward to debug the issue further.
A6	Failing RAM instance	Write/Read line not off during time <time> of <test proc name> procedure. Refer to the test procedure file to debug the problem further.
A7	Failing RAM instance	Setting all read controls off failed to force off RAM read line. Trace read control lines backward to debug the issue further.
C3	Source of violation	Clocked by same clock/clock_path.
	Failing instance	Captures data from sequential element <source_gate> clocked by same clock </clock_path>.
C4	Source of violation	Clocked by same clock/clock_path.
	Failing instance	Captures data from sequential element <source_gate> clocked by same clock </clock_path>.
C5	Failing instance	Multiple clock inputs of <clock names> are in the same clock cone and the clock inputs may be on at the same time. Trace back on the clock cone to debug the problem further.
C6	Failing instance	Clock <clock_path> affects both data and clock input.
C7	Failing instance	Clock input </clock_path> cannot capture data with a single clock on.
C8	Primary output pin	Primary output <PO name> is connected to clock <clock name>.

Table 7-1. DRC Violation Messages (cont.)

DRC Rule	Instance or Port Callout Box is Attached To	Callout Message Displayed
C9	Primary output pin	Path from clock <clock name> is gated by scan cell that uses same clock.
C16	Failing instance	Load value of scan cell is disturbed by clock input <input_num> at the beginning of the capture phase when pin constraints are forced.
DFT_C1	A primary input is reached	<p>When stopped on a port, the callout is “add_clock -period missing for this port.” The error message is:</p> <pre>// Error: The memory clock pin 'blockB_clka_i1/CLK' // (63.14) is sourced by port 'clkb' (2.0) but its // period was // not defined using the 'add_clocks -period' command. // (DFT_C1-2).</pre> <p>When stopped on a pin, the callout is “Clock tracing blocked here, and no ‘add_clock -reference’ or ‘add_clock -period’ was defined.” The error message is:</p> <pre>// Error: The memory clock pin 'blockA_clka_i1/CLK' //(26.16) source tracing stop at pin 'clock_mux1/Y' (84.0) // Correct the block conditions or use the 'add_clocks // -period' if this is an embedded oscillator or // 'add_clocks -reference' if this an active PLL or clock // divider. (DFT_C1-1)</pre>
DFT_C2	The pin or port on which the trace stopped	Not declared as a clock
DFT_C3	The pin or port on which the trace stopped	Not declared as a clock
DFT_C4	The pin on which the clock is defined	(derived) clock source
DFT_C5	The clock with the missing period	No period specified
D1	Failing instance	Scan cell disturbed during time <time> procname.
D2	Failing copy instance	Copy cell failed data capture design rule check. See Scan Cell Data Rules (D Rules) for conditions that cause this DRC violation.

Table 7-1. DRC Violation Messages (cont.)

DRC Rule	Instance or Port Callout Box is Attached To	Callout Message Displayed
D3	Failing Master FF	Not successfully observed by master observe procedure. Refer to the test procedure file to debug the problem further.
D4	Failing Master FF	Skew load procedure not successful for MASTER. Refer to the test procedure file to debug the problem further.
D5	Failing FF	Non-scan memory element converted to <gate type>: TIEX, TIE0, TIE1, INIT-0, INIT-1, INIT-X, and TLA.
D6	Non-scan latch instance	Latch not transparent due to <reason for failure>.
D7	Failing instance	Clock port set to stable high at the end of shift procedure.
D8	Failing Master latch	Master latch allows data capture while clocks off. Refer to the test procedure file to debug the problem further.
D9	Failing FF	<Type of disturbance> disturbance in procedure <sequential transparent proc name>. Refer to the test procedure file to debug the problem further.
D10	Failing FF	Invalid transparency (X/Y) in clock procedure <clock proc name>.
E7	Failing bidirectional pin	Bidirectional pin <pin name> not set to input mode at time <time> of <test proc name> procedure. Refer to the test procedure file to debug the problem further.
F2	Failing gate	Trace stopped here. Refer to the netlist or trace the schematic to debug the problem further.
F5	Failing gate	Trace stopped here. Refer to the netlist or trace the schematic to debug the problem further.
	Failing channel input	Channel input is not driving any decompressor.
F6	1st Failing state element	Trace stopped here. Refer to the netlist or trace the schematic to debug the problem further.
	2nd Failing state element	Channel input is not driving any decompressor.
F7	Failing state element	Driven by a primary input which is not defined as a channel input in the dofile.
	Channel input	Not defined as a channel input in the dofile, but drives a decompressor. Refer to the dofile or the netlist to debug the problem.

Table 7-1. DRC Violation Messages (cont.)

DRC Rule	Instance or Port Callout Box is Attached To	Callout Message Displayed
F8	Channel out port	The channel output is not driven by a compactor. Refer to the netlist or trace the schematic to debug the problem further.
	Channel in port	Trace stopped here. Refer to the netlist or trace the schematic to debug the problem further.
F9	Failing state element	Trace stopped here. Refer to the netlist or trace the schematic to debug the problem further.
F12	Scan in pin	Scan in pin of the uncompressed scan chain was not defined using “add scan chains” command.
	Scan out pin	Scan out pin of the uncompressed scan chain was not defined using “add scan chains” command.
F13	Failing state element	State element is not reset correctly prior to shift. Refer to the netlist or test procedure file to debug the problem further. Simulated Value = Expected Value =
F14	Failing state element	State element does not hold its value during capture. Refer to the netlist or test procedure file to debug the problem further.
F15	Failing state elements in the path	Initialized to wrong value <val> after test_setup and load_unload. Expected value is <val>. Refer to the netlist or test procedure file to debug the problem further.
F16	Failing state element	State element does not preserve its value during capture and load_unload. Refer to the netlist or test procedure file to debug the problem further.
F17	Failing state element	Failing state elements of the MISR.
F18	Failing Mask hold register	State element does not load expected values mask shift register before shift in load_unload. Refer to the netlist or test procedure file to debug the problem further. Simulated Value = <val> Expected Value = <val>
	2nd Failing state element	The driving mask shift register.
F19	Failing state elements	Does not preserve its value during shift. Refer to the netlist or test procedure file to debug the problem further.

Table 7-1. DRC Violation Messages (cont.)

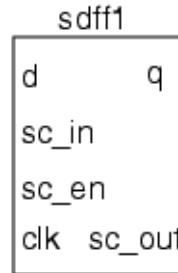

DRC Rule	Instance or Port Callout Box is Attached To	Callout Message Displayed
I1	Failing instance	Ports found in ICL module are not found on corresponding design module.
I2	Failing instance	ICL port does not have a valid direct path to or from another ICL port function.
I3	Failing instance	ICL port is connected to an incompatible ICL port function.
I4	Failing instance	ICL port is connected to a primary input or output port previously inferred to be an incompatible ICL port function.
I5	Failing instance	Input constraint verification failed for an input pin on an ICL-attributed design instance.
P92	Failing gate	Internal primary input <path> is not controlled.
R2	Scan input pin	Tracing back from this scan input pin/scan_input_path could not reach a top-level port.
	Top-level gate	Could not trace further back from this gate.
R4	Failing pin	This pin had an input constraint of expected value (core module_name mode internal/external) but currently has value (actual Val).
R5	Failing instance	The stable_after_setup value of pin was expected val but currently has an actual value.
R8	Failing gate	Last traced gate.
V8	Scan cell	Power Domain: < name >, Power Mode (CPF) or Power State: <name>.
V9	Scan cell	Power Domain: < name >, Power Mode (CPF) or Power State: <name>.
V13	1st failing gate	Power Domains <power_domain_name>.
	2nd failing gate	Power Domains <power_domain_name>.
V14	1st failing gate	Power Domains <power_domain_name>.
	2nd failing gate	Power Domains <power_domain_name>.

How to Set the Level of Gate Data

The tools can report data at different levels; therefore, you should specify the level of information before you issue the `report_gates` command.

You do this with the `set_gate_level` command. Setting the gate level to design (the default) reports information at the design cell (library model) level. The following figure depicts a scannable-equivalent DFF cell library model at the design level.

Figure 7-1. Example of Design Level

If the gate level is set to design, the `report_gates` command displays the following information:

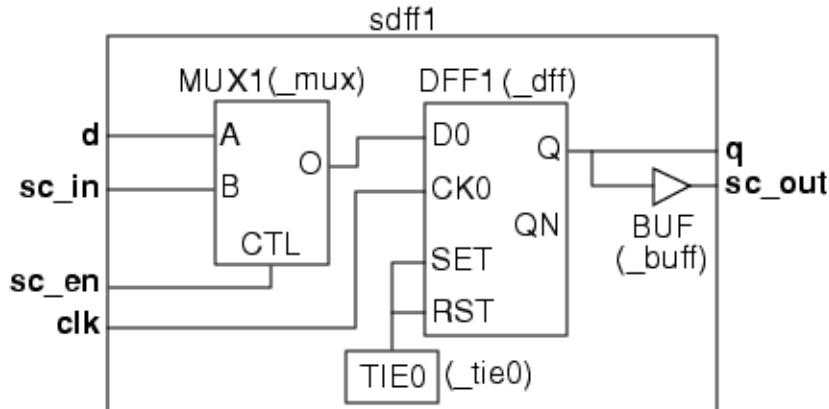

```

instance_name      cell_type
  input_pin_name   I  (data)    pin_pathname ...
  input_pin_name   I  (data)    pin_pathname ...
.
  input_pin_name   0  (data)    pin_pathname ...

```

Setting the gate level to primitive reports information at the simulation gate level. The following figure depicts the `sdff1` library model at the primitive level.

Figure 7-2. Example of Primitive Level

If you set the gate level to primitive, the `report_gates` command displays the following information:

```

instance_name      (gate_id#)    gate_type
  input_pin_name   I  (data)    gate_id#-pin_pathname ...
  input_pin_name   I  (data)    gate_id#-pin_pathname ...
.
  input_pin_name   0  (data)    gate_id#-pin_pathname...

```

In the DFTVisualizer Flat Schematic window, you can change between the Primitive and Design levels by pressing **Ctrl + L**, or by selecting **Display > Gate Level (Ctrl + L) > Design | Primitive**.

How to Set the Gate Information Type

The `set_gate_report` command specifies the type of information that you want to appear when you report_gates data with the `report_gates` command. The multitude of options this command supports varies somewhat depending on which tool you are using.

The common usage of the `set_gate_report` command is as follows:

```
set_gate_report {Normal | Trace | Error_pattern | TlE_value  
| [Drc_pattern procedure_name {time | -All}] {-COnstrain_value [ON | OFF]}}
```

- The Trace option displays the values of the gates obtained during scan chain tracing. That is, this option displays data obtained on an error condition (not warning) during simulation of the **shift** procedure. You can use this option to help determine why a scan chain was not properly sensitized.
- The Error_pattern option displays the simulated values of the gate and its inputs, for the pattern (event) that had an error. This option displays such information as cell disturbances during the **load_unload** procedure or bus contention problems.
- The Normal option is the default. It displays only standard connectivity data.
- The Drc_pattern option displays an identified procedure's simulated gate values during the designated time. This option is similar to the Trace option, but is more versatile because it allows access to the data obtained from simulation of any of the test procedures.
- The Parallel_pattern option displays simulated values for a selected pattern in the last simulation pass. A “pattern” is any time event that occurs during the test procedure. When the ATPG tool encounters problems in generating patterns, you can access the simulation data with this option.
- The -COnstrain_value {ON | OFF} option, when on, displays the simulated values that result from all naturel tied gates, learned constant value non-scan cells, constrained pins, and constrained cells, the blocked flag (B), and the unused flag (UU).

How to Report Gate Data

If you encounter rules violations when you attempt to exit the Setup mode, you may need more information about specific gates in the design for troubleshooting purposes. While the violation message may give some information as to the location of the problem, you may need to track down the source of the problem by reporting on a sequence of gates in the design. The `report_gates` command is a very powerful command you can use to report on netlist data.

The following subsections show how to use report_gates to display various types of information for troubleshooting purposes. For more information on this command, refer to the report_gates reference page.

In DFTVisualizer, you can report data on selected gates by clicking the  Report Gates icon, pressing **Ctrl + R**, or pressing the right mouse button and selecting **Commands > Report Gates**. For more information, see “[Reporting Gates](#)” in the *Tessent Shell User’s Manual*.

How to Report on a Specific Gate

You can use the report_gates command to display information for selected gates, which you identify by either a gate index number or a pin pathname of a pin connected to the gate. This command reports the gate name, its gate type, and its connectivity to other gates. For example, to use report_gates in this manner, you could specify:

```
report_gates 74493
```

[Figure 7-3](#) shows a report with primitive-level information for a gate with an ID number of 74493.

Figure 7-3. Data Reported for a Specific Gate

Instance Name	Gate ID#	Learned Behavior (Inactive High Latch)
<pre>rep ga 74493 // /b5/u12.u1_0_M (74493) LA-IH // "S I (000) 11426- // "R I (000) 6694- // "C0 I (000) 36060- // d I (XXX) 53753-/b2/u4/Y // scnck I (010) 28049-/b5/BOS595/CK2 // sd I (XXX) 11775-/b5/u12.u1_1_S/q // "OUT O (XXX) 11427- // MASTER cell_id=0 chain+c1 group=g1 invert_data=FFFF</pre>	<pre>// /b5/u12.u1_0_M (74493) LA-IH // "S I (000) 11426- // "R I (000) 6694- // "C0 I (000) 36060- // d I (XXX) 53753-/b2/u4/Y // scnck I (010) 28049-/b5/BOS595/CK2 // sd I (XXX) 11775-/b5/u12.u1_1_S/q // "OUT O (XXX) 11427- // MASTER cell_id=0 chain+c1 group=g1 invert_data=FFFF</pre>	<pre>Connectivity Data</pre>

<pre>Scan Chain Data</pre>		

How to Report on All Gates of a Specified Type

You can use report_gates to report on all gates of a specified type. The report_gates usage for this case is:

```
report_gates {-Type gate_type}...
```

The supported gate types are those listed as simulation primitives in the “[Simulation Primitives of the Flattened Model](#)” section of the *Tessent Scan and ATPG User’s Manual*.

The following example shows how to report on all TIE0 gates.

```
report_gates -type tie0

// -----
// List of TIE0 gates
// -----
// /u1/inst_565_ff_d_0_dff (13) TIE0
//   "OUT" O 267- 266-
// /u1/inst_565_ff_d_1_13 (14) TIE0
//   "OUT" O 269- 268-
// /u1/inst_565_ff_d_2_13 (15) TIE0
//   "OUT" O 271- 270-
// Total number of tie0 gates = 3
```

How to Report a Histogram of All Gate Types

You can use report_gates to show a distribution (histogram) of all gates in the design. To use report_gates in this manner, specify:

report_gates -type Histogram

The following example shows the type of data this command displays.

```
// -----
// List of histogram of gates
// -----
// BUF=175 INV=30 AND=3 NAND=17 OR=7 NOR=5 XOR=2 LA=14
// PI=12 PO=7 TIE0=7 MUX=7
```

How to Report on a Path Between Two Gates

You can also use report_gates to display information on the circuitry between two specified gates. To use report_gates in this manner, specify:

report_gates -path <gate1_ID#> <gate2_ID#>

How to Report on the First Input of a Gate

The report_gates command can display data on the gate connected to the first input of the previously reported gate. This lets you quickly and easily trace backward through circuitry. To use report_gates in this manner, first report on a specific gate and then enter:

back

The following example shows how to use report_gates and back to trace backward through the first input of the previously reported gate.

report_gates 26

```
// /u1/inst_565_ff_d_1_13 (26) BUF
//   "I0" I 269-
//   "OUT" O 268- 75-
```

back

```
// /u1/inst_565_ff_d_1_13 (269) LA
// "S" I 14-
// "R" I 145-
// SCLK I 4-/clk
// D I 265-/u1/_g32/X
// ACLK I 2-/scan_mclk
// SDI I 20-/u1/inst_565_ff_d_0_dff/Q2
// "OUT" O 26- 27-
```

back

```
// /u1/inst_565_ff_d_1_13 (14) TIE0
// "OUT" O 269- 268-
```

How to Report on the First Fanout of a Gate

Similar to tracing backward through circuitry, you can also trace forward through the first fanout of the previously reported gate. To use report_gates in this manner, first report on a specific gate and then enter:

forward

The following example shows how to use report_gates and forward to trace forward through the first fanout of the previously reported gate.

report_gates 269

```
// /u1/inst_565_ff_d_1_13 (269) LA
// "S" I 14-
// "R" I 145-
// SCLK I 4-/clk
// D I 265-/u1/_g32/X
// ACLK I 2-/scan_mclk
// SDI I 20-/u1/inst_565_ff_d_0_dff/Q2
// "OUT" O 26- 27-
```

forward

```
// /u1/inst_565_ff_d_1_13 (26) BUF
// "I0" I 269-
// "OUT" O 268- 75-
```

forward

```
// /u1/inst_565_ff_d_1_13 (268) LA
// "S" I 14-
// "R" I 145-
// BCLK I 1-/scan_sclk
// "D0" I 26-
// "OUT" O 24- 25-
```

Flattening Rule Violations

If you encounter flattening rule violations, you can use the report_flattener_rules command to display either a summary of the flattening rule violations or the data for a specific violation, for troubleshooting purposes.

In addition, you can use the set_flattener_rule_handling command to change the handling of the net, pin, and gate rules.

Design Rule Output

Many error messages provide a line number and file name to help you resolve the error condition. However, some error messages may relate to problems with internally generated data and do not provide a line number and file name.

For example, a syntax error (P1) in a test procedure file would produce the following message:

```
The following occurred at line 10 in file testproc
Syntax error in line number 10. (P1-1)
```

RAM Rules (A Rules)

The tool checks RAM gates to identify proper test methods. You can select the handling of any RAM rule to be error, warning, note, or ignore.

Tip

 In DFTVisualizer, you can press Ctrl + R to execute a report_gates command on selected gates.

A1

Category: RAM

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

When all write control lines are at their off-state, all write, set, and reset inputs of RAMs must be at their inactive state. The tool performs this check using the simulated values that result when all defined write control lines are at their off-state, the constrained pins are set to their constrained values, and the initialized non-scan cells are set to their stable states. The rule violation occurs if any write, set, or reset input of any RAM gate is not off.

The default handling for this rule violation is a warning. When an error condition occurs, you can access the simulated values by setting the gate reporting to error_pattern and using the report_gates command for the gate ID number displayed on the error message. This identifies the input that is not held off, and by tracing back from this input, you can identify how to correct the problem. The usual cause of this error condition is not defining all write control lines (including those that are RAM set and reset lines) or defining the wrong off-state.

The occurrence message is:

```
Write controls off failed to force off RAM T line of N (G). (A1-1)
```

T is the type of input (write, set, or reset), N is the instance name of the RAM gate, G is the gate ID number, and A1-1 is the rule and violation ID number.

The summary message is:

```
N RAM write/set/reset lines not forced off when write controls are off.  
(A1)
```

N is the number of occurrences of rules violation A1.

A2

Category: RAM

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Ignore

report_drc_rules: Supported

A defined scan clock must not propagate to a RAM gate, except for its read lines. The tool performs this check by determining the forward cone of influence for all clock pins (clock cone). The bounds for the cone of influence are scan cells and circuitry set to a fixed value when constrained pins are set to their constrained values and the initialized non-scan cells are set to their stable states. The rule violation occurs when a RAM gate is in a clock cone.

The default setting for this DRC is “Ignore.” You can enable this check with the set_drc_handling command. When the DRC is enabled and an error condition occurs, you can access the cone data by setting the gate reporting to error_pattern and using the report_gates command for the gate ID number displayed in the error message. This identifies the problem input, and by tracing back from this input, you can identify how to correct the problem. C indicates clock cone, W indicates write control line cone, B indicates both, and “-” indicates no cone.

The occurrence message is:

```
Scan clock is connected to RAM N (G). (A2-1)
```

N is the instance name of the RAM gate and G is the gate ID number.

The summary message is:

N RAMs are connected to a scan clock. (A2)

N is the number of occurrences of rules violation A2.

A3

Category: RAM

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

A write or read control line must not propagate to an address line of a RAM gate. The tool performs this check by determining the forward cone of influence for all write and read control lines (write/read cone). The bounds for the cone of influence are scan cells, RAM gates, and circuitry set to a fixed value when constrained pins are set to their constrained values and the initialized non-scan cells are set to their stable states. The rule violation occurs when an address line of a RAM gate is in the write/read cone.

The default handling for this rule violation is warning. When an error condition occurs, you can access the cone data by setting the gate reporting to error_pattern and using the report_gates command for the gate ID number displayed in the error message. This identifies the problem input, and by tracing back from this input, you can identify how to correct the problem. C indicates clock cone, W indicates write/read control line cone, B indicates both, and “-” indicates no cone.

The occurrence message is:

RAM control line connected to address input of RAM N (G) . (A3-1)

N is the instance name of the RAM gate and G is the gate ID number.

The summary message is:

N RAM address inputs are connected to a RAM control line. (A3)

N is the number of occurrences of rules violation A3.

A4

Category: RAM

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

A write or read control line must not propagate to a data line of a RAM gate. The tool performs this check by determining the forward cone of influence for all write and read control lines (write/read cone). The bounds for the cone of influence are scan cells, RAM gates, and circuitry set to a fixed value when constrained pins are set to their constrained value, and the initialized non-scan cells are set to their stable stated. The rule violation occurs when a data-in line of a RAM gate is in the write/read cone.

The default handling for this rule violation is warning. When an error condition occurs, you can access the cone data by setting the gate reporting to error_pattern and using the report_gates command for the gate ID number displayed in the error message. This identifies the problem input, and by tracing back from this input, you can identify how to correct the problem. C indicates clock cone, W indicates write/read control line cone, B indicates both, and “-” indicates no cone.

The occurrence message is:

```
RAM control line connected to data input of RAM N (G) . (A4-1)
```

N is the instance name of the RAM gate and G is the gate ID number.

The summary message is:

```
N RAM data inputs are connected to a RAM control line. (A4)
```

N is the number of occurrences of rules violation A4.

A5

Category: RAM

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

A RAM gate must not propagate to another RAM gate. The tool performs this check by determining the forward cone of influence for all RAM gates (RAM cone). The bounds for the cone of influence are scan cells, RAM gates, and circuitry set to a fixed value when constrained pins are set to their constrained values and the initialized non-scan cells are set to their stable states. The rule violation occurs when an input of a RAM gate is in the RAM cone.

The default handling for this rule violation is warning. The occurrence message is:

```
RAM N1 (G1) connected to RAM N2 (G2) . (A5-1)
```

N1 is the instance name of one RAM gate, G1 is its gate ID number, N2 is the instance name of the other RAM gate, and G2 is its gate ID number.

The summary message is:

N RAMs are connected to RAMs. (A5)

N is the number of occurrences of rules violation A5.

A6

Category: RAM

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

All the write inputs of all RAMs and all the read inputs of all data_hold RAMs must be at their off-state during all test procedures, except **test_setup**. The tool performs this check using the simulated values that result when it simulates the test procedures. The rule violation occurs if any write, set, or reset input of any RAM, or a read input of a data_hold RAM is not off.

The default handling for this rules violation is warning. Failure to satisfy this rule for write inputs results in the RAM being unavailable to hold its contents during scan operation, which may cause a loss in test coverage. When an error condition occurs, you can access the simulated values by setting the gate reporting to error_pattern and using the report_gates command for the gate ID number displayed in the error message. This identifies the input that is not held off, and by tracing back from this input, you can identify how to correct the problem. The usual cause of this error condition is not defining all write or read control lines, or defining the wrong off-state.

The occurrence message is:

L line of RAM N (G) not off during time T of P procedure. (A6-1)

L is the type of input (write, read, set, or reset), N is the instance name of the RAM gate, G is the gate ID number, T is the time, and P is the procedure name.

The summary message is:

There were N occurrences of uncontrolled RAMs during test procedures.
(A6)

N is the number of occurrences of rules violation A6.

A7

Category: RAM

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

When all read control lines are at their off-state, all read inputs of RAMs with the `read_off` attribute set to hold must be at their inactive state. The tool performs this check using the simulated values that result when all defined read control lines are at their off-state, the constrained pins are set to their constrained values, and the initialized non-scan cells are set to their stable states. The rule violation occurs if any read input of a `data_hold` RAM gate is not off.

The default handling for this rules violation is warning. When an error condition occurs, you can access the simulated values by setting the gate reporting to `error_pattern` and using the `report_gates` command for the gate ID number displayed in the error message. This identifies the input that is not held off, and by tracing back from this input, you can identify how to correct the problem. The usual cause of this error condition is not defining all read control lines or defining the wrong off-state.

The occurrence message is:

```
Read controls off failed to force off RAM read line of N (G). (A7-1)
```

N is the instance name of the RAM gate and G is the gate ID number.

The summary message is:

```
N RAM read lines not forced off when read controls are off. (A7)
```

N is the number of occurrences of rules violation A7.

A9

Category: RAM

Contexts Supported: `dft -scan`, `patterns -scan_diagnosis`

Default Handling: Warning

`report_drc_rules`: Supported

A read-only RAM model should define an initialization file. If an initialization file is not defined, the tool will treat instances of the RAM as TIEX, reducing test coverage.

The default handling for this rule violation is warning. To correct the problem, be sure the Tessent Cell library model of the RAM includes an `init_file` attribute that correctly specifies an initialization file.

The occurrence message is:

```
The initialization file is not defined for read-only RAM N (G). (A9-1)
```

N is the instance name of the RAM gate and G is the gate ID number.

The summary message is:

```
N read-only RAMs do not have initialization file. (A9)
```

N is the number of occurrences of rules violation A9.

A10

Category: RAM

Contexts Supported: dft -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

The content of a read-only RAM that does not have a write port must not be disturbed by any procedures except test_setup.

The default handling for this rule violation is warning. When an error condition occurs, you can access the simulated values by setting the gate reporting to error_pattern and using the report_gates command for the gate ID number displayed in the error message. This identifies the set or reset port that is not held off during simulation of a procedure, and by tracing back from this input, you can identify how to correct the problem. The usual cause of this error condition is not forcing the primary inputs, or not initializing the state elements, that control the RAM's set or reset port to an appropriate value.

When the A10 and/or A11 rule is violated, the tool will treat the RAM as TIEX, which may reduce fault coverage.

The occurrence message is:

```
The content of read-only RAM N (G) can be disturbed through L line during time T of P procedure. (A10-1)
```

N is the instance name of the RAM gate, G is the gate ID number, L is the type of input (set or reset), T is the time, and P is the procedure name.

The summary message is:

```
There were N occurrences of disturbed read-only RAMs during test procedures. (A10)
```

N is the number of occurrences of rules violation A10.

A11

Category: RAM

Contexts Supported: dft -scan, patterns -scan_diagnosis

Default Handling: Warning
report_drc_rules: Supported

The content of a read-only RAM that does not have a write port must not be disturbed through the set or reset lines during capture.

The default handling for this rule violation is warning. When an error condition occurs, you can access the simulated values by setting the gate reporting to error_pattern and using the report_gates command for the gate ID number displayed in the error message. This identifies the set or reset port that is not held off during capture, and by tracing back from this input, you can identify how to correct the problem. The usual cause of this error condition is not constraining the primary inputs or the state elements that control the RAM's set or reset port.

When the A10 and/or A11 rule is violated, the tool will treat the RAM as TIEX, which may reduce fault coverage.

The occurrence message is:

The content of read-only RAM N (G) can be disturbed through L line in capture window. (A11-1)

N is the instance name of the RAM gate, G is the gate ID number, and L is the type of input (set or reset).

The summary message is:

There were N occurrences of disturbed read-only RAMs in capture window. (A11)

N is the number of occurrences of rules violation A11.

A12

Category: RAM

Contexts Supported: dft -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

The content of a read-only RAM that has a write port must not be disturbed by any procedure except test_setup (in order for the initialization file to be usable for test generation).

The default handling for this rule violation is warning. When an error condition occurs, you can access the simulated values by setting the gate reporting to error_pattern and using the report_gates command for the gate ID number displayed in the error message. This identifies the set or reset port that is not held off during a procedure, and by tracing back from this input, you can identify how to correct the problem. The usual cause of this error condition is not defining the write, set or reset operation properly.

When rule A12 and/or A13 is violated, the tool will ignore the RAM's contents initialized through the initialization file.

The occurrence message is:

The initialization file of RAM N (G) cannot be used during test pattern generation since RAM content can be disturbed through L line during time T of P procedure. (A12-1)

N is the instance name of the RAM gate, G is the gate ID number, L is the type of input (write, set or reset), T is the time, and P is the procedure name.

The summary message is:

There were N occurrences of disturbed RAM initialization file during test procedures. (A12)

N is the number of occurrences of rules violation A12.

A13

Category: RAM

Contexts Supported: dft -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

The content of a read-only RAM that has a write port must not be disturbed through the write, set or reset lines during capture (in order for the initialization file to be usable for test generation).

The default handling for this rule violation is warning. When an error condition occurs, you can access the simulated values by setting the gate reporting to error_pattern and using the report_gates command for the gate ID number displayed in the error message. This identifies the set or reset port that is not held off during capture, and by tracing back from this input, you can identify how to correct the problem. The usual cause of this error condition is not defining the write, set or reset operation properly.

When rule A12 and/or A13 is violated, the tool will ignore the RAM's contents initialized through the initialization file.

The occurrence message is:

The initialization file of RAM N (G) cannot be used during test pattern generation since RAM content can be disturbed through L line in capture window. (A13-1)

N is the instance name of the RAM gate, G is the gate ID number, and L is the type of input (write, set or reset).

The summary message is:

```
There were N occurrences of disturbed RAM initialization file in capture  
window. (A13)
```

N is the number of occurrences of rules violation A13.

A14

Category: RAM

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

RAM should be observable. The tool performs this check by forcing all pin constraints and tied cells and check if there is any sensitizable path from the outputs of a RAM to any observation point. The rule violation occurs if there is none.

The default handling for this rule violation is a warning. When an error condition occurs, you can access the simulated values by setting the gate reporting to error_pattern and use the report_gates command for the gate ID number displayed on the error message.

```
// Warning: RAM N (G) is unobservable. (A14-1)
```

N is the instance name of the RAM gate and G is its gate ID number.

This identifies the RAM gate that cannot be observed. The usual cause of this error condition is constraints blocking the output of the RAM.

A15

Category: RAM

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

RAM should be able to read. The tool performs this check by forcing all pin constraints and cell constraints and check the simulation values at the read enable and read clock lines of each read control port of a RAM. The rule violation occurs if the simulation values indicate that all read control ports are off.

The default handling for this rule violation is a warning. When an error condition occurs, you can access the simulated values by setting the gate reporting to error_pattern and use the report_gates command for the gate ID number displayed on the error message.

```
// Warning: RAM N (G) cannot read because its read control ports are  
// constrained off. (A15-1).
```

N is the instance name of the RAM gate and G is its gate ID number.

This identifies the RAM gate that cannot be observed. The usual cause of this error condition is constraints that prevent the read enable or read clock lines of a RAM to be turned ON.

A16

Category: RAM

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

RAM should be able to write. The tool performs this check by forcing all pin constraints and cell constraints and check the simulation values at the write enable and write clock lines of each write control port of a RAM. The rule violation occurs if the simulation values indicate that all write control ports are off. This rule checking will not be performed for read-only ROMs.

The default handling for this rule violation is a warning. When an error condition occurs, you can access the simulated values by setting the gate reporting to error_pattern and use the report_gates command for the gate ID number displayed on the error message.

```
// Warning: RAM N (G) cannot write because its write control ports are
// constrained off. (A16-1).
```

N is the instance name of the RAM gate and G is its gate ID number.

A17

Category: RAM

Contexts Supported: dft -edt, dft -logic_bist, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

This rule checks if a RAM cannot capture fault effects because its read port cannot be set to an active state.

The information provided by A17 helps you debug low fault coverage caused by read port issues. To check for A17, the tool forces and propagates constant values such as pin constraints, tied non-scan elements, and constant cell constraints. It also calculates forbidden values. The tool then processes each clock port. If the constrained value of the RAM's read_enable or read_clock is X, and if either of two signals cannot be justified to 1, the tool reports an A17 violation.

To minimize the number of violations reported, the tool traces from rule violation read ports to a common source point, which can be a primary input or internal pin. The violating sources are

reported in order by number of affected elements with the first violation having the most, and so on. This is an example of the reported message when the read enable or read clock is X:

report_drc_rule A17

```
// Warning: Internal gate N1 (G1) has a value of X and cannot be justified
// to 1.
// This prevents read by C memory elements, one of which is N2 (G2).
// (A17-1)
```

N1 is the name of the gate with X value, G1 is the gate ID of that gate. C is the number of memory elements, N2 is the name of the gate whose read is prevented, G2 is the gate ID of that gate.

When a single primary input (PI) drives both the read_enable and the read_clock which are inverted from each other, this is the warning message:

```
// Warning: Primary input P (S) cannot be justified to both 0 and 1
// simultaneously to control read enable and clock ports that are
// inverted from each other.
// This prevents read by C memory elements, one of which is N (G).
// (A17-1)
```

P is the primary input name, S is the net ID number, C is the count of memory elements, N is the gate name, and G is the gate ID number.

When the read clock and read enable pins cannot be justified to the on state simultaneously, this is the warning message:

```
// Warning: Internal gate N1 (G1) and N2 (G2) that control read enable
// and clock respectively cannot be justified to 1 and 1 simultaneously.
// This prevents read by C memory elements, one of which is N3 (G3).
// (A17-1)
```

N1 is the name of the read_enable gate, G1 is the gate ID of that gate. N2 is the name of the read_clock gate, G2 is the gate ID number of that gate, C is the number of memory elements, N3 is the name of the gate whose read is prevented, G3 is the gate ID of that gate.

The default handling of A17 is Warning. It is performed during system mode transition from Setup to Analysis. The summary message is:

```
A17: #fails=1 handling=warning (memory elements cannot read because clock
ports cannot be fully controlled).
```

To debug A17 violations, use the “[set_gate_report -constrain_value on](#)” command to look at the constrained values on the read ports of affected RAMs.

A18

Category: RAM

Contexts Supported: dft -edt, dft -logic_bist, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

This rule checks if a RAM cannot capture fault effects because its write port cannot be set to an active state.

The information provided by A18 helps you debug low fault coverage caused by write port issues. To check for A18, the tool forces and propagates constant values such as pin constraints, tied non-scan elements, and constant cell constraints. It also calculates forbidden values. The tool then processes each clock port. If the constrained value of the RAM's write_enable or the write_clock is X, and if either of the two signals cannot be justified to 1, the tool reports an A18 violation.

To minimize the number of violations reported, the tool traces from rule violation write ports to a common source point, which can be a primary input or internal pin. The violating sources are reported in order by number of affected elements with the first violation having the most, and so on. This is an example of the reported message:

report_drc_rule A18

```
// Warning: Internal gate N1 (G1) has a value of X and cannot be justified
to 1.
//           This prevents write by C memory elements, one of which is N2
(G2). (A18-1)
```

N1 is the name of the gate with X value, G1 is the gate ID of that gate. C is the number of memory elements, N2 is the name of the gate whose write is prevented, G2 is the gate ID of that gate.

When a single primary input (PI) drives both the write_enable and the write_clock which are inverted from each other, this is the warning message:

```
// Warning: Primary input P (S) cannot be justified to both 0 and 1
simultaneously to control write enable and clock ports that are inverted
from each other.
//           This prevents write by C memory elements, one of which is N
(G). (A18-1)
```

P is the primary input name, S is the net ID number, C is the count of memory elements, N is the name of the gate whose write is prevented, and G is the gate ID number of that gate.

When the write clock and write enable pins cannot be justified to the on state simultaneously, this is the warning message:

```
// Warning: Internal gate N1 (G1) and N2 (G2) that control write enable
and clock respectively cannot be justified to 1 and 1 simultaneously.
//           This prevents write by C memory elements, one of which is N3
(G3). (A18-1)
```

N1 is the name of the write_enable gate, G1 is the gate ID of that gate. N2 is the name of the write_clock gate, G2 is the gate ID number of that gate, C is the number of memory elements, N3 is the name of the gate whose write is prevented, G3 is the gate ID of that gate.

The default handling of A18 is Warning. It is performed during system mode transition from Setup to Analysis. The summary message is:

```
// Warning: There were 264 A18 violations (memory elements cannot write because clock ports cannot be fully controlled).
```

To debug A18 violations, use the “[set_gate_report](#)-constrain_value on” command to look at the constrained values on the write ports of affected RAMs.

Assertion Rules (ASSERT Rules)

DRC checks that the assertion values on the pins of models from read_cell_library occur during DRC simulation over the specified period.

Enforcement of Assertions	2680
ASSERT1	2680
ASSERT2	2682
ASSERT3	2683

Enforcement of Assertions

DRC checks that instances of read_cell_library models with an assert_shift, assert_capture or assert_pattern have the value specified at the time the assertion is enforced.

Currently, there are a total of five phases to a typical ATPG simulation, as follows:

1. test_setup before 1st load_unload.
2. load_unload before shift.
3. shift procedures (and the changes between them).
4. Going from shift to capture at end load_unload when pin constraints are forced.
5. Capture.

assert_shift is enforced in phase 3 only (no assertion checks in 1,2,4,5).

assert_capture is enforced in phase 5 only (no assertion checks in 1,2,3,4).

assert_pattern is enforced in phases 2,3,4,5 (no assertion checks in 1).

ASSERT1

Category: DRC Simulation Value Checks

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

Values defined on Tessent cell library model pins via assert_shift should be as defined.

Values which should occur on all instances of a model throughout shift should be specified by an assert_shift on the input of the model. These values can be specified in Tessent cell library

syntax or as Verilog assertions using Verilog syntax. Libcomp can be used to translate the Verilog assertions into Tessent syntax. For example:

```
module mux_scan (Q, CK, D, SI, SE);
    output Q;
    reg Q;
    input CK;
    input D;
    input SI;
    (* assert_shift = 1*) input SE;
    assign Din = SE ? SI : D;
    always @ (posedge CK) begin
        Q <= Din;
    endmodule
```

Using Libcomp, both the Verilog hardware and assertions are translated to Tessent syntax.

```
model mux_scan
    (Q, CK, D, SI, SE)
(
    model_source = verilog_module;
    input (CK) ( )
    input (D) ( )
    input (SI) ( )
    input (SE) ( assert_shift = 1)
    output (Q) ()
)
(
    primitive = _mux  mlc_mux_1 ( D, SI, SE, Din );
    primitive = _dff  mlc_dff_1 ( , , CK, Din, Q, );
)
)
```

Netlist instances with assert_shift are checked against stable shift simulation values for compliance. Violations default to error which halts the tool and returns to the prompt. set_drc_handling can be used to change the default to Warning, Note or Ignore.

Example:

```
// command: set_drc_handling assert1 warn verbose
```

An example violation after the above setting follows:

```
// Warning: assert_shift=Stable but sim val = "X" (not known and
// constant) from driver '/clk_01' (11)
// Assertion on instance/pin 'ff10/CLK'
// Assertion came from pin 'CLK' of model 'sff'
//           line 500 file 'data/adk.atpg' (ASSERT1-1)
```

report_drc_rules supports assert_shift (ASSERT1) as follows:

```
// command: report drc rules assert1
// Warning: assert_shift=Stable but sim val = "X" (not known and
// constant) from driver '/clk_01' (11)
//      Assertion on instance/pin 'ff10/CLK'
//      Assertion came from pin 'CLK' of model 'sff'
//          line 500 file 'data/adk.atpg' (ASSERT1-1)
```

report_gate also supports ASSERT1 (assert_shift) after issuing:

```
set_gate_report drc_pattern stable_shift
```

You can have an assert_shift and an assert_capture both on the same input, as shown below:(*)

```
assert_shift = 1, assert_capture = 0 *) input SE; // Verilog syntax
input (SE) (assert_shift = 1; assert_capture = 0) // Tesson syntax
```

ASSERT2

Category: DRC Simulation Value Checks

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

Values defined on Tesson cell library model pins via assert_capture should be as defined.

Values which should occur on all instances of a model throughout capture should be specified by an assert_capture on the input of the model. These values can be specified in Tesson cell library syntax or as Verilog assertions using Verilog syntax. Libcomp can be used to translate the Verilog assertions into Tesson syntax. For example:

```
module mux_scan (Q, CK, D, SI, SE);
    output Q;
    reg Q;
    input CK;
    input D;
    input SI;
    (*assert_capture = 0*) input SE;
    assign Din = SE ? SI : D;
    always @ (posedge CK) begin
        Q <= Din;
    endmodule
```

Using Libcomp, both the Verilog hardware and assertions are translated to Tesson syntax.

```

model mux_scan
  (Q, CK, D, SI, SE)
(
  model_source = verilog_module;
  input (CK) ( )
  input (D) ( )
  input (SI) ( )
  input (SE) ( assert_capture = 0 )
  output (Q) ( )
(
  primitive = _mux  mlc_mux_1 ( D, SI, SE, Din );
  primitive = _dff  mlc_dff_1 ( , , CK, Din, Q, );
)
)

```

Netlist instances with assert_capture are checked against stable capture simulation values for compliance. Violations default to error which halts the tool and returns to the prompt. set_drc_handling can be used to change the default to Warning, Note or Ignore.

Example:

```
// command: set_drc_handling assert2 note verbose
```

An example violation after the above setting follows:

```

// Note: assert_capture=0 but sim val = "X" (not known and constant) from
driver '/d1' (1)
// Assertion on instance/pin 'ff10/D'
// Assertion came from pin 'D' of model 'sff'
// line 500 file 'data/adk.atpg' (ASSERT2-1)

```

report_drc_rules supports assert_capture (ASSERT2) as follows:

```

// command: report drc rules assert2
// Note: assert_capture=0 but sim val = "X" (not known and constant) from
driver '/d1' (1)
// Assertion on instance/pin 'ff10/D'
// Assertion came from pin 'D' of model 'sff'
// line 500 file 'data/adk.atpg' (ASSERT2-1)

```

report_gate also supports ASSERT2 (assert_capture) after issuing:
set_gate_report drc_pattern stable_capture

You can have an assert_shift and an assert_capture both on the same input, as shown below:(*
assert_shift = 1, assert_capture = 0 *) input SE; // Verilog syntax
input (SE) (assert_shift = 1; assert_capture = 0) // Tesson syntax

ASSERT3

Category: DRC Simulation Value Checks

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

Values defined on Tessent cell library model pins via assert_pattern should be as defined.

Values which should occur on all instances of a model throughout the entire pattern should be specified by an assert_pattern on the input of the model. These values can be specified in Tessent cell library syntax or as Verilog assertions using Verilog syntax. Libcomp can be used to translate the Verilog assertions into Tessent syntax. For example

```
primitive prim_not(out, in);
(* Assert_capture = "1'b0", ASSERT_pattern = "stable" *)
  input in;
(* assert_capture = "Stable", assert_pattern = "Z", assert_shift = 1'bz *)
  output out;
  table
    // in : out
    0 : 1 ;
    1 : 0 ;
    X : X ;
  endtable
endprimitive
```

Using Libcomp, both the Verilog hardware and assertions are translated to Tessent syntax.

```
model prim_not
  (out, in)
(
  model_source = verilog_udp;

  input (in)  (  Assert_capture = 1'b0;    ASSERT_pattern = stable;  )
  output (out) (  assert_capture = Stable;   assert_pattern = Z;   assert_shift = 1'bz;
)  (
  primitive = _inv mlc_gate0 (in, out);
)
)
```

Netlist instances with assert_pattern are checked against stable pattern simulation values for compliance. Violations default to error which halts the tool and returns to the prompt. set_drc_handling can be used to change the default to Warning, Note or Ignore.

Example:

```
// command: set_drc_handling assert3 warn verbose
```

Two example violations after the above setting follow. Note that the second example says to see stable_shift, because the pattern violation occurred within shift. This is more helpful for finding the root cause of the violation to fix it. If the violation is only in capture, it will indicate that. The first violation shown below does not occur within shift or within capture, so it says to see stable_after_setup which shows values across the entire pattern.

```
// Warning: assert_pattern=1 but sim val = "X" (not known and constant)
(see stable_after_setup) from driver '/don_in' (10)
// Assertion on instance/pin 'not1/A'
// Assertion came from pin 'A' of model 'inv01'
// line 266 file 'data/adk.atpg' (ASSERT3-1)
// Warning: assert_pattern=1 but sim val = "0" (see stable_shift) from
driver '/not1/Y' (64)
// Assertion on instance/pin 'not2/A'
// Assertion came from pin 'A' of model 'inv01'
// line 266 file 'data/adk.atpg' (ASSERT3-2)
```

report_drc_rules supports assert_pattern (ASSERT3) as follows:

```
// command: report drc rules assert3
// Warning: assert_pattern=1 but sim val = "X" (not known and constant)
(see stable_after_setup) from driver '/don_in' (10)
// Assertion on instance/pin 'not1/A'
// Assertion came from pin 'A' of model 'inv01'
// line 266 file 'data/adk.atpg' (ASSERT3-1)
```

report_gate also supports ASSERT3 (assert_pattern) after issuing:

set_gate_report drc_pattern stable_after_setup

However, as stated above, it may be more helpful to use stable_shift or stable_capture, and the violation message will indicate when this is true.

BIST Rules (B Rules)

Whenever LFSRs are defined, the tool performs BIST rules checking to ensure proper application of BIST patterns to the circuit. You cannot change the handling of the BIST rules from their default conditions of either error or warning—with the exception of rule B2.

B2	2686
B4	2686

B2

Category: BIST

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported

Every scan chain input pin must connect to an LFSR. Correct this error condition by connecting the scan chain input pin of the indicated chain to an LFSR.

You can change how the rules checker handles this check with the set_drc_handling command.

The error message is:

```
Input of chain C has no LFSR connection. (B2-1)
```

C is the name of the scan chain.

B4

Category: BIST

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported

Every scan chain output pin must connect to an LFSR. Correct this error condition by connecting the scan chain output pin of the indicated chain to an LFSR.

The error message is:

```
Output of chain C has no MISR connection. (B4)
```

C is the name of the scan chain.

Clock Rules (C Rules)

The application checks the scan clocks to ensure their proper definition and operation. You may select the handling of any clock rule to be error, warning, note, or ignore.

The following subsections describe the clock rules and the special handling you can set for them.

Tip

 In DFTVisualizer, you can press Ctrl + R to execute a report_gates command on selected gates.

Clock Terminology	2687
The ATPG Analysis Option	2692
C1	2692
C2	2697
C3	2698
C4	2705
C5	2711
C6	2713
C7	2716
C8	2717
C9	2718
C10	2720
C16	2721
C17	2722
C19	2723
C21	2724
C22	2725
C23	2728
C24	2729
C25	2730

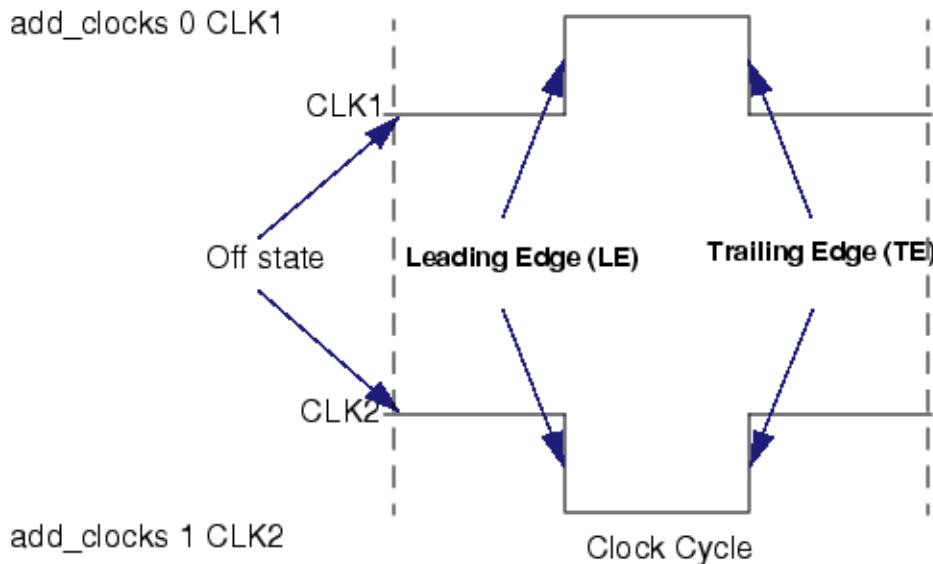

Clock Terminology

The clock rule information contains a couple of recurring concepts. To make optimal use of the information, you should understand these concepts.

Clock Signals

The tool considers any signal to be a clock if it can change the state of a sequential element, including system clocks, sets, and resets. When you define each clock primary input (a required setup step you perform using the `add_clock` command or “`analyze_control_signals -Auto_fix`”), a key piece of information specified with either of these commands is the pin value that represents the clock’s off state. Two important terms arise out of this definition, as shown in the following figure.

Figure 7-4. Clock Cycle Terminology

The transition of the clock from the off state to the on state is considered the leading edge of the clock, while the transition from the on state to the off state is considered the trailing edge of the clock.

Clock Cones and Effect Cones

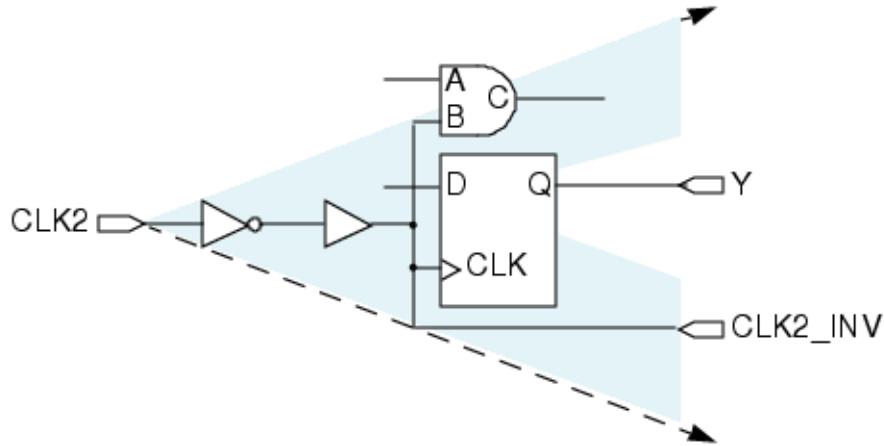

A gate pin or output pin is considered to be in the *clock cone* of a clock signal when they are connected through combinational logic gates and transparent latches (TLAs) to the clock primary input.

Note

 The tools treat a latch as a transparent latch (TLA) rather than as a normal level-sensitive sequential element (LA) if it will be continuously enabled at the start of the capture cycle when all clocks are at their defined off values. This treatment therefore depends on tool setups and how the latch is wired into the design. A TLA passes values without holding state and thus acts like a buffer. For more information, refer to “[Simulation Primitives of the Flattened Model](#)” in the *Tessent Scan and ATPG User’s Manual*.

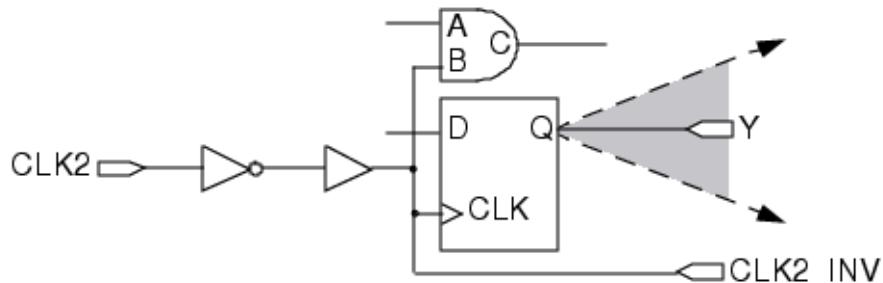

The clock cone is basically the fanout of the clock signal through strictly combinational logic and TLAs. Pins B, C, CLK and CLK2_INV in the circuit excerpt shown in the following figure are all in CLK2's clock cone.

Figure 7-5. Example Clock Cone

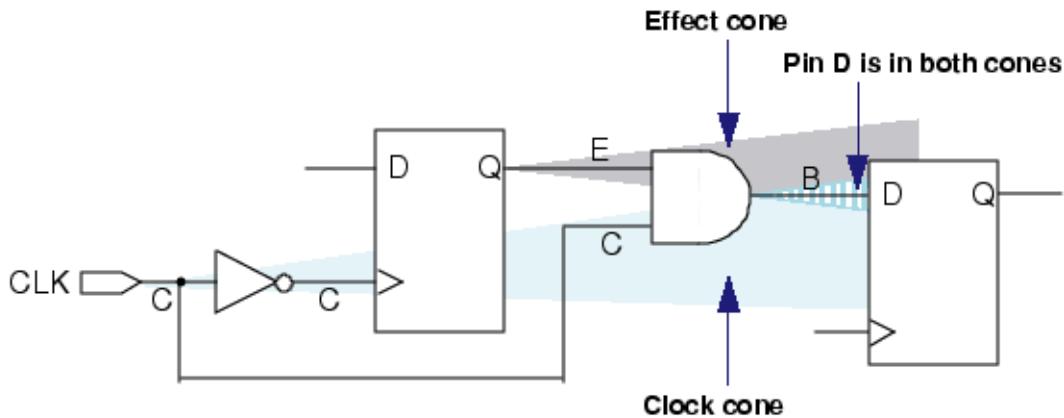

The tools consider a gate pin or output pin to be in a clock's *effect cone* if there is a sequential element between the clock net and the gate pin or output pin. In the following figure, pin Y is in the effect cone of CLK2.

Figure 7-6. Example Effect Cone

A pin can be in both the *clock cone* and the *effect cone* as shown for pin D on one of the flip-flops in the following figure.

Figure 7-7. Pin in Both Cones

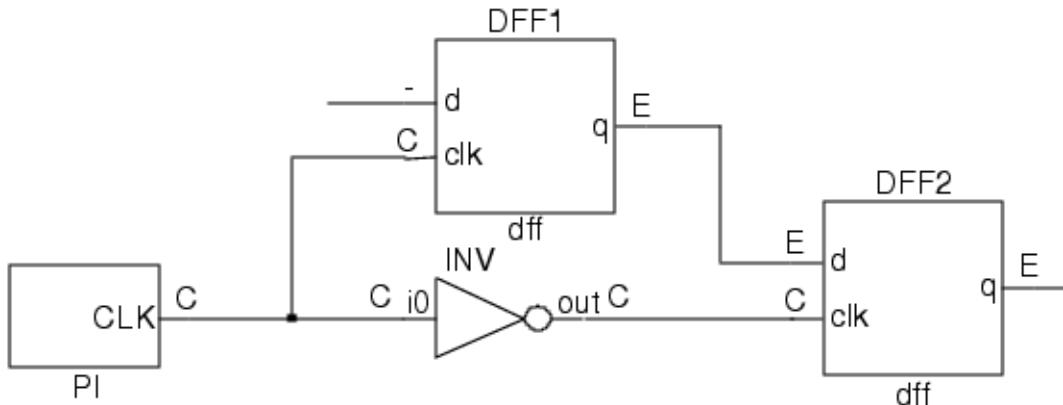

You can get the Flat Schematic window of DFTVisualizer to show a C, E or B near device pins that are in the clock (C), effect (E), or both (B) cones of a particular clock by issuing the `set_gate_report` command with the `Clock_cone` option after the tool has flattened the design. For example:

```
create_flat_model  
set_gate_report clock_cone CLK
```

Alternatively, you can choose **Data > Clock Cone** from the DFTVisualizer menu (with the Flat Schematic window active) and in the dialog box specify the clock. The following figure shows an example of how this might look for a circuit fragment in the Flat Schematic window of DFTVisualizer.

Figure 7-8. DFTVisualizer Flat Schematic Window View Showing Clock Cones

When the `Clock_cone` option is in effect, the output of the `report_gates` command also displays clock cone data:

report_gates /DFF1

```
// /DFF1 dff
//   clkI  (C) 2-/CLK
//   d   I  (-) 1-/C
//   q   O  (E) 5-
```

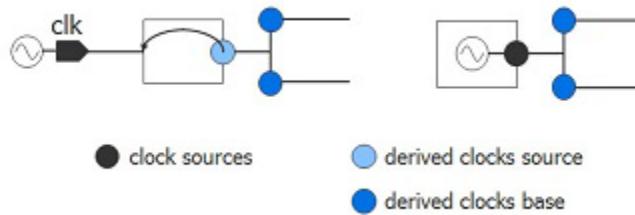

Note

 The tool shows clock and effect cone data for just one clock at a time—the clock whose primary input *pin_name* you specified in the last “set_gate_report Clock_cone” command.

Clock Source and Derived Clocks

For clock rule checks, Scan Cell Data Rules (D rules) through DFT_C5 (Memory BIST clock tracing), three different types of clocks can be defined at primary ports or instance pins: synchronous and asynchronous clock sources, derived clock sources, and derived clock branches. The differences between these clock types are shown in the following figure:

Figure 7-9. Clock Source And Derived Clocks

The different clock types are described as follows:

- **clock source (synchronous or asynchronous)** — is defined at a primary or instance pin where a clock pulse is available in the design. It can be a well-defined pin where an external clock generator is connected, or it can be a well-defined instance pin where an internal clock generator produces a clock signal.
- **derived clock source** — is a defined instance pin where a reference pin has to be specified because a tracing path to the corresponding “clock source” is blocked. One typical case is a PLL instance represented as a blackbox in the design. Using the add_clocks -reference option, you can link the derived clock source instance pin to a clock source.
- **derived clock branch** — a derived clock branch describes the case in which the clock tree of a design, sometimes different branches of the tree, can be unbalanced even if they are derived from the same clock source. That is, clock branches are not guaranteed to be synchronous between these clock branches. You define such a clock branch using the add_clocks -branch option. A derived clock branch must always be driven by a “clock source” or a “derived clock source”. Clock branches can also be used for later network manipulations.

The ATPG Analysis Option

Clock rules C1, C3, C4, and C5 can run full ATPG analysis during their checks.

For more information on ATPG analysis, refer to “[How to Turn on ATPG Analysis](#).”

The Memory BIST Analysis Option

Clock rule checks DFT_C1 through DFT_C5 run only in the dft context, and only if there are memory instances in the design and the `set_dft_specification_requirements-memory_test` option is set to “on”.

These clock rule checks are skipped entirely for all other cases. For more information, see the [set_dft_specification_requirements](#) command.

C1

Category: Clock

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

A scan or non-scan cell must not capture data when all specified clocks are set to their off states.

When all clocks are at their off state as defined with the `add_clocks` command, all clock inputs (including sets and resets) of scan and non-scan cells must be at their off state. For non-scan cell violations, the tool converts these to TIEX.

In the case of a DFF scan cell, the clock input must be a stable binary value (0 or 1).

Note

 If the clock input value of a DFF scan cell simulates as X, the tool by default performs additional analysis to determine if the X represents a stable binary value. An X that represents a stable binary value satisfies the C1 rule’s clock input requirement for a DFF. (To turn off the additional analysis, use the `set_drc_handling` command’s `Noatpg_analysis` argument.)

The tool performs this check using the simulated values that result when all defined clocks are at their defined off states, constrained pins are set to their constrained values, initialized non-scan cells (initialized during `test_setup` or `load_unload`) are set to their stable states, and C0, C0DX, C1, and C1DX cell constraint values are applied. The rule violation occurs if any clock input, including set and reset lines, of any scan cell memory element is not at its off state.

When the C1 violation occurs on a set/reset port or a level-sensitive latch port, the tool does not issue an error message and does not stop the DRC process. Instead, the tool issues the following summary messages to indicate such situation exist:

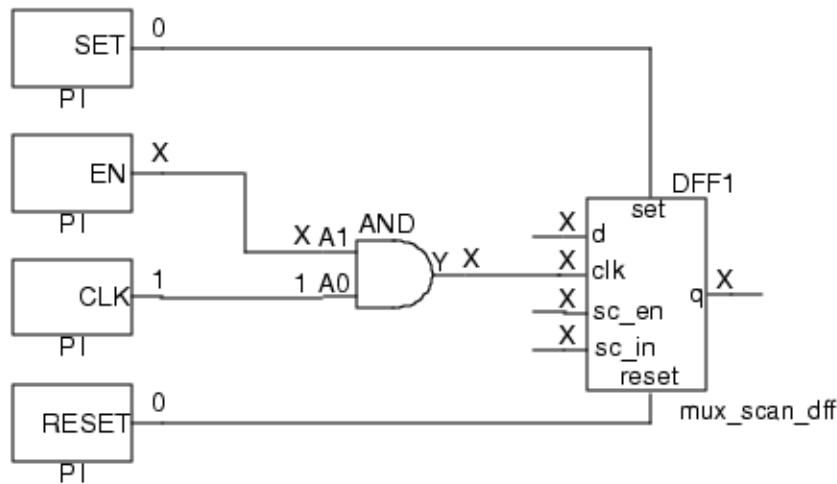

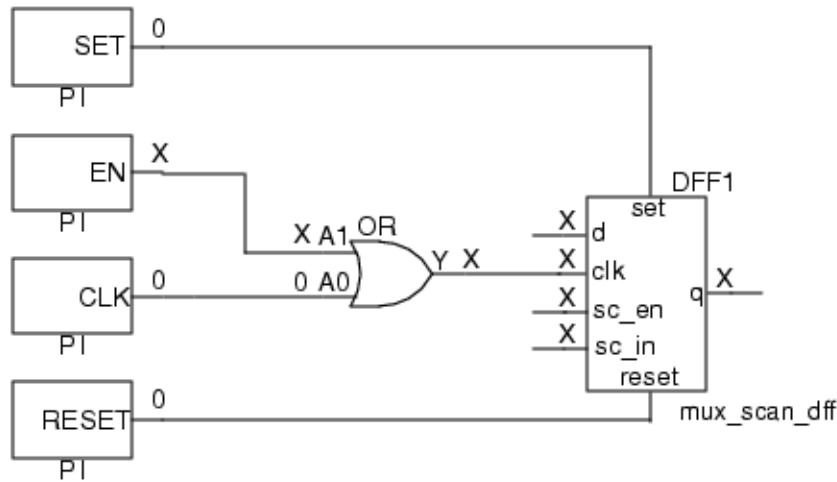

```
// Note: n scan cells whose clock ports are not off when all clocks are
// off will be handled through additional ATPG effort.

// The scan cells have been excluded from the list of C1 DRC violations.
// Use "report_drc_rules C1 -excluded" to report these C1 violations
```

If the number of such scan cells is large, ATPG runtime is increased. One common root cause of these C1 violations is a set/reset pin not defined as a clock. You can define a set/reset pin as a clock to fix the problem and avoid ATPG performance impact.

[Figure 7-10](#) shows an example of a circuit segment that produces a C1 violation due to an indeterminate value (X) at the clk input of DFF1 when the off state of the clocks at the PIs is defined as a logic 0 and all defined clocks are off.

Figure 7-10. C1 Violation Example

The clock input value to the scan cell is X because the EN signal value is X. If EN is left at X, the signal arriving at the clk input of the scan cell cannot be held off.

Effect on Testability

Failure to satisfy this rule can result in unstable scan and non-scan cell values going into or coming out of load_unload, or between cycles. This can result in lower test coverage.

How to Debug C1 Violations

The occurrence message is:

```
// Clock PIs off failed to force off a clock line of T N (G) . (C1-1) .
```

T is the type of scan cell (MASTER, SLAVE, etc.), N is the instance name of the gate, and G is the gate ID number.

The summary message is:

```
// There were N clock rule C1 fails (unstable scan cells when clocks off).
```

N is the number of occurrences of rules violation C1.

For debugging, be sure C1 handling is set to error (the invocation default setting) before you enter a “set_system_mode analysis” command to leave setup mode. Use the following command to check the setting:

```
report_drc_rules -fails_summary
```

If the handling is other than error, you can change it back to error with:

```
set_drc_handling c1 error
```

When C1 handling is set to error, the first C1 violation that occurs will stop the DRC process and return the tool to Setup mode.

Tip

The C1 violation on which the tool stops is the C1 you must debug. Fixing the C1 violations the tool singles out in this manner will often fix other C1's with no extra effort on your part, so is very efficient.

The tool will transcript details about the violation and save the simulation data related to the violation, so you can report it.

You can then debug the violation using DFTVisualizer or by issuing commands from the tool's command line. Examples of both methods follow.

How to Debug with DFTVisualizer

To view the location of a C1 DRC error using DFTVisualizer, use the following command:

```
open_visualizer
```

Choose the **DRC Violations** tab in the Design Browser window, then open the listed DRC's by selecting the “+” symbols as needed to find the violation ID of the desired DRC violation. Double clicking the listed violation, or right clicking and selecting **Analyze DRC Violation** from the popup menu will analyze the violation. The scan cell affected by that occurrence is displayed in the Flat Schematic window.

Tip

i Alternatively, you can issue the analyze_drcViolation command with the C1-1 argument at the tool command line. For example:

analyze_drcViolation c1-1

Once the offending scan cell is displayed, trace backward from the cell's clock input to the primary input that drives the clock. Ensure the clock's off state, which you defined using the add_clocks command, is correct. To change the defined off state, delete the old definition with the delete_clocks command, then reissue add_clocks. To see a clock's current defined off state, use the report_clocks command.

How to Debug from the Tool Command Line

To view the location of a C1 DRC error from the tool command line, use the following example command steps:

1. set_drc_handling C1 Error
2. set_gate_report Error_pattern
3. set_system_mode analysis
4. report_drc_rules C1-
5. report_gates *offending_gate's_id#*
6. report_gates -Endpoints -Backward *id#_of_gate_connected_to_offending_gate's_clock*

The following transcript excerpt shows an example of the use of this command sequence starting at step 4:

```
report_drc_rules c1-1
// Error: Clock PIs off failed to force off a clock line of /U$1/DFF1
// (14). (C1-1)
report_gates 14
// /U$1/DFF1 (14) DFF
// "S" I (0) 10-
// "R" I (0) 11-
// clk I (X) 12-/OR/Y
// d I (X) 13-/MUX/out
// "OUT" O (X) 8- 9-
report_gates -endpoints -backward 12
// -----
// Begin backward trace for gate /OR (12).
// -----
// /CLK (3) PI
// CLK O (0) 12-/OR/A0
// /EN (4) PI
// EN O (X) 12-/OR/A1
// Number gates in trace = 2.
```

Possible Resolutions

If your debugging effort shows an offending clock's off state is incorrect, use the add_clocks command to redefine the clock with the correct off state. If the off state is correct, the problem typically is due to an indeterminate value (X) in related logic that causes the clock's value at a scan cell to be X. This is the case in the example shown in the figure above. You can fix these by using the add_input_constraints command to constrain a primary input pin to a value that removes the X:

add_input_constraints -c0 EN

This allows the tool to consider the CLK signal to be the only clock signal to the clk input of the scan cell.

For further explanation and examples of possible C1 rule violations, refer to the “[Clock Gaters](#)” appendix in the *Tessent Scan and ATPG User’s Manual*.

C2

Category: Clock

Contexts Supported: dft -scan, dft -test_points, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

Each clock must have a structural path to the clock port of at least one memory element. The application performs this check by a backward tracing from the clock port, SET/RESET port, and read/write enables of all memory elements toward primary inputs. The rule violation occurs if a clock primary input cannot be reached.

When an error condition occurs, you can access the simulated values by setting the gate reporting to error_pattern and using the report_gates command. Defining a pin to be a clock, when it does not behave as a clock, is the most usual cause of this error condition. The default handling for this rule violation in all contexts is warning. Failure to satisfy this rule indicates a defined clock cannot capture data, thus reducing test coverage.

When a floating pin is defined as a clock, it is suppressed from C2 violation when the design also defines some internal clocks. This exception prevents false C2 violations for a design with PLL clocking where the external reference clock is disconnected from the netlist in the flat model.

The occurrence message is:

Clock P cannot reach the clock port of any memory element. (C2-1)

P is the pin name of the clock.

The summary message is:

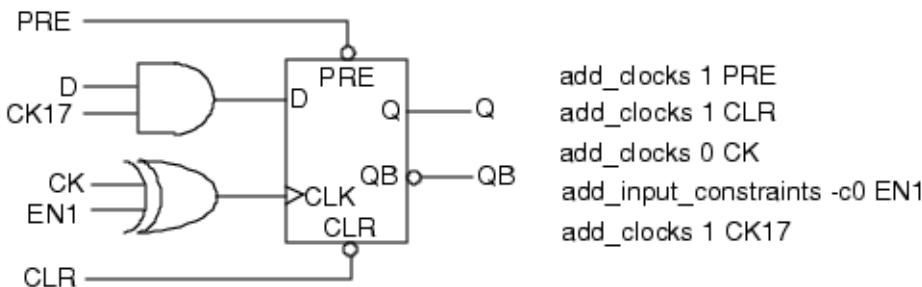

There were N clock rule C2 fails (reachability check).

N is the number of occurrences of rules violation C2.

C2 Rule Violation Example

[Figure 7-11](#) shows an example circuit and circuit setup specified in the tool.

Figure 7-11. C2 Rule Example Circuit

If you run rules checking on this design, you will get a C2 rules violation because while the CK17 signal appears to be a clock (due to its name), it cannot be reached from the clock port or SET/RESET ports of the flip-flop. To fix this problem, add the command:

delete_clocks CK17

Then, you must re-run checks.

C3

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Note

report_drc_rules: Supported

When a sequential element (or RAM) source and sink are clocked by the same clock and the sink captures data from the source, a potential exists for the captured data to pass through both the source and sink in the same clock cycle. That is, the sink might capture the source's new data (captured in the same cycle) instead of the source's old data (captured in the previous cycle).

[Table 7-2](#) lists four clocking relationships that can produce this problem.

Table 7-2. Clocking that Can Result in a C3 Signal Race

Source	Sink
LS	LS

Table 7-2. Clocking that Can Result in a C3 Signal Race (cont.)

Source	Sink
LS	TE
LE	LS
LE	TE

This condition violates the tool's default assumption that the sink captures only old data from the source, so results in a C3 violation and may require special handling. Failure to address this issue can result in simulation mismatches when you verify the test patterns in a timing-based simulator. Each sequential element is either level sensitive (LS), leading edge triggered (LE), or trailing edge triggered (TE).

Note

 Adequate special handling for most C3 situations is to simply issue “set_split_capture_cycle On” as explained under “[Possible Resolutions](#).”

[Figure 7-12](#) shows an example DFTVisualizer Flat Schematic window display of a circuit segment that produces a C3 violation when the off state of the clock at the PI is defined as a logic 0. (In Tessent FastScan and Tessent TestKompress, you define the off state of each clock with the add_clocks command or with analyze_control_signals -Auto_fix as a part of required tool setups). DFF1 updates on the leading edge (LE) of the clock, while DFF2 updates on the clock's trailing edge (TE) due to the inverter. Under certain timing conditions (if captured data propagates through DFF1 to its q output in less than half a clock cycle for example), data will pass through both DFF1 and DFF2 in a single clock cycle.

Note

 The same situation would occur if the clock pin was connected directly (rather than through an inverter) to DFF2, and DFF2 was negative-edge triggered.

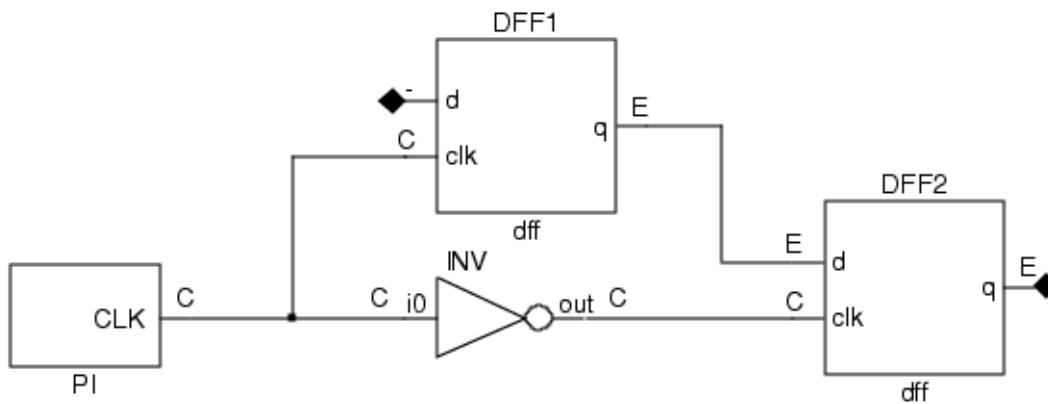

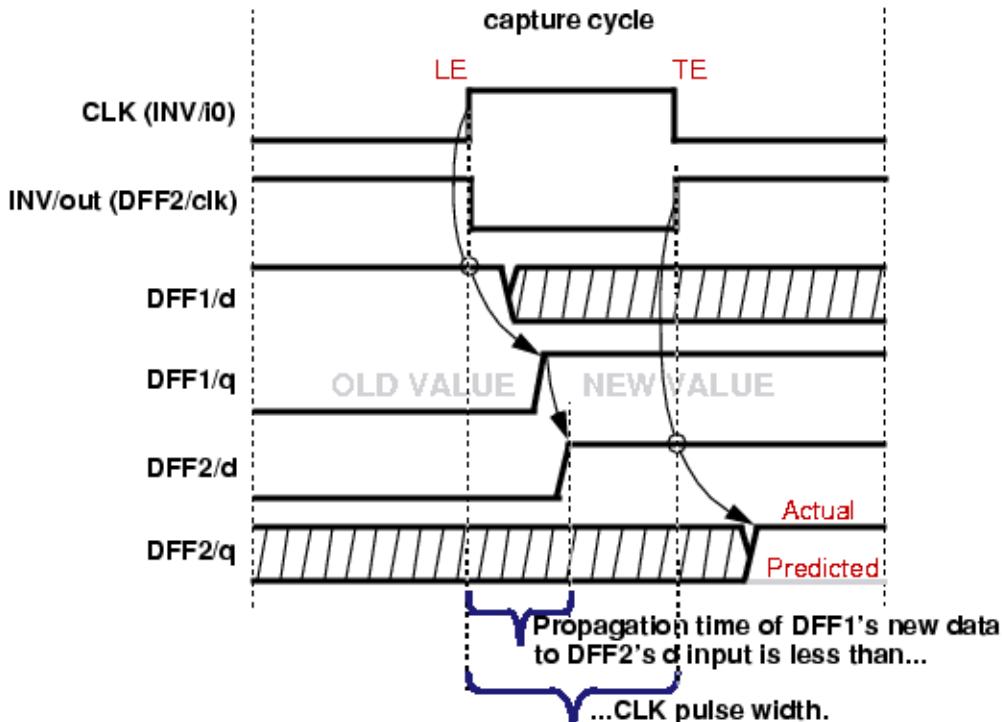

Figure 7-12. C3 Violation Example

Figure 7-13 shows a possible timing scenario for the preceding circuit segment.

Figure 7-13. Example Timing That Allows Sink to Capture Source's New Data

The tool performs this check by determining the forward cones of influence for a clock pin (its clock cones). For an introduction to clock and effect cones, refer to the clock cones and effect cones discussion under “[Clock Signals](#).” The bounds for the clock cones are scan cells and circuitry set to a fixed value when the constrained pins are set to their constrained values and the initialized non-scan cells are set to their stable states. The clock cone stops at read ports of RAMs that have the `read_off` attribute set to hold, and then the effect cone propagates from its outputs.

Note

 In the C3 violation example, the data input for DFF2 is in the effect cone of CLK and its clock input is in the clock cone of CLK as indicated by the E and the C in the Flat Schematic window display of DFTVisualizer.

The rule violation may occur for a clock if one of the following is true:

- The clock input of a DFF state element is in the clock cone, its input data is in the effect cone, the element is trailing edge triggered, and the effect data comes from an element that is leading edge triggered.
- The clock input of a LA state element is in the clock cone and its input data is in the effect cone.

- The write input of a RAM is in the clock cone and a data input or address input of the associated write port is in the effect cone.
- The read input of a RAM is in the clock cone and an address input of the associated read port is in the effect cone.

The tool performs a mutual exclusivity check to determine if the clock/write/read inputs associated with the failure can be active at the same time. To obtain the most benefit from this check, turn on ATPG analysis prior to DRC by issuing the `set_drc_handling` command with the `Atpg_analysis` argument. By default, the rules checker performs a partial ATPG analysis to find potential C3 rule violations. This partial analysis justifies clock/data conflicts in the affected circuitry, but stops at decision nodes, RAM, ROM, TIEX, TLA, and all other non-scan state element gates. With complete ATPG analysis explicitly turned on, the rules checker justifies the conflicting values back to PIs or scan cells.

Note

 In some situations, violations of this rule may occur when there is no real problem with the design. For information on performing enhanced checking to screen out these false violations, refer to “[Screening Out False C3 Violations](#).”

Effect on Testability

Failure to satisfy this rule can result in inaccurate test pattern simulation results (simulation mismatches) during verification in a timing-based simulator and failing patterns on the tester.

How to Debug C3 Violations

For C3 violations, the tool transscripts a message similar to the following:

```
// Note: There were N clock rule C3 fails (clock may capture data
// affected by its captured data).
```

N is the number of times a C3 violation occurred.

Use the `report_drc_rules` command to obtain additional information about the violations. For example, to report the occurrence messages for all the C3s, issue “`report_drc_rules C3`.” The occurrence messages list gate names and gate IDs you can copy and paste into commands during later debugging. You can report on a specific occurrence by issuing the command with “C3-” and the occurrence number. For example:

```
report_drc_rules c3-1
// Note: Clock /CLK failed rule C3 on input 3 of /DFF2 (9). (C3-1)
//       Source of violation: input 3 of /DFF1 (8).
```

You can debug a specific occurrence of a C3 violation using DFTVisualizer or by issuing commands from the tool’s command line. Examples of both methods follow.

How to Debug with DFTVisualizer

To view the location of a C3 DRC violation using DFTVisualizer, use the following command steps:

1. set_system_mode analysis
2. Choose **Tools > Analyze DRC** from the DFTVisualizer menu and select the desired C3 DRC violation in the dialog box. The gates between the source cell and the failing cell, including the clock cone data for the failing clock, are displayed in the Flat Schematic window.

Tip

 Alternatively, you can issue the `analyze_drcViolation` command with the `rule_id-occurrence#` argument at the tool's command line. For example:
`analyze_drcViolation c3-1`

Note

 In some situations, the tool's analysis may require significant CPU run time. You can interrupt the process and return to the command prompt using the Control-C key (intermediate results are not retained if you interrupt the analysis), or you can display periodic progress using the `-Interval` switch with the `set_drc_handling` command.

How to Debug from the Tesson Tool Command Line

To view the location of the first occurrence of a C3 DRC violation from the tool command line, use the following example command steps:

1. set_system_mode analysis
2. report_drc_rules C3-*occurrence#*
3. set_gate_report Clock_cone *pin_name*
4. report_gates *source_gate_id* *sink_gate_id*

The following transcript excerpt shows an example of the use of this command sequence starting at step 2:

```
report_drc_rules c3-1
// Note: Clock /CLK failed rule C3 on input 3 of /DFF2 (9). (C3-1)
// Source of violation: input 3 of /DFF1 (8)
set_gate_report clock_cone /CLK
report_gates /DFF1 /DFF2
// /DFF1 dff
// "IO" I (-) 4-
// "I1" I (-) 3-
// clkI (C) 2-/CLK
// d I (-) 1-/C
// "OUT" O (E) 5-
// /DFF2 (9) dff
// "IO" I (-) 4-
// "I1" I (-) 3-
// clkI (C) 7-/INV/out
// dI (E) 5-/DFF1/q
// "OUT" O (E) 6-
```

Possible Resolutions

Note

 There are special cases where C3 rule violations do not cause problems and can be ignored. Although these cases are rare, be sure you understand how your circuit behaves versus what the tool simulates before deciding to ignore C3s.

There are two methods you can use to assure that valid C3 rule violations do not result in simulation mismatches:

- Split Capture Cycle

The first and preferred method is to enable the `set_split_capture_cycle` command (the tool enables it automatically if you use `create_patterns`). This forces a second evaluation of the cells affected by C3 DRC violations. The additional evaluation allows the new data to propagate and in turn be captured into the sink gate. If additional evaluation is required, a side effect of this command is an increase in simulation run time. If the increase in run time is excessive, you may want to use the other method, capture handling.

Note

 When you use “`set_split_capture_cycle on`,” you will still get C3 rule violations but you can ignore them.

- Capture Handling

The second method of addressing C3 DRC violations is to use the `set_capture_handling` command. A side effect of this command is reduced test coverage if the number of C3s is significantly high. The item to consider is that only one simulation value is used for a

given source. As a result, the sink gates can only capture either new or old data. Given the case where a source drives two sinks and one sink captures old data and the other sink captures new data, one of the sinks must capture X. The advantage of the `set_capture_handling` command is there is no impact on ATPG run time.

Mentor Graphics recommends you use “`set_split_capture_cycle on`.” In cases where the impact on run time is severe and the number of C3 violations is small, then the use of capture handling is recommended. Do not use both methods simultaneously, however.

Screening Out False C3 Violations

For performance reasons, the tool’s default DRC may occasionally report a false C3 violation. There are three additional analyses you can do to screen out these false C3s:

- Use the `set_drc_handling` command with the `Atpg_analysis` option. This option causes DRC to additionally check the clocks of the source and sink to see if they are gated off.
- For LSSD based designs, use the `-Mode A` option to the `set_drc_handling` command.

When you specify this option for a selected clock, the rules checker evaluates all latches associated with the specified clock and categorizes their clock ports. It then uses these categories to determine if a violation exists. The following list describes each of the clock port categories:

- **Inactive low (IL)**
When the selected clock is low, the clock port of the latch is inactive.
- **Inactive high (IH)**
When the selected clock is high, the clock port of the latch is inactive.
- **Active high slave (AHS)**
When the selected clock is high, the clock port of the latch is active. The data line of this latch connects (through buffers and inverters) to another latch called the data latch. When the clock port of the latch is active, all clock inputs of the data latch must be inactive. When the clock port of the latch is inactive, at least one clock input of the data latch must be active. Finally, non-clock primary inputs must not affect the clock inputs of the data latch.
- **Active low slave (ALS)**
When the selected clock is low, the clock port of the latch is active. The data line of this latch connects (through buffers and inverters) to another latch called the data latch. When the clock port of the latch is active, all clock inputs of the data latch must be inactive. When the clock port of the latch is inactive, at least one clock input of the data latch must be active. Finally, non-clock primary inputs must not affect the clock inputs of the data latch.

During this evaluation, the rules checker prints a summary message that identifies the number of latches with clock ports placed in each category. If you enable learn reporting with “`set_learn_report On`,” you can then use `report_gates` to report on the individual latches in these categories.

You can screen out false violations of the C3 rule by issuing the `set_drc_handling` command before rules checking. The command usage in this context is:

```
set_drc_handling C3 [-Mode A clock_name]
```

The tool ignores violations of the C3 rule if the following conditions are true:

- The failing latch port is IL or AHS, and the source latch port is IH or ALS.
- The failing latch port is IH or ALS, and the source latch port is IL or AHS.
- All clock, set, and reset inputs of the failing latch are low in the case that all defined clocks are off, the violation source clock is high, and all other clock, set, and reset inputs of the source latch are low.

C4

Category: Clock

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

When a sequential element (or RAM) source and sink are clocked by the same clock and the output of the source is connected through combinational logic to the clock port of the sink, a potential exists for the source's captured data to alter the clocking of the sink in the same clock cycle. That is, the source's new value (captured in the current cycle) might propagate through the connected logic and affect the clocking of the sink. By default, the tool expects the source's old value (captured in the previous cycle) in the downstream combinational logic.

Table 7-3 lists four clocking relationships that can produce this problem.

Table 7-3. Clocking that Can Result in a C4 Signal Race

Source	Sink
LS	LS
LS	TE
LE	LS
LE	TE

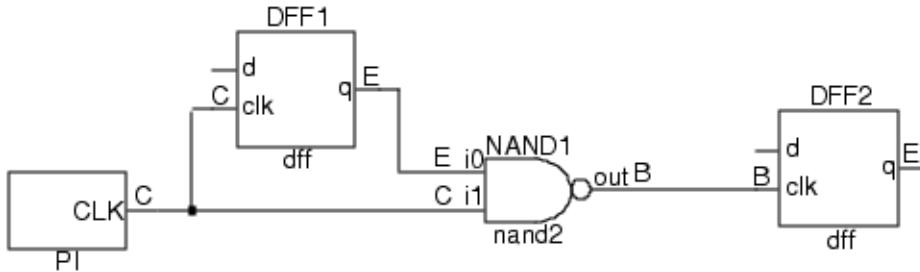

This condition violates the tool's default assumption that the sink's clocking is affected by only old data from the source, so results in a C4 violation and may require special handling. Failure to address this issue can result in simulation mismatches when you verify the test patterns in a timing-based simulator. Each sequential element is either level sensitive (LS), leading edge triggered (LE), or trailing edge triggered (TE).

Note

 Adequate special handling for most C4 situations is to simply issue “set_split_capture_cycle on” as explained under “[Possible Resolutions](#).”

[Figure 7-14](#) shows an example DFTVisualizer Flat Schematic window display of a circuit segment that produces a C4 violation when the off state of the clock at the PI is defined as a logic 0. (In Tessent FastScan and Tessent TestKompress, you define the off state of each clock with the add_clocks command or with analyze_control_signals -Auto_fix as a part of required tool setups).

Figure 7-14. C4 Violation Example

[Figure 7-15](#) shows a possible timing scenario for the preceding circuit segment, where DFF1 updates on the leading edge (LE) of the clock, while DFF2 updates on the clock’s trailing edge (TE) due to the gating of the CLK signal with the output of DFF1. Notice that the old value of DFF1/q disables the clock input to DFF2. The tool’s default simulation will therefore predict there will be no clock pulse to DFF2 and that it will hold its state as a result. But the leading edge of CLK almost immediately enables the clock gate and DFF2’s clock port does receive a pulse. So rather than holding state as the tool expects, DFF2 captures it’s D input value on the TE of the now enabled clock gate.

Figure 7-15. Example Where Actual Behavior Differs from Tool's Prediction

The tool performs this check by determining the forward cones of influence for a clock pin (its clock cones) and the forward cones of influence for each scan cell influenced by the clock pin (effect cones). For an introduction to clock and effect cones, refer to the clock cones and effect cones discussion under “[Clock Signals](#).” The bounds for the cones are scan cells and circuitry set to a fixed value when the constrained pins are set to their constrained values and the initialized non-scan cells are set to their stable states.

Note

In the C4 violation example, the clock input of DFF2 is in both the clock and effect cones of CLK as indicated by the B in the Flat Schematic window display. This is the main difference from a C3 violation in which the clock input of the sink is in the clock cone but *not* in the effect cone and the data input is in the effect cone.

The rule violation occurs for a clock if one of the following is true:

- The clock input of a DFF state element is in both the clock and effect cones, the element is trailing edge triggered, and the effect data comes from an element that is leading edge triggered.
- The clock input of a LA state element is in both the clock and effect cones.
- The write input of a RAM is in both the clock and effect cones.
- The read input of a RAM is in both the clock and effect cones.

The tool performs a mutual exclusivity check to determine if the clock/write/read inputs associated with the failure can be active at the same time. To obtain the most benefit from this check, turn on ATPG analysis prior to DRC by issuing the `set_drc_handling` command with the

Atpg_analysis argument. By default, the rules checker performs a partial ATPG analysis to find potential C4 rule violations. This partial analysis justifies clock/data conflicts in the affected circuitry, but stops at decision nodes, RAM, ROM, TIEX, TLA, and all other non-scan state element gates. With complete ATPG analysis explicitly turned on, the rules checker justifies the conflicting values back to PIs or scan cells.

Note

 In some situations, violations of this rule may occur when there is no real problem with the design. For information on performing enhanced checking to screen out these false violations, refer to “[Screening Out False C4 Violations](#).”

How to Debug C4 Violations

For C4 violations, the tool transmits a message similar to the following:

```
// Warning: There were N clock rule C4 fails (clock may be affected by its captured data).
```

N is the number of times a C4 violation occurred.

Use the report_drc_rules command to obtain additional information about the violations. For example, to report the occurrence messages for all the C4s, use:

```
report_drc_rules c4
```

The occurrence messages list gate names and gate IDs you can copy and paste into commands during later debugging. You can report on a specific occurrence by issuing the command with “c4-” and the occurrence number. For example:

```
report_drc_rules c4-1
```

```
//Warning: Clock /CLK failed rule C4 on input 3 of /DFF2 (9). (C4-1)
//          Source of violation: input 3 of /DFF1 (8).
```

You can debug a specific occurrence of a C4 violation using DFTVisualizer or by issuing commands from the tool’s command line. Examples of both methods follow.

How to Debug with DFTVisualizer

To view the location of a C4 DRC violation using DFTVisualizer, use the following command steps:

1. set_system_mode analysis
2. open_visualizer

Choose the **DRC Violations** tab in the Design Browser window, then open the listed DRC’s by selecting the “+” symbols as needed to find the violation ID of the desired DRC violation. Double clicking the listed violation, or right clicking and selecting **Analyze DRC Violation**

from the popup menu will analyze the violation. The gates between the source cell and the failing cell, including the clock cone data for the failing clock, are displayed in the Flat Schematic window.

Tip

 Alternatively, you can issue the `analyze_drcViolation` command with the `rule_id-occurrence#` argument at the tool's command line. For example:
`analyze_drcViolation c4-1`

Note

 In some situations, the tool's analysis may require significant CPU run time. You can interrupt the process and return to the command prompt using the Control-C key (intermediate results are not retained if you interrupt the analysis), or you can display periodic progress using the `-Interval` switch with the `set_drc_handling` command.

How to Debug from the Tool Command Line

To view the location of the first occurrence of a C4 DRC violation from the tool command line, use the following example command steps:

1. `set_system_mode analysis`
2. `report_drc_rules C4-occurrence#`
3. `set_gate_report Clock_cone pin_name`
4. `report_gates source_gate_id sink_gate_id`

The following transcript excerpt shows an example of the use of this command sequence starting at step 2:

```
report_drc_rules c4-1
// Warning: Clock /CLK failed rule C4 on input 3 of /DFF2 (10). (C4-1)
// Source of violation: input 3 of /DFF1 (9)
set_gate_report clock_cone /CLK
report_gates /DFF1 /DFF2
// /DFF1 dff
//     clk    I  (C) /CLK
//     d      I  (-) 1-
//     q      O  (E)  5-/DFF2/d /NAND1/i0
// /DFF2 dff
//     clk    I  (B)  7-/NAND1/out
//     d      I  (-)  5-/DFF1/q
//     q      O  (-)  6-/q2
```

You can see that the DRC violation is occurring because the clock input of /DFF2 is in both the clock and effect cones of /CLK.

Possible Resolutions

Note

-  There are special cases where C4 rule violations do not cause problems and can be ignored. These cases are rare, however, so be sure you understand how your circuit behaves versus what the tool simulates before deciding to ignore C4s.
-

There are two methods you can use to assure C4 rule violations do not result in simulation mismatches:

- Split Capture Cycle

The first and preferred method is to enable the `set_split_capture_cycle` command (the tool enables it automatically if you use `create_patterns`). This forces a second evaluation of the cells affected by C4 DRC violations. The additional evaluation allows the new data to propagate and in turn be captured into the sink gate. If additional evaluation is required, a side effect of this command is an increase in simulation run time. If the increase in run time is excessive, you may want to use the other method, capture handling.

Note

-  When you use “`set_split_capture_cycle on`,” you will still get C4 rule violations but you can ignore them.
-

- Capture Handling

The second method of addressing C4 DRC violations is to use the `set_capture_handling` command. A side effect of this command is reduced test coverage if the number of C4s is significantly high. The item to consider is that only one simulation value is used for a given source. As a result, the sink gates can only capture either new or old data. Given the case where a source drives two sinks and one sink captures old data and the other sink captures new data, one of the sinks must capture X. The advantage of `set_capture_handling` is there is no impact on ATPG run time.

Mentor Graphics recommends you use “`set_split_capture_cycle on`.” In cases where the impact on run time is severe and the number of C4 violations is small, then the use of capture handling is recommended. Do not use both methods simultaneously, however.

Screening Out False C4 Violations

For performance reasons, the tool’s default DRC may occasionally report a false C4 violation. There are three additional analyses you can do to screen out these false C4s:

- Use the `set_drc_handling` command with the `Atpg_analysis` option. This option causes DRC to additionally check the clocks of the source and sink to see if they are gated off.
- For LSSD based designs, use the `-Mode A` option to the `set_drc_handling` command.

When you specify this option for a selected clock, the rules checker evaluates all latches associated with the specified clock and categorizes their clock ports. It then uses these categories to determine if a violation exists. The following list describes each of the clock port categories:

- **Inactive low (IL)** — When the selected clock is low, the clock port of the latch is inactive.
- **Inactive high (IH)** — When the selected clock is high, the clock port of the latch is inactive.
- **Active high slave (AHS)** — When the selected clock is high, the clock port of the latch is active. The data line of this latch connects (through buffers and inverters) to another latch called the data latch. When the clock port of the latch is active, all clock inputs of the data latch must be inactive. When the clock port of the latch is inactive, at least one clock input of the data latch must be active. Finally, non-clock primary inputs must not affect the clock inputs of the data latch.
- **Active low slave (ALS)** — When the selected clock is low, the clock port of the latch is active. The data line of this latch connects (through buffers and inverters) to another latch called the data latch. When the clock port of the latch is active, all clock inputs of the data latch must be inactive. When the clock port of the latch is inactive, at least one clock input of the data latch must be active. Finally, non-clock primary inputs must not affect the clock inputs of the data latch.

During this evaluation, the rules checker prints a summary message that identifies the number of latches with clock ports placed in each category. If you enable learn reporting with “set_learn_report on,” you can then use report_gates to report on the individual latches in these categories.

You can screen out false violations of the C4 rule by issuing the set_drc_handling command before rules checking. The command usage in this context is:

set_drc_handling C4 [-Mode A *clock_name*]

The tool ignores violations of the C4 rule if the following conditions are true:

- The source latch port is IL or AHS and all paths from the source latch to the failing latch are blocked when the selected clock is high.
- The failing latch port is IH or ALS and all paths from the source latch to the failing latch are blocked when the selected clock is low.
- The violation source clock input is high and all other clock, set, and reset inputs are low for the source latch.

C5

Category: Clock

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

A clock pin must not be capable of simultaneously capturing data on multiple ports of the same scannable memory element. The application performs this check by determining the forward cone of influence for a clock pin (clock cone). The bounds for the cone of influence are scan cells and circuitry set to a fixed value when constrained pins are set to their constrained value, and initialized non-scan cells are set to their stable state.

The rule violation occurs on a clock pin when multiple clock inputs of a scannable memory element are in the same clock cone and the clock inputs may be on at the same time. The tool performs a mutual exclusivity check to determine if both clock inputs associated with the failure can be active at the same time. If the justification results in a conflict without justifying decision nodes, it will not be considered a rules violation.

The default handling for this rule violation is warning. Failure to satisfy this rule may result in a race condition that creates inaccurate simulation results. When an error condition occurs, you can access the cone data by setting the gate reporting to error_pattern and using the report_gates command for the gate ID number displayed in the error message. This identifies the problem input, and by tracing back from this input, you can identify how to correct the problem. C indicates clock cone, E indicates effect cone, B indicates both, and “-” indicates no cone.

The occurrence message is:

```
Clock P failed rule C5 on input I of N (G) . (C5-1)
```

P is the pin name of the clock, C5 is the rule ID number, I is the gate input number of the clock line, N is the instance name of the gate, and G is the gate ID number.

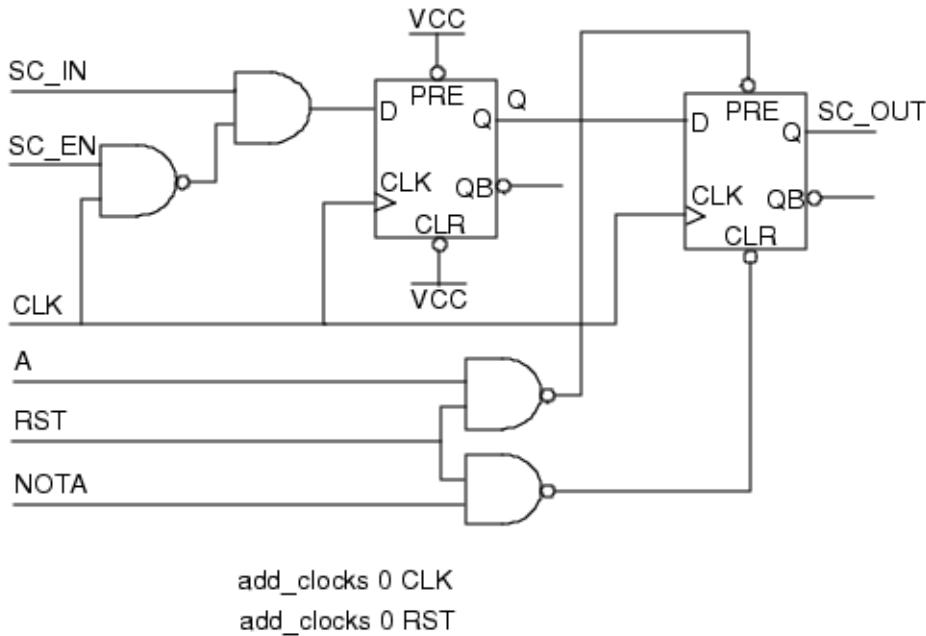

The summary message is:

```
There were N clock rule C5 fails (clock is connected to multiple ports of same latch) .
```

N is the number of occurrences of rules violation C5.

C5 Rule Violation Example

[Figure 7-16](#) shows an example circuit and circuit setup specified in the tool.

Figure 7-16. C5 Rule Example Circuit

If you run rules checking on this design given the setup commands shown, you will get a C5 rules violation. In this design, the RST signal connects to both the PRE and CLR pins of the second flip-flop. If you examine the inputs, you should see that A and NOTA should always have opposite values. If the tool knows this information, it knows that only one of the CLR or PRE signals can be active at any given time. To specify this information and fix the C5 rules violation, add the command:

add_input_constraints a -inv nota

C6

Category: Clock

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

A clock must not affect data that it is capturing. If it does, a race condition may result that produces inaccurate simulation results.

The application performs this check by determining the forward cone of influence for a clock pin (clock cone). The bounds for the clock cone are scan cells and circuitry set to a fixed value when constrained pins are set to their constrained values and initialized non-scan cells are set to their stable states. The rule violation occurs on a clock pin when a clock input of a scannable memory element and its data line are in the same clock cone.

The default handling for this rule violation is warning. When a violation occurs, you can access the clock cone data by the command “set_gate_report drc C6-N,” where N is the c6 fail occurrence number, then issuing the report_gates command for the gate ID number displayed in the occurrence message. This identifies the problem input. By tracing back from this input, you can identify how to correct the problem. C indicates clock cone, E indicates effect cone, B indicates both, and “-” indicates no cone.

By default, C6 analysis treats clocks in the same synchronous clock group as if they are equivalent. You can use the “set_drc_handling C6 -ignore_synchronous_clock_groups on” command to turn off this behavior.

For more information on synchronous clock groups, see [add_synchronous_clock_group](#).

Note

 Default C6 checking may miss some C6 violations when “set_clock_restriction off” is used. A more conservative analysis that identifies those C6 violations can be enabled by “set_drc_handling c6 -CONSERvative on.” However, we generally recommend not to turn off clock restriction so that the -conservative switch does not need to be used.

The occurrence message is:

```
Clock P failed rule C6 on input I of N (G) . (C6-1)
```

P is the pin name of the clock, C6 is the rule ID number, I is the gate input number of the clock line, N is the instance name of the gate, and G is the gate ID number.

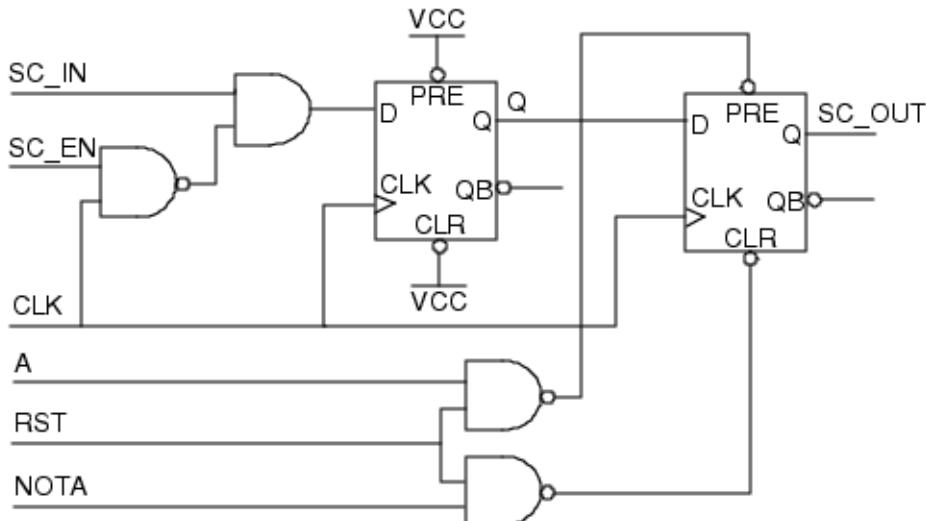

The summary message is:

```
There were N clock rule C6 fails (clock may capture data affected by itself) .
```

N is the number of times a C6 rule violation occurred.

C6 Rule Violation Example

[Figure 7-17](#) shows an example circuit and circuit setup specified in the tool.

Figure 7-17. C6 Rule Example Circuit

```
add_clocks 0 CLK
add_clocks 0 RST
```

If you ran rules checking on this design, given the setup commands shown, you would get a C6 rules violation. The default handling for this rule violation is warning. In this design, the CLK signal goes to both the CLK and D inputs of the first flip-flop. Thus, data can be captured in this flip-flop that may be affected by the capturing clock. To prevent the CLK signal from influencing the data, add the command:

add_input_constraints -c0 SC_EN

Constraining the SC_EN signal to 0 ensures that changes in the clock will not change the data.

For ATPG, you can handle C6 rule violations by issuing a “set_clock_off_simulation on” command prior to creating patterns. See the set_clock_off_simulation command description for additional information.

In some designs, different flip-flops may capture the off state and on state of the clock causing the simulation to fail. In this case, you can use one of the following two commands to mask the signal creating the C6 violation. Note the add_cell_constraints command is more restrictive than the set_simulation option command.

add_cell_constraints -Drc C6

set_simulation_options -C6_mask_races ON

For more information, see the add_cell_constraints and set_simulation_options commands.

C7

Category: Clock

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

Each clock input (not including set and reset lines) of a scan or non-scan cell memory element must be capable of capturing data when a single clock primary input line is on and all other clocks are off. It is acceptable that this may require placing values on non-clock primary inputs or scan cells. The application performs this check using the simulated values that result when one clock is set to X, all other defined clocks are at their off-state, the constrained pins are set to their constrained values, and the initialized non-scan cells are set to their stable states. The rule violation occurs when a clock input of a scan cell always remains off.

The default handling for this rule violation is warning. Failure to satisfy this rule indicates a scan cell clock input cannot capture data, resulting in some loss of test coverage.

The occurrence message is:

```
Clock input I of N (G) cannot capture data with a single clock on. (C7-1)
```

I is the input number, N is the instance name, G is its gate index number, and C7 is the rule ID number.

The summary message is:

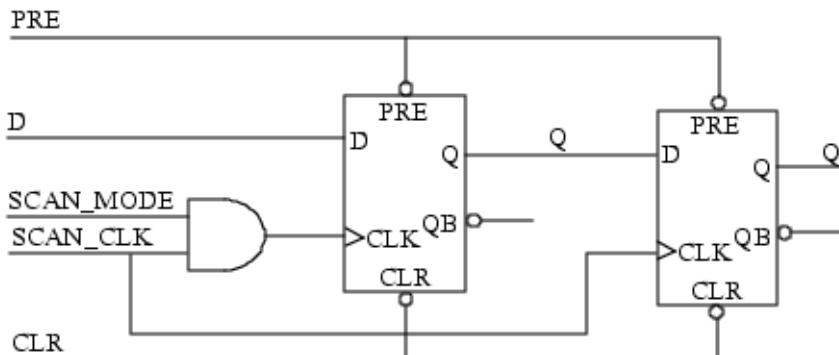

```
There were N clock rule C7 fails (scan cell capture ability check).
```

N is the number of occurrences of rules violation C7.

C7 Rule Violation Example

[Figure 7-18](#) shows an example circuit and circuit setup specified in the tool.

Figure 7-18. C7 Rule Example Circuit

```
add_clocks 1 PRE CLR  
add_clocks 0 SCAN_CLK  
add input constraints -c0 SCAN MODE
```

If you run rules checking on this design given the setup commands shown, you will get a C7 rules violation. This type of error commonly occurs when incorrect clock or set/reset gating occurs in the design. This design constrains the SCAN_MODE signal to a constant 0 during ATPG. This constraint prevents the first flip-flop from ever being clocked, and from ever capturing data. To fix this problem, delete the pin constraint:

delete_input_constraints -all

C8

Category: Clock

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report drc rules: Supported

You may not directly connect a clock to a primary output (PO). The application performs this check by determining the forward cone of influence for a clock pin (clock cone). The bounds for the cone of influence are scan cells and circuitry set to a fixed value when constrained pins are set to their constrained values, and initialized non-scan cells are set to their stable states. The rule violation occurs when a primary output is in the clock cone.

The default handling for this rule violation is warning. Failure to satisfy this rule will result in the occasional usage of a different type of scan pattern, in which the tool observes only the POs directly connected to clocks. There will be no loss of test coverage or risk of inaccurate simulation results. When an error condition occurs, you can access the cone data by setting the gate reporting to `error_pattern` and using the `report_gates` command for the gate ID number displayed in the error message. This identifies the problem input, and by tracing back from this input, you can identify how to correct the problem. C indicates clock cone, E indicates effect cone, B indicates both, and “-” indicates no cone.

The occurrence message is:

Primary output P is connected to clock C. (C8-1)

P is the pin name of the primary output and C is the pin name of the clock.

The summary message is:

There were N clock rule C8 fails (PO connected to a clock line).

N is the number of occurrences of rules violation C8.

C8 Rule Violation Example

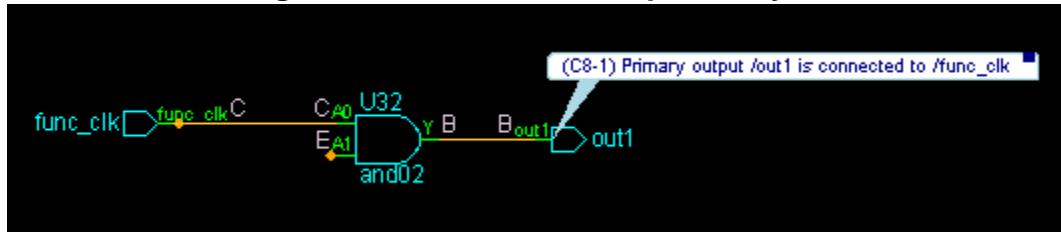

The tool setup for the clocks is:

```
add_clocks 0 func_clk
```

If you run rules checking on this design given the setup command shown, you will get a C8 rule violation. This type of violation is not usually a problem.

Figure 7-19 shows the results of the C8 DRC analysis in DFTVisualizer.

Figure 7-19. C8 Rule Example Analysis

In this example, C8 is caused by the connection of the primary output, out1, through U32 to a clk, func_clk. An acceptable solution is to accept this warning, or turn it off with the command:

```
set_drc_handling c8 ignore
```

C9

Category: Clock

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

Data captured by any clock with a direct path (through combinational logic only) to a primary output must not affect the direct path to a primary output of that same clock. The application performs this check by determining the forward cone of influence for a clock pin (clock cone) and for each scannable memory element influenced by the clock pin (effect cone). The bounds

for the cones of influence are scan cells and circuitry set to a fixed value when constrained pins are set to their constrained values and initialized non-scan cells are set to their stable states. The rule violation occurs on a clock pin when a primary output is in both the clock cone and the effect cone.

The default handling for this rule violation is warning. Failure to satisfy this rule may result in a small loss in test coverage. There will be no risk of inaccurate simulation results. When an error condition occurs, you can access the cone data by setting the gate reporting to error_pattern and using the report_gates command for the gate ID number displayed in the error message. This identifies the problem input, and by tracing back from this input, you can identify how to correct the problem. C indicates clock cone, E indicates effect cone, B indicates both, and “-” indicates no cone.

The occurrence message is:

```
PO P path from clock C is gated by scan cell that uses same clock. (C9-1)
```

P is the pin name of the primary output and C is the pin name of the clock.

The summary message is:

```
There were N clock rule C9 fails (PO connected to a clock line gated by
scan cell that uses same clock).
```

N is the number of occurrences of rules violation C9.

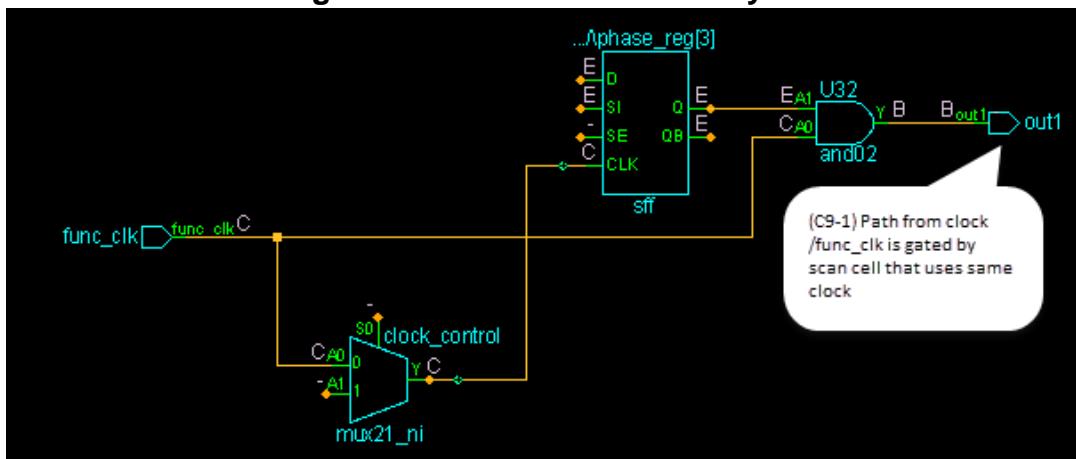

C9 Rule Violation Example

The tool setup for the clocks is:

```
add_clocks 0 func_clk
```

If you run rules checking on this design given the setup command shown, you will get a C9 rule violation. The results of performing DRC Analysis in DFTVisualizer on the C9 DRC in this example is shown in [Figure 7-20](#)

Figure 7-20. C9 Rule DRC Analysis

This type of violation is not usually a problem. However, a C9 violation can result in reduced coverage because it may introduce sequential effects into the generated clock patterns. In this case, the violation is at the out1 line. The func_clk signal can affect the data of the flip-flop and the gate at the output of the scan cell. An acceptable solution is to accept this warning, or turn it off with the command:

```
set_drc_handling c9 ignore
```

C10

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

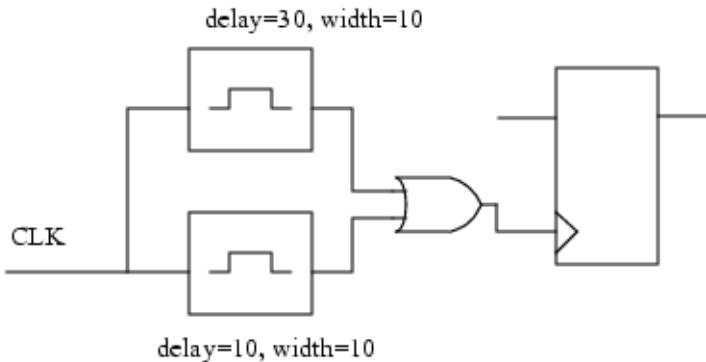

A sequential element (latch or flip-flop) can only be clocked once in any one pattern cycle. The tool will only pulse a clock primary input once in each cycle, or apply a clock procedure only once, therefore a failure of this rule implies that the circuit generates two or more internal pulses from a single clock pulse or clock procedure.

The default handling of this rule violation is error. Failure to satisfy this rule will result in creation of patterns which are likely to be incorrect and to fail both in verification and on the tester.

The occurrence message is:

```
Cell c might capture more than once by applying clock ck. (C10-1)
```

Figure 7-21 shows an example circuit which will generate a C10 error.

Figure 7-21. C10 Rule Example Circuit

In order to remove the violation, the circuit must be modified. Test logic can be added to block the path from one pulse generator to the OR gate during test mode.

Note

It is also possible to violate this rule by OR-ing together two clocks which are pulsed at different times in a clock procedure.

C16

Category: Clock

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

When switching from the load_unload phase to the capture phase, sometimes the loading values of scan cells can be disturbed due to pin constraints specified in the capture phase. The C16 clock rule checks for this situation and issues a violation if it occurs.

For example, consider a DFF scan cell with two clock ports: the first port is used for scan loading and the second is used for normal operation. Assume the second port's clock signal (whose off state is defined as 1) is ANDed with an enable signal to produce the actual clock input value. If in the load_unload procedure the enable is forced to 0, the load value cannot be disturbed by the second clock port during scan loading. However, if you issued an add_input_constraints command in setup mode to set the enable signal to 1, the scan load value can be disturbed at the start of the capture cycle when switching from load_unload to capture. This is because the clock input at the second port will change from 0 to 1 when the enable changes from 0 to 1 as a result of the pin constraint.

Note

The C16 rule check will ignore an X at a scan cell's clock port, as it is possible to assign a proper value at the PIs to keep the scan cell stable at the beginning of the capture phase. Xs on scan cell clock ports will, however, cause C1 violations.

The default handling for rule C16 is error. Failure to satisfy this rule may result in simulation mismatches during verification.

To debug a C16 rule violation, issue a “set_gate_report_error_pattern” command, then use report_gates for the gate instance named in the C16 occurrence message.

Caution

 If you choose to ignore C16 violations (not recommended), you should add a CX cell constraint to each scan cell where a violation occurred—in order to avoid simulation mismatches. Be aware that each cell you constrain in this manner reduces test coverage. You can obtain the instance name of the scan cell from the occurrence message and use the add_cell_constraints command to apply the constraint to the cell’s output pin. For example:
report drc rule c16
// Warning: The load value of scan cell /dff2/dff1/Q_reg (47) is disturbed by clock input 3 at the beginning of the capture phase when pin constraints are forced. (C16-1)
add_cell_constraints /dff2/dff1/Q_reg/Q CX

The occurrence message is:

The load value of scan cell N is disturbed by clock input I at the beginning of the capture phase when pin constraints are forced. (C16-1)

N is the instance name of the gate, I is the gate input number of the clock line, and C16 is the rule ID number.

The summary message is:

There were N clock rule C16 fails (scan cell load value disturbed at beginning of capture phase when pin constraints are forced).

N is the number of occurrences of rules violation C16.

C17

Category: Clock

Contexts Supported: dft -scan, dft -test_points, patterns -scan, patterns -scan_diagnosis

Default Handling: Ignore for patterns -scan context. Warning for dft -scan and dft -test_points contexts.

report_drc_rules: Supported

The default handling for the C17 rule in patterns -scan context is Ignore. Setting the handling to Ignore bypasses the C17 rule completely, cutting run time.

The default handling for the C17 rule in the dft -scan and dft -test_points contexts is Warning. When handling is set to Warning, all internally-driven glitches are identified (as C17 violations) and are also remodeled as possible X sources during DRC and pattern generation.

You can change the DRC handing for C17 in any of the supported contexts. In addition to setting handling to Ignore and Warning, you can also set handling to Error or Note. Setting handling to Error reports the first violation and then aborts the system mode transition. When handling is set to Note, all internally-driven glitch sources in a design are identified (as C17 violations), but they are not remodeled and will maintain a constant value during DRC and pattern generation.

An internally driven glitch source consists of either a two-input AND gate, or a two-input OR gate where both inputs are driven from a common source (either directly or through buffers and inverters), such that one path is inverting and the other path is not. This type of circuit maintains the same constant output value regardless of the state of the driving node, but the output will probably contain a glitch when the driving node changes state.

With this rule, gates are identified as internally-driven glitch sources if they are both driven by a sequential element and also drive the clock or set/reset line of a sequential element.

Note

 Internally-driven is defined as a glitch generator driven from a sequential element, and not from a primary output.

Remodeling these internally-driven glitch sources as a constant value (TIE0 or TIE1) may cause failures during scan chain tracing. For this reason, if handling is set to Warning, C17 identifies these internally-driven glitch sources and remodels them as an X source (TIEX gate).

You can use the `report_drc_rules` command to display a list of the internally-driven glitch sources identified in your design.

C19

Category: Clock

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

The C19 rule checks any clock gating structure where a leading edge (LE) or trailing edge (TE) flop is gating a clock path that drives any state elements that can capture a value at the same edge.

Note that the violation can lead to simulation mismatch due to a race condition between the clock enable path and the data ports of the controlled state elements. You should investigate and fix C19 violations by changing the design or adding constraints to prevent the clock enable signal from changing the value while the data ports of the controlled state elements are capturing data.

To debug a C19 rule violation, issue the `analyze_drcViolation` command to display the following in the Flat Schematic window:

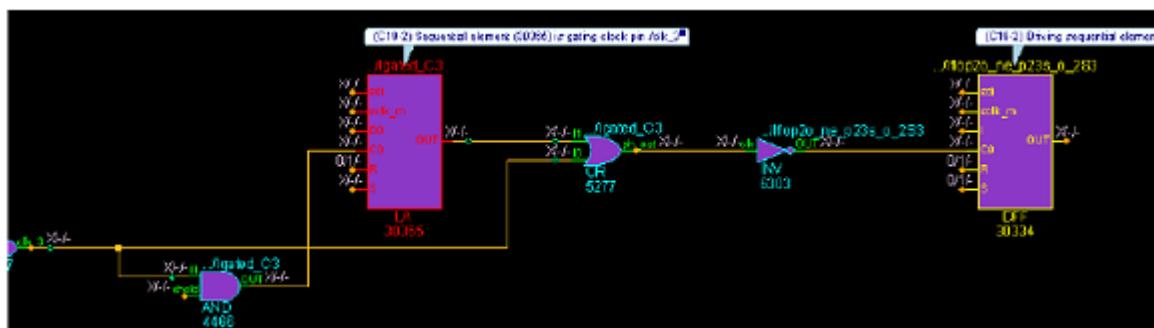

- path from the clock enable flop to the driving flop with the violation
- path from clock pin to enable flop
- constraint value
- clock enable flop and driving flop with the violation

Example of C19 Violation

The following example shows a design with 10 C19 violations:

```
SETUP> set_system_mode analysis
...
// 10 sequential elements are gating clock path and driving sequential elements on the same
// clock edge which can create a race condition. (C19)
...
ANALYSIS> report_drc_rules c19-2
// Warning: Active-high latch /lbasic_gates/l gated_C3/ (30365) is gating clock pin /clk_3 (17)
// and driving some leading-edge flops which can create a race condition. (C19-2)
// The first traced sequential element driven by /lbasic_gates/l gated_C3/ (30365) that can
// create a race condition is /lbasic_gates/l flop2o_ne_p23s_o_2S3/ (30334).
ANALYSIS> report_drc_rules
...
C19: #fails=10 handling=warning/atpg (clock gater race condition check)
...
ANALYSIS> analyze_drcViolation C19-1
```

This command produces the following display in the Flat Schematic window:

C21

Category: Clock

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Note

report_drc_rules: Supported

The C21 DRC detects when multiple active shift clocks converge at the same combinational gate.

When two or more active shift clocks converge at a combinational gate pin (except for MUX gates) and there is an unblocked path to at least one sequential element, the C21 DRC violation is issued. C21 identifies the gate pin location and lists the clocks that converge at that gate pin.

The default handling of C21 is Note, but it is allowed to be set to Warning, Ignore, or Error.

The occurrence message is:

```
// Error: At least 2 active shift clocks (/clk1, /clk2) converge at gate
'gate13/Y' (33) during shift. (C21-1)
```

The summary message is:

```
C21: #fails=1 handling=error/verbose (multiple shift clocks converge at
same gate)
```

C22

Category: Clock

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

The C22 DRC reports a violation when the tool identifies asynchronous cross domain clock paths where the launch and capture clocks are forced to pulse, which could lead to simulation mismatches.

C22 checks a pair of clocks, one of which must be pulse-always or pulse-in-capture, whether there is any interaction between the pair and they are not defined within a synchronous clock group.

C22 also checks if any interaction exists between an internal clock of a clock_control procedure and its source clock when the clocks are not defined within a synchronous clock group. In such a case, C22 reports a violation.

When you issue a [read_profile](#) command that adds, deletes, or modifies the clock_control procedures, the C22 DRC will be re-analyzed and any false paths derived by C22 will be updated.

[Figure 7-22](#) and [Figure 7-23](#) include examples of cross clock domain paths.

The default C22 DRC handling is Warning, and can be set to Error, Warning, Note, or Ignore.

The occurrence message is one of these:

```
// Warning: Pulse-always clock '/clk1' (7) interacts with clock domain
// '/clk2' (8) and may cause simulation mismatches. Use "report_clock_domains
// -race_points 7 8" to see the clock interactions. (C22-1)

// Warning: Pulse-in-capture clock '/CLK2' (2) interacts with clock
domain '/CLK1' (1) and may cause simulation mismatches. Use
"report_clock_domains -race_points 2 1" to see the clock interactions.
(C22-1)

// Warning: Clock control source clock '/CLK1' (1) interacts with clock
domain '/CLK1_GATED' (25) and may cause simulation mismatches. Use
"report_clock_domains -race_points 1 25" to see the clock interactions.
(C22-1)
```

The summary message is:

```
// Warning: There were 2 C22 violations (interacting clocks not in
synchronous clock group but forced to pulse concurrently)
```

Unless the C22 handling is set to Error, the tool adds a false path between the clock pair to prevent simulation mismatch due to C22. If set to Ignore, no false paths will be added, because no C22 is flagged. The `-mask_interactions` and `-interactions` switches of the `set_drc_handling` command allow you to disable the false path addition and to determine the type of clock interaction for C22.

You can report the number of sequential elements impacted by each C22 violated clock pair using this command in ANALYSIS mode:

```
report_clock_domains -race_points clk1 clk2

//      /clk_gater_2/pipe_dff1_1/ (98) scan
// 1 state element causes clocks '/clk1' (7) and '/clk2' (8) to be
incompatible.
```

With the information returned by the `report_clock_domains` command, you can trace backwards to locate the clocks using the `report_gates` command or within DFTVisualizer. [Figure 7-22](#) shows the most basic C22 DRC violation example. The C22 violation is between CLK1 (a pulse-always clock) and CCB2 because of the cross domain path from SFF1 to SFF2.

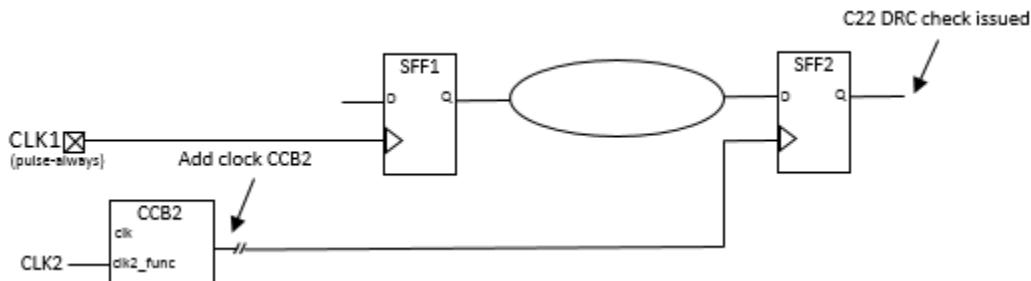

Figure 7-22. C22 DRC Example Design 1

Figure 7-22 also demonstrates the interaction of an internal clock of a `clock_control` procedure (CCB2) and its source (CLK1) when the clocks are not defined within a synchronous clock group. This is the `clock_control` procedure for this example:

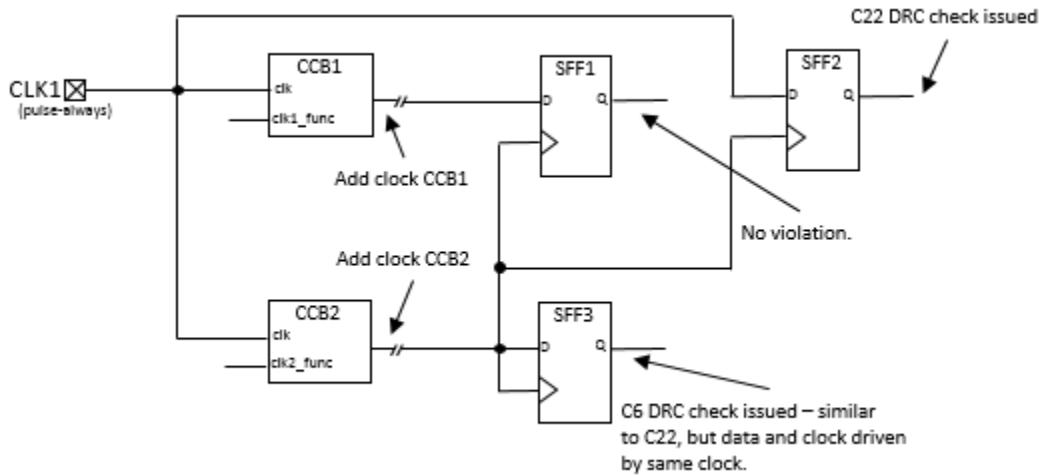

```
clock_control CCB2 =
  source_clock CLK1;
  atpg_cycle 0 =
    condition /sff2_CC/Q 1;
  end ;
  atpg_cycle 1 =
    condition /sff1_CC/Q 1;
  end;
end;
```

When a source and internal clock pair are defined in a `clock_control` procedure, it is not necessary for the source (CLK1, in this case) to be defined as a pulse-always or pulse-in-capture for C22 to trigger a violation.

Figure 7-23 shows another C22 DRC violation example. The C22 violation is between CLK1 and CCB2 and their interaction on SFF2. SFF1 does not violate C22 because it is driven by the added clocks CCB1 and CCB2, neither of which is pulse-always nor pulse-in-capture.

A C6 DRC is issued for SFF3 and is shown in this example to demonstrate that while C22 is similar to C6, C22 flags different clocks and C6 involves the same clock.

Figure 7-23. C22 DRC Example Design 2

Possible Resolutions For C22 Violation

One possible resolution is to change the design to eliminate the cross domain path. If the clocks are synchronous, another solution would be to use the `add_synchronous_clock_group` command to place the clock pair in the same synchronous clock group in Setup mode.

C23

Category: Clock

Contexts Supported: `dft -edt`, `dft -logic_bist`, `patterns -scan`, `patterns -scan_diagnosis`

Default Handling: Warning

`report_drc_rules`: Supported

This rule checks if a scan cell cannot capture fault effects because its clock port is constrained to 0 or 1.

The information provided by C23 helps you debug low fault coverage caused by clocking issues. To check for C23, the tool forces and propagates constant values such as pin constraints, tied non-scan elements, and constant cell constraints. It also calculates forbidden values. The tool then processes each clock port, except those meant to be used only for scan shift, and checks for these conditions:

- Are the clock ports of level-sensitive latches constrained to 0?
- Are the clock ports of edge-triggered DFFs constrained to 0 or 1?

If all the clock ports of a scan cell satisfies either of these conditions, a C23 violation is reported because none of its clock ports can be turned on.

To minimize the number of violations reported, the tool traces from rule violation clock ports to a common source point, which can be a primary input or internal pin. The violating sources are

reported in order by number of affected sequential elements with the first violation having the most, and so on. This is an example of the reported message:

report_drc_rule C23

```
// Warning: Primary input '/clk (4)' has a constrained value of 0. This
// prevents capture by 32 scan cell elements, one of which is '/inst/sdff1
// (880)'. (C23-1)

// Warning: Internal pin '/inst1/udp/A (567)' has a constrained value of
// 1. This prevents capture by 18 scan cell, one of which is '/inst/sdff2
// (990)'. (C23-2)
```

The default handling of C23 is Warning. It is performed during system mode transition from Setup to Analysis. The summary message is:

```
// Warning: There are N clock rule C23 fails (scan cell elements cannot
// capture or launch transition because clock ports are constrained).
```

To debug C23, use the “[set_gate_report -constrain_value on](#)” command to view the constrained values for the clock ports of affected scan cells.

C24

Category: Clock

Contexts Supported: dft -edt, dft -logic_bist, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

This rule checks if a scan cell cannot capture fault effects because its clock port cannot be set to an active state. A scan cell must first pass the C23 DRC in order to be checked by C24.

The information provided by C24 helps you debug low fault coverage caused by clocking issues. To check for C24, the tool forces and propagates constant values such as pin constraints, tied non-scan elements, and constant cell constraints. It also calculates forbidden values. The tool then processes each clock port, except those meant to be used only for scan shift, and checks these for conditions:

- The constrained value of the clock ports of level-sensitive latches is X, but its forbidden value is 1, or the clock cannot be justified to 1.
- The constrained value of the clock ports of edge_triggered latches is X, but its forbidden value is either 0, 1, or both, or the clock cannot be justified to both 0 and 1.

If all the clock ports of a scan cell satisfies either of these conditions, a C24 violation is reported because none of its clock ports can be turned on.

To minimize the number of violations reported, the tool traces from rule violation clock ports to a common source point, which can be a primary input or internal pin. The violating sources are

reported in order by number of affected sequential elements with the first violation having the most, and so on. This is an example of the reported message:

report_drc_rule C24

```
// Warning: Primary input '/clk (4)' has a value of X and cannot be
justify to 1. This prevents capture by 32 scan cell elements, one of
which is '/inst/sdff1 (880)'. (C24-1)

// Warning: Internal pin '/inst1/udp/A (567)' has a value of X and cannot
be justified to both 0 and 1. This prevents capture by 18 scan cell
elements, one of which is '/inst/sdff2 (990)'. (C24-2)
```

The default handling of C24 is Warning. It is performed during system mode transition from Setup to Analysis. The summary message is:

```
// Warning: There are N clock rule C24 fails (scan cell elements cannot
capture or launch transition because clock ports cannot be fully
controlled).
```

To debug C24 violations, use the “[set_gate_report -constrain_value on](#)” command to look at the constrained values on clock ports of affected scan cells.

C25

Category: Clock

Contexts Supported: dft -edt, dft -logic_bist, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

This rule checks if a scan cell cannot capture fault effects because its asynchronous controls (SET and RESET ports) cannot be set to the off state.

To check for C25, the tool forces and propagates constant values such as pin constraints, tied non-scan elements, and constant cell constraints. It also calculates forbidden values. The tool then processes the set and reset ports of every scan cell and checks for these conditions:

- If the port’s constrained value is 0, it passes.
- If the port’s constrained value is a 1, it fails because the scan cell is always setting or resetting and is unable to capture fault effects through its data port.
- If the ports constrained value is X, and its forbidden value is 0 or cannot be justified to 0, it fails, because the port cannot be at its off state. Otherwise, it passes, because ATPG can justify the port to its off state and allow the cell to capture.

To minimize the number of violations reported, the tool traces back constant or X paths to a common source point, which can be a primary input or internal pin. The violating sources are

reported in order by number of affected sequential elements with the first violation having the most, and so on. This is an example of the reported message:

report_drc_rule C25

```
// Warning: Primary input '/clk (4)' is has a constrained value of 1. As a result, set or reset ports cannot be turned off for 32 scan cell elements, one of which is '/inst/sdff1 (880)'. (C25-1)
```

```
// Warning: Internal pin '/inst1/udp/A (567)' has a value of X and cannot be justified to 0. As a result, set or reset ports cannot be turned off for 18 scan cell elements, one of which is '/inst/sdff2 (990)'. (C25-2)
```

The default handling of C25 is Warning. It is performed during system mode transition from Setup to Analysis. This is the summary message:

```
// Warning: There are N clock rule C25 fails (scan cell elements' set/reset port cannot be justified to off state).
```

To debug C25 violations, use the “[set_gate_report -constrain_value on](#)” command to look at the constrained values on set and reset ports of affected scan cells.

Scan Cell Data Rules (D Rules)

The DFT tools check scan cells to ensure they are able to properly control and observe their data. You may select the handling of these scan cell data rules to be error, warning, note, or ignore.

The following subsections describe these rules.

Tip

 In DFTVisualizer, you can press Ctrl + R to execute a report_gates command on selected gates. For more information, see “[How to Report Gate Data](#).”

D12.....	2746

D1

Category: Data

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

Checks for the possible disturbance of data values loaded or captured into scan cells.

During the application of the test procedures, if other circuitry disturbs the data values loaded or captured into scan cells, those cells cannot be controlled or observed. The tool performs this check using the simulated values of each time period of the test procedures. A violation occurs if any clock input (including set and reset lines) of any scan cell allows data capture at an inappropriate time, in which case the control value loaded or the capture value unloaded from the scan cell cannot be trusted. Common sources of D1 violations are undefined clocks, problems in the test procedure file, or possibly design errors.

Effect on Testability

Failure to satisfy this rule can result in simulation mismatches when you verify the test patterns in a timing-based simulator. If the violations occur during the shift procedure, you may see related simulation mismatches in the serial pattern test bench only, not the parallel test bench.

If the number of D1 violations is small compared to the number of scan cells in the design, you may choose to handle this rule violation as a warning by issuing the `set_drc_handling D1` Warning command prior to DRC. When “`set_drc_handling d1`” warning is in effect for DRC, the tool automatically applies an XX cell constraint to each D1 failing scan cell. This prevents the mismatches, but may reduce test coverage slightly. See the `add_cell_constraints` command description for information about the XX cell constraint.

Note

 If “`set_drc_handling d1`” note is in effect for DRC, the tool will *not* apply any XX cell constraints for D1 violations, which ensures test coverage is not affected. However, you should use “note” handling only for cell architectures you know will not produce mismatches.

If the number of D1 violations is large, you should isolate and resolve the source of the failure(s) to avoid a major impact on test coverage.

How to Debug D1 Violations

The occurrence message is:

```
// N (G) disturbed during time T of P procedure. (D1-1)
```

N is the instance name of the scan cell memory element, G is the gate ID number, T is the time period, and P is the group test procedure name.

The summary message is:

```
// There were N occurrences of scan cell disturbs. (D1)
```

N is the number of occurrences of rules violation D1.

Use the `report_drc_rules` command to obtain additional information about the violations. For example, to view the occurrence messages for all D1s, use:

```
report_drc_rules d1
```

The occurrence messages list gate names and gate IDs you can copy and paste into commands during later debugging. You can report on a specific occurrence by issuing the command with “D1-” and the occurrence number. For example:

```
report_drc_rules d1-1
```

```
// Error: /dataout/reg_q_0_ (373) disturbed during time 0 of grp1
load_unload procedure. (D1-1)
```

When a D1 error occurs, you can access the simulated values at the gate where the error occurred by issuing the command, `set_gate_report Error_pattern`, then using the `report_gates` command to report the gate whose ID number is displayed in the error message. In the resultant display, you can identify the clock input not held at its off state. By tracing back from this input, you can usually identify how to correct the problem.

You can debug a specific occurrence of a D1 violation using DFTVisualizer or by issuing commands from the tool's command line. Examples of both methods follow.

How to Debug with DFTVisualizer

To view the location of a D1 violation using DFTVisualizer, use the following command steps:

1. `open_visualizer`
2. `set_gate_level Primitive`

Choose the **DRC Violations** tab in the Design Browser window, then open the listed DRC's by selecting the “+” symbols as needed to find the violation ID of the desired DRC violation.

Double clicking the listed violation, or right clicking and selecting **Analyze DRC Violation** from the popup menu will analyze the violation. DFTVisualizer will display the scan cell affected by that occurrence.

Tip

 Alternatively, you can issue the `analyze_drcViolation` command with the `rule_id-occurrence#` argument at the tool's command line. For example, to display the first occurrence of a D1 violation: `analyze_drcViolation d1-1`

Once the offending scan cell is displayed, trace back from the cell's clock input to the primary input that drives the clock. Ensure the clock's off state, which you defined using the `add_clocks` command, is correct.

How to Debug from the Tool Command Line

To view the location of a D1 violation from the command line, use the following example command steps:

1. `set_gate_report Error_pattern`
2. `set_gate_level Primitive`
3. `report_drc_rules D1-occurrence#`
4. `report_gates offending_gate's_id#`

The following transcript excerpt shows an example of the use of this command sequence:

```
set_gate_report error_pattern
set_gate_level primitive
report_drc_rules d1-1
// ERROR: /dataot/reg_q_0_ (373) disturbed during time 0 of grp1
//          load_unload procedure. (D1-1)
report_gates 373
// /dataot/reg_q_0_ (373) DFF
//   "S"    I  (0)  43-
//   R     I  (0)  157-
//   CLK   I  (1)  313-/dataot/ix104/Y
//   "D0"   I  (X) 255-
//   "OUT"  O  (X) 127- 128-
```

You would then trace back from the CLK input to try to determine why it is in an active state, which disturbed the cell's value.

In some of the more complex cases, the problem can be a clock disturb early in the capture cycle. In these cases, the error report does not provide enough detail to isolate the failure. To get more information, you can use the following command steps:

1. set_gate_report Drc_pattern State_stability
2. set_system_mode analysis
3. report_gates *offending_gate's_id#*

The following transcript excerpt shows an example of the use of this command sequence:

```
set_gate_report drc_pattern state_stability
// Creating schematic for 3 instances (0 were compacted).
set_system_mode analysis
// -----
// Begin scan chain identification process, memory elements = 56.
// -----
// Reading group test procedure file fast.testproc.
// WARNING: Pin tclk is used for both write control and pulse clock
// Simulating load/unload procedure in grp1 test procedure file.
// Chain = chain1 successfully traced with scan_cells = 12.
// Chain = chain4 successfully traced with scan_cells = 12.
// Chain = chain3 successfully traced with scan_cells = 12.
// Chain = chain2 successfully traced with scan_cells = 12.
// 48 scan cells have been identified in 4 scan chains.
// Longest scan chain has 12 scan cells.
// WARNING: 8 edge-triggered clock ports set to stable high. (D7)
// ERROR: /dataot/reg_q_0_ (373) disturbed during time 0 of grp1
//        load_unload procedure. (D1-1)
// ERROR: Rules checking unsuccessful, cannot exit SETUP mode.
report_gates 373
// /dataot/reg_q_0_ (373) DFF
//           (ts) (ld) (shift) (cap) (stbl)
// "S"   I  ( 0 ) ( 0 ) (000~0) (000) (    0)  43-
// R    I  ( 0 ) ( 0 ) (000~0) (XXX) (    X)  157-
// CLK  I  ( 1 ) ( 1 ) (101~1) (XXX) (    X)  313-  /dataot/ix104/Y
// "D0"  I  ( X ) ( X ) (XXX~X) (XXX) (    X)  255-
// "OUT" O  ( X ) ( X ) (XXX~X) (XXX) (    X)  127-  128-
```

The item to notice is the clock values during the capture cycle. In this case the value of the clock is (XXX). This indicates the clock is not at its off state at the beginning or end of the capture cycle. The correct values should be either:

- (0X0)—For a leading edge device with an off state of 0 for the clock, or
- (1X1)—For a trailing edge device with an off state of 1 for the clock

Possible Resolutions

If your debugging effort shows an offending clock's off state is incorrect, use the add_clocks command to redefine the clock with the correct off state. To change the defined off state, first delete the old definition with the delete_clocks command, then reissue add_clocks. To see a clock's current defined off state, use the report_clocks command.

If the clocks are working correctly, examine the test procedure file. By tracing through the design, you may find an incorrect constraint or force value that can be fixed in the test procedure file.

Note

 If you make any changes in the test procedure file, execute the read_procfile command with the correct filename before re-checking the design rule checks.

D2

Category: Data

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

During system data capture, if the scan path from a MASTER or SLAVE element to its COPY is sensitized, it must be unique. The tool performs this check by comparing the inputs of the COPY with its associated memory element. A violation occurs if there are multiple paths from the associated memory element (MASTER or SLAVE) to the COPY and these paths can be sensitized at the same time.

The application checks for the following conditions:

- The value on the data line of the COPY element must be able to be propagated back to its associated memory element along the scan path when constrained pins are set.
- The scan path, when sensitized from the associated memory element to the COPY, must be unique.
- The COPY and its associated memory element may have only a single clock port.
- For a COPY and its associated memory element, all non-tied clock, set, and reset inputs must have the same or equivalent source.

Note

 DRC does not consider it a D2 violation if a COPY element can capture a value through a different path other than from its associated memory element during system capture.

Failure to satisfy this rule usually reduces test coverage. You can avoid the coverage loss by using the command, set_split_capture_cycle On.

The occurrence message is:

```
COPY N (G) failed data capture check. (D2-1)
```

N is the instance name of the COPY memory element, and G is the gate ID number.

The summary message is:

```
N COPY scan elements failed data capture check. (D2)
```

N is the number of occurrences of rules violation D2.

D3

Category: Data

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

For all scan cells that contain a SLAVE, the **master_observe** procedure must propagate the data value of the MASTER memory element to the SLAVE. The application performs this check using the simulated values of each time period of the **master_observe** procedure to trace back from the SLAVE to the MASTER. The rule violation occurs if the **master_observe** procedure does not properly sensitize the path between the SLAVE and MASTER.

The default handling for this rule violation is error. You may ignore this error condition by issuing the command set_drc_handling D3 Warning.

When the handling is set to other than error, the tool will automatically make the necessary MASTER unobservable to prevent a potential simulation mismatch. This applies only to the MASTER of the scan cell containing a SLAVE. The scan cell without a SLAVE retains its original observability. Due to the loss of observability on some MASTERS, test coverage may be reduced.

When an error condition occurs, you can access the simulated values by setting the gate reporting to drc_pattern (with the master_observe argument and the desired time) and using the report_gates command for the gates in the SLAVE to MASTER path. This identifies the location of the blockage; by tracing back from the inputs, you can identify how to correct the problem.

The occurrence message is:

```
N (G) not successfully observed by master_observe procedure. (D3-1)
```

N is the instance name of the MASTER memory element, and G is the gate ID number.

The summary message is:

```
N MASTERS not successfully observed by master_observe procedure. (D3)
```

N is the number of occurrences of rules violation D3.

D4

Category: Data

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

If you define the **skew_load** procedure, it must propagate the data value of the preceding scan cell (or scan chain input pin) to a MASTER memory element. The application performs this check using the simulated values of each time period of the **skew_load** procedure to trace back from a MASTER to its preceding scan cell output or scan chain input pin. The rule violation occurs if the **skew_load** procedure does not properly sensitize the path.

The default handling for this rule violation is error. Failure to satisfy this rule may result in inaccurate simulation results when you use the skew load option. The **skew_load** procedure is optional and you can avoid rules violations by removing the procedure definition.

When an error condition occurs, you can access the simulated values by setting the gate reporting to drc_pattern (with the skew_load argument and the desired time) and using the report_gates command for the gates in the path. This identifies where the blockage occurred; by tracing back from the inputs, you can identify how to correct the problem.

The occurrence message is:

```
Skew_load procedure not successful for MASTER %N (G). (D4-1)
```

N is the instance name of the MASTER memory element and G is the gate ID number.

The summary message is:

```
Skew_load procedure not successful for N MASTERS. (D4)
```

N is the number of occurrences of rules violation D4.

D5

Category: Data

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

All memory elements (latches and flip-flops) must be scannable. The application performs this check after identifying all scan memory elements. The rule violation occurs for all memory elements not identified as part of a scan cell.

Note

 The D5 check simulates the circuit as purely combinational by using a sequential depth of 0 or 1 (as if the “set_pattern_type -Sequential” command is set to 0 or 1).

When the tool identifies a non-scan memory element, the tool classifies each element into one of the following types:

- INIT-0: If it is at 0 at the beginning of the first capture cycle.

- INIT-1: If it is at 1 at the beginning of the first capture cycle.
- INIT-X: If its state is unknown at the beginning of the first capture cycle and it may go to any state during capture.
- TIE-0: If it is always at 0 during capture.
- TIE-1: If it is always at 1 during capture.
- TIE-X: If it is always at an unknown state during capture.
- TLA: If it is always transparent when its clock is at its off state.

The model used (and reported in the D5 violation message) is determined from the element's value in the D5 simulation, at the end of load_unload and before entering capture. For example, if the element's value is 1 at that time, the tool models the element as a TIE-1. Note, however, that the tool simulates the TIE-0, TIE-1, and TIE-X models as INIT-0, INIT-1, and INIT-X models, respectively. This means, for example, that a non-scan TIE-0 model can be evaluated after the beginning of the first capture cycle and get a value other than 0.

Latches modeled as TIE-X gates become candidates for transparent latches, sequential transparent cells, or clocked sequential cells if you set the pattern type appropriately with the set_pattern_type command.

The default handling for this rule violation is warning. Failure to satisfy this rule will result in some loss of test coverage.

The occurrence message is:

N (G) is a non-scan T1 converted to T2. (D5-1)

N is the instance name of the non-scan memory element, G is the gate ID number, T1 is the gate type (latch or flip-flop), and T2 is the gate type that models it (TIEX, TIE0, or TIE1).

The summary message is:

N non-scan memory elements converted to T gates. (D5)

N is the number of occurrences of rules violation D5, and T is the gate type that models the non-scan cell. The tool displays a summary message for each remodeled gate type.

D6

Category: Data

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

All non-scan latches must behave as transparent latches. The application performs this check for all nonscan latches that are not set to a stable binary value. The rule violation occurs if a candidate latch fails one of the following conditions:

- If the latch creates a potential feedback path, that path must be broken by scan cells or non-scan cells other than transparent latches. For more information, refer to the `set_tla_loop_handling` command.
- The latch must have a propagable path to an observable point.
- The latch must be capable of passing a value when all defined clocks are at their off-state.
- All clock, set, and reset inputs of the latch must either be set to a determinate state when all clocks are off and pin constraints are set, or must not connect to defined clocks.
- The latch must not have more than one set/reset/clock input on when all defined clocks are at their off-state.

Failure to satisfy this rule can reduce test coverage. The default handling for this rule violation is warning. If you set the handling for this rule to ignore, the tool will not perform this check and the design's latches will not be checked for transparency.

For scan insertion in the dft -scan context, if you want the tool to consider non-transparent latches as scan candidates, you must turn test logic on (with the `set_test_logic` command) and do one of two things: 1) set the handling of D6 to ignore, in which case the tool does not perform the transparency check and automatically considers the non-scannable latches for scan insertion; or 2) use the `set_latch_handling` Scan command, in which case the tool performs the check and considers non-transparent latches for scan insertion.

The occurrence message is:

```
Latch N (G) not transparent due to R. (D6-1)
```

N is the instance name of the non-scan latch, G is the gate ID number, R is the reason it cannot be transparent, and D6 is the rule ID number.

The summary message is:

```
N latches not transparent due to R. (D6)
```

N is the number of occurrences of rules violation D6, and R is the reason. The application displays a summary message for each reason.

D7

Category: Data

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning
report_drc_rules: Supported

At the end of the **shift** procedure, the clock inputs of scan flip-flops must not be set to a one state. The application performs this check using the simulated values of the last time period of the **shift** procedure. The rule violation occurs if any clock input (not including set and reset lines) of any scan flip-flop (except COPY) is set to 1. A possible cause of a rules violation is an incorrect definition of the off-state of a clock.

Note

 Some design practices consider this condition acceptable.

The default handling for this rule violation is warning. Failure to satisfy this rule will result in scan cells capturing data on the trailing edge of the capture clock pulse.

The occurrence message is:

```
Flip-flop N (G) has clock port set to stable high. (D7-1)
```

N is the instance name of the non-scan memory element, G is the gate ID number, and D7 is the rule ID number.

The summary message is:

```
N edge-triggered clock ports set to stable high. (D7)
```

N is the number of occurrences of rules violation D7.

D8

Category: Data

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

If a MASTER latch only propagates to a SLAVE and can only capture data when the SLAVE is inactive, a clock input of the MASTER latch must not be active when all clocks are off. The system uses the **master_observe** procedure to observe the values placed into the scan cell and no longer considers the SLAVE to be observable.

The application performs this check using the simulated values that result when all defined clocks are at their off-state, the constrained pins are set to their constrained values, and the initialized non-scan cells are set to their stable states.

The rule violation occurs if a clock input of a MASTER latch is not off, the MASTER latch only propagates to a SLAVE, and can only capture data when the SLAVE is inactive.

Note

 Some design practices consider this condition acceptable.

When an error condition occurs, you can access the simulated values by setting the gate reporting to error_pattern and using the report_gates command for the gate ID number displayed in the error message. This identifies the clock input not held off, and by tracing back from this input, you can identify how to correct the problem.

The default handling for this rule violation is error because for certain rare LSSD scan cell designs it can result in a simulation mismatch during pattern verification in a timing-based simulator. Failure to satisfy this rule will result in data captured into the MASTER without the application of a capture clock.

Note

 If “set_drc_handling d8 warning” is in effect for DRC, the tool will automatically apply an SX cell constraint to each D8 failing master cell. This prevents the mismatches, but may reduce coverage. See the add_cell_constraints command description for information about the SX cell constraint.

If “set_drc_handling d8 note” is in effect for DRC, the tool will *not* apply any SX cell constraints for D8 violations, which ensures test coverage is not affected. However, you should use “note” handling only for cell architectures you know will not produce mismatches.

The occurrence message is:

```
MASTER latch N (G) allows data capture while clocks off. (D8-1)
```

N is the instance name of the non-scan memory element, and G is the gate ID number.

The summary message is:

```
Clocks at off-state allow data capture for N MASTER latches. (D8)
```

N is the number of occurrences of rules violation D8.

D9

Category: Data

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

Seq_transparent procedures must not disturb scan cells, primary outputs, or previously calculated seq_transparent cells. The default handling for this rule violation is warning. The application performs this check during simulation of the **seq_transparent** procedure.

A rule violation occurs under any of the following conditions:

- If scan cell state elements change during the application of a **seq_transparent** procedure. Unless these scan state elements capture new data at the application of the capture clock, the system cannot observe them during patterns that apply the procedure.
- If disturbed scan cells supply the inputs of other scan cell state elements. The system cannot observe these other scan cell state elements during patterns that apply the procedure.
- If a primary output comes from disturbed circuitry, the system cannot observe these primary outputs during patterns that apply the procedure.
- If the application of the **seq_transparent** procedure disturbs a non-scan state element that previously captured an undisturbed value.

Failure to satisfy this rule results in restrictions on the use of these points for observation during simulation and test generation for patterns that apply the procedure. This can reduce test coverage.

If a disturbed cell must support a valid seq_transparent cell, the tool identifies the disturbed cell as a seq_transparent cell and issues a violation of type seq_transparent cell disturb. Otherwise, the tool will not identify it as a seq_transparent cell, and will instead issue a D9 violation of type unused seq_transparent cell disturb.

The occurrence message is:

T disturb occurred on N (G) in procedure P. (D9-1)

T is the type of disturb, N is the instance name of the disturbed gate, G is the gate ID number, P is the name of the **seq_transparent** procedure, and D9 is the rule ID number.

The summary message is:

N T disturbs occurred in procedure P. (D9)

N is the number of occurrences of a disturbance type, T is the type of disturbance, P is the name of the **seq_transparent** procedure, and D9 is the rule ID number. The tool issues a summary message for each disturbance type.

D10

Category: Data

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported for patterns -scan context only.

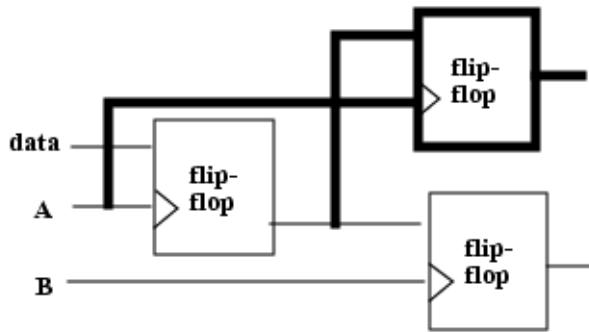

The transparent capture cells in **clock** procedures must not propagate both old and new data to other state elements. For example, a violation can occur when a clock procedure pulses two clocks, and a memory element clocked by the first applied clock feeds at least two other memory elements, clocked by each of the clocks.

To illustrate this, assume the clock procedure is as follows:

```
procedure clock clock_proc1 =
    force A 1 1;
    force A 0 2;
    force B 1 3;
    force B 0 4;
end;
```

Given this procedure, the highlighted flip-flop in the following figure, which gets old data from the first flip-flop when A pulses, violates this requirement.

Figure 7-24. Rule D10 Violation Example

The default handling for this rule violation is error. Failure to satisfy this rule will result in the source gate being modeled as a TIEX gate. You can suppress reporting the results of this check using `set_drc_handling`. However, regardless of how you set the handling, Tessent FastScan and Tessent TestKompress always perform this check on model violating gates with TIEX behavior.

The occurrence message is:

```
Cell N (G) has invalid transparency (X/Y) in procedure P. (D10-1)
```

N is the cell name, G is the gate ID number of the cell, X is the ID number of the gate capturing old data, Y is the ID number of the gate capturing new data, and P is the clock procedure name.

The summary message is:

```
There were N cells with invalid transparency. (D10)
```

N is the number of cells found to violate this rule.

D12

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

In the state stability analysis stage, DRC simulates a number of shift cycles to calculate the stable value (load value) of nonscan memory elements at the beginning of capture.

If some nonscan memory elements need more than one shift cycle to be initialized, and its load value is observed into a scan cell, the parallel simulation test bench may have simulation mismatches. This is because in parallel simulation test bench the tool generally only has one parallel shift cycle, leading to insufficient shift cycles to initialize those nonscan elements.

If state stability analysis takes more than one cycle to calculate nonscan load value, then the tool issues the following warning message:

```
// Warning: DRC simulated N shift cycles to initialize some non-scan
// memory elements to their load values. (D12-1)
// Note: In order to avoid potential parallel simulation mismatches,
// M post shift cycles will be automatically added to the testbench as
// if the SIM_POST_SHIFT parameter keyword were set to M.
// This will slow down parallel simulation. To avoid slowing down
// parallel simulation, the number of cycles DRC simulates can be
// restricted using "set_stability_check -max_shift_cycles 1". However,
// initializing fewer non-scan memory elements may lead to lower test
// coverage.
```

N is number of shift cycles and M is the number of shifts required.

Pre-DFT Clock Rules (DFT_C Rules)

The tool uses the DFT_C rules to verify the clock specification and circuitry before DFT structures such as memory BIST, logic BIST, boundary scan, EDT, and OCC are inserted.

The tool invokes the DFT_C rules when the [check_design_rules](#) command is issued if the context has been specified as either dft -rtl or dft -no_rtl, with the [set_context](#) command, and the [set_dft_specification_requirements -memory_test](#) option and/or [-logic_test](#) options are set to “on”.

The following subsections describe these rules.

Simulation Contexts for Pre-DFT DRCs	2747
DFT_C1	2751
DFT_C2	2754
DFT_C3	2755
DFT_C4	2756
DFT_C5	2757
DFT_C6	2758
DFT_C7	2760
DFT_C8	2761
DFT_C9	2762
DFT_C10	2765
DFT_C11	2771
DFT_C12	2772
DFT_C13	2773

Simulation Contexts for Pre-DFT DRCs

This section describes the simulation contexts which are created by the DFT_C rules. This DRC always runs when transitioning from setup to analysis mode in the DFT context when no sub context is specified.

The created simulation contexts are used by the pre-DFT DRC rules described in the following sections. They can also be re-used by custom DRC rules you may have registered using the [register_drc](#) command.

Listed below are the simulation contexts created when transitioning from setup to analysis mode in the DFT context when no sub context is specified. You can obtain this list by using the

[get_simulation_context_list](#) command. To display those values in the GUI, you need to issue the following two commands:

```
set_gate_report simulation_context
set_current_simulation_context simulation_context_name
```

The *simulation_context_name* string is one of the names returned by the [get_simulation_context_list](#) command. When you have DRC violations for any of the DFT_C* types, the associated simulation context is set when you issue the “[analyze_drcViolation drc_name](#)” command or when you issue the “[set_gate_report drc_name](#)” command.

The simulation contexts are all derived from the stable_after_setup simulation context. This context is created by simulating the test_setup procedure followed by a state stability analysis using the specified input constraints. When ICL is elaborated, the reset and control signals of the IJTAG scan interface are auto constrained off to make sure the values loaded in the “scan resource instrument” side of the network are not disturbed by the state stability analysis. Refer to the [Sib wrapper](#) section for an explanation of the difference between the “scan resource instrument” and the “scan tested instrument” sides of the network.

When ICL is elaborated, the IJTAG network is always reset even if no [set_test_setup_icall](#) or [set_static_dft_signal_values](#) commands are issued. The DFT signals defined on the DataOutPorts of IJTAG nodes are forced directly on the pin of the associated instances because the pins need to be set to different values in different contexts. You typically only need to use the [set_test_setup_icall](#) or [set_static_dft_signal_values](#) commands when using “[set_dft_specification_requirements -logic_test on](#)” because you need to configure the child blocks so that sub_chain tracing can be done on them. When only using “[set_dft_specification_requirements -memory_test on](#)”, you typically do not need any test_setup iCall. The network is also typically not even created at that point. If the network is already created and you do need to use a test_setup iCall, you must request the IJTAG network to be synthesized if you are running in -rtl mode. The test_setup simulator only knows how to simulate gates. You will typically get E14 violations if you try to use an iCall in the test_setup and the IJTAG network is not synthesized. Use the following command to get the IJTAG network synthesized. You do note need these commands when “[set_dft_specification_requirements -logic_test on](#)” because it already causes the entire design to be synthesized.

```
set_attribute_value -name synthesize_before_analysis \
[get_modules -of_instances [get_ijtag_instances]]
```

In the following section, the DFT signals are mentioned and their attributes are referenced. For a description of their usage, [reset_value](#), [default_value_in_all_test](#) and [value_in_pre_scan_drc](#) property, refer to the description of the [add_dft_signals](#) and the [register_static_dft_signal_names](#) commands.

Simulation Contexts

- [dft_glb](#)

This simulation context is created on top of the stable _after_ setup simulation context. The DFT signals with usage “global_dft_control” are forced to their “default_value_in_all_test” value. The targets of the [add_dft_control_points](#) command using a DFT signal with usage “global_dft_control” are also forced taken into account the -inverse_dft_signal_source switch. All clocks (source, generated and branch) are forced to X. This allows providing better isolation of the violations. For example, if the source of a branch clock is driven by a constant, it will be reported once by [DFT_C2](#), yet [DFT_C1](#) and [DFT_C6](#) will still allow checking that the memories and the scan elements are properly driven by the branch clock.

- [dft_glb_fe](#)

This simulation context is created on top of the [dft_glb](#) simulation context. All func_en pins of clock gaters are forced to their active value. The func_en pins are typically learned or specified in the Tessent cell library. When the clock gaters are not cells described in the Tessent cell library, they are declared using the “[add_dft_clock_enables](#)-usage func_en” command. The tool only forces the clock gaters in the combinational fanin of memory clocks, branch clocks, or the reference of generated clocks. The other clock gaters are not forced so as not to disturb the test_setup logic that may be holding their state using those other clock gaters. This is because those clock gaters are needed to remain off to maintain the value of the test_setup. If you need to have one of those forced, use the [add_dft_clock_enables](#) command to point directly in the func_en pin you want asserted anyway.

- [dft_glb_ns](#)

This simulation context is created on top of the [dft_glb](#) simulation context. The “nonscan_test” DFT signal is forced to its active value. The DFT signals with usage “logic_test_control” are forced to their reset value. The “scan_en” and the “edt_update” DFT signals are also forced to their inactive value. The target of the [add_dft_control_points](#) command using any of those DFT signals are forced accordingly taking into account the -inverse_dft_signal_source switch.

- [dft_glb_ns_fe](#)

This simulation context is created on top of the [dft_glb_ns](#) simulation context. All func_en pins of clock gaters are forced to their active value. The func_en pins are typically learned or specified in the Tessent cell library. When the clock gaters are not cells described in the Tessent cell library, they are declared using the “[add_dft_clock_enables](#)-usage func_en” command. The tool only forces the clock gaters in the combinational fanin of memory clocks, branch clocks, or the reference of generated clocks. The other clock gaters are not forced so as not to disturb the test_setup logic that may be holding their state using those other clock gaters. This is because those clock gaters are needed to remain off to maintain the value of the test_setup. If you need to have one of those forced, use the [add_dft_clock_enables](#) command to point directly in the func_en pin you want asserted.

- [dft_glb_ns_fe_tck](#)

This simulation context is created on top of the [dft_glb_ns_fe](#) simulation context. The tck_select DFT signal is forced to its active value, justifying TCK onto the functional clock trees.

- [dft_glb_ns_fe_x](#)

This simulation context is created on top of the [dft_glb_ns](#) simulation context. All func_en pins of clock gaters are forced to X. The func_en pins are typically learned or specified in the Tessent cell library. When the clock gaters are not cells described in the Tessent cell library, they are declared using the “[add_dft_clock_enables -usage func_en](#)” command. The tool only forces the clock gaters in the combinational fanin of memory clocks, branch clocks, or the reference of generated clocks. The other clock gaters are not forced so as not to disturb the test_setup logic that may be holding their state using those other clock gaters. This is because those clock gaters are needed to remain off to maintain the value of the test_setup. If you need to have one of those forced, use the [add_dft_clock_enables](#) command to point directly in the func_en pin you want asserted.

- [dft_glb_s](#)

This simulation context is created on top of the [dft_glb](#) simulation context. All DFT signals with usage “logic_test_control” are forced to their “value_during_pre_scan_drc” value. All DFT signal with usage “scan_mode” are forced to X. The DFT signal “edt_update” is forced to 0.

- [dft_glb_s_se_0](#)

This simulation context is created on top of the [dft_glb_s](#) simulation context. The “scan_en” DFT signal is forced to 0. The target of the [add_dft_control_points](#) command using the “scan_en” DFT signals are forced accordingly taking into account the -inverse_dft_signal_source switch.

- [dft_glb_s_se_0_te_1](#)

This simulation context is created on top of the [dft_glb_s_se_0](#) simulation context. All test_en pins of clock gaters are forced to their active value. The test_en pins are typically learned or specified in the Tessent cell library. When the clock gaters are not cells described in the Tessent cell library, they are declared using the “[add_dft_clock_enables -usage test_en](#)” command. Only the clock gaters that fanout to at least one DFF primitive with the is_non_scannable attribute equal to false are forced. The others clock gaters are not forced so as not to disturbed test_setup logic that may be holding their state using those other clock gaters. This is because those clock gaters are needed to remain off to maintain the value of the test_setup. If you need to have one of those forced, use the [add_dft_clock_enables](#) command to point directly in the test_en pin you want asserted.

- [dft_glb_s_se_0_te_x](#)

This simulation context is created on top of the [dft_glb_s_se_0](#) simulation context. All test_en pins of clock gaters are forced to X. The test_en pins are typically learned or specified in the Tessent cell library. When the clock gaters are not cells described in the Tessent cell library, they are declared using the “[add_dft_clock_enables](#) -usage test_en” command. Only the clock gaters that fanout to at least one DFF primitive with the is_non_scannable attribute equal to false are forced. The others clock gaters are not forced so as not to disturbed test_setup logic that may be holding their state using those other clock gaters. This is because those clock gaters are needed to remain off to maintain the value of the test_setup. If you need to have one of those forced, use the [add_dft_clock_enables](#) command to point directly in the test_en pin you want asserted.

- [dft_glb_s_se_x](#)

This simulation context is created on top of the [dft_glb_s](#) simulation context. The “scan_en” DFT signal is forced to X. The target of the [add_dft_control_points](#) command using the scan_en DFT signals are also forced to X.

- [dft_glb_s_se_1](#)

This simulation context is created on top of the [dft_glb_s](#) simulation context. The “scan_en” DFT signal is forced to 1. The target of the [add_dft_control_points](#) command using the scan_en DFT signals are forced accordingly taking into account the -inverse_dft_signal_source switch.

DFT_C1

Category: Clock

Context Supported: dft

Default Handling: Error

report_drc_rules: Supported

Verifies that each memory clock port has a defined clock in its controlling fanin. The default handling of this rule violation is error and cannot be changed.

This rule check is executed only for designs that have memory instances, as reported by the [report_memory_instances](#) command or when the [set_dft_specification_requirements](#) -memory_test command option are set to “on”. It is not executed in any other case or context. This DRC rule is performed using the [dft_glb_ns_fe](#) simulation context.

This rule check ensures that each clock pin on a memory instance is driven by a clock source that was previously defined with the [add_clocks](#) command. The check is performed with a backward trace from each memory instance clock pin. A rule violation occurs if the backward trace stops at a port or at a pin that has not been declared as a clock using the [add_clocks](#)

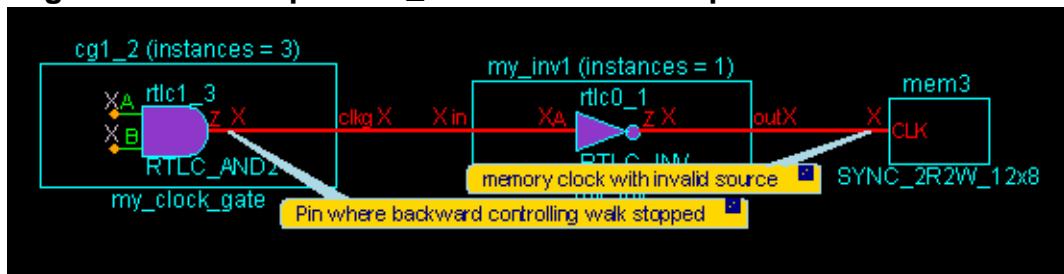

command. The tool will then report this port or pin in an error message similar to the one shown here:

```
// Error: The memory clock pin 'blockA_I1/mem1/CLKW' (23.28) source
// tracing stopped at pin 'pll_Inst/pll_out_2' (13.0)
// Correct the block conditions or use the 'add_clocks -period' if this
// is an embedded oscillator or 'add_clocks -reference' if this is an active
// PLL or clock divider. (DFT_C1-1)
```

This type of trace violation can have many different reasons. You should check your test_setup procedure and/or design constraints and ensure that they are properly sensitizing a controlling backward path from the memory instance clock pin to the design's clock source. If the blockage is caused by a clock gating cell, you can use the [add_dft_clock_enables](#) command to point to the functional enable pin. If the blockage is caused by a clock multiplexer where the select is controlled by uninitialized functional logic, you use the [add_dft_control_points](#) command.

Another typical situation that causes a backward path to be blocked is the presence of a black box instance in the path; this is shown in [Figure 7-25](#) where a PLL instance is black boxed. In this type of case, you can use the -reference or -reference_inv option of the [add_clocks](#) command to bridge the black box tracing gap. Assuming that this black box was an internal clock oscillator, you can use the [add_clocks -period](#) option to generate an internal clock source (for example, `add_clocks pll_Inst/pll_out_2 -period 10ns`). If you have an associated ICL module for the PLL or embedded oscillator module, the [add_clocks](#) command will automatically be inferred as described in the Description section of the [add_clocks](#) command.

Figure 7-25. Example DFT_C1 violation in the presence of a blackbox

The error messages generated by those checks are listed in [Table 7-4](#).

Table 7-4. Error Messages Generated by the Clock Tracing Checks

Type 1: The <clock> source tracing stopped at <location>. Correct the blocking conditions or use the 'add_clocks -period' if this is an embedded oscillator or 'add_clocks -reference' if this is an active PLL or clock divider.
Type 2: The <clock> is sourced by port <post> but its period was not defined using the 'add_clocks -period' command.
Type 3: The <clock> is sourced by a constant value of '0'.
Type 4: The <clock> has no source.

Table 7-4. Error Messages Generated by the Clock Tracing Checks (cont.)

Type 5: The memory <clock> source tracing stopped at <location> and this node was the target of an add_dft_clock_mux. An add_dft_clock_mux node can only be behind a clock, and cannot feed directly to the memory clocks.

If a clock becomes differential, the differential buffer must be modeled with a WIRE gate as shown below:

```
model diff_buf (out_p, out_n, in_p, in_n) (
    input (in_p, in_n) (
        output (out_p, out_n) (
            primitive = _inv (in_n, in_n_inv);
            primitive = _buf (in_p, in_p_buf);
            primitive = _wire (in_p_buf, in_n_inv, out_p);
            primitive = _inv (out_p, out_n);
        )
    )
)
```

[Figure 7-27](#) on page 2754 shows the schematic view of a differential clock path as well as the flat model representation. When a backward trace reaches a WIRE gate, a set of checks is performed to make sure the differential clock path is correct. The error messages generated by those checks are listed in [Table 7-5](#) on page 2753.

Table 7-5. Error Messages Generated by Differential Clock Checks

Type 1: The <clock> became differential but failed a rule along the differential clock path. A side of the differential pair traced to an add_dft_clock_mux location <location> which is illegal for a differential signal.
Type 2: The <clock> became differential but only one side of the differential source traced to a defined clock source. When one element of a differential clock reaches a defined clock, the other must too.
Type 3: The <clock> became differential but failed a rule along the differential clock path. A side of the differential pair traced to a constant value.
Type 4: The <clock> became differential but it reached a source on one of the differential sides that is not a declared clock nor a WIRE gate used to model a differential buffer.
Type 5: The <clock> became differential but reached two different WIRE gates. A differential buffer must be modeled with a single 2 input WIRE gate.
Type 6: The <clock> became differential but the inversion from the two inputs of one WIRE gate was different when reaching the other WIRE gate. A Differential clock buffer is modeled with a WIRE gate and there must be no relative inversion between the two input of the WIRE gate and the WIRE gate sourcing them.
Type 7: The memories on clock domain <domain_label> are sourced by two different differential clock buffers: <differential buffer 1> <differential buffer 2> You must separate them into two clock domains using 'add_clock <clock> -branch' on at least one of them.

Table 7-5. Error Messages Generated by Differential Clock Checks (cont.)

Type 8: The differential clock <p_side> and <n_side> reached a WIRE gate but the inversion from both of them was not different when reaching that WIRE gate.

Figure 7-26 shows example of a violation that is generated when an inverter is added on one side of the differential clock path and not on the other.

Figure 7-26. Example DFT_C1 Violation on Differential Clocks

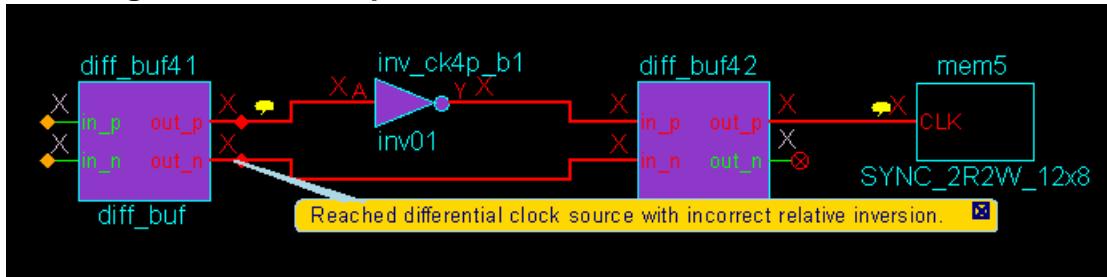

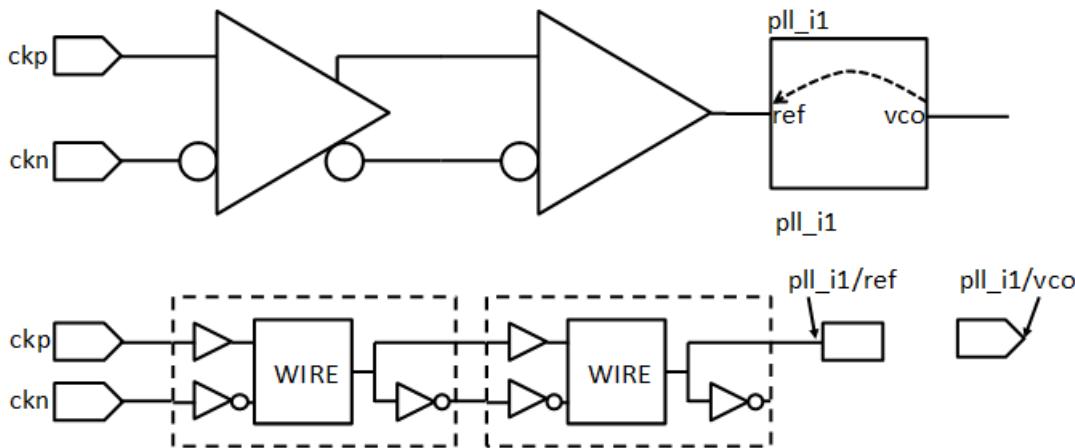

Figure 7-27. Schematic and Flat Model View of a Differential Clock Path

DFT_C2

Category: Clock

Context Supported: dft

Default Handling: Error

report_drc_rules: Supported

Verifies that each clock of type “branch” has a defined clock in its controlling fanin. The default handling of this rule violation is error and cannot be changed.

This rule check is executed only for designs that have designed branch clocks (as defined using the [add_clocks](#) -branch command) and when the [-memory_test](#) and/or [-logic_test](#) option of the [set_dft_specification_requirements](#) command is set to “on”. It is not executed in any other case

or context. It is not executed in any other case or context. This DRC rule is performed using the [dft_glb_fe](#) simulation context.

This rule check ensures that each identified clock of type branch (as defined by the [add_clocks](#)-branch option) is driven by a clock source defined using the [add_clocks](#) command. The check is performed using a backward trace from each clock branch. A rule violation occurs if the backward trace ends at a port or instance pin that has not been declared as a clock using the [add_clocks](#) command as shown in [Figure 7-26](#). The tool reports the port or pin where the traced stopped as shown in the error message below:

```
// Error: The clock branch 'clk_B_buf_2/Y' (1706.0) is sourced by
// 'clk_B' (2.0) but the source was not declared as a clock using the
// 'add_clocks' command. (DFT_C2-1)
```

This type of a trace violation can have many different reasons. You should check your test_setup procedure and/or design constraints to ensure that they are properly sensitizing a controlling backward path from the memory instance clock pin to the design's clock source. If the blockage is caused by a clock gating cell, you can use the [add_dft_clock_enables](#) command to point to its functional enable pin. If the blockage is caused by a clock multiplexer where the select is controlled by uninitialized functional logic, you can use the [add_dft_control_points](#) command. Finally, to inject an alternative source to a clock net, you use the [add_dft_clock_mux](#) command.

Another typical situation that causes a backward path to be blocked is the presence of a black box instance in the path. In this case, you can use the -reference or -reference_inv option of the [add_clocks](#) command to bridge the black box tracing gap. Assuming that the black box was an internal clock oscillator, you can use the [add_clocks](#)-period option to generate an internal clock source (for example, [add_clocks pll_Inst/pll_out_2 -period 10ns](#)). If you have an associated ICL module for the PLL or embedded oscillator modules, the [add_clocks](#) command will automatically be inferred as described in the Description section of the [add_clocks](#) command.

See [Figure 7-25](#) and [Figure 7-26](#) in the [DFT_C1](#) section for examples showing how the violations are displayed in the schematic. The error messages generated when checking the rules are listed in [Table 7-4](#) and [Table 7-5](#). The bottom error message in [Table 7-4](#) and the bottom two error messages in [Table 7-5](#) are only relevant to [DFT_C1](#) and do not apply to [DFT_C2](#).

DFT_C3

Category: Clock

Context Supported: dft

Default Handling: Error

report_drc_rules: Supported

Vерifies that each generated clock has a defined clock in the controlling fanin of its reference. The default handling of this rule violation is error and cannot be changed. For a description of what constitutes a generated clock, see the description of the `add_clocks` command.

This rule check is executed only for designs that have defined, generated clocks (as defined using the `add_clocks`-reference command) and when the -memory_test and/or the -logic_test options of the `set_dft_specification_requirements` command is set to "on". It is not executed in any other case or context. This DRC rule is performed using the `dft_glb_fe` simulation context.

The check is performed using a backward trace from the specified reference and optional reference inverse pin. A rule violation occurs if the backward trace ends at a port or a pin that has not been declared as a clock using the `add_clocks` command. The tool reports the port or pin where the trace stopped in an error message similar to the one shown here:

```
// Error: The reference pin 'clk_REF' (3.0) of the derived clock source
// at 'pll_Inst/pll_out_2' (5.0) is sourced by 'clk_REF' (3.0)
// but the source was not declared as a clock using the 'add_clocks'
// command. (DFT_C3-1)
```

This type of a trace violation can have many different reasons. You should check your test_setup procedure and design constraints to ensure that they are properly sensitizing a controlling backward path from the memory instance clock pin to the design's clock source. If the blockage is caused by a clock gating cell, you can use the `add_dft_clock_enables` command to point to its functional enable pin. If the blockage is caused by a clock multiplexer where the select is controlled by uninitialized functional logic, you can use the `add_dft_control_points` command. Finally, to inject an alternative source to a clock net, you use the `add_dft_clock_mux` command.

Another typical situation that causes a backward path to be blocked is the presence of a black box instance in the path. In this case, you can use the -reference or -reference_inv option of the `add_clocks` command to bridge the black box tracing gap. Assuming that the black box was an internal clock oscillator, you can use the `add_clocks`-period option to generate an internal clock source (for example, `add_clocks pll_Inst/pll_out_2 -period 10ns`). If you have an associated ICL module for the PLL or embedded oscillator modules, the `add_clocks` command will automatically be inferred as described in the Description section of the `add_clocks` command.

See [Figure 7-25](#) and [Figure 7-26](#) in the [DFT_C1](#) section for examples showing how the violations are displayed in the schematic. The error messages generated when checking the rules are listed in [Table 7-4](#) and [Table 7-5](#). The bottom error message in [Table 7-4](#) and the bottom two error messages in [Table 7-5](#) are only relevant to [DFT_C1](#) and do not apply to [DFT_C3](#).

DFT_C4

Category: Clock

Context Supported: dft

Default Handling: Error

report_drc_rules: Supported

Verifies that a clock of type “generated” or “branch” is not itself in the fanin of its reference source. A generated clock is a clock that was defined with the add_clocks -reference option specified. The default handling of this rule violation is error and cannot be changed.

This DRC rule is performed using the [dft_glb_ns_fe](#) simulation context. This rule check is executed only for designs that have declared branch clocks (as defined using the [add_clocks -branch](#) command) or generated clocks (as defined using the [add_clocks -reference](#) command) and when the [-memory_test](#) option of the [set_dft_specification_requirements](#) command is set to “on”. It is not executed in any other case or context.

This rule check ensures that the reference of each generated clock source traces to a source that is not affected by itself. A rule violation occurs if a loop is detected in the fanin of the referenced pin. The tool reports the violation as shown below. The schematic that is shown you issue the [analyze_drcViolation](#) command highlights the circular path:

```
// Error: The reference pin 'clk_pll_buf/Y' (1683.0) of the derived clock
// source at 'pll_Inst/pll_out_3' (5.0)
// is driven by itself via the clock source. (DFT_C4-1)
```

Figure 7-28. Example of DFT_C4 Violation

DFT_C5

Category: Clock

Context Supported: dft

Default Handling: Error

report_drc_rules: Supported

Verifies that each clock source has a specified period set using the “add_clocks -period” command. The default handling of this rule violation is error and cannot be changed.

This rule check is executed only for designs that have memory instances or declared generated or branch clocks and when the [-memory_test](#) option of the [set_dft_specification_requirements](#) is set to “on”. It is not executed in any other case or context. This rule does not use a simulation context. It simply verifies the source of the clock extracted by [DFT_C1](#), [DFT_C2](#), and [DFT_C3](#) have a specified period so that the SDC clocks with a known period can be created later in the flow when running the [extract_sdc](#) command. The clock periods are also used by the

[create_patterns_specification](#) when creating the signoff and manufacturing patterns specification wrappers.

This rule check ensures that each clock has a well-defined period.

A rule violation occurs if a clock source is found that does not have a well-defined period, as shown in this example:

```
add_clocks clk_REF
# add_clocks clk_REF -period 100ns
add_clocks clk_A -pulse_always -period 10ns
add_clocks clk_B -period 15ns

add_clocks pll_Inst/pll_out_1 -reference_pin clk_REF
add_clocks pll_Inst/pll_out_2 -reference_pin clk_REF

check_design_rules
```

Notice that the clock port “clk_REF” does not have a defined period. However, it is used as the reference of the generated clocks pll_Inst/pll_out_1 and pll_Inst/pll_out_2. The tool reports a violation for the above example as shown here:

```
// Error: The clock 'clk_REF' must be defined with a period.
//         The clock is used by memory_bist. (DFT_C5-1)
```

DFT_C6

Category: Clock

Context Supported: dft

Default Handling: Error

report_drc_rules: Supported

Verifies that each scannable flip-flop clock port has a defined clock in its controlling fanin. The default handling of this rule violation is error and cannot be changed.

This rule check is executed when the [set_dft_specification_requirements -logic_test](#) command option is set to “on”. It is not executed in any other case or context. This DRC rule is performed using the [dft_glb_s_se_0_te_1](#) simulation context.

This rule check ensures that each clock pin on a scannable flip-flop is driven by a clock source that was previously defined with the [add_clocks](#) command. The check is performed with a backward trace from each scannable flip-flop instance. The clock gaters which becomes open because of the [dft_glb_s_se_0_te_1](#) simulation context are verified for proper operation in [DFT_C8](#). A rule violation occurs if the backward trace stops at a port or at a pin that has not

been declared as a clock using the [add_clocks](#) command. The tool will then report this port or pin in an error message similar to the one shown here:

```
// Error: The clock pin 'blockA_I1/mem1/CLKW' (23.28) source
// tracing stopped at pin 'pll_Inst/pll_out_2' (13.0)
// Correct the block conditions or use the 'add_clocks -period' if this
// is an embedded oscillator or 'add_clocks -reference' if this an active
// PLL or clock divider. (DFT_C6-1)
```

This type of trace violation can have many different reasons. You should check your test_setup procedure and/or design constraints and ensure that they are properly sensitizing a controlling backward path from the scannable flip-flop instance clock pin to the design's clock source. If the blockage is caused by a clock gating cell, you can use the “[add_dft_clock_enables](#) -usage test_en” command to point to the test_en enable pin. If the blockage is caused by a clock multiplexer where the select is controlled by uninitialized functional logic, you use the [add_dft_control_points](#) command.

Another typical situation that causes a backward path to be blocked is the presence of a black box instance in the path where a PLL instance is black boxed. In this type of case, you can use the -reference and -reference_inv option of the [add_clocks](#) command to bridge the black box tracing gap. Assuming that this black box was an internal clock oscillator, you can use the [add_clocks](#) -period option to generate an internal clock source (for example, add_clocks pll_Inst/pll_out_2 -period 10ns). If you have an associated ICL module for the PLL or embedded oscillator module, the [add_clocks](#) command will automatically be inferred as described in the description section of the [add_clocks](#) command. See the description of the [ProcedureStep](#) wrapper for an example of such ICL module.

The error messages generated by those checks are listed in [Table 7-6](#). [Figure 7-29](#) below is an example of the schematic shown when the [analyze_drcViolation](#) command is issued on a Type 1 violation.

Figure 7-29. Example DFT_C6 Violation

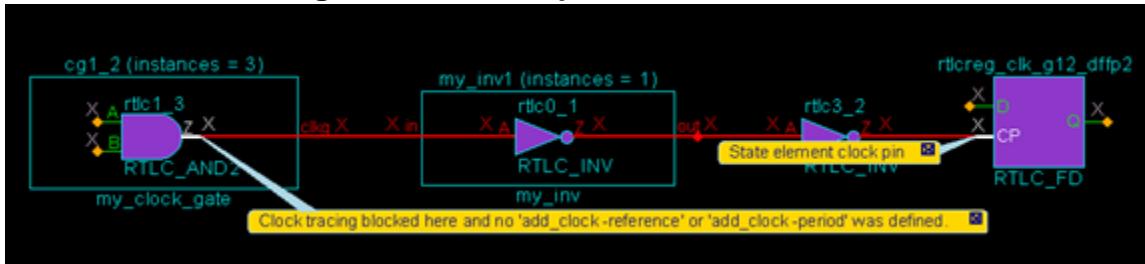

Table 7-6. Error Messages Generated by the Clock Tracing Checks

Type 1: The <clock> source tracing stopped at <location>. Correct the blocking conditions or use the “ add_clocks -period ” command if this is an embedded oscillator or “ add_clocks -reference ” if this is an active PLL or clock divider.

Type 2: The <clock> is sourced by port <post> but its period was not defined using the “ add_clocks -period ” command.
--

Table 7-6. Error Messages Generated by the Clock Tracing Checks (cont.)

Type 3: The <clock> is sourced by a constant value of “0”.
Type 4: The <clock> has no source.
Type 5: The scannable flip-flop <clock> source tracing stopped at <location> and this node was the target of an add_dft_clock_mux. An add_dft_clock_mux node can only be behind a clock, and cannot feed directly to the memory clocks.

For differential paths, the same handling of different clocks shown in the [DFT_C1](#) description applies to DFT_C6 except that the start points are clock pins of scannable flip-flops instead of memory clocks.

DFT_C7

Category: Clock

Context Supported: dft

Default Handling: Error

report_drc_rules: Supported

Verifies that the clock gating cells in the fanin of memory clocks are properly implemented.

This rule check is executed only for designs that have memory instances or declared generated or branch clocks and when the -memory_test option of the [set_dft_specification_requirements](#) is set to “on”. It is not executed in any other case or context. This DRC rule is performed using the [dft_glb_s](#) simulation context. Any gate that was marked between a clock and a memory clock pin, a branch clock or the reference of a generated clock which becomes blocking when the simulation context is switch from [dft_glb_ns_fe](#) to [dft_glb_ns](#) is checked in this DRC rule.

Several checks are performed to verify that the clock gating meets the specific checks to make sure that they will remain compatible to logictest. You can use the [add_dft_control_points](#) command on the func_en pin to disable the clock gating completely. If you fail one of those violations, however, those clock gaters will remain untestable during logictest. Only clock gaters disabled by a specified or inferred [add_dft_clock_enables](#) signal are verified by this DRC. See [report_dft_clock_enables](#) for more information. The error messages generated by those checks are listed in [Table 7-7](#). clock gaters feeding branch clocks or the reference of generated clocks are disabled with the DFT signal “all_test” because they need to be disable in both the non-scan and scan based test modes.

Table 7-7. Error messages Generated by DFT_C7 Checks

A unique dft_clock_enable signal of type func_en could not be found in the fanin of <node>. The multiple dft_clock_enable signals of type func_en found in the fanins are: <node1> <node2> ...
The clock gating cell <instance> is a primitive cell of type <type>. A clock gating cell must be a primitive of type AND or OR.

Table 7-7. Error messages Generated by DFT_C7 Checks (cont.)

The clock gating cell 'clock_gate_and_bad1/and3/Y' is a primitive cell of type 'AND (OR)' but it has 3 inputs. Only 2 input primitives are allowed as clock gating cells.
The clock gating cell <node> has no latch in its enable path.
The clock gating cell <node> is an AND gate but the latch in its enable path is active high instead of active low.
The clock gating cell <node> has a latch in its enable path but its clock input is not connected to the same driver that feeds the clock input of the clock gating cell.
The clock gating cell <node> is an OR gate but the latch in its enable path is active low instead of active high.

DFT_C8

Category: Clock

Context Supported: dft

Default Handling: Error

report_drc_rules: Supported

Verifies that the clock gating cells in the fanin of scannable flip-flops are properly implemented. The default handling of this rule violation is error but it can be downgraded to warning.

This DRC rule is performed using the [dft_glb_s_se_0_te_x](#) simulation context. Any gate which was marked between a clock and a scan element which becomes blocking when the simulation context is switch from [dft_glb_s_se_0_te_1](#) to [dft_glb_s_se_0_te_x](#) is checked in this DRC rule.

This rule check is executed only for designs that have scannable flip-flops and when the [-logic_test](#) option of the [set_dft_specification_requirements](#) is set to “on”. It is not executed in any other case or context.

Several checks are performed to verify that the clock gating meets the specific checks to make sure that they will remain compatible to logictest. If you fail one of those violations, you can permanently disable the clock gater using “[add_dft_control_points -dft_signal ltest_en](#)” on the test_en pin of the clock gater. However, the fanin of the func_en pin of the clock gater will be untestable during logictest. Only clock gaters disabled by a specified or inferred [add_dft_clock_enables](#) signal are verified by this DRC. The error messages generated by those checks are listed in [Table 7-8](#). Note that those checks are run only if the clock gater is not a cell with the [simulation_function](#) attribute equal to “clock_gating_and” or “clock_gating_or”. Those clock gaters already go through a formal verification when the cell library is loaded and don’t need to be checked again. The formal check of the library parser is more flexible and allows NAND and NOR gates.

Table 7-8. Error messages Generated by DFT_C8 Checks

The clock gating cell <instance> is a primitive cell of type <type>. A clock gating cell must be a primitive of type AND or OR.
The clock gating cell 'clock_gate_and_bad1/and3/Y' is a primitive cell of type 'AND (OR)' but it has 3 inputs. Only 2 input primitives are allowed as clock gating cells.
The clock gating cell <node> has no latch in its enable path.
The clock gating cell <node> is an AND gate but the latch in its enable path is active high instead of active low.
The clock gating cell <node> has a latch in its enable path but its clock input is not connected to the same driver that feeds the clock input of the clock gating cell.
The clock gating cell <node> is an OR gate but the latch in its enable path is active low instead of active high.

DFT_C9

Category: Asynchronous Set Reset

Context Supported: dft

Default Handling: Error

report_drc_rules: Supported

Verifies that it is possible to disable the asynchronous set or reset pin of every scannable flip-flop. The default handling of this rule violation is error but it can be downgraded to ignore.

This rule check is executed only for designs that have scannable flip-flops, and when the -logic_test option of the [set_dft_specification_requirements](#) is set to “on”. It is not executed in any other case or context. This DRC rule is performed using the [dft_glb_s_se_1](#) simulation context.

Three types of errors can be generated by the DFT_C9 DRC, and they are all shown in [Table 7-9](#). The situation detected by the first two errors are not auto fixed and must be corrected explicitly. The situation detected by the last error is auto fixed if “[set_drc_handling](#) DFT_C9 -auto_fix” was specified or left to default to on.

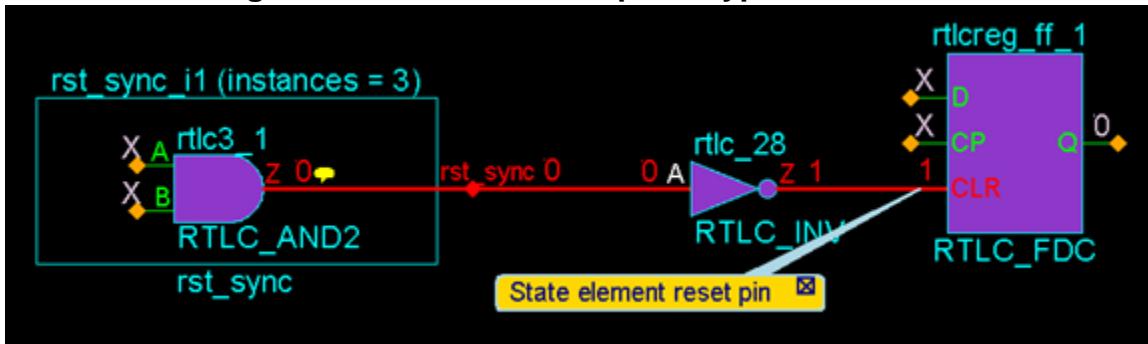

Table 7-9. Error messages Generated by DFT_C9 Checks

Type 1: When the async_set_reset source <node_name> is asserted '0' '1' <num1> set reset pins on DFFs are forced off but <num2> set reset pins on DFF are forced on. Use another 'add_dft_control_point' command to break the path to those flops or declare them as non-scannable using 'add_nonscan_instance' command. The list of set pins on DFF which are activated when the source is asserted '0' '1' are: <pin1> <pin2> ...
Type 2: The active high low set reset pin <gate_pin1> is sourced by <gate_pin2> and it has a constant simulated value of '1' '0' which forces the set reset pin active.

Table 7-9. Error messages Generated by DFT_C9 Checks (cont.)

Type 3: The active high|low set|reset pin <gate_pin1> source tracing stopped at pin <gate_pin2>. Correct the blocking conditions or use 'add_dft_control_point -type async_set_reset' to make it controllable during logic test

The first type of error reports nodes that source asynchronous set and reset of scannable flip-flops having different active polarity. You have two options to resolve this issue. Solution 1 is to use the “[add_dft_control_points nodes](#) -type [async_set_reset](#)” command to specify additional locations so that the active polarity of the asynchronous set and reset of all scannable flip-flop in the fanout of the specified **nodes** is the same. The other option is to declare the group of flip-flops listed in the error message as non-scannable using the [add_nonscan_instances](#) command. [Figure 7-30](#) is an example of the schematic shown when using the [analyze_drcViolation](#) command on a violation of type 1. The path between the source and one of the flops that has its set or reset pin forced on is shown. The source node is simulated to the value that makes the set or reset pins on on the minority group of scannable flip-flops.

Figure 7-30. DFT_C9 example of type 1 violation

The second type of error reports nodes that sources asynchronous set and reset pins of scannable flip-flops which simulate to a constant value and the constant value activates the set and reset pins of scannable flip-flops. To correct this situation, you must verify your [test_setup](#) procedure or your specified [add_dft_control_points](#) specification to understand if they not responsible for those scannable flip-flops to be held in reset or set. If this is truly the functional intent, declare those flip-flops as non-scannable using the [add_nonscan_instances](#) command.

The third type of error will not happen if you disable auto fixing by issuing the following command:

```
set_drc_handling DFT_C9 -auto_fix off
```

The tool traces the controlling fanin of the set/reset pins and issues the “[add_dft_control_points](#) -type [async_set_reset](#)” command and switch at the node where the trace stopped. The tool issues a summary message similar to the following:

```
// Note: There were 9 'add_dft_control_points -type async_set_reset'
// commands inferred from DRC. Use report_dft_control_points to see them.
```

Note

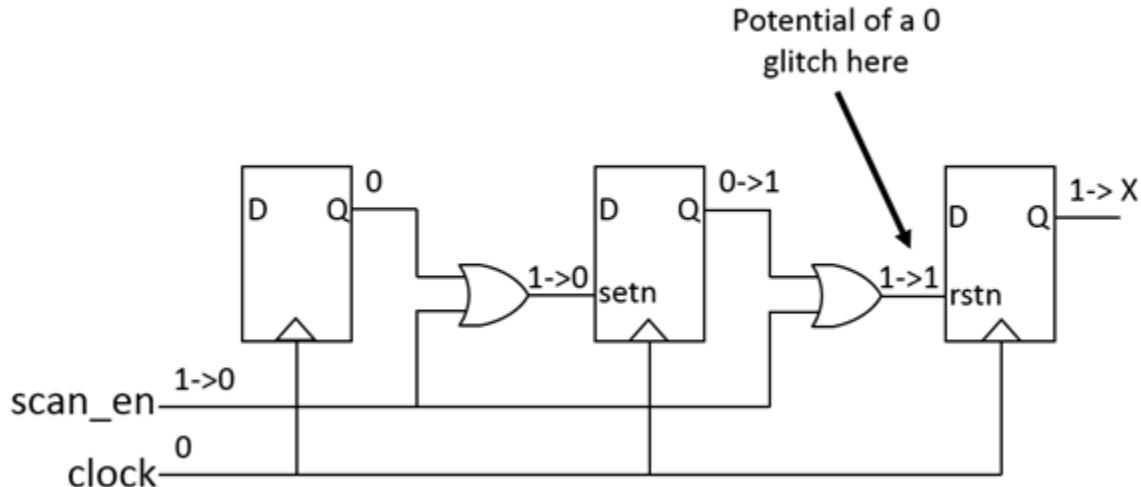

If the auto connection is inferred on a port of the current design and the port connects to the pad_io function of a pad cell, the DFT connection will be inserted on the core side of the pad buffer. If the boundary scan cell is already inserted, it will be connected on the core side of the boundary scan cell. If there is no boundary scan cell associated to the port, it will connect to the from_sji_mux function when it exists, otherwise it will connect to the from_pad function.

If you are running on a gate-level netlist, it is possible that you will have more inferred DFT control than was actually needed. This happens when the synthesis tools perform complex restructuring and introduced X re-convergence logic in the set and reset logic paths. This is rare in RTL because the quick synthesis tool does not do any restructuring. If it happens in the RTL, then it means you have X re-convergence logic coded in your RTL. To remove this pessimism, explicitly specify the “[add_dft_control_points](#)-type `async_set_reset`” commands on the nodes where you want them to be, and the nodes will be simulated to determine their effects. If the DRC is able to force the specified node to a value to make all the asynchronous set and reset of the scannable flop-flop in its fanout inactive, then the presence of X re-convergence path will not matter.

If you have set or reset signals going to flip-flops which themselves are the source of the set or reset signals of other flip-flops, the tool performs an extra check to verify that no race condition can occur in the scan test when the `scan_en` signal is toggled from 1 to 0.

As shown in [Figure 7-31](#), the race condition happens if the reset/set value of the flip-flops feeding the set or reset signals of the other flip-flops is the inactive value for the set or reset signals of the other flip-flops. When `scan_en` goes low, the gating of the resets is removed. If the source flop was scan loaded with the active value for the set or reset signals of the flip-flops it drives and its reset becomes active when `scan_en` goes low, the flip-flops in the fanout may or may not be reset.

Figure 7-31. Race Condition Check

If the source flop had time to reset to the inactive value before the scan_en released the set/reset signal of the flip-flops in its fanout, the flip-flops in the fanout may not be reset or set.

Conversely, if the source flop did not have time to reset to its inactive value before the scan_en released the set/reset signal of the flip-flops in its fanout, the flip-flops in the fanout will be reset or set.

ATPG will most often recognize this situation and X out the state of the destination flip-flops, which causes lots of masking. To prevent the race, the set or reset signal of the source or destination flip-flops is disabled with the ltest_en signal instead of the scan_en signal based on which one has less affected logic that can no longer be tested. When this happens, the tool issues the following note:

```
// Note: The DFT_C9 DRC found the following node sourcing set reset pins
//        of scannable flip-flops:
//        rst
//        It is disabled with 'ltest_en' because it is involved in a
//        cascaded set/reset configuration that generates glitches during
//        scan test.
```

DFT_C10

Category: Clock

Context Supported: dft

Default Handling: Error/Warning

report_drc_rules: Supported

Verifies that an injection node for an OCC or TCK MUX can properly control a clock source. The default handling of the rule violation is a warning for the logic test DFT specification, and an error for the -dft etchecker sub context.

This rule check is executed with severity warning if you issue the [set_dft_specification_requirements](#) command with the -logic_test switch as follows:

```
set_dft_specification_requirements -logic_test on
```

It is executed with a severity of error in the context dft -etchecker.

The validated DFT injection node can then be used using the “get_clock_option -dft_inject_node” command and switch to determine where to inject the TCK multiplexer—see the [-tck_injection](#) switch description to the [set_dft_specification_requirements](#) command.

You can upgrade or downgrade this DRC to error, warning, note, or ignore using the [set_drc_handling](#) command.

You specify the DFT injection node when you create a new clock using the “add_clocks -dft_inject_node” command and switch. To specify the injection node for an existing clock, use the “set_clock_options -dft_inject_node” command and switch. This DRC rule is performed using the [dft_glb_s_se_0_te_1](#) simulation context.

The DFT_C10 runs to ensure that the injected DFT node meets the following requirements:

- Only one injection node should be defined for a clock source. The clock source can be an ordinary clock source (a primary pin) or a derived clock source (for example, a PLL output).
- An injection node does fanout to scan elements and memories as the corresponding clock source.
- The DFT inject node is in the controlling fanout of a defined clock source. In case of differential inputs, the DFT inject node is the node or is in the controlling fanout of the node where the clock became single ended.
- All scan elements sourced by clock source are in the fanout of the DFT inject node.
- There are no references of generated clock in the fanout of the DFT inject node.
- All branch clocks sourced by a clock source are in the fanout of the DFT inject node.
- The injection node is not specified where a constant setting is propagated or the node is open.
- An injection node has to be specified in case of a clock source that is driving a generated clock source reference and scan elements/memories.
- The path between the clock source and the injection node must be transparent to ensure that the above rules can be fully checked.

Table 7-10. Error and Warning Messages Generated by DFT_C10

Warning/Error: The backward tracing from the specified -dft_inject_node '<injection_node>' did not reach the clock '<defined_clock_source>'. The tracing stopped at node '<tracing_end_node>'. [<stop_location_reason_addendum>] (DFT_C10-x).
Warning/Error: The backward tracing from the specified -dft_inject_node '<injection_node>' which is where the clock '<defined_clock_source>' becomes single ended at node <differential_output_node>. The tracing stopped at node '<tracing_end_node>'. (DFT_C10-x).
Warning/Error: Clock '<clock_source>' fanouts to ['<number>' scannable element[s]] [and] ['<number>' BIST'ed memory cell inputs[s]] which [is][are] not in the fanout of the specified -dft_inject_node '<injection_node>', which are 'failing_element_1' 'failing_element_2' ... 'failing_element_10' (DFT_C10-x)
Warning/Error: The clock source '<clock_source>' is the source of the reference of the generated clock '<gen_clock_source>' and require the specification of a correct injection node. Use 'set_clock_option clk -dft_inject_node' to specify a node that matches the following criteria: 1) The DFT inject node is in the controlling fanout of '<clock_source>'. 2) All scan elements and all memories sourced by '<clock_source>' are in the fanout of the DFT inject node. 3) There are no references of generated clock in the fanout of the DFT inject node. 4) There are no branch clocks in the fanout of the DFT inject node. (DFT_C10-x)

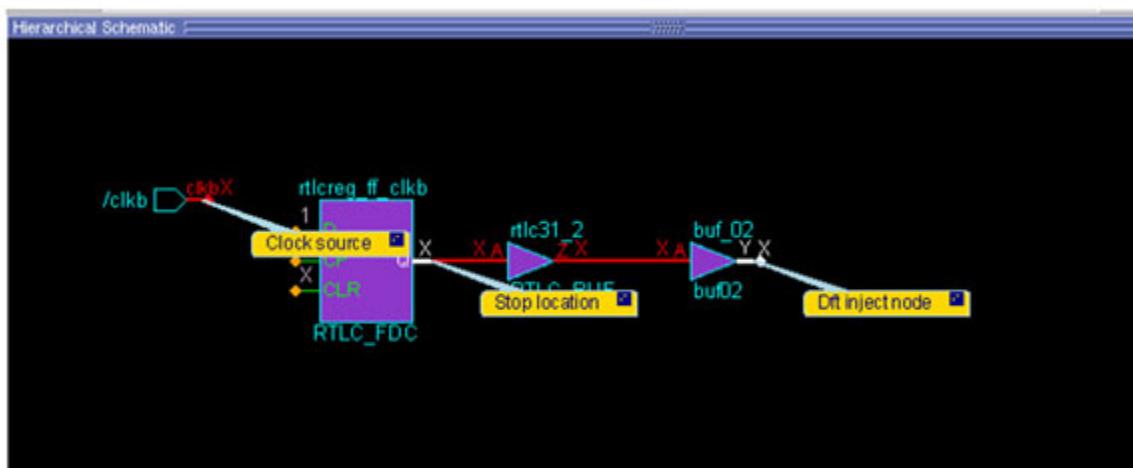

Table 7-10. Error and Warning Messages Generated by DFT_C10 (cont.)

Warning/Error: The clock source '<clock_source>' is the source of the reference of the generated clock '<gen_clock_source>' and require the specification of a correct injection node. Use 'set_clock_option <clock_source> -dft_inject_node' to specify a node that matches the following criteria: 1) The DFT inject node is in the controlling fanout of '<clock_source>'. 2) All scan elements and memories sourced by '<clock_source>' are in the fanout of the DFT inject node. (DFT_C10-x)
Warning/Error: The branch clock '<clock_branch_node>' is sourced by the clock '<clock>' without going through its "dft_inject_node '<injection_node>'." (DFT_C10-x)
Warning/Error: The specified -dft_inject_node '<injection_node>' for clock '<clock_source>' has no source. (DFT_C10-x)
Error/Warning: The clock '<clock_source>' is the source of the branch clock '<clock_branch_node>' and require the specification of a correct injection node. Use 'set_clock_option <clock_source> -dft_inject_node' to specify a node that matches the following criteria: 1) The DFT inject node is in the controlling fanout of '<clock_source>'. 2) All scan elements and all memories sourced by '<clock_source>' are in the fanout of the DFT inject node. 3) There are no references of generated clock in the fanout of the DFT inject node. 4) There are no branch clocks in the fanout of the DFT inject node. (DFT_C10-x)
Error/Warning: The dft injection node '<injection_node>' is defined for the clock source '<clock_source_1>' and for the clock source '<clock_source_2>'. Only differential clock pairs can share the same injection node. (DFT_C10-x)
Warning/Error: The specified -dft_inject_node '<injection_node>' for clock '<clock_source>' has a constant value of <0/1>. (DFT_C10-x)

Examples

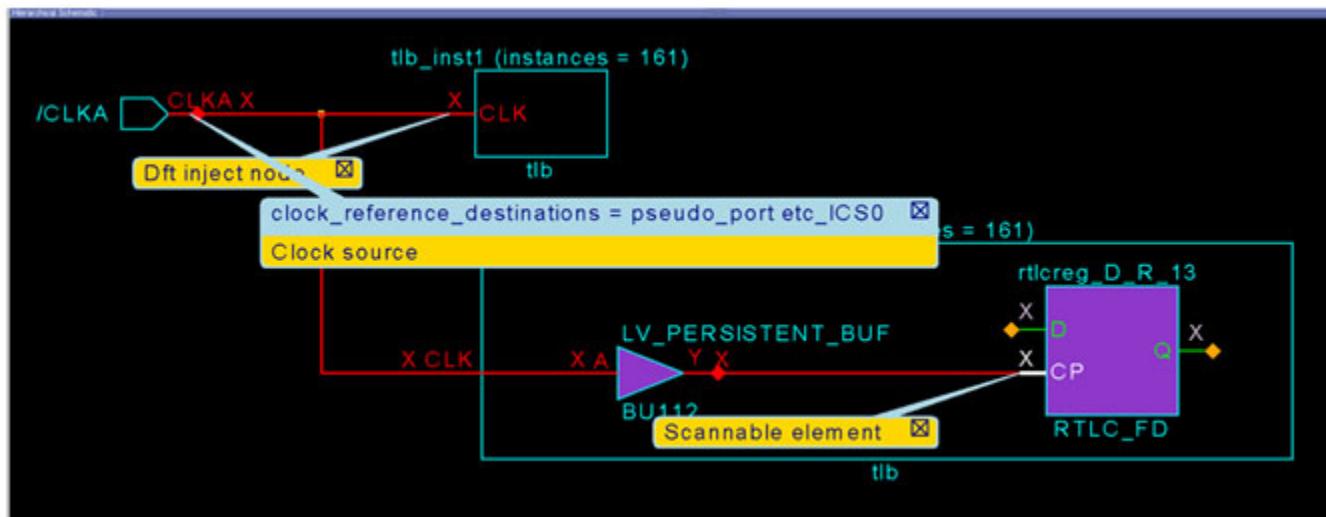

Example 1

```
// Error: The backward tracing from the specified -dft_inject_node
//        'buf_02/Y' did not reach the clock 'clkb'. The tracing stopped
//        at node 'rtlcreg_ff_clkb/Q'. (DFT_C10-6)
```

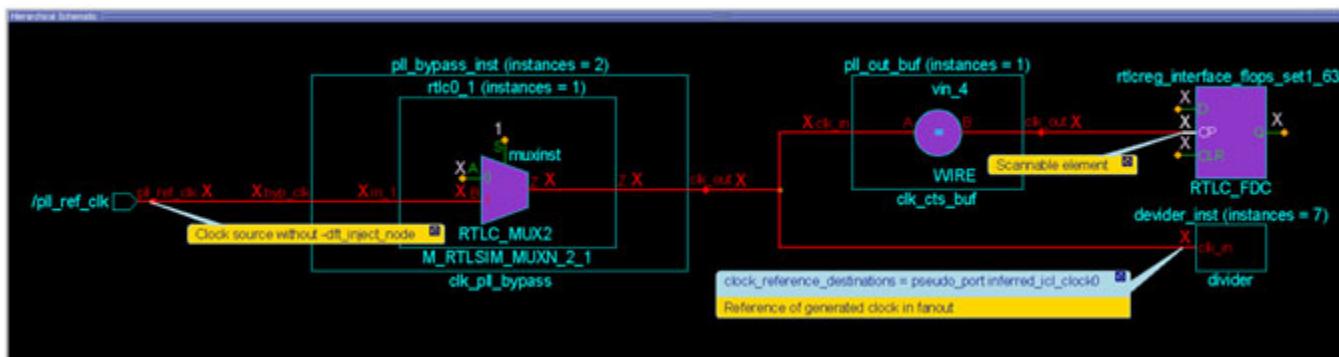

Example 2

```
// Error: The clock 'CLKA' fanouts to 156 scannable elements which are
// not the fanout of the specified -dft_inject_node 'tlb_inst1/CLK',
// which are:
//      'tlb_inst2/rtlcreg_D_R_13/CP'
//      'tlb_inst2/rtlcreg_D_R_12/CP'
//      'tlb_inst2/rtlcreg_D_R_11/CP'
//      'tlb_inst2/rtlcreg_D_R_10/CP'
//      'tlb_inst2/rtlcreg_D_R_9/CP'
//      'tlb_inst2/rtlcreg_D_R_8/CP'
//      'tlb_inst2/rtlcreg_D_R_7/CP'
//      'tlb_inst2/rtlcreg_D_R_6/CP'
//      'tlb_inst2/rtlcreg_D_R_5/CP'
//      'tlb_inst2/rtlcreg_D_R_4/CP'
//      ...
//      ... (DFT_C10-1)
```

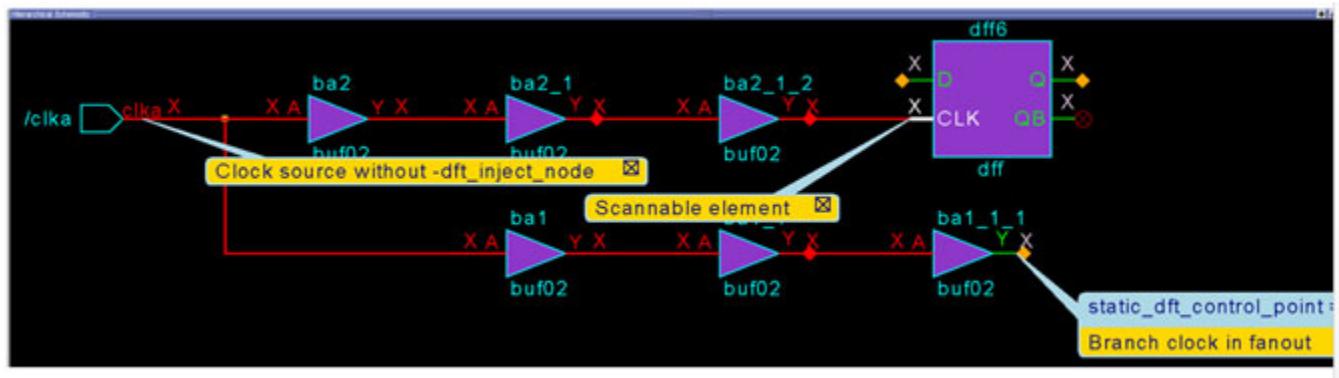

Example 3

```
// Error: The clock 'pll_ref_clk' is the source of the reference of the
// generated clock 'devider_inst/clk_out2' and requires the
// specification of a correct injection node.
// Use 'set_clock_option pll_ref_clk -dft_inject_node' to specify
// a node that matches the following criteria:
// 1) The DFT inject node is in the controlling fanout of
//    'pll_ref_clk'.
// 2) All scan elements and all memories sourced by
//    'pll_ref_clk' are in the fanout of the DFT inject node.
// 3) There are no references of generated clock in the fanout of
//    the DFT inject node.
// 4) There are no branch clocks in the fanout of the DFT inject
//    node. (DFT_C10-1)
```

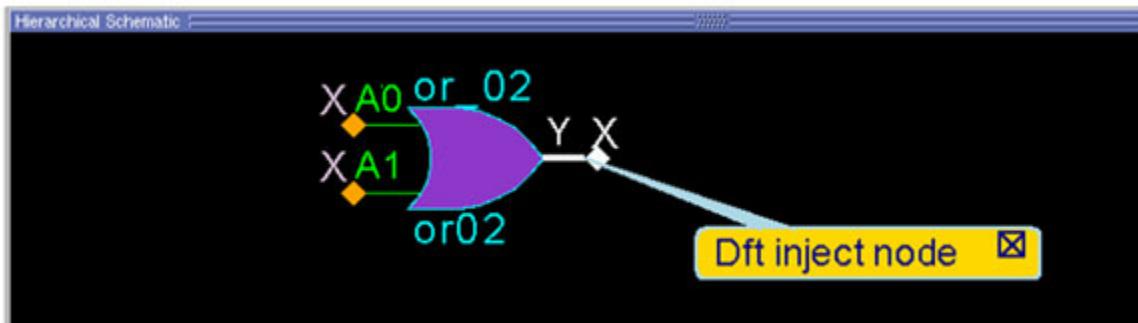

Example 4

```
// Error: The clock source 'clka' is the source of the branch clock
// 'ba1_1_1/Y' and require the specification of a correct
// injection node.
// Use 'set_clock_option clka -dft_inject_node' to specify a node
// that matches the following criteria:
// 1) The DFT inject node is in the controling fanout of 'clka'.
// 2) All scan elements and all memories sourced by 'clka' are in
//    the fanout of the DFT inject node.
// 3) There are no references of generated clock in the fanout of
//    the DFT inject node.
// 4) There are no branch clocks in the fanout of the DFT inject
//    node. (DFT_C10-1)
```

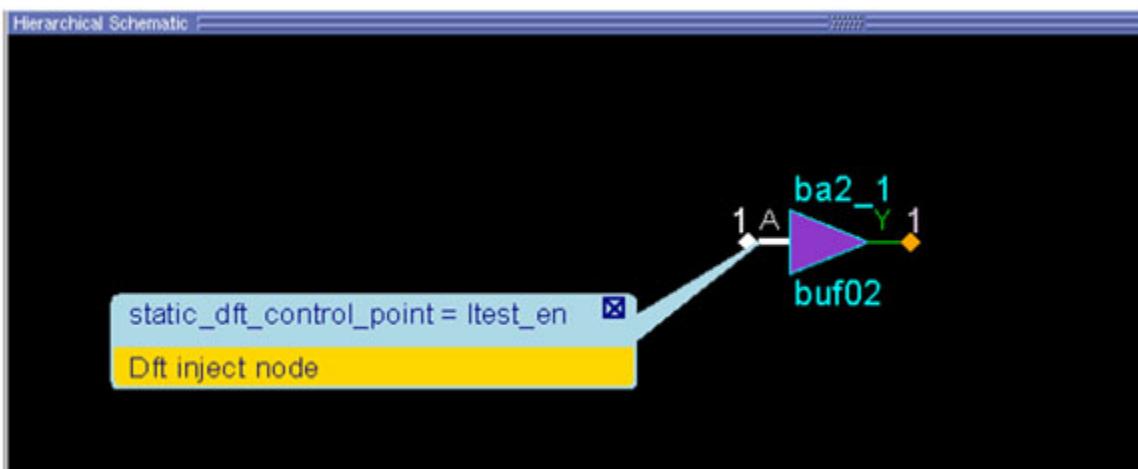

Example 5

```
// Error: The backward tracing from the specified -dft_inject_node
//          'or_02/Y' did not reach the clock 'clk1'. The tracing stopped
//          at node 'or2/Y'. (DFT_C10-2)
```

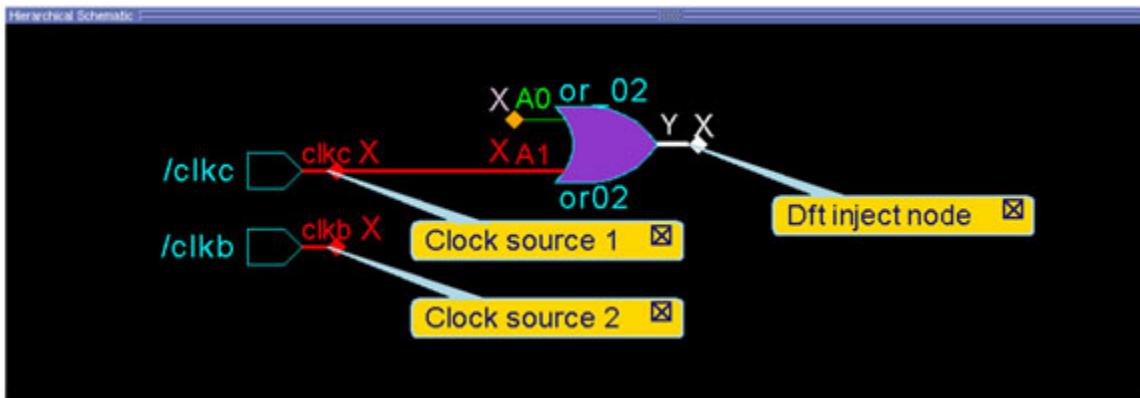

Example 6

```
// Error: The specified -dft_inject_node 'ba2_1/A' for clock 'clka' has a
//          constant value of 1. (DFT_C10-1)
```

Example 7

```
// Error: The dft injection node 'or_02/Y' is defined for the clock
// source 'clkc' and for the clock source 'clkb'.
// Only differential clock pairs can share the same injection
// node. (DFT_C10-1)
```

DFT_C11

Category: Clock

Context Supported: dft

Default Handling: Warning

report_drc_rules: Supported

Identifies and verifies the clock location and polarity for TCK mode injection. The default handling of this rule violation is warning, but it can be downgraded to note.

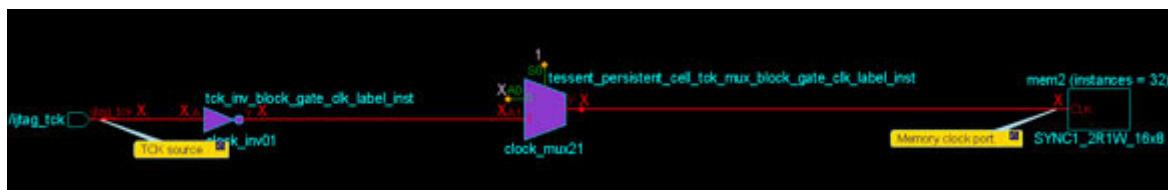

This DRC rule identifies clocks requiring the injection of TCK to run TCK mode patterns on all memories and child blocks. It also identifies existing TCK injection that is controlled by the tck_select DFT signal. The polarity of the existing TCK injection will be verified.

This rule check is executed only when the -tck_injection option of the `set_dft_specification_requirements` command is specified to “on” or “internal_sources_only”. This DRC rule is performed using the `dft_glb_ns_fe_tck` simulation context.

The warnings reported by this DRC rule are shown in [Table 7-11](#) and illustrated in the figure below.

Table 7-11. Warning Messages Generated by DFT_C11 Checks

The TCK clock that reaches the clock pin <clock_location> for TCK mode is inverted to the source. During TCK mode tests, memory BIST instruments require to be driven by a TCK that has a consistent polarity. The BAP, controllers and memory interfaces must receive an identical TCK clock. The polarity of TCK reaching the memory itself does not have to be consistent with the memory BIST instruments.

This warning reports existing TCK injection that could be incompatible with Tessent Shell's TCK mode. It is required that the TCK clock injected on the functional clock path, driving the memory BIST controllers and memory interfaces, be of the same polarity as the IJTAG network's TCK clock driving the memory BIST BAP. Since the polarity of the network's TCK clock is not yet known, this warning is issued.

DFT_C12

Category: Clock

Context Supported: dft

Default Handling: Error

report_dft_rules: Supported

Verifies that it is possible to edit the identified TCK injection points and verifies the direction for internal pin cases. The default handling of this rule violation is error, but it can be downgraded to note.

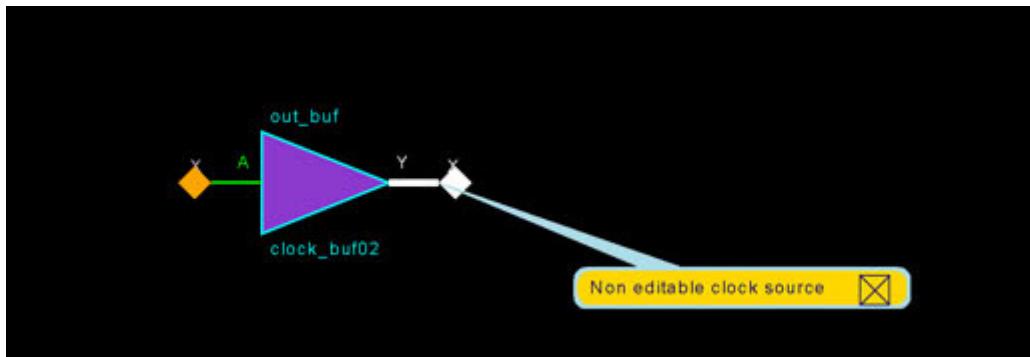

This rule check is executed only when the -tck_injection option of the `set_dft_specification_requirements` command is specified to “on” or “internal_sources_only”. This DRC rule is performed on the data collected during [DFT_C11](#).

Two types of errors are generated by this DRC rule:

The clock source <node_name> would require TCK injection but is not editable. Use the “-dft_inject_node” option of the `add_clocks` command to specify an editable location.

The clock source <clock_name> is pointing to input pin <node_name>. This is currently not supported for TCK injection. Define clocks on output pins or use the “-dft_inject_node” option of the `add_clocks` command to specify an output pin.

The first rule violation, illustrated in the figure below, occurs if a clock source requires the insertion of a clock mux and possibly an inverter for TCK injection, but that location is not editable.

The solution for this violation is to specify the first editable location following the clock source using the “-dft_inject_node” option of the [add_clocks](#) command. The other option is to downgrade the handling of this DRC, which will remove the violating locations reported from the [TCKInjectionPoints](#) wrapper during [create_dft_specification](#). The impact of this choice is that for TCK mode patterns, you will be required to inject TCK on the functional clock primary input port, bypassing any PLL or divider on the clock path.

The second error type reports a current limitation with TCK injection. TCK can only be injected on clocks defined on internal output pins. The solution is to define the clock on an output pin or to define an output pin using the “-dft_inject_node” option of the [add_clocks](#) command. If you choose to downgrade the handling of this DRC, the problematic <node_name> locations will be omitted from the [TCKInjectionPoints](#) wrapper during [create_dft_specification](#). The impact of this choice is that for TCK mode patterns, you will be required to inject TCK on the functional clock primary input port, bypassing any PLL or divider on the clock path.

DFT_C13

Category: Clock

Context Supported: dft

Default Handling: Error

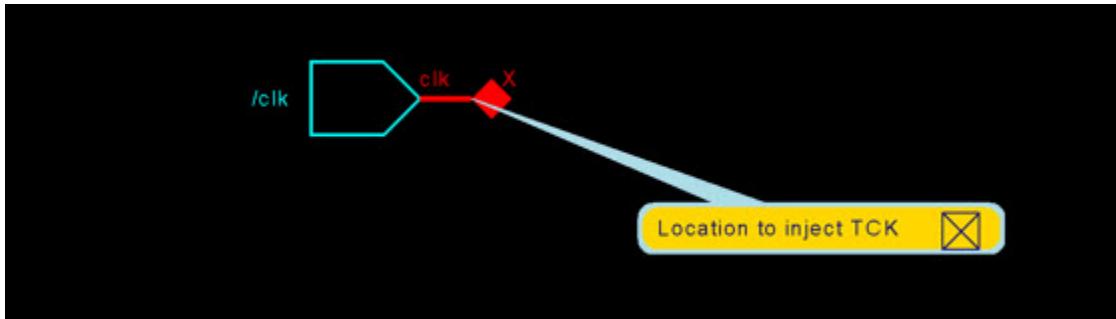

report_dft_rules: Supported

This rule verifies the existence or the scheduled addition of the required tck_select DFT signal.

This DRC rule is performed on the data collected during the [DFT_C12](#) rule check. DFT_C13 is executed only when the -tck_injection option of the [set_dft_specification_requirements](#) command is specified to “on” or “internal_sources_only”, and when clock locations have been identified for TCK injection.

The following error is generated if the tck_select DFT signal is not found, and illustrated in the figure below:

Clocks have been identified for TCK injection but the DFT signal tck_select does not exist. It is required to control the select of the inserted muxes. You must add the tck_select DFT signal to continue with the -tck_injection option of set_dft_specification_requirements.

The tck_select DFT signal is required to drive the select pin of the TCK injection muxes that will be inserted for memory BIST TCK mode. The solution for a DFT_C13 violation is to use the [add_dft_signals](#) command to add the tck_select signal. If it is chosen to downgrade the handling of this DRC to ignore, no TCK injection point will be identified and exported to the DftSpecification [TCKInjectionPoints](#) wrapper.

Extra Rules (E Rules)

Extra rules identify potential design requirement problems.

The following subsections describe the extra rules.

Tip

-  In DFTVisualizer, you can press Ctrl + R to execute a report_gates command on selected gates. For more information, see “[How to Report Gate Data](#).”

E1

Category: Extra

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Ignore

report_drc_rules: Supported

All scan cells must be LSSD scan cells that contain a master and a slave latch. They may also contain shadow latches. This rule is meant to enforce a strict LSSD architecture within a design. The application performs this check by inspecting the memory elements of all scan cells. The rule violation occurs when any memory element (that is not a latch or a scan cell) does not contain a SLAVE.

The default handling for this rule violation is ignore. Failure to satisfy this rule will have no effect. The occurrence message is:

MASTER N (G) is not an LSSD latch. (E1-1)

N is the instance name of the MASTER gate, and G is the gate ID number.

The summary message is:

N scan cells are not LSSD. (E1)

N is the number of occurrences of rules violation E1.

E2

Category: Extra

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Ignore

report_drc_rules: Supported

There must be no data inversion between adjacent scan cells, the scan chain input pin (SCI) and its adjacent scan cell, and the scan chain output pin (SCO) and its adjacent scan cell. The application performs this check by inspecting the inversion data for all scan cells. The rule violation occurs when any adjacent scan cells (including SCI and SCO) have an inversion difference.

The default handling for this rule violation is ignore. Failure to satisfy this rule will have no effect. The occurrence message is:

Scan chain has inversion between N1 (G1) and N2 (G2). (E2-1)

N1 is the instance name of one MASTER (or SCI) gate, G1 is its gate ID number, N2 is the instance name of the other MASTER (or SCO) gate, and G2 is its gate ID number.

The summary message is:

There were N scan chain inversions. (E2)

N is the number of occurrences of rules violation E2.

E3

Category: Extra

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Ignore

report_drc_rules: Supported

There must be no inversion between MASTER and SLAVE for any scan cell. The application performs this check by inspecting the inversion data for the memory elements of all scan cells. The rule violation occurs when the MASTER is inverted relative to its SLAVE.

The default handling for this rule violation is ignore. Failure to satisfy this rule will have no effect. The occurrence message is:

```
SLAVE N (G) is inverted relative to MASTER. (E3-1)
```

N is the instance name of the SLAVE, G is its gate ID number, and E3 is the rule ID number.

The summary message is:

```
There were N SLAVES inverted relative to MASTER. (E3)
```

N is the number of occurrences of rules violation E3.

E4

Category: Extra

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

Checks for conflicting values driving the same net during evaluation of the test procedures.

Tri-state drivers must not have conflicting values when driving the same net during the application of the test procedures. The tool performs this check using the simulated values of each time period of all test procedures except the capture procedure. A rule violation occurs if any bus gate is at an X state and two or more of its inputs are not at Z.

The default handling for this rule violation is warning.

Effect on Testability

Failure to satisfy this rule does not affect coverage, but will result in the risk of bus contention.

How to Debug E4 Violations

The occurrence message is:

```
Bus contention on N (G) occurred at time T of P procedure. (E4-1)
```

N is the instance/net name of the bus gate, G is the gate ID number, T is the time period, and P is the procedure name.

The summary message is:

There were N occurrences of bus contention in test procedures. (E4)

N is the number of times an E4 violation occurred.

You can access the simulated values at the gate where the error occurred by issuing the set_gate_report command with the Drc_pattern argument, then using the report_gates command to report the gate whose ID number is displayed in the error message. If this is the only DRC violation, or if you have changed the default handling to error, you can also view simulated values of the gate of interest by issuing set_gate_report with the Error_pattern argument prior to using report_gates. Gate reporting with the proper simulation data helps you identify the conflicting inputs; by tracing back from these inputs, you can identify how to correct the problem.

If you see an “A” appended to the “E4” in the occurrence message (E4-1-A for example), it indicates the occurrence is due to the tool aborting the E4 check before it was completed. As these are “possible” but unproven E4s, the tool may be able to screen out some of them if you raise the abort limit. Refer to “[Possible Resolutions](#)” for more information.

How to Debug with DFTVisualizer

To view the location of an E4 DRC violation using DFTVisualizer, use the following command steps:

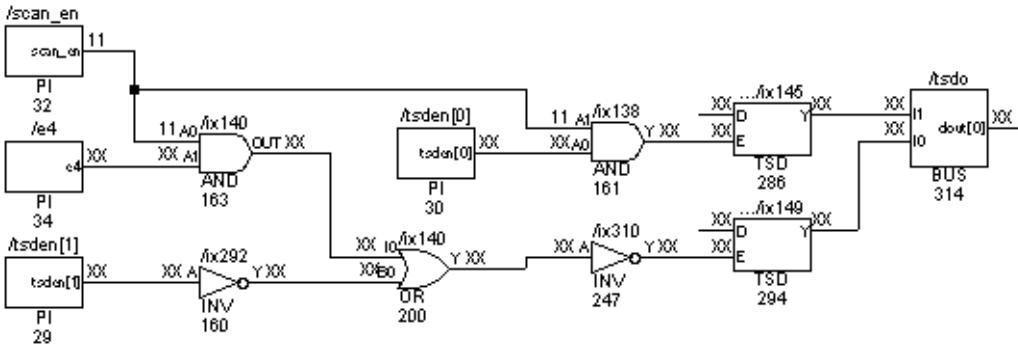

1. set_gate_level Primitive
2. open_visualizer

Choose the **DRC Violations** tab in the Design Browser window, then open the listed DRC’s by selecting the “+” symbols as needed to find the violation ID of the desired DRC violation. Double clicking the listed violation, or right clicking and selecting **Analyze DRC Violation** from the popup menu will analyze the violation. The tool will automatically change the gate reporting to “drc_pattern load_unload” and display the bus gate affected by that violation in the Flat Schematic window of DFTVisualizer.

Tip  Alternatively, you can issue the [analyze_drcViolation](#) command with the rule_id-occurrence# and -Display arguments at the tool’s command line. For example, to display the first occurrence of an E4 violation: analyze_drcViolation e4-1 -display

Once the offending bus gate is displayed, trace backward from the bus gate. [Figure 7-32](#) shows an example DFTVisualizer display of such a trace, where the starting point of the trace is the offending gate, /tsdo.

Figure 7-32. Example E4 Violation Trace in Flat Schematic Window of DFTVisualizer

How to Debug from the Tool Command Line

To view the location of the first occurrence of an E4 violation, use the following steps:

1. set_system_mode analysis
2. report_drc_rules E4-*occurrence#*
3. set_gate_level Primitive
4. set_gate_report Drc_pattern Load_unload
5. report_gates *gate_id*

The following transcript excerpts show an example of the use of this command sequence starting at step 2:

```
report_drc_rules e4-1
// Warning: Bus contention on /tsdo/dout [0] (314) occurred at time 0 of
// load_unload procedure. (E4-1)
set_gate_level primitive
set_gate_report drc_pattern load_unload
report_gates 314
// /tsdo (314) BUS
//     "I0"    I (XX)  294-/tsdo/ix149/Y
//     "I1"    I (XX)  286-/tsdo/ix145/Y
//     "OUT"   O (XX)  396-/dout [0]  330-
```

The Xs on the two inputs to the bus gate in this example are the source of the problem. A reasonable way to proceed is to choose one input and trace back through the gates driving it until you find the source of the Xs. For example, you might first look at where the “I0” input comes from:

```
report_gates 294
// /tsdo/ix149 (294)  TSD
//     E      I (XX)  247-/ix310/Y
//     "D"    I (XX)  221-
//     Y      O (XX)  314-
```

Notice the Xs on the enable (E) input. This input is of particular interest because an X here results in an X on the TSD's output regardless of the value on its D input. So tracing back from the enable would be a logical next step:

```
report_gates -endpoints -backward 247
// -----
// Begin backward trace for gate /ix310 (247).
// -----
// /tsden[1] (29) PI
//     tsden[1] O (XX) 160-/ix292/A
// /scan_en (32) PI
//     scan_en O (11) 163-/ix140/A0 161-/ix138/A1 162-/senmux/ix9/A1
// /e4 (34) PI
//     e4 O (XX) 163-/ix140/A1
// Number gates in trace = 3.
```

If you could get a 0 on the net connected to this TSD's enable, it would remove the Xs on its output.

Possible Resolutions

Cell constraints and ATPG constraints (dynamic or static) have no impact on the E4 rule. Pin constraints can have an impact because the tool may add extra cycles at the end of the test_setup procedure if the procedure does not preserve the constrained value. The constrained value can be overridden by another force value in the test procedure.

It is common during test_setup, when a design is being initialized, to have valid but momentary bus contention before the design reaches its initialized state. The E4 rule often detects these momentary occurrences of bus contention and as a result, the tool may report many E4 violations for the test_setup procedure. If you know these momentary occurrences of bus contention are not a problem and do not wish to be reminded of them, you can disable the E4 checks for the test_setup procedure by issuing the command “set_drc_handling -Skip_procedure Test_setup.”

Increasing the abort limit with the set_abort_limit command can help screen out false E4 violations by enabling the tool to perform more extensive contention checking. This works for E4A violations only.

E5

Category: Extra

Contexts Supported: dft -scan, dft -test_points, patterns -scan, patterns -scan_diagnosis

Default Handling: Note in patterns -scan contexts only. Ignore otherwise.

report_drc_rules: Supported

When the application places constrained states on constrained pins and binary states on PIs and scan cells, X states must not propagate to an observable point. Failure to satisfy this rule will result in the risk of X states propagating to an observable point. This is a serious condition for

BIST circuits, may reduce the effective compression obtainable with EDT, and has no effect on uncompressed ATPG. For compressed designs, the number of E5 violations should be minimized in order to reduce the impact on compression.

Note

 Tessent TestKompress uses X-masking to handle the X states, but they typically increase the number of patterns generated, lowering the effective compression.

The application performs this check on gates that can create an X state with their inputs at binary values. It will not consider gates that do not have a path to an observable point, or that have all paths blocked by tied or constrained circuitry. The tool checks for the following conditions:

- A violation on a wired gate (WIRE) occurs if the tool can place different values on its inputs and the net resolution is set to wire.
- A violation on a BUS gate occurs if more than one of the BUS-connected tri-state drivers or switches turn on simultaneously, or all drivers turn off simultaneously and the Z state behaves as an X.
- A violation on a tri-state driver gate (TSD) or a switch gate (SW) occurs if it does not connect to a BUS gate. You can turn off the enable line, and the Z state behaves as an X.
- A violation on a TIE-X gate occurs if the gate is locally sensitizable up to the point where it has multiple fanouts (or observable points).
- A violation on a transparent latch (TLA) occurs if a single clock line is not set to its on-state, or the set and reset lines are not off.
- A violation on a ROM or RAM gate occurs if you can set a read line to off, the read_off value is X, and an output is sensitizable when the read line is off.
- A RAM/ROM violation also occurs if any memory element is uninitialized and an output is sensitizable to an observation point.
- PI pins can propagate Z to PO when Z handling is X (default). To prevent this, NO_Z constraints on PIs are considered by E5. Additionally, NO_Z constraints added in setup mode are not allowed to be deleted in a non-setup mode so the E5 check assumption is preserved.

The default handling for this rule violation in patterns -scan context is note; in other contexts, it is ignored. When a violation occurs, you can access the tied/constrained simulated values by setting the gate reporting to “constrain_value” and using the report_gates command for the gate ID number displayed in the DRC message. The tool needs to be in a non-setup system mode. By tracing back and forward from this gate, you can identify why the violation occurred.

The occurrence message is:

```
T gate N (G) may have an observable X-state. (E5-1)
```

T is the gate type, N is the instance/net name of the gate, and G is the gate ID number.

The summary message is:

N gates may have an observable X-state. (E5)

N is the number of occurrences of rules violation E5.

E6

Category: Extra

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Ignore

report_drc_rules: Supported

When the tool places constrained states on constrained pins, the inputs of a gate must not have sensitizable connectivity to more than one memory element of a scan cell.

The tools consider a scan cell to have multiple memory elements if the cell contains, for example, a shadow element or copy element (refer to [Slave Element](#) and [Shadow Element](#) in the *Tessent Scan and ATPG User's Manual* for detailed information about these memory elements and their use in scan cells).

The application performs this check by tracing the forward cones of influence of all scan cell memory elements through unconstrained and untied circuitry. The rule violation occurs when any gate is in the cone of influence of more than one memory element of a single scan cell.

The default handling for this rule violation is ignore. Failure to satisfy this rule may result in some loss of test coverage, but most faults should be detectable using a skewed load test procedure.

The occurrence message is:

Multiple memory elements of scan cell P (C) are connected to N (G). (E6-1)

P is the position number of the scan cell, C is the chain name, N is the instance name of the gate, and G is its gate ID number.

The summary message is:

There were N scan cells with multiple memory element connectivity to a gate. (E6)

N is the number of occurrences of rules violation E6.

E7

Category: Extra

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Ignore

report_drc_rules: Supported

External bidirectional drivers must be at the high impedance (Z) state during the application of the test procedures. You can use this rule to ensure that no bus contention can occur at bidirectional pins independent of the force values on the bidirectional pins. The application performs this check using the simulated values of each time period of all test procedures (except test_setup). The rule violation occurs if any bidirectional tri-state driver is not at a Z state. Using the -Mode option with the set_drc_handling command and the report_drc_rules command, you can check the value being forced on the bidirectional pins.

The default handling for this rule violation is ignore. If rule E4 (which ensures bus-mutual exclusivity) passes, a violation of rule E7 has no effect. Failure to satisfy this rule (normally) has no effect if there is no violation of rule E4, which ensures no bus contention actually occurs.

You can access simulated gate values using the report_gates command with the gate data set to DRC_pattern. If this is the only DRC violation or if you have changed the default handling to error, you can also view simulated values using report_gates with gate reporting set to error_pattern. Gate reporting with the proper simulation data helps you identify the bidirectional pin that failed, and by tracing connectivity from this point, you can identify how to correct the problem.

Note

 You should set the gate data prior to any violation analysis, to ensure the gate data reported is for the correct violation.

The occurrence message is:

```
BIDI pin P not set to input mode at time T of P procedure. (E7-1)
```

P is the pin name of the bidirectional pin, T is the time period, and P is the procedure name.

The summary message is:

```
There were N occurrences of BIDIs not set to input mode during scanning.  
(E7)
```

N is the number of occurrences of rules violation E7.

E8

Category: Extra

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Ignore

report_drc_rules: Supported

All scan cell MASTER elements of a scan chain must use a single shift clock. If the scan cells contain slaves, all slaves of all scan cells of a scan chain must also use a single shift clock. You can use this rule to ensure that the tester does not cause clock skew problems during the loading and unloading of the scan chains. The application performs this check by inspecting the memory elements for all scan cells of a chain. The rule violation occurs when a chain uses multiple clocks to shift master or slave data.

If multiple shift clocks pulse in the shift procedure and they are blocked from reaching the scan chain by the effects of pin constraints, you must specify the set_drc_handling command with the Atpg_analysis option to avoid an error. This checking considers only pin constraints that have not been overridden by force statements during the shift and load_unload procedures.

The default handling for this rule violation is ignore. Failure to satisfy this rule will have no ATPG effect. The occurrence message is:

Multiple clocks were used to shift T of scan chain C. (E8-1)

T is the type of scan cell memory element (MASTERs or SLAVEs), and C is the chain name.

The summary message is:

There were N occurrences of multiply clocked scan chains. (E8)

N is the number of occurrences of rules violation E8.

Note

 If you set the DRC E8 handling to anything other than Ignore, the report_scan_chains command additionally displays the clock of each scan cell. This enhanced report is only available in non-Setup mode.

E9

Category: Extra

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Ignore

report_drc_rules: Supported

The drivers of wire gates must not be capable of driving opposing binary values. The application performs this check by attempting to satisfy the placement of opposing binary values on all combinations of the two drivers of a wire gate. The rule violation occurs at a wire gate if it is possible to satisfy those conditions for at least one combination of drivers. When a

violation occurs, the tool identifies the failing wire gate and the drivers capable of being placed at opposing values.

This rule ensures that there is no possible contention (for the good machine) on wire gates. The tool will not perform this rule check on wire gates whose behavior you changed to AND or OR using the set_net_resolution command. Also, the tool does not consider pin constraints and equivalences with this check.

The default handling for a violation of this rule is set to ignore. A violation of this rule indicates the possibility that patterns exist that have contention on wire gates. The occurrence message is:

```
WIRE gate N (G) has possible contention on drivers G1 and G2. (E9-1)
```

N is the gate name of the wire gate, G is its gate ID number, and G1 and G2 are the gate ID numbers of the driver gates.

The summary message is:

```
There were N WIRE gates which may have possible contention. (E9)
```

N is the number of occurrences of rules violation E9.

E10

Category: Extra

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

Checks for bus contention mutual-exclusivity during measure_po events in test procedures.

Tri-state drivers must not have conflicting values when driving the same net during the measurement of primary output (PO) values (measure_po events in test procedures). This rule differs from the E4 rule in that it is not checked during test procedure events other than measure_po events. The tool performs this check by analyzing each dominant strong bus to determine if it can cause contention. The analysis places each bus in one of the following categories:

- Pass - Test generation analysis determines a contention condition cannot occur.
- Fail - Test generation analysis identifies a possible contention condition.
- Abort - Test generation analysis terminated while attempting to determine if a contention condition could occur.
- Bidi - Test generation determines that the bidirectional pin (which can only have a single tri-state driver) can potentially create a contention condition.

Buses in either the fail or abort categories violate this rule. Buses in the bidi category require checking during post-DRC ATPG processes because they do not exhibit natural mutual-exclusivity behavior and can potentially cause contention. You get the tool to perform this additional analysis by using the Atpg_analysis option with the set_drc_handling command. Buses in the pass category require no further checking.

Refer to “[Bus Mutual Exclusivity Analysis](#)” in the *Tessent Scan and ATPG User’s Manual* for background information about the tool’s bus mutual exclusivity checking. For more information about the measure_po statement, refer to the “[Test Procedure File](#)” in the *Tessent Shell User’s Manual*.

Effect on Testability

Failure to satisfy this rule will result in the risk of bus contention during measurement of PO values (measure_po events in test procedures).

How to Debug E10 Violations

The occurrence message is:

```
Bus gate N (G) has possible contention on drivers G1 and G2. (E10-1)
```

N is the gate name of the bus gate, G is the gate ID number, and G1 and G2 are the gate ID numbers of the driver gates.

The summary message is:

```
There were N bus gates which may have possible contention (E10)
```

N indicates the number of bus gates failing the E10 rule.

If you see an “A” appended to the “E10” in the occurrence message (E10-1-A for example), it indicates the occurrence is due to the tool aborting the E10 check before it was completed. As these are “possible” but unproven E10s, the tool may be able to screen out some of them if you raise the abort limit. Refer to “[Possible Resolutions](#).”

How to Debug with DFTVisualizer

To view the location of an E10 DRC violation using DFTVisualizer, use the following command steps:

1. set_gate_level Primitive
2. open_visualizer

Choose the **DRC Violations** tab in the Design Browser window, then open the listed DRC’s by selecting the “+” symbols as needed to find the violation ID of the desired E10 DRC violation. Double clicking the listed violation, or right clicking and selecting **Analyze DRC Violation**

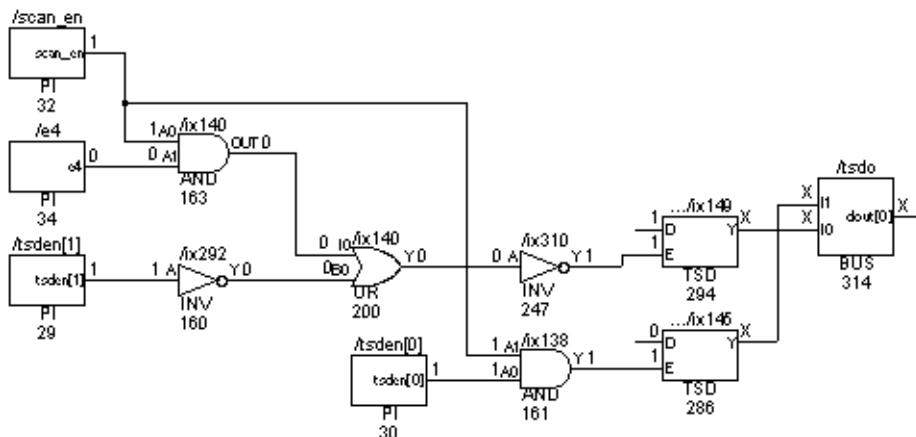

from the popup menu will analyze the violation. The tool will automatically change the gate reporting to “parallel_pattern 0” and display the bus gate affected by that violation in the Flat Schematic window of DFTVisualizer. Think of “parallel_pattern 0” as an example of one possible pattern (created for DRC purposes only) that, if included in a test pattern set, would cause contention.

Tip

i Alternatively, you can issue the `analyze_drcViolation` command with the `rule_id-occurrence#` argument at the tool’s command line. For example, to display the first occurrence of an E10 violation: `analyze_drcViolation e10-1`

Once the offending bus gate is displayed, trace backward from the bus gate. The following figure shows an example DFTVisualizer display of such a trace, where the starting point of the trace is the offending gate, `/tsdo`. Notice that TSDs `/ix145` and `/ix149` have conflicting values and both are enabled.

Figure 7-33. Example E10 Violation Trace in Flat Schematic Window of DFTVisualizer

You could use DFTVisualizer to trace back on the enable line of each TSD to the primary inputs and see that both `tsden[1]` and `/scan_en` are 1, causing the conflict.

How to Debug from the Tool Command Line

To view the location of the an occurrence of an E10 DRC violation from the tool command line, you can use the following command steps:

1. `set_drc_handling E10 Warning`
2. `set_system_mode analysis`
3. `report_drc_rules E10-occurrence#`
4. `analyze_bus gate_id`

5. set_gate_report Parallel_pattern *pattern_number*
6. report_gates *gate_id*

The following transcript excerpts show an example of the use of this command sequence starting at step 3:

```
report_drc_rules e10-1
// Warning: BUS gate /tsdo/dout[0] (314) has possible contention on
//           drivers 294 and 286. (E10-1)
analyze_bus 314
// ATPG bus checking performed on /tsdo/dout[0] (314) for 2 bussed TSDs.
// Failure occurred while checking TSDs 294 and 286 (data in
// parallel_pattern 0).
set_gate_report parallel_pattern 0
report_gates 294 286
// /tsdo/ix149 (294) TSD
//   E     I (1) 247-/ix310/Y
//   "D"   I (1) 221-
//   Y     O (X) 314-
// /tsdo/ix145 (286) TSD
//   E     I (1) 161-/ix138/Y
//   "D"   I (0) 213-
//   Y     O (X) 314-
```

The conflicting values on the input (“D”) of each TSD in this example while both are enabled (1 on the “E” input) is the source of the problem. Assuming the two TSDs should not be enabled simultaneously, a reasonable way to proceed is to choose one enable input and trace back through the gates driving it until you find the source of the 1. For example, you might first look at where the /tsdo/ix149 (294) input comes from:

```
report_gates -endpoints -backward 294
// -----
// Begin backward trace for gate /tsdo/ix149 (294).
// -----
// /tsden[1] (29) PI
//   tsden[1] O (1) 160-/ix292/A
// /scan_en (32) PI
//   scan_en O (1) 163-/ix140/A0 161-/ix138/A1 162-/senmux/ix9/A1
// /e4 (34) PI
//   e4 O (0) 163-/ix140/A1
// /dataot/reg_q_0_ (373) DFF
//   "S" I (X) 43-
//   R I (X) 157-
//   CLK I (X) 313-/dataot/ix104/Y
//   "DO" I (X) 255-
//   "OUT" O (1 [X]) 127- 128-
//   MASTER cell_id=8 chain=chain3 group=grp1 invert_data=TFFT
// Number gates in trace = 4.
```

This shows that /tsden[1] is a 1. A similar backward trace from instance 286 to /tsden[0] shows that it too is a 1. If you could get a 0 on one of the /tsden inputs, it would remove the contention.

Possible Resolutions

Be aware you may not need to care about E10 violations in certain cases. If you are not concerned about contention after the capture clock is pulsed and you are satisfied with test coverage, you do not need to do anything. On the other hand, if the tool is rejecting many patterns due to contention during simulation and as a result, run time is excessive and coverage low, you may want to do something. By default, the tool will check for contention prior to the capture clock pulse in the capture cycle. If you are concerned about contention after the capture clock is pulsed, you need to direct the tool to check for this type of contention. The key point to remember is you only need to do something if you are not happy with what the tool does by default or the run time or coverage is unacceptable, in which case the following commands are helpful:

Note

 These command suggestions will not make E10 rule violations go away, but will help you generate contention-free patterns when E10 violations are present.

- [add_input_constraints](#) — Adds a pin constraint to a primary input pin. This command is useful if you determine from your troubleshooting and knowledge of the design that forcing a particular primary input pin to a specific value would resolve a contention issue. Typically, the need for such a constraint would have been anticipated during the design phase and perhaps simply overlooked when setting up for ATPG.
- [add_atpg_functions](#) and [add_atpg_constraints](#) — These commands allow you to create user-defined ATPG function constraints. This can be useful if you know where in the design constraints can be applied to remove contention. Constraints you apply will save time the tool would have to spend learning those locations through its own analysis.

Following is an example of the use of these commands to specify constraints:

```
add_atpg_functions func1 select1 tsden[0] ~tsden[1]
add_atpg_constraints 1 func1
```

- [set_drc_handling E10 Atpg_analysis](#) — Directs the tool to perform additional analysis toward the end of DRC to determine if buses that the initial E10 DRC placed in the bidi category can cause contention. Increases the tool's DRC effort.
- [set_drc_handling E10 -Mode Sequential](#) — This command considers the inputs to a single level of sequential cells behaving as “staging” latches in the enable lines of tri-state drivers. All of the latches found in a back trace must share the same clock. There must also be only a single clocked data port on each cell, and both set and reset inputs must be tied (not pin constrained) to the inactive state. This check ensures that there is no connectivity from the cells in the input cone of the sequential cells and enable of the tri-state devices except through the sequential cells. Using this option will increase run time.

- **set_abort_limit** — Changes the abort limit. Increasing the abort limit can help screen out false E10 violations by enabling the tool to perform more extensive contention checking. This works for E10-*occurrence#*-A violations only.

E11

Category: Extra

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Ignore

report_drc_rules: Supported

This rule checks for the ability of a bus gate to attain a Z state. This check analyzes each dominant strong bus to determine if conditions can place a Z value on the bus gate.

As a result, the analysis places each bus in one of the following categories:

- **Pass** - Test generation analysis determines that no condition could place a Z value on the bus gate.
- **Fail** - Test generation analysis determines that conditions could place a Z value on the bus gate.
- **Abort** - Test generation analysis terminated while attempting to determine if conditions could place a Z value on the bus gate.
- **Bidi** - The bus is a bidirectional bus.

Buses in both the fail and abort categories violate this rule.

The default settings for this rule are ignore, noverbose, and atpg_analysis. You can change the handling with the set_drc_handling command. For more information on ATPG analysis, refer to “[How to Turn on ATPG Analysis](#).”

The occurrence message is:

```
BUS gate N (G) is capable of attaining a Z state. (E11-1-A)
```

N is the gate name of the bus gate, and G is its gate ID number. The -A following the violation ID number indicates the check aborted.

The summary message is:

```
There were N BUS gates capable of attaining a Z state. (E11)
```

N indicates the number of buses failing the E11 rule.

E12

Category: Extra

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Ignore

report_drc_rules: Supported

This rule determines if the test procedures violate any ATPG constraints. The default handling for this rule is ignore. You can change the handling with the set_drc_handling command.

For more information on ATPG analysis, refer to “[How to Turn on ATPG Analysis](#).”

The occurrence message is:

```
ATPG constraint violation on N (G) occurred at time T of P procedure.  
(E12-1-A)
```

N is the gate name, G is its gate ID number, T is the simulated time period, and P is the procedure name. The -A following the violation ID number indicates the check aborted.

The summary message is:

```
There were N occurrences of ATPG constraint violations in test procedures.  
(E12)
```

N indicates the number of E12 rule violations.

E13

Category: Extra

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Ignore

report_drc_rules: Supported

This rule determines if it is possible to satisfy both ATPG constraints and bus contention prevention (for buses that fail rule E10). The default settings for this rule are ignore and noverbose. You can change the handling with the set_drc_handling command.

The occurrence message is:

```
Contention prevention/ATPG constraints satisfiability check failed. (E13-  
1)
```

This rule does not issue a summary message.

E14

Category: Extra

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis,
patterns -scan_retargeting

Default Handling: Error

report_drc_rules: Supported

The expected simulation values listed in the test_setup procedure must match the actual simulated values.

E14 ensures the test_setup procedure is correct.

This DRC simulates the test_setup procedure when setup mode is exited and compares the simulated values with the expected values listed in the test_setup procedure.

Exception

Not applicable.

Messaging

If the test_setup procedure file fails E14, the following message displays:

```
// Error: Mismatch on <signal_name> at time <n>, cycle <cycle>
//          of procedure <proc>. Expected <val>, simulated <val>. (E14-#)
```

When the E14 violation originates from an iRead, it reports the original iRead target, the iCall that called the iProc containing the iRead, the chain flip-flop name if appropriate core data exists, and the iReadVar if applicable. The following message displays:

```
// Error: Mismatch on <signal_name> at time <n>, cycle <cycle> of
//          procedure <proc>. Expected <val>, simulated <val>.
//          This compare event originates from
//          an iRead command targeting <iRead_target> in iCall <iCall_name>.
//          Use the command 'report_procedures -expand_iprocs' to help debug
//          failures within iProcs. (E14-1)
```

If an ICL ScanRegister has a capture source with known values (that is, if the bits of the CaptureSource property consist of constant values, references to primary inputs, or references to the parallel outputs of other ScanRegister bits with known content) and there is no explicit iRead targeting the Scan Register, then Tesson Shell creates an implied iRead for each of those ScanRegister bits with known capture source. The implied iRead commands are created only

for the scan loads in which this ScanRegister is active. If the E14 violation originates from such an implied iRead, one of the following messages displays:

```
// Error: Mismatch on <signal_name> at time <n>, cycle <cycle> of
// procedure <proc>. Expected <val>, simulated <val>.
// This compare event originates from an implied iRead command
// targeting <register> (<register> captures the constant value <val>)
// in iCall <iCall_name>.
// Use the command 'report_procedures -expand_iprocs' to help debug
// failures within iProcs. (E14-1)

// Error: Mismatch on <signal_name> at time <n>, cycle <cycle> of
// procedure <proc>. Expected <val>, simulated <val>.
// This compare event originates from an implied iRead command
// targeting <register> (<register> captures the value from the
// scan register <other_register>) in iCall <iCall_name>.
// Use the command 'report_procedures -expand_iprocs' to help debug
// failures within iProcs. (E14-1)

// Error: Mismatch on <signal_name> at time <n>, cycle <cycle> of
// procedure <proc>. Expected <val>, simulated <val>.
// This compare event originates from an implied iRead command
// targeting <register> (<register> captures the value from the
// primary input <primary_input>) in iCall <iCall_name>.
// Use the command 'report_procedures -expand_iprocs' to help debug
// failures within iProcs. (E14-1)
```

Tessent Shell also verifies the iWrite commands in the test_setup and test_end procedures, if possible. During the processing of an iWrite command that targets an ICL pin, Tessent Shell tries to map the ICL pin to a design pin using the “tessent_design_instance” attributes of the relevant ICL instances. The iWrite verification of a particular ICL pin is only done if all “tessent_design_instance” attributes on the ICL instance path from the top level to the targeted ICL pin are set. As the tessent_design_instance attribute usually contains the rtl name of the instance, Tessent Shell also uses the rtl-to-gate mapping mechanism (see the [add_rtl_to_gates_mapping](#) command) to find the design pin in the gate level netlist. If this mapping fails, the following warning appears:

```
// Warning: In the test_setup iCall <iCall_name>, there is an iWrite command
// targeting the ICL object <icl_object>, which has been resolved
// to the driving ICL pin <icl_pin>. The effect of this iWrite
// command cannot be verified during the E14 check. The rtl path
// <rtl_path> of the associated design pin, which has been composed
// from all 'tessent_design_instance' attributes on the ICL instance
// path to the ICL pin, cannot be mapped to an existing design pin
// in the netlist.
// Either the netlist is incomplete or the mapping between rtl
// description and gatelevel netlist failed. If this problem
// originates from a mapping failure, use the command
// 'add_rtl_to_gates_mapping -instance_name_map_list' to
// specify the appropriate instance mapping.
```

If the design pin can be found and it is tied off to a value that conflicts with the iWrite command, the following warning appears:

```
// Warning: In the test_setup iCall <iCall_name>, there is an iWrite command
// targeting the ICL object <icl_object>, which has been resolved
// to the driving ICL pin <icl_pin>. The effect of this iWrite
// command cannot be verified during the E14 check, because the
// associated design pin <design_pin> is tied to <val>, while the
// iWrite command tries to apply the value <other_val> to this pin.
```

If the design pin is an internal input with a constraint that conflicts with the iWrite command, the following warning appears:

```
// Warning: In the test_setup iCall <iCall_name>, there is an iWrite command
// targeting the ICL object <icl_object>, which has been resolved
// to the driving ICL pin <icl_pin>. The effect of this iWrite
// command cannot be verified during the E14 check, because the
// associated design pin <design_pin> is constrained to <val>, while
// the iWrite command tries to apply the value <other_val> to this pin.
```

When the E14 violation originates from the verification of an iWrite command, it reports the original iWrite target and the iCall that called the iProc containing the iWrite. The following message displays:

```
// Error: Mismatch on <signal_name> at time <n>, cycle <cycle> of
// procedure <proc>. Expected <val>, simulated <val>.
// This compare event originates from the verification of an
// iWrite to <iWrite_target> during test
// setup in iCall <iCall_name>.
// Use the command 'report_procedures -expand_iprocs' to help debug
// failures within iProcs. (E14-1)
```

The summary message for E14:

```
E14: #fails=1 handling=warning (Miscompare on test_setup/test_end values)
```

Troubleshooting

1. Use DFTVisualizer to compare the DRC simulated values from the test_setup procedure with the simulated values for associated nodes in the design.
2. Correct the expect statements in the test_setup procedure to match the DRC simulation values.
3. For iMerges, both the [write_procfile](#) command and the [report_procedures](#) commands have an optional switch (-EXPand_iprocs) to allow for the expansion of the iCalls within a given procedure. If an iCall is used within an iMerge, then that entire iMerge is expanded.

E15

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis,
patterns -scan_retargeting

Default Handling: Warning

report_drc_rules: Supported

This DRC checks if the PDL-based test setup is stable until the end of the test_setup procedure.

If the test_setup procedure contains iCall statements or iCalls added by means of the `set_test_setup_icall` command, and if there are iWrite commands in the iProcs referenced by the iCalls, then Tesson Shell creates the required patterns to ensure that the iWrite values are present at the specified locations in the design. The tool identifies the values which can be expected to persist until the end of the test_setup procedure, only considering the ICL and PDL input. Finally, E15 checks if these relevant iWrite values match the results of the test_setup simulation in the stable_after_setup simulation context. As the DRC compares the results of the IJTAG-based value tracking with the results of the design-based test_setup simulation, a failure indicates either that the IJTAG-based test setup has been corrupted by other (non-IJTAG related) actions in the test_setup procedure, or that there are inconsistencies between the design and the ICL description of the IJTAG network.

Like the iWrite verification of the E14 DRC, the E15 DRC also requires a successful mapping between ICL pins and design pins. The same conditions (presence of the "tesson_design_instance" attributes and so on) apply. See the description of E14 for details.

Messaging

If the test_setup procedure file fails E15, the following message displays:

```
// Error: Mismatch on pin '<pin>' at the end of the test_setup procedure.  
// Expected '<val>', simulated '<val>'.  
// During test_setup, the value '<val>' has been applied to ICL element <icl elem>  
// by means of an iWrite command in 'iCall <icall>'.  
// This value is still expected to be present at this pin at the end  
// of test_setup as it has not been overwritten by subsequent iWrite commands  
// or other PDL retargeting activities. (E15-#)
```

EDT Finder Rules (F Rules)

F rules verify the EDT logic connectivity and operation prior to scan chain tracing.

F3

Category: EDT

Contexts Supported: patterns -scan

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Supported

The design must contain at least one state element able to change states during shift. F3 verifies that at least one state element in the design is clocked and not constrained to a fixed value.

You cannot change the handling with the set_drc_handling command.

The error message is:

At least one state element should be able to change its state during shift. None were found. (F3)

F4

Category: EDT

Contexts Supported: patterns -scan

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Supported

EDT requires a design containing at least one decompressor. F4 verifies there is a decompressor in the design.

You cannot change the handling with the set_drc_handling command.

The error message is:

No decompressors found. (F4)

F5

Category: EDT

Contexts Supported: patterns -scan

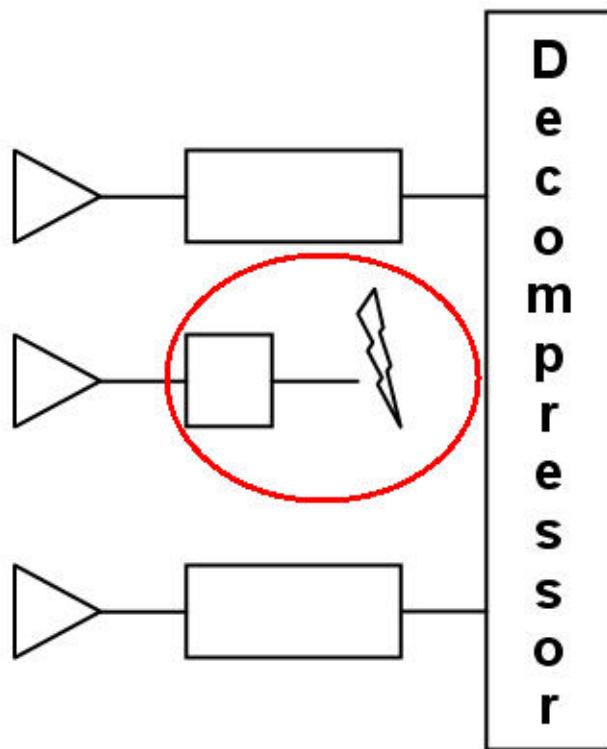

Default Handling: Error

report_drc_rules: Supported

All defined channel inputs must drive a decompressor. F5 verifies that all defined input channels are driving an identified decompressor by tracing the path from the channel input to the decompressor.

[Figure 7-34](#) shows an error condition.

Figure 7-34. Blocked Decompressor Input

The error message is:

Channel input P (N) [of EDT block E] is not driving a decompressor.
Either no structural connection exists, or the path is blocked.
Trace stopped at state element(s) S (G). (F5-1)

Where P is the channel index and N the pin name, E is the name of an EDT block, S is an instance name and G is the corresponding gate ID number. Multiple state elements may be listed in case of fan-outs.

Troubleshooting

Check the procedure file for incorrect or missing shift procedure settings.

F6

Category: EDT

Contexts Supported: patterns -scan

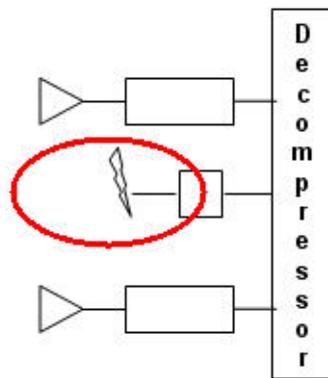

Default Handling: Warning

report_drc_rules: Supported

Channel input pins that control the decompressors must be defined. F6 traces each decompressor input pipeline to verify that decompressors are controlled by channel input pins, and verifies that the state elements in the channel input pipelines are properly clocked during shift.

Figure 7-35 shows an error condition.

Figure 7-35. Blocked Channel Input to Decompressor

This check is performed even when F5 violations exist.

If the decompressor is driven by one or more defined channel inputs, each blocked input pipeline is reported as follows:

The input pipeline of decompressor D [of EDT block E] is broken between decompressor state element L (G1) and the channel input after tracing N state elements. The last state element reached is: M (G2). (F6-1)

If all input pipelines of a decompressor are blocked the following message is reported once per decompressor.

All input pipelines of decompressor D are blocked. One of the input pipelines is broken between decompressor state element L (G1) and the channel input after tracing N state elements. The last state element reached is: M (G2). (F6-1)

If the clock input of a channel input pipeline is not set active during shift, the following message is reported:

The input pipeline of decompressor D [of EDT block E] is broken between decompressor state element L (G1) and the channel input after tracing N state elements. The clock inputs of state element M are never set active during the shift procedure (F6-1)

Where D is the internal identification number of the decompressor, E is the name of an EDT block, L is the instance name of the decompressor state element and G1 is the corresponding gate ID number, N is the number of found pipeline stages, M is the instance name of the last traced state element and G2 is its gate ID number.

F7

Category: EDT

Contexts Supported: patterns -scan

Default Handling: Error

report_drc_rules: Supported

Decompressors must be controlled by defined channel inputs. F7 traces all inputs to the decompressor to verify that they are connected to channel input pins.

If the decompressor is driven by at least one defined channel input, each rule violation is reported as follows:

The pin P is not a channel input but drives decompressor state element L (G) of decompressor D [of EDT block E]. (F7-1)

If the decompressor is only driven by pins not defined as channel inputs, the following error message is reported once per decompressor:

None of the primary input pins driving decompressor D is defined as a channel input. One of the traced pins is P. (F7-1)

Where P is a pin name, D is the internal identification number of the decompressor, E is the name of an EDT block, L is the instance name of the decompressor state element and G is the corresponding gate ID number.

Note

 In the EDT mapping flow, the reported pins are channel inputs mapped to the top level of the design.

F8

Category: EDT

Contexts Supported: patterns -scan

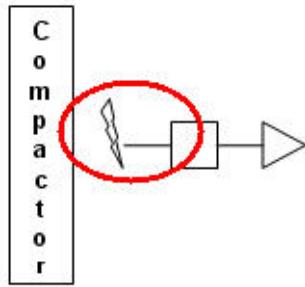

Default Handling: Error

report_drc_rules: Supported

Verifies that all channel outputs are driven by a compactor. F8 traces all channel outputs to verify that they are driven by a compactor, and verifies that the state elements in the channel output pipelines are properly clocked during shift.

Figure 7-36 shows an error condition.

Figure 7-36. Output Channel and Compactor Connection Blocked

The error message is:

Channel output P (N) [of EDT block E] is not driven by a compactor. Either no structural connection exists, or the path is blocked. The last state element reached while tracing back is: M (G). The following gate drives the channel output and blocks the path: M (G) (F8-1)

If the clock input of a channel output pipeline is not set active during shift, the following message is reported:

Channel output P (N) [of EDT block E] is not driven by a compactor. Either no structural connection exists, or the path is blocked. The clock inputs of state element M (G) are never set active during the shift procedure (F8-1)

If a primary input was reached the message is:

The primary input pin PI was reached while tracing back from channel output P (N) [of EDT block E]. (F8-1)

If an unclocked element is driving the channel output, the message is:

N state elements drive the channel output but could not be identified as mask hold registers (because they are not driven by mask shift registers) nor as part of scan chains (because the clock inputs are never set active during the shift procedure). One of those is: M1 (G1).

...
N is the number of unclocked state element driving the channel output,
M1 is the instance name of one of those, G1 is its gate ID number.

If the tracing problem is caused by a defined value on a channel output, the message is:

The channel output P (N) [of EDT block E] cannot be traced back because it is constrained to V. An unconstrained simulation value of X is expected. (F8-1)

If the tracing problem is caused by wrong values in mask hold registers, the message is:

```
Wrong values detected in mask hold registers after disabling EDT X masking logic and simulating load_unload until first clock event in apply shift. One of the failing state elements is: M (G). Simulated value: V1. Expected value: V2. (F8-1)
```

Where P is the channel index and N is the pin name, E is the name of the EDT block, M is the instance name of the last traced state element, G is its gate ID number, PI is the name of the reached primary input pin, and V, V1, V2 are gate values.

How to Debug Using DFTVisualizer

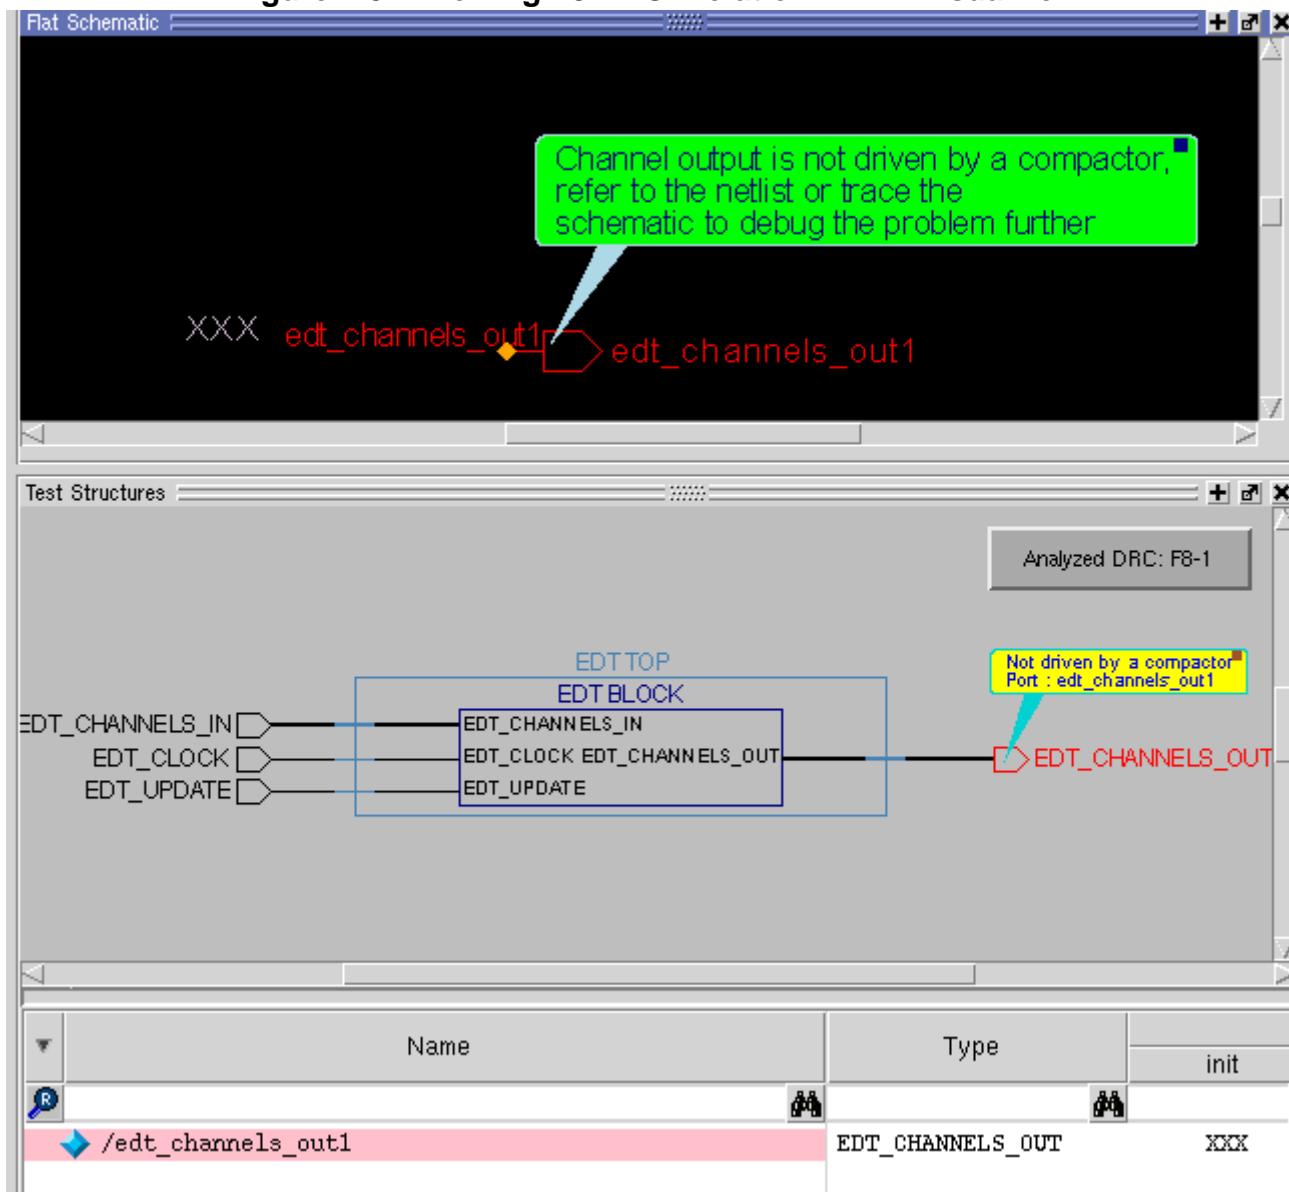

An F8 error can occur when the ATPG model for the pad is incorrect or the pad is incorrectly sensitized. When running in EDT, the F8 failure report may show:

```
// Error: Channel output 1 ('edt_channels_out1') is not driven by a compactor.  
// Either no structural connection exists, or the path is blocked.  
// No state elements reached while tracing back. (F8-1)
```

To view the location of the F8 error, use the following command:

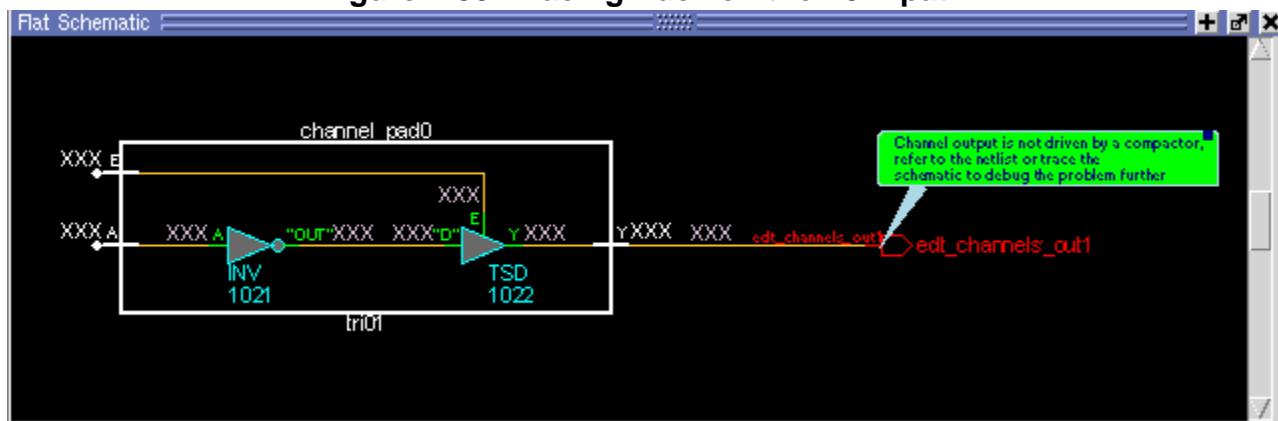

analyze_drcViolation F8-1

This command invokes DFTVisualizer and opens both the Flat Schematic window and the Test Structures window. The Test Structures window highlights the channel output with a callout message of the channel's name as shown in [Figure 7-37](#). The text pane displays the name of the channel, the channel type, and lists the init, capture, load, and shift values. The Analysis field provides a message about the violation.

Figure 7-37. Viewing F8 DRC Violation in DFTVisualizer

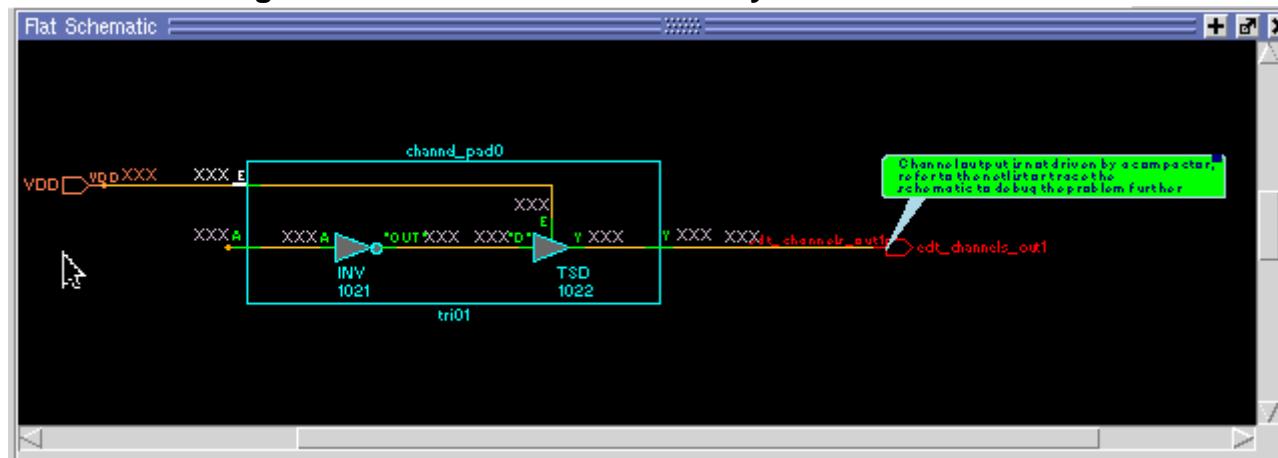

To determine why the data is X, you trace backward from the output channel following the X path. Figure 7-38 shows that `edt_channels_out1` is driven by a tri-state pad.

Figure 7-38. Tracing Back on the F8 X path

Notice that the enable pin of the tri-state device is driven X. As you continue to trace back from the enable pin, Figure 7-39 shows that it is driven by the VDD port.

Figure 7-39. Tri-State Driven to X by connection to VDD

Use this command to solve the problem:

add_input_constraint VDD -CT1

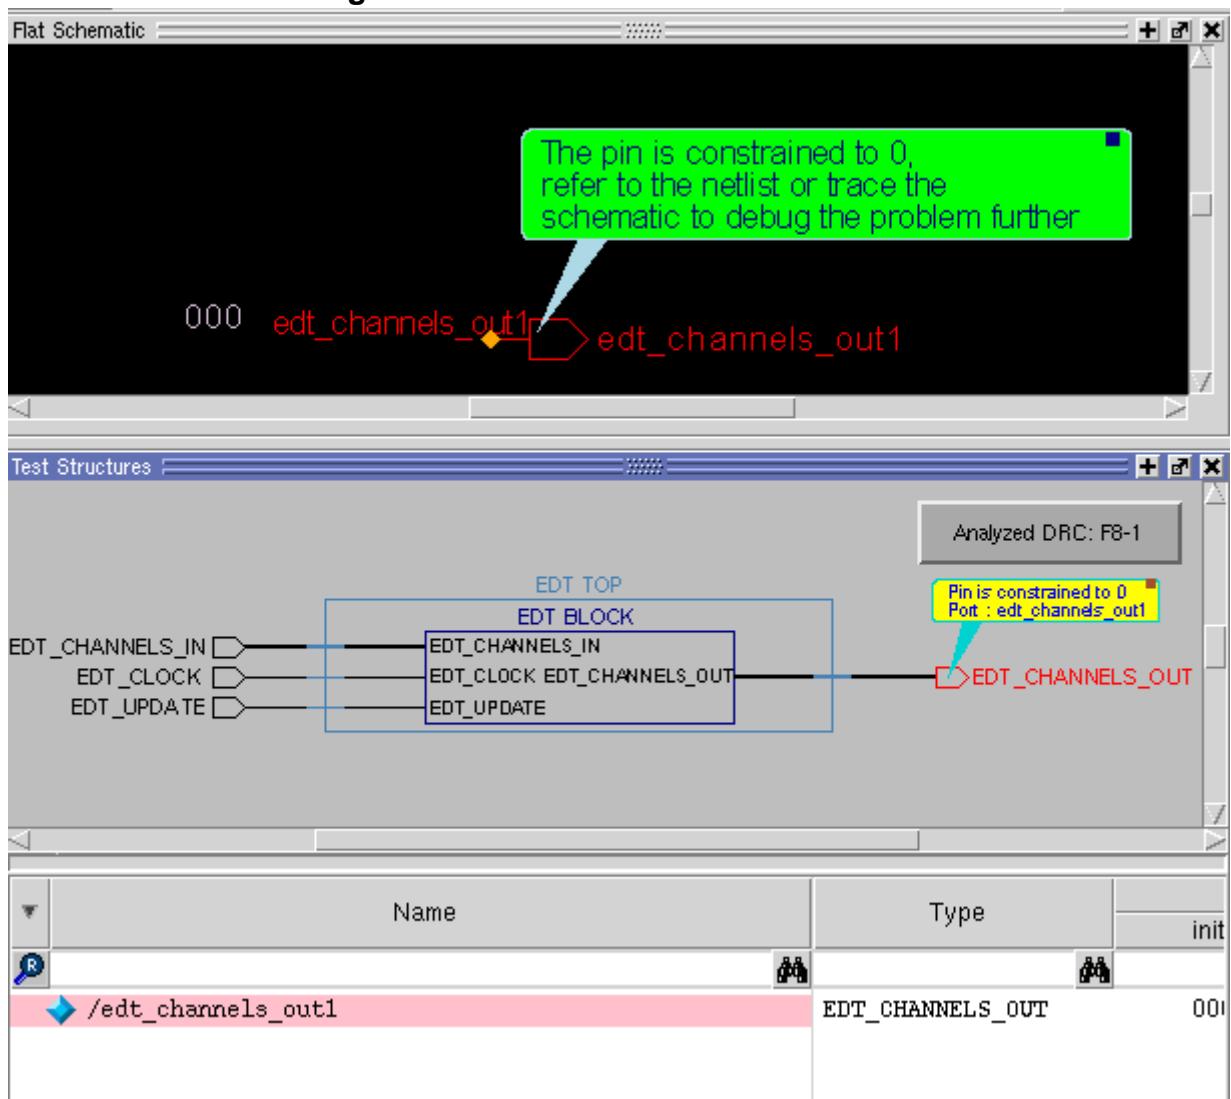

Another possible F8 DRC violation will show:

```
// Error: Channel output 1 ('edt_channels_out1') cannot be traced back
// because it is constrained to 0.
// An unconstrained simulation value (X) is expected. (F8-1)
```

You can use DFTVisualizer to debug it.

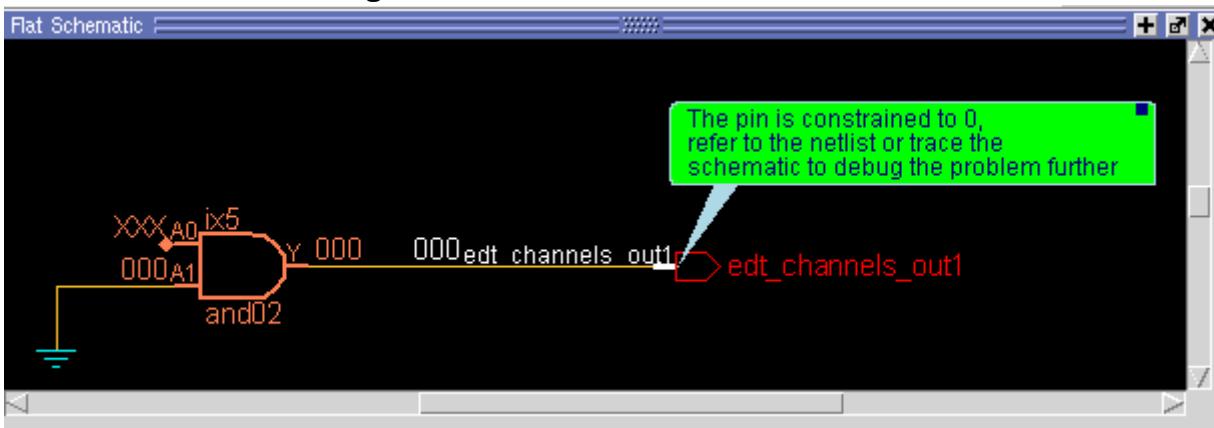

analyze_drcViolation F8-1

Figure 7-40 shows the violation location.

Figure 7-40. F8 DRC Violation - Blocked

To determine why the data is 0, trace back from the `edt_channels_out1` pin. In this case, you will find the output is driven by an AND gate with one pin tied to 0, as shown in Figure 7-41.

Figure 7-41. F8 DRC Violation Cause

To resolve this problem, you must fix the design to ensure that the AND gate driving the output channel does not have one input tied to 0.

F9

Category: EDT

Contexts Supported: patterns -scan

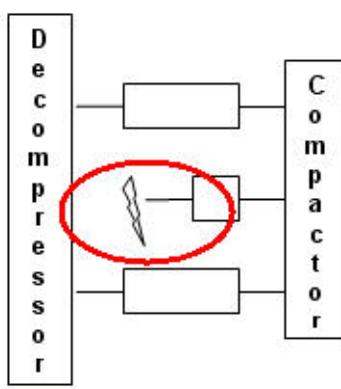

Default Handling: Error

report_drc_rules: Supported

Verifies that all compressed scan chains are connected to a decompressor. F9 traces all channel outputs to verify they connect to a decompressor.

Figure 7-42 shows an error condition.

Figure 7-42. Blocked Scan Chain Path

The error message is:

Compressed scan chain driving channel output P (N) [of EDT block E] blocked after tracing C cells. The last gate reached while tracing back is: M (G). (F9-1)

Where P is the channel index and N is the pin name, E is the name of an EDT block, C is the number of scan cells traced in the scan chain, M is the instance name of the last traced gate and G is its gate ID number.

F10

Category: EDT

Contexts Supported: patterns -scan

Default Handling: Error

report_drc_rules: Supported

This DRC verifies that the EDT logic found matches the EDT logic expected by the tool.

The EDT logic verification steps include, for example, checking the number of found scan chains compared to the number specified in the dofile, comparing the identified decompressor input taps with the expected ones, and checking if the channel pins driving/connected to a decompressor are consistent with the dofile specifications.

These are examples of the error messages for this case:

The size I1 of decompressor D [of EDT block E] does not match the expected size I2. (F10-1)

The input taps of decompressor D [of EDT block E] do not match the ones expected by the tool. For details about the found decompressor use 'report_edt_finder -Decompressors -Id D -Verbose'. (F10-2)

The expected decompressor taps of scan chain S [of EDT block E] do not match the taps of any found scan chain. (F10-3)

The input taps of channel input N (P) do not match the ones expected by the tool. Verify that the channel inputs are defined in the correct order. (F10-4)

The found number of scan chains (8) driven by the decompressor does not match the expected number (7). (F10-1)

The scan chain 'chain3' could not be found because it does not drive a channel output. Check if its scan output 'ff6/Q' (268) is properly connected to the compactor. (F10-2)

Decompressor 3 is driven by a channel input defined for EDT blocks 'blk1' and 'blk2' ('core2_5_edt_channels_in1'), but is connected to a channel output defined for EDT block 'blk3' ('top_out_7'). Please double-check the EDT channel pin specifications in the dofile. (F10-1)

Where D is the name of the decompressor, E is the name of an EDT block, S is the name of the scan chain, N is the index number of the channel input, and P is the pin name.

This DRC also verifies that the status of the low-power hardware is consistent with the user-specification of the set_edt_power_controller command in the dofile. If the tool identifies low-power hardware but the set_edt_power_controller command in the dofile disables it, the tool issues an error.

If the tool is unable to identify any low-power hardware but the set_edt_power_controller command in the dofile enables it, the tool also issues an error.

Low power hardware was found but should be disabled according to the dofile. Verify that the hardware is disabled in the test procedures.
(F10-1)

The defined low power hardware of EDT block 'blk2' could not be found. Verify that the hardware is enabled in the test procedures. (F10-1)

Examples

This DRC also identifies channel pin definition mismatches. These are examples of the error messages for the case:

```
// Error: Decompressor 2 is connected to channel outputs defined for EDT
// blocks 'm2_4x32' ('m2_edt_channels_out3', 'm2_edt_channels_out4')
// and 'm3_50x187' ('m2_edt_channels_out1', 'm2_edt_channels_out2').
// It is driven by channel inputs defined for EDT block 'm2_4x32'.
// Please double-check the EDT channel pin specifications in the
// dofile. (F10-1)

// Error: Decompressor 2 is driven by channel inputs defined for EDT
// blocks 'm2_4x32' ('m2_edt_channels_in2', 'm2_edt_channels_in3',
// 'm2_edt_channels_in4') and 'm3_50x187' ('m2_edt_channels_in1').
// It is connected to channel outputs defined for EDT block 'm2_4x32'.
// Please double-check the EDT channel pin specifications in the
// dofile. (F10-1)

// Error: Decompressor 3 is driven by channel inputs defined for EDT block
// 'm3_50x187', but is connected to channel outputs defined for EDT
// block 'm2_4x32'.
// One of the channel inputs is 'm3_pdata[0]' and one of the channel
// outputs is 'm3_paddr[0]'.
// Please double-check the EDT channel pin specifications in the
// dofile. (F10-1)

// Error: Decompressor 3 is driven by channel inputs defined for EDT
// blocks 'm2_4x32' ('m3_pdata[0]')
// and 'm3_50x187' ('m3_pdata[1]', 'm3_pdata[2]', 'm3_pdata[3]').
// It is connected to channel outputs defined for EDT blocks
// 'm1_28x16' ('m3_paddr[2]', 'm3_paddr[3]') and 'm3_50x187'
// ('m3_paddr[0]', 'm3_paddr[1]').
// Please double-check the EDT channel pin specifications in the
// dofile. (F10-3)
```

F11

Category: EDT

Contexts Supported: patterns -scan

Default Handling: Ignore

report_drc_rules: Supported

Verifies that all decompressors connect to at least one scan chain and that the path from the decompressor to the scan chains is not blocked due to wrong or missing shift procedure settings.

The default handling for this DRC is “ignore”.

No correction is required if the decompressor is not needed for testing.

The occurrence message is:

Decompressor D has been found but is not used in the current mode. It contains S state elements, one of which is N (G). (F11-1)

Where D is the internal identification number of the decompressor and S is the number of its state elements, N is the instance name of a decompressor state element and G is the corresponding gate ID number.

F12

Category: EDT

Contexts Supported: patterns -scan

Default Handling: Warning

report_drc_rules: Supported

Verifies that all uncompressed scan chains are defined with the add_scan_chains command.

The warning message is:

An uncompressed scan chain has been found that was not defined with the "add scan chain" command. Its scan input is P1, scan output is P2, and it contains S state elements. (F12-1)

Where P1 is a primary input pin, P2 is a primary output pin and S is the number of state elements in the scan chain.

F13

Category: EDT

Contexts Supported: patterns -scan

Default Handling: Error

report_drc_rules: Supported

Verifies that the decompressor, Xpress mask shift register state elements, and low-power shift registers are reset correctly prior to shift.

The error message in the case of the decompressor is:

The decompressor [of EDT block E] is not reset correctly prior to shift.
Simulated value: V1. Expected value: V2.
One of the failing decompressor state elements is: M (G). (F13-1)

In the case of an Xpress compactor, the state elements of the mask shift registers are checked in the same way. The error message is:

The mask shift register driven by channel input P (N) [of EDT block E] is not reset correctly prior to shift. One of the failing mask shift register state elements is: M (G). (F13-1)

In the case of a low-power shift register, the error message is:

The low power shift register driven by channel input P (N) [of EDT block E] is not reset correctly prior to shift.
Simulated value: V1. Expected value: V2.
One of the failing low power shift register state elements is: M (G). (F13-1)

In these messages, P is the channel index and N the pin name, E is the name of the EDT block, M is the name of the failing state element, and G is the gate ID number, and V1 and V2 are gate values.

F14

Category: EDT

Contexts Supported: patterns -scan

Default Handling: Error

report_drc_rules: Supported

Verifies that the state elements of the mask shift registers and the low-power shift registers hold their value during capture.

Only one violation per EDT block is reported.

The error message for mask shift registers (Xpress compactor) is:

The mask shift register driven by channel input P (N) [of EDT block E] does not hold its value during capture. One of the failing mask/power shift register state elements is: M (G). (F14-1)

The error message for mask shift registers (basic compactor) is:

The mask shift register [of EDT block E] does not hold its value during capture. One of the failing mask shift register state elements is: M (G) . (F14-1)

The error message for a low-power shift register is:

The low power shift register driven by channel input P (N) [of EDT block E] does not hold its value during capture. One of the failing low power shift register state elements is: M (G) . (F14-1)

In these messages, P is the channel index and N the pin name, E is the name of the EDT block, M is the name of the failing state element and G its gate ID number.

F15

Category: EDT

Contexts Supported: patterns -scan

Default Handling: Error

report_drc_rules: Supported

Verifies that input pipeline state elements are initialized correctly. F15 verifies that any state elements that exist between a channel input and the EDT logic are initialized to the right value so that 0s get propagated into the EDT logic during the first shift.

Only one violation per EDT block is reported.

You cannot change the handling with the set_drc_handling command.

The error message is:

State elements in the input pipeline driven by channel input P (N) [of EDT block E] are initialized to wrong values after test_setup and load_unload. One of the failing input pipeline state elements is: M (G) . Simulated value: V1. Expected value: V2. (F15-1)

Where P is the channel index and N the pin name, E is the name of the EDT block, M is the name of the failing state element, G is the gate ID number, and V1 and V2 are gate values.

F16

Category: EDT

Contexts Supported: patterns -scan

Default Handling: Error

report_drc_rules: Supported

Input pipeline state elements must preserve their value during capture and load_unload. F16 verifies that any state elements between a channel input and the EDT logic preserve the value shifted into them during capture and load_unload procedure.

For additional information on pipelining, see “[Input Channel Pipelines Must Hold Their Value During Capture](#)” in the *Tessent TestKompress User’s Manual*.

Only one violation per EDT block is reported.

The error message is:

```
State elements in the input pipeline driven by channel input P (N)
[of EDT block E] do not preserve their value during capture and
load_unload. One of the failing state elements is: M (G). (F16-1)
```

Where P is the channel index and N the pin name, E is the name of the EDT block, M is the name of the failing state element, and G is the gate ID number.

F17

Category: EDT

Contexts Supported: patterns -scan

Default Handling: Error

report_drc_rules: Supported

Verifies that the state elements of the mask hold registers and the low-power hold registers are clocked during load_unload.

Only one violation per EDT block is reported.

The error message reported when mask hold registers violate this rule is:

```
Mask hold register state elements [of EDT block E] are not clocked during
load_unload. One of the failing mask hold register state elements is:
M (G). (F17-1)
```

The error message reported when a low-power hold register violates this rule is:

```
Low power hold register state elements [of EDT block E] are not clocked
during load_unload. One of the failing low power hold register state
elements is: M (G).
(F17-1)
```

In these messages, E is the name of the EDT block, M is the name of the failing state element of the low-power hold register and G is its gate ID number.

F18

Category: EDT

Contexts Supported: patterns -scan

Default Handling: Error

report_drc_rules: Supported

Verifies that the state elements of the mask hold registers load their values from the state elements of the mask shift registers before shift in the load_unload procedure; verifies that the state elements of the low-power hold registers load values from the low-power shift registers before shift in the load_unload procedure

Only one violation per EDT block is reported.

The error message reported for mask hold registers is:

```
Mask hold register state elements [of EDT block E] do not load values from
mask shift registers before shift in the load_unload procedure.
One of the failing mask hold register state elements is: M1 (G1).
The driving mask shift register state element is: M2 (G2).
Simulated value: V1. Expected value: V2.
```

The error message reported when a low-power hold register violates this rule is:

```
Low power hold register state elements [of EDT block E] do not load values
from low power shift registers before shift in the load_unload procedure.
One of the failing low power hold register state elements is: M1 (G1).
The driving low power shift register state element is: M2 (G2).
Simulated value: V1. Expected value: V2. (F18-1)
```

In these messages, E is the name of the EDT block, M1 is the name of the failing state element, G1 is its gate ID number, M2 is the name of the driving state element of the low-power hold register and G2 its gate ID number, and V1 and V2 are gate values.

F19

Category: EDT

Contexts Supported: patterns -scan

Default Handling: Error

report_drc_rules: Supported

Verifies that the state elements of the mask hold registers and low-power hold registers preserve their values during shift.

Only one violation per EDT block is reported.

The error message reported for mask hold registers is:

Mask hold register state elements [of EDT block E] do not preserve their values during shift. One of the failing mask hold register state elements is: M (G) . (F19-1)

The error message reported for low-power hold registers is:

Low power hold register state elements do not preserve their values during shift. One of the failing low power hold register state elements is: M (G) . (F19-1)

In these messages, E is the name of an EDT block, M is the name of the failing state element of the low-power hold register and G is its gate ID number.

F20

Category: EDT

Contexts Supported: patterns -scan

Default Handling: Error

report_drc_rules: Supported

The F20 design rule check verifies the masking modes of a compactor.

F20 programs the compactor to the various masking modes by directly loading the mask hold registers and tracing backward from the channel outputs (or from the first pipeline stage in case of a pipelined channel output) to verify that only the expected scan chains are driving the channel outputs. F20 also checks for masked chains with incorrect unload specification.

If the F20 DRC has verified the masking modes (that is, if the check is not set to “ignore”), the tool skips the corresponding K22 DRCs.

Mask-all Masking Mode

If the compactor supports the mask-all masking mode, F20 verifies that all scan chains are masked in that mode; that is, the channel output receives a “0” (or a “1” in the case of an inversion). In the case of a violation, the error message is:

Mask-all masking mode: The channel output P (N) [of EDT block E] receives an X although all scan chains driving it are expected to be masked. The last reached gate while tracing back is: M (G) [which is the scan output of scan chain 'S'] . (F20-1)

Where P is the channel index and N is the pin name, E is the name of an EDT block, M is the instance name of the last traced gate and G is its gate ID number, and S is the name of the found

scan chain. Note, the string “[which is the scan output of scan chain ‘S’]” is only reported if M is the scan output of a scan chain.

1-Hot Masking Mode

F20 verifies that only the expected scan chain drives the expected channel output. All other scan chains are masked. If the expected channel output is not driven by the expected scan chain the error message is:

```
1-hot masking mode for scan chain 'S1':  
The channel output P (N) [of EDT block E] is not driven by gate M1 (G1)  
which is the scan output of scan chain 'S1'.  
The last reached gate while tracing back is:  
M2 (G2) [which is the scan output of scan chain 'S2']. (F20-1)
```

Where P is the channel index and N is the pin name, E is the name of an EDT block, S1 is the name of the expected scan chain, M1 is the instance name of the scan output gate of scan chain S1 and G1 is its gate ID number, M2 is the instance name of the last traced gate and G2 is its gate ID number, and S2 is the name of the found scan chain. Note, the string “[which is the scan output of scan chain ‘S2’]” is only reported if M is the scan output of a scan chain.

F20 checks for masked chains with incorrect unload specification and produces an error message similar to the following:

```
// Finding internal scan chains.  
// Error: The found number of scan chains (2) driven by the decompressor  
// does not match the expected number (1). (F10-1)  
// Error: 1-hot masking mode for scan chain 'chain1':  
//     The channel output 1 (/edt_channels_out1) is driven by gate  
//     '/skeleton_design_top_i/chain1_cell0/Q' (12) which is the scan  
//     output of chain 'chain1' but the scan chain is defined to be  
//     masked and to unload a constant 0.  
//     The last gate reached while tracing back is:  
//     '/skeleton_design_top_i/chain1_cell0/Q' (12) which is the scan  
//     output of chain 'chain1' (F20-1)  
  
// Error: XOR masking mode 2: The channel output 1 (/edt_channels_out1)  
// is not driven by the expected scan chains.  
//     The following unexpected driver has been found:  
//     '/skeleton_design_top_i/chain1_cell0/Q' (12) which is the scan  
//     output of chain 'chain1' (F20-2)
```

Xpress Masking Mode

If the compactor supports the Xpress masking modes, F20 verifies that only the expected scan chains drive the expected channel outputs. All other scan chains are masked. If the expected channel output is not driven by the expected scan chains, the error message is:

```
XOR masking mode K: The channel output P (N) [of EDT block E] is not driven
by the following scan chains:
S1, S2, ..., SN as expected.
The last reached gate while tracing back is:
M (G) [which is the scan output of scan chain 'S']. (F20-1)
```

Where K is the index of the masking mode, P is the channel index and N is the pin name, E is the name of an EDT block, S1, S2, ..., SN are the names of the expected scan chains, M is the instance name of the last traced gate and G is its gate ID number, and S is the name of the found scan chain. Note, the string [which is the scan output of scan chain 'S'] is only reported if M is the scan output of a scan chain.

F21

Category: EDT

Contexts Supported: patterns -scan

Default Handling: Error

report_drc_rules: Supported

The F21 design rule check verifies that all scan chains driving a compactor have the expected latency; that is, the expected number of pipeline stages between the scan output and the channel output.

In some cases, EDT Finder learns and adjusts the number of compactor and output channel pipeline stages to match what was found in the design. If it succeeds in learning and adjusting the number of pipeline stages, the F21 DRC is not issued.

EDT Finder only adjusts the number of compactor pipeline stages if the number of compactor pipeline stages in the EDT IP was not passed from the IP Creation phase. Normally this information is passed through and any discrepancy will result in a DRC violation.

In the case of a violation, the error message is:

```
Incorrect number of pipeline stages between the scan chain 'S'
and the channel output P ('N') [of EDT block 'E']: identified=N1
expected=N2.
The scan output of scan chain 'S' is M (G)
The following pipeline stages have been identified:
P1 (G1)
P2 (G2)
...
PN (GN) (F21-1)
```

Where S is the name of the scan chain, P is the channel index and N is the pin name, E is the name of an EDT block, N1 and N2 are the number of identified and expected pipeline stages, M is the scan output of the scan chain and G is its gate ID number, and P1, P2, ..., PN are the identified pipeline stages and G1, G2, ..., GN their gate ID numbers.

F22

Category: EDT

Contexts Supported: patterns -scan

Default Handling: Warning

report_drc_rules: Supported

When two adjacent memory elements (source and sink) in the scan path are clocked by different shift clocks, the sink must not capture data from the source at the same time that the source changes its value. Failure to satisfy this rule can result in unwanted shoot-through during scan shifting when clock skew exists between the different shift clocks.

This DRC verifies this rule for EDT-related state elements. This DRC complements the T24 DRC that verifies this rule for the scan chains. Together, these two DRCs cover the complete scan path.

In the case of a violation, the error message is:

Two adjacent pipeline cells of channel input P (N) [of EDT block E]
are clocked on the same edge by different clocks.

N1 (G1), driven by clock N3 (G3), and
N2 (G2), driven by clock N4 (G4)

Consider adding a lockup cell between them, or modifying the clock timing.
(F22-1)

The first sentence of the error message depends on the location of the violation. Other possibilities are:

Two adjacent cells of the pipeline of channel input P (N) and the decompressor [of EDT block E] ...

Two adjacent cells of the decompressor [of EDT block E] and scan chain 'C1' ...

Two adjacent cells of scan chain 'C1' and the compactor [of EDT block E] ...

Two adjacent cells of scan chain 'C1' and the pipeline of channel output P (N) [of EDT block E] ...

Two adjacent cells of the compactor [of EDT block E] ...

Two adjacent cells of the compactor and the pipeline of channel output P (N) [of EDT block E] ...

Two adjacent pipeline cells of channel output P (N) [of EDT block E] ...

N1 and N2 are the instance names of the adjacent elements clocked by different clocks, N3 and N4 are the instance names of the clocks, G1-G4 are the corresponding gate IDs, P is the channel index and N the pin name, E is the name of an EDT block, and C1 is the name of a scan chain.

Note

 If the F22 DRC has verified this rule (that is, the set_drc_handling command is not set to "ignore" F22 violations) the K21 DRC is skipped. This only applies to the pattern generation phase and not the IP creation phase.

How to Debug Using DFTVisualizer

To view the location of a F22 DRC violation using DFTVisualizer, use the following command:

analyze_drcViolation F22-1

This command invokes DFTVisualizer and opens both the Flat Schematic window and the Test Structures window. The Test Structures window shows a representation of the test structure and highlights the location of the two adjacent cells with a callout message of the cell's name as shown in [Figure 7-43](#) on page 2819. The text pane displays the name of the cell, the type of cell, and, in the Analysis field, lists the controlling clock for that cell.

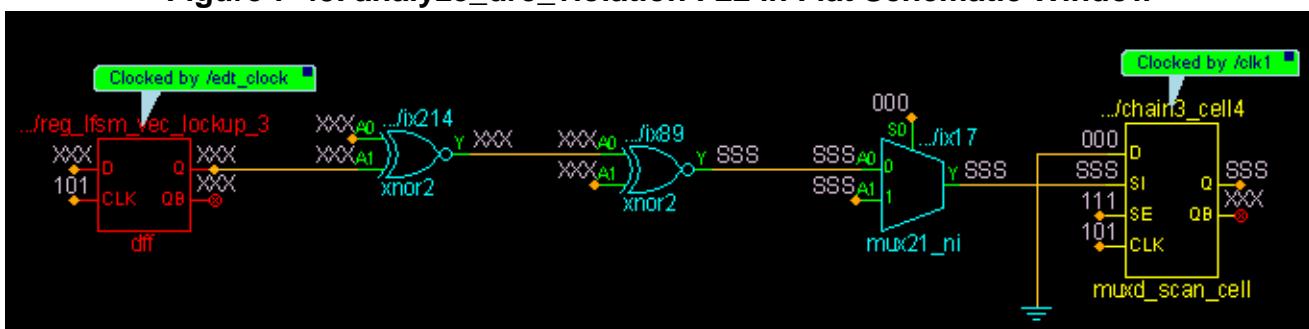

Figure 7-43. analyze_drcViolation F22 in Test Structures Window

In this example, the Test Structures window callouts indicate that the F22 violation occurs because a lockup cell is missing in the path from the decompressor to the scan chain. As shown in [Figure 7-44](#), this typically happens if you use the skeleton flow and define incorrect clock timing for the first cell of the scan chain.

Figure 7-44. Callout Text for reg_lfsm_vec_lockup_3

Consider adding a lockup cell, or modifying the clock timing
 FF : reg_lfsm_vec_lockup_3

The Flat Schematic window shows the connected path between the two adjacent cells and displays in the callouts the two different clocks that pulse on the same edge. The gate report is set to the shift procedure so you can see that both cells capture on the same edge.

Figure 7-45. analyze_drcViolation F22 in Flat Schematic Window

This type of violation typically occurs because during IP creation the clock of the first scan cell in the chain is leading edge (010), but after synthesis the first cell is actually a trailing edge flop (101). When you are using the skeleton flow, it is important that the edge of the first and last cell is defined correctly or the tool may end up with an extra or missing lockup cell.

Solution

You can correct this violation by inserting a lockup cell between the adjacent memory elements reported in the violation message, or by regenerating the EDT IP using the correct edges for the first cell.

Flattening Rules (FN, FP, and FG Rules)

The flattening rules check the hierarchical design's suitability for flattening.

The flattening rule violations and their identification literals are divided into the following three groups:

- Net rules — FN1 through FN9
- Pin rules — FP1 through FP13.
- Gate rules — FG1 through FG8.

You can use the `set_flattener_rule_handling` command to change the handling of the net, pin, and gate flattening rules.

FN1

Category: Flattened Net

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if a module net is floating. By default, the tool ignores this rule in the RTL context. You can overwrite this default handling by using the set_flattener_rule_handling command.

FN2

Category: Flattened Net

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if a module net has a driver and a constant value property. The constant value property is ignored.

FN3

Category: Flattened Net

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning for non-RTL contexts, Ignore for RTL contexts. (You can overwrite this default handling by using the set_flattener_rule_handling command.)

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if an instance net is floating.

FN4

Category: Flattened Net

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if an instance net is not used.

FN5

Category: Flattened Net

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule identifies a wired net with multiple drivers.

FN6

Category: Flattened Net

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if a bus net attribute cannot be used.

FN7

Category: Flattened Net

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if two connected nets have inconsistent net attributes. Both inconsistent attributes are ignored.

FN8

Category: Flattened Net

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule identifies parallel wired behavior.

FN9

Category: Flattened Net

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if the bus net has multiple bus keepers. The effects of the bus keepers are additive.

FP1

Category: Flattened Pin

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if the circuit has no primary inputs.

FP2

Category: Flattened Pin

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if the circuit has no primary outputs.

FP3

Category: Flattened Pin

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if a primary input drives logic gates and switch gates.

FP4

Category: Flattened Pin

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if a pin was moved.

FP5

Category: Flattened Pin

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if a pin was deleted by merging.

FP6

Category: Flattened Pin

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule identifies merged wired in/out pins.

FP7

Category: Flattened Pin

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule identifies merged wired input and output pins.

FP8

Category: Flattened Pin

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if a module boundary pin has no name.

FP9

Category: Flattened Pin

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Ignore

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if an inout pin is used as output only.

FP10

Category: Flattened Pin

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Ignore

report_drc_rules: Not Supported. Use [report_flattener_rules](#)

This rule determines if an output pin is used as an inout pin.

FP11

Category: Flattened Pin

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Ignore

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if an input pin is used as an inout pin.

FP12

Category: Flattened Pin

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Ignore

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if an output pin has no fan-out.

FP13

Category: Flattened Pin

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if an input pin is floating. By default, the tool ignores this rule in the RTL context. You can overwrite this default handling by using the `set_flattener_rule_handling` command.

FG1

Category: Flattened Gate

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

`report_drc_rules`: Not Supported. Use [report_flattener_rules](#).

This rule determines if the defining model of an instance does not exist. If you reduce the handling to warning or note, this primitive is treated as undefined.

FG2

Category: Flattened Gate

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

`report_drc_rules`: Not Supported. Use [report_flattener_rules](#).

This rule determines if the feedback gate is not in feedback loop.

FG3

Category: Flattened Gate

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

`report_drc_rules`: Not Supported. Use [report_flattener_rules](#).

This rule determines if the bus keeper has no functional impact.

FG4

Category: Flattened Gate

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

`report_drc_rules`: Not Supported. Use [report_flattener_rules](#).

This rule determines if the RAM/ROM read attribute is not supported.

FG5

Category: Flattened Gate

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if the RAM attribute not supported.

FG6

Category: Flattened Gate

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if the RAM type is not supported.

FG7

Category: Flattened Gate

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if the netlist module has a primitive that is not supported. If you reduce the handling to warning or note, this primitive is treated as undefined.

FG8

Category: Flattened Gate

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported. Use [report_flattener_rules](#).

This rule determines if the library model has a primitive that is not supported. If you reduce the handling to warning or note, this primitive is treated as undefined.

General Rules (G Rules)

G rules are general rules that identify inconsistencies in scan data and other definitions. G rules are the first rules checked during the DRC process and all violations generate error conditions that must be corrected. You cannot change the handling of these rules.

G1	2829
G2	2829
G3	2830

G5	2830
G6	2831
G7	2831
G8	2831
G9	2832
G10	2832
G11	2833
G12	2833

G1

Category: General

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported

Each defined scan chain group, except for “dummy,” must contain at least one scan chain. You can correct this error condition by either adding a scan chain to the group or by deleting the scan chain group.

The error message is:

```
No scan chains have been defined for group N. (G1-1)
```

N is the name of the scan chain group, and G1-1 indicates the rule and violation ID numbers.

G2

Category: General

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported

If you define scan chains and do not use the “dummy” scan chain option, you must define at least one clock. You can correct this error condition by either defining a clock that controls the defined scan chains or by deleting all scan chain groups.

The error message is:

```
Scan chains exist but no synchronous clocks have been defined. (G2-1)
```

G3

Category: General

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported

If the circuit has no memory elements, you cannot define clocks. You can correct this error condition by deleting all clocks.

The error message is:

```
Clocks are defined but no memory elements exist in the circuit. (G3-1)
```

G4

Category: General

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported

If the circuit has no memory elements, you cannot define scan chain groups. You can correct this error condition by deleting all scan chain groups.

The error message is:

```
Scan groups are defined but no memory elements exist in the circuit. (G4-1)
```

G5

Category: General

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported

If there are no RAMs in the circuit, you cannot define write control lines. You can correct this error condition by deleting all write control lines.

The error message is:

```
Write controls are defined but no RAMs exist in the circuit. (G5-1)
```

G6

Category: General

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported

If you define a linear feedback shift register (LFSR), you cannot use the “dummy” scan chain option. You can correct this error condition by either deleting all LFSRs or deleting the dummy scan chain group.

The error message is:

```
Cannot use dummy scan chain with BIST LFSRs. (G6-1)
```

G7

Category: General

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported

The RAM/ROM instance name given on a preceding read_modelfile command must contain a single RAM or ROM gate. You can correct this error condition by using the correct RAM or ROM instance name for the read_modelfile command. Or, you can do nothing and re-invoke the rules checker, in which case, the tool will not use a modelfile for the intended RAM or ROM.

The error message is:

```
Cannot use RAM/ROM modelfile M for invalid instance N. (G7-1)
```

M is the modelfile name, N is the instance name, and G7-1 indicates the rule and violation ID numbers.

G8

Category: General

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported

All ROM gates must have a defined initialization file, unless you use the random initialization option. You can correct this error condition by: specifying a modelfile in the model cell library, using the read_modelfile command to specify a modelfile, using random initialization, or changing the model cell library to treat the ROM gate as undefined.

The error message is:

```
ROM initialization file not defined for N (G) . (G8-1)
```

N is the instance name of the ROM, G is the gate ID number, and G8-1 indicates the rule and violation ID numbers.

G9

Category: General

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported

For all constrained scan cells identified by chain and position, the scan chain must be a valid scan chain, the position must be less than the length of the chain, and the scan cell must not be the same as another constrained scan cell. You can correct this error by identifying and correcting all invalid scan cell constraints.

The error message is:

```
Invalid cell constraint position P for chain C. (G9-1)
```

P is the cell position number (0-based, where 0 is the scan cell closest to the scan-out pin), C is the scan chain name, and G9-1 indicates the rule and violation ID numbers.

G10

Category: General

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported

For all constrained scan cells identified by pin pathname, the pin must be a valid output pin of a cell, the pin must connect to a scan memory element through a path that only contains buffers and inverters, and the scan cell must not be the same as another constrained scan cell. To correct this error, you must identify and correct all invalid scan cell constraints.

The error message is:

```
Invalid cell constraint pin name P. (G10-1)
```

P is the pin pathname of an output pin of a cell, and G10-1 indicates the rule and violation ID numbers.

G11

Category: General

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported

If you define a “dummy” scan chain group with a test procedure file, you cannot define any scan chains. The purpose of the dummy scan group is to provide the ability to use a **test_setup** procedure when no scan cells exist. To correct this error (if scan cells do exist), you should place the **test_setup** procedure in the test procedure file for a defined scan chain group.

The error message is:

```
Scan chains may not be defined when using dummy scan group procedure file.  
(G11-1)
```

G12

Category: General

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported

General rule 12 reports add_cone_blocks command pin-pathname violations because their checking is delayed until DRC is performed.

ICL Extraction Rules (I Rules)

Tessent Shell currently performs limited ICL Extraction rule checks on the design.

Table 7-12 lists the ICL-specific DRC rules that check the mandatory pre-conditions the design must have in order to extract the ICL top level from the netlist.

Table 7-12. ICL Extraction DRCs

DRC	Description
I1	Performs consistency checks on each design module that was mapped to an ICL module during the execution of the set_current_design command. Also verifies that the direction of each port on the mapped ICL module is consistent with the direction of the corresponding port in the design module.
I2	Verifies that a connection can be identified from an ICL-attributed pin to another ICL-attributed pin or to a top-level port. Also checks if the simulated value for every ICL-attributed instance input pin is compatible with the tied value of 1 or 0 specified in the ICL.
I3	Verifies that the port functions of an identified connection between an ICL-attributed port on an ICL-attributed module match the port function connection rules.
I4	This rule checks if an inferred port function and polarity for the primary input/output port is consistent for all found connections.
I5	Checks the consistency of specified pin constraints on ICL-attributed design instances.
I6	Checks all latches that have been previously identified during forward tracing of design instance pins with a scan out ICL attribute, and verifies that the backward tracing of the enable port of those latches reaches an identified primary port with TCK ICL attribute. In addition, all these latches have to be enabled by a low signal on the TCK port.

The ICL-specific DRC rules described in this section are based on the [IEEE 1687-2014](#) (IJTAG) standard. These checks are only performed in the Tessent Shell patterns -ijtag context—see “[ICL Extraction](#)” in the *Tessent IJTAG User’s Manual*.

Refer to “[Design Rule Checks](#)” in the *Tessent IJTAG User’s Manual* for complete information.

I1

Category: ICL Extraction

Contexts supported: patterns -ijtag

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Performs consistency checks on each design module that was mapped to an ICL module during the execution of the set_current_design command.

Specifically, the tool verifies that all ports on the mapped ICL module are present in the corresponding design module. If an ICL module port is not found in the corresponding design module, the tool issues the following error messages:

The port 'P' exists in the description of the ICL module 'M1' but not on the matching design module 'M2'.

Where:

'P' is the name of the ICL module port, 'M1' is the name of the ICL module, and 'M2' is the name of the design module matching the ICL module 'M1'.

The tool also verifies that the direction of each port on the mapped ICL module is consistent with the direction of the corresponding port in the design module. If a design module port has a conflicting direction, the tool issues the following error messages:

DataInPort 'PI' exists in the description of the ICL module 'M1'. However, the corresponding port in the design module 'M2' is not of a compatible direction. An ICL port of type DataInPort must map to a design port that is either an input or bidirectional port.

DataOutPort 'PO' exists in the description of the ICL module 'M1'. However, the corresponding port in the design module 'M2' is not of a compatible direction. An ICL port of type DataOutPort must map to a design port that is either an output or bidirectional port.

Where:

'PI' and 'PO' are the names of the ICL module ports, 'M1' is the name of the ICL module, and 'M2' is the name of the design module matching the ICL module 'M1'.

I2

Category: ICL Extraction

Contexts supported: patterns -ijtag

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that a connection can be identified from an ICL-attributed pin to another ICL-attributed pin or to a top-level port.

This DRC violation typically occurs when a pin is unconnected. Specifically, this rule checks that every ICL-attributed instance input pin is connected to either an ICL-attributed instance

output pin or a primary input port, and every ICL-attributed instance output pin is connected to either an ICL-attributed instance input pin or a primary output port.

The tool also checks if the simulated value for every ICL-attributed instance input pin is compatible with the tied value of 1 or 0 specified in the ICL using the allowed_tied_high or allowed_tied_low value for the connection_rule_option attribute, and reports an I2 violation if there is a mismatch. If the simulated value is X and the connection_rule_option is not allowed_no_source then the failure to drive the input pin is reported.

These checks are performed for all ICL input ports and for ICL output ports with the port functions DataOutPort and ScanOutPort.

If a connection cannot be identified, the tool issues the following error message:

```
The DataOutPort 'Q' on ICL-attributed design instance 'I', module 'M' does
not trace to any primary or ICL module port.
Either no structural connection exists, or the path is blocked.
```

If the trace stopped at only one gate, which is always the case in the backward trace, the tool issues one of the following error messages which includes the gate information:

```
The DataOutPort 'Q' on ICL-attributed design instance 'I', module 'M' does
not trace to any primary or ICL module port.
Either no structural connection exists, or the path is blocked.
The backward trace stopped at gate '/I/Q'.
```

```
The DataOutPort 'Q' on ICL-attributed design instance 'I', module 'M' does
not trace to any primary or ICL module port.
Either no structural connection exists, or the path is blocked.
The forward trace stopped at gate '/I/Q'.
```

If there is a mismatch between the simulated value and the tied value, the tool issues one of the following error messages:

```
Mismatch between permissible tied value (1) declared by attribute
'connection_rule_option' for DataInPort 'P' on ICL-attributed design
instance 'I', module 'M' and the observed simulated value 0.
```

```
Mismatch between permissible tied value (0) declared by attribute
'connection_rule_option' for DataInPort 'P' on ICL-attributed design
instance 'I', module 'M' and the observed simulated value 1.
```

Where:

'P' is the name of the DataInPort, 'Q' is the name of the DataOutPort, 'I' is the instance name of the ICL-attributed start instance, 'M' is the module name of the ICL-attributed start instance. The DFTVisualizer can then highlight the starting instance 'I' and pin 'P' and the last gates that was reached during the tracing process.

I3

Category: ICL Extraction

Contexts supported: patterns -ijtag

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the port functions of an identified connection between an ICL-attributed port on an ICL-attributed module match the port function connection rules.

If the port functions do not match, the tool issues the following error message:

```
The connection between ScanOutPort 'SO' on ICL-attributed design instance
'I1', module 'M1' and ClockPort 'SI' on ICL-attributed design instance
'I2', module 'M2' violates the ICL port function connection rules.
```

```
An instance ClockPort is only allowed to be driven by the following
sources: ClockPort on the parent module or ToClockPort reference from an
instance within the parent module. Where recognized values of the
function_modifier attribute are used to alter ICL port semantics they
must be applied consistently.
```

Where:

'I1' and 'I2' are the instance names of the ICL-attributed instances, 'M1' and 'M2' are the module names of the ICL-attributed instances, 'SO' is the name of the ScanOutPort on ICL-attributed design instance I1, 'SI' is the name of the ClockPort on ICL-attributed design instance 'I2'.

The port functions of the top-level module ports are inferred from the identified connections according to [Table 7-13](#) and are attached as port function attributes on the top level module ports.

Table 7-13. Port Connections

Start ICL-attributed Instance Port Function	Inferred Top Module Port Function
scan_in	scan_in
shift_en	shift_en
capture_en	capture_en
update_en	update_en
data_in	data_in
select	select
address	data_in
write_en	data_in

Table 7-13. Port Connections (cont.)

Start ICL-attributed Instance Port Function	Inferred Top Module Port Function
read_en	data_in
scan_out	scan_out
data_out	data_out
to_shift_en	to_shift_en
to_capture_en	to_capture_en
to_update_en	to_update_en
to_select	to_select
to_ir_select	to_select
to_reset	to_reset
to_clock	to_clock

I4

Category: ICL Extraction

Contexts supported: patterns -ijtag

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

This rule checks if an inferred port function and polarity for the primary input/output port is consistent for all found connections.

For example, a top-level module input port cannot be both a scan_in signal and a tck clock; it must be one or the other. If the inferred port function of port 'SI' is 'scan_in' due to an identified connection to port 'P1' and the inferred port function of port 'SI' is also 'TCK' due to another identified connection to port 'P1', the tool issues this error message.

```
Inconsistent port functions found for primary port /TCK.
Port function ScanInPort inferred due to a connection started at port 'SI'
on ICL-attributed design instance 'I1', module 'M1' is not consistent
with port function TCKPort inferred due to a connection started at port
'TCK' on ICL-attributed design instance 'I2', module 'M2'.
```

Where:

'SI' is the ICL-attributed start port of the first connection, 'I1' is the instance name of the ICL-attributed start instance of the first connection, 'M1' is the module name of the ICL-attributed start instance of the first connection, 'TCK' is the inferred port function of the primary port due to the second connection, 'I2' is the instance name of the ICL-attributed start instance of the

second connection, and ‘M2’ is the module name of the ICL-attributed start instance of the second connection.

If the polarity inferred due to the connection from the primary input ‘P’ to the module port ‘P1’ is different from the polarity inferred due to the connection from that primary input to another module port ‘P2’, the following error message will be issued:

```
Inconsistent polarity for reset port functions found for primary port P.  
Polarity 'Low'/'High' inferred due to a connection started at port 'P1' on  
ICL-attributed design instance 'I1', module 'M1' is not consistent with  
the polarity 'High'/'Low' inferred due to a connection started at port  
'P2' on ICL-attributed design instance 'I2', module 'M2'.
```

Where:

‘P’ is the primary port name, ‘P1’ is the ICL-attributed start port of the first connection, ‘I1’ is the instance name of the ICL-attributed start design instance of the first connection, ‘M1’ is the module name of ‘I1’, ‘P2’ is the ICL-attributed start port of the second connection, ‘I2’ is the instance name of the ICL-attributed start design instance of the second connection, ‘M2’ is the module name of ‘I2’.

I5

Category: ICL Extraction

Contexts supported: patterns -ijtag

Default Handling: Error

report_drc_rules: Supported

Checks the consistency of specified pin constraints on ICL-attributed design instances.

This DRC checks that the input ports specified in the forced_high_input_port_list are actually simulated to 1 in the stable_after_setup simulation conditions. It also checks that the input ports specified in the forced_low_input_port_list are actually simulated to 0 in the stable_after_setup simulation conditions. You typically need to adjust your test_setup procedure to correct this situation.

The error message is:

```
Input constraint verification failed for input pin 'P' on ICL-attributed  
design instance 'I', module 'M'.
```

```
The corresponding design module port was specified with the attribute 'A'  
in file 'F' on or near line 'L'.
```

```
Expected V1, simulated V2.
```

Where:

'P' is the name of the failing pin, 'I' is the instance name of the ICL-attributed design instance of 'P', 'M' is the module name of 'I', 'A' is the input constraint attribute name (either forced_high_input_port_list or forced_low_input_port_list) defined for 'P' in the ICL file 'F' on line number 'L'. 'V1' and 'V2' are the simulation values on the gate corresponding to the failing pin in the flat netlist.

I6

Category: ICL Extraction

Contexts supported: patterns -ijtag

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks all latches that have been previously identified during forward tracing of design instance pins with a scan out ICL attribute, and verifies that the backward tracing of the enable port of those latches reaches an identified primary port with TCK ICL attribute. In addition, all these latches have to be enabled by a low signal on the TCK port.

If no primary input port has been identified as TCK port, the tool issues the following error message:

```
Enable check of latch instance (LI) failed, driven by output pin (P)
on ICL-attributed design instance (I) of module (M) because no extracted
primary port with TCK attribute has been identified. (I6-1)
```

Where:

(LI) is the instance name of a latch found during forward tracing of the pin with a scan out functionality, (P) is the name of the start point of the forward tracing, (I) is the instance name of the ICL-attributed design instance of (P), and (M) is the module name of (I).

If the enable port of a latch does not have a fixed simulation value and the backward tracing from the enable port does not end at the primary input port that has been identified before as TCK port, the tool issues the following error message:

```
Enable check of latch instance (LI) failed, driven by output pin (P) on
ICL-attributed design instance (I) of module (M) because it requires an
inverted connection to the extracted primary port (P2) with TCK
attribute. Either no structural connection exists, or the path is blocked.
The backward trace stopped at gate (G). (I6-2)
```

Where:

(LI) is the instance name of a latch found during forward tracing of the pin with a scan out ICL attribute, (P) is the name of the start point of the forward tracing, (I) is the instance name of the ICL-attributed design instance of (P), (M) is the module name of (I), (P2) is the name of the primary input identified as TCK port during extraction and (G) is the name and ID of the last traced gate.

The DFT visualizer can then highlight the starting instance (LI), the identified primary port TCK (P2), the scan out pin (P) and the last gates that were reached during the backward tracing process of the latch enable port.

If the enable port of a latch has a fixed simulated value, the following error message is issued:

```
Enable check of latch instance (LI) failed, driven by output pin (P) on
ICL-attributed design instance (I) of module (M) because it requires an
inverted connection to the extracted primary port (P2) with TCK
attribute. The path is blocked by a signal setting. (I6-3)
```

Due to the blocking signal settings the DFT visualizer will highlight the gates that were reached during a structural backward tracing process of the latch enable port, the starting instance (LI), the identified primary port TCK (P2) and the scan out pin.

Where:

(P) is the name of the start point of the forward tracing, (I) is the instance name of the ICL-attributed design instance of (P), and (M) is the module name of (I),

If the enable port of a latch does not have a fixed simulated value and the backward tracing ends at the primary input port that has been identified before as TCK port, but a low signal simulation does not enable the latch, the error message is:

```
Enable check of latch instance (LI) failed, driven by output pin (P) on
ICL-attributed design instance (I) of module (M) because a low signal at
the extracted primary pin (P2) with TCK attribute will not enable the
latch. (I6-4)
```

The DFT visualizer can then highlight the starting instance (LI), the identified primary port TCK (P2), the scan out pin (P) and the path from the enable port of the latch to the (P2) port.

Where:

(P) is the name of the start point of the forward tracing, (I) is the instance name of the ICL-attributed design instance of (P), (M) is the module name of (I),

I7

Category: ICL Extraction

Contexts supported: patterns -ijtag

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

This DRC only applies to design ports which have been subject to the add_clocks command.

These ports are referred to as clocks.

This rule checks if the properties of the clocks are consistent with the port functions and function_modifier attributes of the related extracted ICL ports.

The following is checked in detail:

- If a clock is mapped to an extracted ICL port, then this ICL port must be one of the following:
 - ClockPort
 - TCKPort
 - CaptureEnPort with attribute function_modifier = "CaptureShiftClock"
 - CaptureEnPort with attribute function_modifier = "CaptureShiftClockInv"
- If a clock is mapped to an extracted ICL port of type TCKPort, then it must not be an asynchronous clock.

The following error message is issued in case of a violation against the first requirement:

```
// Error: The DataInPort 'dat' on ICL-attributed design instance 'inst',
// module 'block' is connected to the primary input port 'DAT',
// which is specified as a clock.
// Top module clock ports are allowed to be connected only to
// module ports defined as ClockPort, TCKPort or module ports
// defined as CaptureEnPort when qualified with the ICL attribute
// function_modifier = "CaptureShiftClock" or
// function_modifier = "CaptureShiftClockInv". (I7-1)
```

The following error message is issued in case of a violation against the second requirement:

```
// Error: The ClockPort 'clk' on ICL-attributed design instance 'inst',
// module 'block' is connected to the primary input port 'CLK',
// which is not specified as a pulse-always clock. (I7-3)
```

The following error message is issued in case of a violation against the third requirement:

```
// Error: The TCKPort 'tck' on ICL-attributed design instance 'inst',
// module 'block' is connected to the primary input port 'TCK',
// which is specified as an asynchronous clock. (I7-4)
```

ICL Semantic Rules (ICL Rules)

The tool performs ICL semantic rule checks upon reading (using the `read_icl` command) an ICL file into the tool. These checks provide a more extensive check of the ICL upon reading the file or files into Tessent IJTAG. Basically, the ICL must conform to all of the semantic rules set out for the ICL in the IEEE 1687-2014 (IJTAG) standard.

The semantic rule checks are as follows:

- **Parser** — When you read in an ICL module, the tool parses the file with a series of checks to detect for errors. The tool terminates the ICL parsing checks if any error is detected.
- **Module** — Once the complete module is available, the tool performs an extensive set of semantic checks using the totality of information contained exclusively within the module.
- **Hierarchical Module** — When the `set_current_design` command is issued the entire ICL module instance hierarchy is traversed and each module is rechecked, taking note of any instance parameter overrides on the module instances. Also, at this time those semantic rules that check the relationships between modules, such as module instance port binding semantics, are validated. If any of these checks fail then the ICL hierarchy is not well formed and cannot be used, the `set_current_design` command will fail.
- **ICL Primitive Model** — A further set of checks are performed, using the more detailed ICL primitive model, these are performed at the primitive model bit level and generally check interconnection semantics locally, within a single module, or on the flattened ICL primitive representation, at the global level. Again, if any of these checks fail then the ICL hierarchy is not well formed and cannot be used, the `set_current_design` command will fail.

Note

Many of the ICL Rules have multiple messages associated with them as some rules have broad classes of failure modes

ICL1

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that the ICL source files have no parser syntax errors.

A failure of this semantic rule occurs if the input ICL source is not in compliance with the formal grammar for ICL. The accompanying message will show where the tool was when it encountered the incorrect syntax:

```
// Error: Incorrect character sequence. Encountered on or near line 5
// of file source.icl:
//           ^
//           ICL1
```

Note that the initial location of the incorrect syntax may actually be found prior to the location reported.

ICL2

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that the ICL source file has no un-terminated multi-line comments.

ICL3

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that a module contains non-overlapping names within the single naming region used for several types of design objects.

This rule checks the following objects:

- Ports
- Registers
- One-hot groups
- Multiplexers
- Alias description
- Logic Signals

ICL4

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that an ICL module does not contain a duplicate attribute name for a single attributed declaration scope, such as a module or a register.

ICL5

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that an ICL module has no duplicate RefEnum usage in those contexts where a binding to an enumeration can be made. ICL allows only a single enumeration set to be referenced.

ICL6

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that the ICL source file does not contain incorrectly cased ICL keywords. ICL keywords are case sensitive.

ICL uses mixed case keywords, that must be typed exactly as specified. This check will report a failure when the reading of an ICL source file encounters a context that is expecting one of these keywords but sees an incorrectly capitalized version of a valid keyword.

ICL7

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that an identifier does not exceed the maximum character length.

The maximum length for an identifier is 1024 characters.

ICL8

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that the ICL source file has at least one module.

ICL9

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that the ICL source file has no duplicate ICL module names.

All of the modules within a single ICL source file must be unique. A source file is allowed to provide a new definition of a module that has previously been read from another ICL source file; in this case the previous definition of the module is replaced with the new module definition, if the ICL source file is read without error.

ICL10

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that an ICL module has no duplicate ICL parameter names within the definition of a single module.

ICL11

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that an ICL module has no duplicate ScanInterface names within the definition of a single module.

ICL12

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that the ICL source file has no duplicate property specifications.

For example, a DataOutPort declaration may provide a specification of the source value for the port using the Source keyword. This specification may only be made once within the declaration of the port.

ICL13

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that an ActivePolarity specification of a ResetPort or ToResetPort has one of the values 0 or 1.

ICL14

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that the ICL source file has no duplicate instance names within a module.

ICL15

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the ICL source file contains no directly self-referential instances.

A module is not allowed to instance itself. Circular instance hierarchies are also not allowed, and are caught by another rule check.

ICL16

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that each module instance within a one hot data group declares the address value for that instance, using the AddressValue specification.

ICL17

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that within a module definition, contained in an ICL source file, each module instance does not have multiple overrides for the same instance parameter name.

ICL18

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that the specification of an address value for a module instance only occurs within module instances that are defined within a one hot data group. Module instances that occur outside of a one hot data group, in the main body of a module, cannot have address value declarations, using the AddressValue specification.

ICL19

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Each scan register declaration must define the source of the scan input, using the ScanInSource specification.

ICL20

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that the ICL source file contains only supported ICL Constructs.

Tessent IJTAG does not yet provide support for the full ICL syntax. This rule will fail when the ICL reader encounters a piece of ICL syntax that is not currently supported.

ICL21

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that the data register declaration within a one hot data group provides a definition of the address value for that data register, using the AddressValue specification.

ICL22

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that a data register declaration that contains no write data source, which implies that the register is read only, also does not provide a write enable source. A read only data register does not require and must not have a write enable control.

ICL23

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that a data register with an address value definition does not also have a write enable definition. Where a data register is defined within a one hot data group and has an address value the address and explicit write enable control will be used to control write accesses to the data register. Such an addressed data register does not require and must not define a write enable source.

ICL24

Reserved for future use.

ICL25

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that an addressed data register does not have a write data source.

An addressed data register will implicitly obtain the write data source from the data inputs of the module.

ICL26

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that a module definition, within an ICL source file, contains no duplicate enumeration declarations. Within an ICL module each enumeration value set must be given a unique name. The same enumeration element name can be reused, possibly with different value bindings, across multiple enumeration value sets.

ICL27

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that the ICL source file does not contain an enumerations using the Enum specification with a duplicate Enum item.

ICL28

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that the ICL source file does not contain an un-terminated string constant.

ICL29

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the iApplyEndState value, defined within an alias declaration, does not contain unknown bits.

ICL30

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks for inverted string constants.

Within a constant value expression the inversion operator (~) can only be applied to numeric constant values.

ICL31

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that the constant value concatenation used to specify the value of a parameter definition in a module is comprised entirely of constant value elements that are of compatible type, either all string values or all sized numeric values.

ICL32

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that a parameter definition, within a module declaration, does not contain a concatenation of values with an unsized numeric constant value.

ICL33

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that there are no self referential parameter definitions.

A parameter definition must be made in terms of explicit immediate constant values or references to other parameter definitions. When the parameter definition hierarchy is resolved it cannot contain cyclical parameter references.

ICL34

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the size preamble for a sized number is a non-zero unsigned decimal number, where the size value is a deferred constant value or a parameter reference whose value is not verified until ICL51 is activated.

ICL35

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that only module parameters (not local parameters) are overridden in a module instance.

ICL36

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that any parameter present in an instance matches the definition in the instantiated module so that the parameter can be substituted wherever it is found in the module.

Additionally, the parameter reference included in a parameter override element must match both the name and type of a parameter definition within the module being instantiated.

ICL37

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error

report_drc_rules: Supported

Checks that a module definition contains at least one port definition. A module without any ports is not valid within ICL.

However, Tessent Shell does not require ICL modules with InSystemTest (IST) functionality to have any port definitions. These modules are not IEEE1687-2014 compliant and might be rejected by third-party tools.

ICL38

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies several conditions related to ports in the design.

Specifically, this rule verifies the following:

- There can be at most one WriteEnPort per module.
- There can be at most one ReadEnPort per module.

ICL39

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that all range specifications of an ICL port have the same index direction.

Within a module, the same base name can be used when defining different vector port elements. However, all of the vector port definitions sharing the same base name must use a consistent index direction (either ascending or descending).

ICL40

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that a module has at most one definition of a port using a scalar only name. If multiple bits are required, then they must be vector bits.

ICL41

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the range specifications of an ICL port do not overlap.

Within a module, the same base name can be used when defining different vector port elements. However, all of the vector port definitions sharing the same base name must have mutually disjoint index ranges.

ICL42

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that elements referenced within a ScanInterface are ports.

ICL43

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that the module that declares a scan input port for a client interface also declares a shift enable control port or a TMS port for that client scan interface. A client scan interface is any scan interface that doesn't contain host scan interface control ports.

ICL44

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that a scan-in port is present in the module if the module declares either a scan register or a scan out port.

ICL45

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that a module with a ToIRSelectPort also has a TMSPort.

ICL48

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies the input port bindings on an instance within a module. Each bit of each input port binding must correspond to an input port bit definition on the instantiated module. Where an input port binding has a vector range constraint the underlying module port must have a port definition with a compatible definition.

ICL49

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that all module input ports that require input port bindings on an instance of a module have the bindings specified.

Table 7-14 lists the port types that require input binding.

Table 7-14. Port Types and Required Input Binding

Port Type
DataInPort ¹
AddressPort ²
WriteEnPort ³
ReadEnPort ⁴
ScanInPort

1. When the instance does not have the AddressValue property.
2. When the instance does not have the AddressValue property.
3. When the instance does not have the AddressValue property.
4. When the instance does not have the AddressValue property.

ICL50

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that each bit of the module instance input port bindings within a module is specified only once. It is not valid to specify more than one input source binding for any bit of a module input port in a module instance.

ICL51

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the width of a sized constant value is greater than 0 (zero).

This check is similar to [ICL34](#), however here the rule also considers the actual resolved values of any parameter references.

ICL52

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that the size of a constant value expression or a reference to a named element within the module is compatible with the size expected at the location that the expression or reference is used.

For example a data register source value must be no wider than the width of the data register itself. This check takes into account unsized expression concatenation filling and truncation behaviors when considering the size compatibility.

ICL53

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the name referenced from a parameter reference corresponds to the name of a parameter or a local parameter within the same module.

ICL54

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the type of a parameter being de-referenced matches the type expected by the context of the point of de-reference. For example, within a range constraint of a vector signal “foo[\$p]” the type of the parameter p must be an unsigned integer.

ICL55

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the parameter reference included in a parameter override element matches both the name and type of a parameter definition within the module being instantiated.

ICL56

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that any instance output port reference matches an output port on an instance within the module.

ICL57

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that any reference to an element as an rvalue makes reference to a name that exists within the same module, or an output or a module instantiated within that module. It is not permitted to make reference to hierarchical aliases. Where the reference uses a vector range constraint, it must actually reference an object that is itself a vector entity with a compatible range. References to module local names must resolve correctly to a readable entity.

ICL58

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that for a known size target, only one unsized number is included with a group of sized numbers. For an unknown size target, no unsized number can be included in concatenation.

ICL59

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that a differential inverse clock is only an inverse of a primary clock. Additionally, the clock port name, an input port connection of a clock port name is required and must be a concat_clock_signal with a matching width and, if differential, a corresponding differential source.

ICL60

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that all instances are instances of modules for which a module definition has been read. It is not valid to use an ICL module hierarchy that contains references to modules that have not been defined.

ICL61

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that attribute values are either strings or sized binary values or unsigned integers.

ICL62

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that when the iApplyEndState option is present, each bit of the resolved alias is a suitable target for an iWrite, specifically a DataInPort or a register bit.

ICL63

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies for a resolved alias with iApplyEndState value that includes register bits that each such bit has a reset value, and that the reset value matches the iApplyEndState value.

ICL64

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that connected ResetPorts and ToResetPorts have consistent ActivePolarity specifications.

ICL65

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the source of an rvalue is of a suitable type to drive the location that the rvalue is being consumed.

ICL66

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that no component has itself as a member of its fanin.

ICL67

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that a ToIRSelectPort only connects to the select input of a 2:1 ScanMux.

ICL68

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that within each module_def that all scan signals have a path from at least one scanInPort_name and to at least one scanOutPort_name.

ICL70

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

`report_drc_rules`: Supported

Verifies that a scan interface is composed of the correct subset of signals along with control signals related by direction.

Specifically:

- Scan Client Interface — {ScanInPort, ScanOutPort, SelectPort, CaptureEnPort, ShiftEnPort, UpdateEnPort}
- Scan Host Interface — {ScanInPort, ScanOutPort, ToSelectPort, ToCaptureEnPort, ToShiftEnPort, ToUpdateEnPort}
- TAP Client Interface — {ScanInPort, ScanOutPort, TMSPort, TRSTPort}
- TAP Host Interface — {ScanInPort, ScanOutPort, ToTMSPort, ToTRSTPort}

Scan client, scan host, TAP client and TAP host ports may not be mixed.

ICL71

Category: ICL Semantics

Rule Check Type: ICL Primitive Model

Contexts supported: All contexts

Default Handling: Error

`report_drc_rules`: Supported

Verifies that the anonymous ScanInterface can be correctly assembled in an ICL module with a ScanInPort and/or a ScanOutPort but without explicit ScanInterface specifications.

This check applies only to the ICL module associated with the current design.

If an ICL module has a ScanInPort and/or a ScanOutPort but does not have an explicit ScanInterface specification, then Tessent Shell creates the anonymous ScanInterface from the existing ScanInPort, ScanOutPort and the ScanInterface control ports of the ICL module. ICL71 checks if this ScanInterface creation is possible as well as unique.

Each ICL71 message starts with the following lines:

```
// Error: ICL module 'test' contains ports of type 'ScanInPort' and ports
// of type 'ScanOutPort', but no ScanInterface specification. However,
// the combination of specified scan ports and ScanInterface control
// ports does not allow an unambiguous assembling of the anonymous
// ScanInterface.
// The module has the following problematic ports:
```

followed by a list of affected ports and explanations of what is wrong (called “port_list” in the following).

Each ICL71 message ends with the source location of the affected module:

```
// Found on or near line 1 of file '../data/icl/test1.icl'. (ICL71-1)
```

The anonymous ScanInterface cannot have more than one ScanInPort or more than one ScanOutPort. The existence of more than one ScanInPort or more than one ScanOutPort in a module without explicit ScanInterface specification makes the anonymous ScanInterface ambiguous. In this case, port_list consists of the following:

```
// 3 ScanInPorts (si1, si2, si3), explicit ScanInterface specification
// required.
// 2 ScanOutPorts (so1, so2), explicit ScanInterface specification
// required.
```

The next step looks for ScanInterface control ports indicating ScanInterfaces of conflicting types. Each ScanInterface can be one of the following:

- client ScanInterface (which has one port with function ShiftEnPort and/or one or many ports with function SelectPort)
- host ScanInterface (which has one port with function ToShiftEnPort and/or one or many ports with function ToSelectPort)
- client-TAP ScanInterface (which has one port with function TMSPort)
- host-TAP ScanInterface (which has one port with function ToTMSPort)

Ports with function SelectPort can also be present in an ICL module with a ScanInterface other than “client”, and ports with function ToSelectPort can also be present in an ICL module with a ScanInterface other than “host”. Therefore, SelectPorts and ToSelectPorts are not part of the first step of the analysis of conflicting ScanInterface types. Only ports of type ShiftEnPort, ToShiftEnPort, TMSPort and ToTMSPort are considered during this analysis. If there is more than one port function out of ShiftEnPort, ToShiftEnPort, TMSPort and ToTMSPort present in the ICL module, the port_list shows the related ports:

```
// 1 ShiftEnPort (se), indicating the ScanInterface type 'client',
// 1 TMSPort (tms), indicating the ScanInterface type 'client-TAP'.
```

If there is no port with function ShiftEnPort, ToShiftEnPort, TMSPort, ToTMSPort, then the ScanInterface type must be derived from the SelectPorts and ToSelectPorts. In this situation, ICL71 checks also conflicts between ports with function SelectPort and ports with function ToSelectPort. If there is more than one port function out of SelectPort and ToSelectPort present in the ICL module, the port_list shows the following:

```
// 1 SelectPort (sel), indicating the ScanInterface type 'client',
// 1 ToSelectPort (tsel), indicating the ScanInterface type 'host'.
```

If there is no port with function ShiftEnPort, ToShiftEnPort, TMSPort, ToTMSPort, SelectPort or ToSelectPort, such that the ScanInterface creation is invalid whatever ScanInterface type is chosen, port_list contains the following:

```
// none of the mandatory ScanInterface control ports.
```

The absence of a ScanInPort or a ScanOutPort also reduces the possible choices for the ScanInterface type. Client and client-TAP ScanInterfaces must have a ScanInPort as well as a ScanOutPort, while host and host-TAP ScanInterfaces need only one of them (but may have both). If there is no ScanInPort or no ScanOutPort, but the existing ScanInterface control ports only allow ScanInterfaces of type “client” or “client-TAP” instead of “host” or “host-TAP”, then the port_list contains the following hints:

```
// one ScanInPort, no ScanOutPort. The anonymous ScanInterface must be of
// type 'host' or 'host-TAP', none of the mandatory control ports for
// ScanInterfaces of type 'host' or 'host-TAP', 1 TMSPort (tms),
// indicating the ScanInterface type 'client-TAP'.
```

If there is exactly one port function out of ShiftEnPort, ToShiftEnPort, TMSPort and ToTMSPort present in the ICL module, then ICL71 still needs to check that there is exactly one port with this function. Otherwise the ScanInterface would be ambiguous. If there is more than one port of type ShiftEnPort, port_list consists of the following:

```
// 2 ShiftEnPorts (sel1, se2), the tool cannot build an anonymous client
// ScanInterface without a unique ShiftEnPort or a unique SelectPort.
```

In case of more than one port of type ToShiftEnPort:

```
// 2 ToShiftEnPorts (tse1, tse2), the tool cannot build an anonymous host
// ScanInterface without a unique ToShiftEnPort or a unique ToSelectPort.
```

In case of more than one port of type TMSPort:

```
// 2 TMSPorts (tms1, tms2), the tool cannot build an anonymous client-TAP
// ScanInterface without a unique TMSPort.
```

In case of more than one port of type ToTMSPort:

```
// 2 ToTMSPorts (ttms1, ttms2), the tool cannot build an anonymous
// host-TAP ScanInterface without a unique ToTMSPort.
```

If there are no ports with function ShiftEnPort, ToShiftEnPort, TMSPort and ToTMSPort, then the ICL module must contain at least ports with function SelectPort or ToSelectPort in order to allow the creation of a valid anonymous ScanInterface. Anonymous ScanInterfaces with more than one SelectPort or more than one ToSelectPort are not created, although they would be allowed according to the standard. If there are several ports with function SelectPort, port_list is as follows:

```
// 2 SelectPorts (sel1, sel2), the tool cannot build an anonymous client
// ScanInterface without a unique ShiftEnPort or a unique SelectPort.
```

In case of more than one port of type ToSelectPort:

```
// 2 ToSelectPorts (tsel1, tsel2), the tool cannot build an anonymous
// host ScanInterface without a unique ToShiftEnPort or a unique
// ToSelectPort.
```

The summary message for ICL71:

```
ICL71: #fails=1 handling=error (assembling of anonymous ScanInterface failed)
```

ICL75

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that the instance output referenced from the Port specification of a one hot scan group or one hot data group is a port with an enable control or that is a port that is driven by a one hot scan group or one hot data group, respectively.

The net effect of this check is to ensure that any port reference will be a reference to an element that has a tri-state driver, either directly (because the port is tri-state enabled) or indirectly because it references a port that is driven by a one hot group.

ICL76

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies rules about ResetValues for data storage elements.

Specifically:

- Data storage elements controlling scan mux must have ResetValue.
- Data storage elements enabling ScanOutPort must have ResetValue.

ICL77

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error

report_drc_rules: Supported

Verifies that a ScanMux or OneHotScanGroup does not deselect a controlling ScanRegister.

Reconfigurable Scan Networks may run into deadlocks if scan registers, which control the scan path configuration, take themselves out of the active path. In such a situation, the scan path through the register cannot be activated without altering the values in the register, and the values in the register cannot be altered without activating the scan path through the register. In order to avoid such situations, ICL77 checks if there is a register which controls a ScanMux or a OneHotScanGroup and which is only accessible through a subset of the inputs of the ScanMux/OneHotScanGroup.

However, such a configuration can be intended, therefore the severity of that rule can be lowered to “Warning”. If a scan path deadlock has happened, it can usually be resolved by a Global Reset or a Local Reset, unless the ResetValue specifications are chosen such that they establish a deadlock from the very beginning.

The ICL77 check does not deal with scan paths which would never be selected by the retargeter anyway, such as scan paths that are unconnected or tied off. It still may be possible to configure the scan network explicitly (by means of iWrite and iApply), such that a deadlock happens, for example, by selecting such an unconnected or tied scan path. ICL77 mainly aims at the prevention of accidental deadlocks which the retargeter could run into.

ICL78

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that a ScanRegister that drives either the data input of a ScanMux whose select input comes from a ToIRSelectPort must be in the active scan chain in either one or the other state of the ToIRSelect signal, but not both.

The two inputs of the ToIRSelect scan mux are considered up until the point at which they reconverge. Scan registers in one path cannot be in the other path.

ICL79

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

When the iApplyEndState option is present, then multiple iApplyEndState values must not specify incompatible values for any target. If there are multiple iApplyEndState values for a single target bit then they must all be of the same value.

The ultimate source of the iApplyEndState value must come directly from a data register, scan register or primary input, there can be no other intervening logic in that path.

ICL80

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

The names associated with a hierarchical alias definition must all be resolvable (they must exist) to entities of an appropriate type and refer to things that have definitions compatible to their usage within the hierarchical alias definition. For example if the reference in the alias definition includes a range constraint then the resolved entity must be a vector object with compatible range definition.

ICL84

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that there are no unknown bits in a constant value expression and that the evaluation of the expression does not cause an integer overflow or a division by zero.

ICL85

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks if there is a LogicSignal expression containing an operand with unknown bits.

ICL86

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks if there is a LogicSignal expression containing operands with incompatible widths. For example, 1'b0 | 2'b11.

ICL87

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks for problems with enumeration references. For example, an enum value is not defined or a register has no enum references but uses it.

ICL88

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that there are no circular instance hierarchies in the ICL design.

If a circular loop is found, the error message also indicates the location of the loop.

```
// Error: Loop in module instantiation tree:  
//         Module 'm1' has instance 'i2' of module 'm2'.  
//         Module 'm3' has instance 'i1' of module 'm1'.  
//         Module 'm2' has instance 'i3' of module 'm3'.  
//         ICL hierarchies with circular instance loops are not supported.  
Found on or near line 12 of file '../data/icl/test.icl'.  
// ICL88
```

This is a module level hierarchical check that is performed only once the set_current_design command has been issued.

ICL89

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

ICL connectivity extraction can be directed by the value of certain special attributes associated with the ICL ports for which a connection is being extracted, such as the ‘connection_rule_option’ attribute.

For more information about directing ICL extraction with ICL attributes see “[Attributes of the ICL Extraction Flow](#)” semantic in the *Tessent IJTAG User’s Manual*. This semantic rule checks that the ICL port connection rule attribute has a value that is compatible with the port direction and will fail if this is not the case.

An error message is issued if the attribute ‘connection_rule_option’ has a value of ‘allowed_no_destination’ for an input port, or one of the following values for an output port: ‘allowed_no_source’, ‘allowed_tied’, ‘allowed_tied_low’, ‘allowed_tied_high’.

For example:

```
// Error: ICL module 'block1' declares the port 'broken_i1' with
attribute 'connection_rule_option' that has the invalid resolved value
'allowed_no_destination'. For an input port the value must be one of:
'allowed_no_source', 'allowed_tied', 'allowed_tied_high' or
'allowed_tied_low'.
// Error: ICL module 'block1' declares the port 'broken_o1' with
attribute 'connection_rule_option' that has the invalid resolved value
'allowed_no_source'. For an output port only the value
'allowed_no_destination' is permitted.
// Error: ICL module 'block1' declares the port 'broken_o2' with
attribute 'connection_rule_option' that has the invalid resolved value
'allowed_tied'. For an output port only the value
'allowed_no_destination' is permitted.
// Error: ICL module 'block1' declares the port 'broken_o3' with
attribute 'connection_rule_option' that has the invalid resolved value
'allowed_tied_low'. For an output port only the value
'allowed_no_destination' is permitted.
// Error: ICL module 'block1' declares the port 'broken_o4' with
attribute 'connection_rule_option' that has the invalid resolved value
'allowed_tied_high'. For an output port only the value
'allowed_no_destination' is permitted.
```

ICL90

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks if there is a problem with the tessent_scan_register attribute.

A scan register with the tessent_scan_register attribute is not allowed to specify a capture source, reset value or default load. If a scan register with the tessent_scan_register attribute specifies a range constraint, it must be in descending order with a right index of 0. A scan register with the tessent_scan_register attribute cannot be the driver of a data out port or a logic signal.

ICL91

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks if there is a problem with the tessent_signature attribute.

If the module contains a tessent_instrument_type attribute which defines the module to be an instrument of type Mentor, the tessent_signature attribute must be present and must contain a valid signature.

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that a module definition, within an ICL source file, contains no duplicate access link opcode active signal set declarations. Within an ICL module an opcode active signal set can be specified only once in an access link.

ICL97

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that a module definition, within an ICL source file, contains no access link declarations if the module does not specify the top module. Only the top ICL module can have access link declarations.

ICL98

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that a module definition, within an ICL source file, contains access link declarations that are associated with valid paths.

ICL99

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that mux selection conditions are not made redundant by previous selections in the same mux.

ICL100

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Checks that the ICL source file has no duplicate chain names within a scan interface.

ICL101

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that a ScanInterface contains ports that allow its unique classification into one of the following four ScanInterface types: client, host, client-TAP or host-TAP.

ICL102

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies rules about addressable data registers.

Specifically:

- Modules containing readable addressable data registers must have a ReadEnPort.
- Modules containing writable addressable data registers must have a WriteEnPort.

ICL103

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error

report_drc_rules: Supported

Verifies that each ScanInPort and each ScanOutPort of the top module is referenced explicitly in at least one ScanInterface specification, if the module contains more than one ScanInPort and/or more than one ScanOutPort.

This check applies only to the ICL module associated with the current design.

ICL104

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Each ‘scan client’ ScanInterface statement in a blackbox module must include a valid DefaultLoadValue definition, which reflects the length of the scan chain behind each ScanInterface after a global reset.

ICL105

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the ports in a ScanInterface conform to certain rules.

Specifically:

A Scan Client Interface shall have

- one or many pairs of ports with function ScanInPort and ScanOutPort
- one port with function ShiftEnPort and/or one or many ports with function SelectPort
- zero or one port with function CaptureEnPort, without function_modifier attribute
- zero or one port with function UpdateEnPort, without function_modifier attribute
- optional port(s) with function CaptureEnPort and distinct function_modifier attributes
- optional port(s) with function UpdateEnPort and distinct function_modifier attributes

A Scan Host Interface shall have

- one port with function ScanInPort and/or one port with function ScanOutPort
- one port with function ToShiftEnPort and/or one or many ports with function ToSelectPort
- zero or one port with function ToCaptureEnPort, without function_modifier attribute
- zero or one port with functionToUpdateEnPort, without function_modifier attribute

- optional port(s) with function ToCaptureEnPort and distinct function_modifier attributes
- optional port(s) with function ToUpdateEnPort and distinct function_modifier attributes

A TAP Client Interface shall have

- one or many pairs of ports with function ScanInPort and ScanOutPort
- one port with function TMSPort
- (optional port with function TRSTPort)

A TAP Host Interface shall have

- one port with function ScanInPort and/or one port with function ScanOutPort
- one port with function ToTMSPort
- (optional port with function ToTRSTPort)

Note

 ScanInterfaces with multiple CaptureEnPorts, UpdateEnPorts, ToCaptureEnPorts or ToUpdateEnPorts are not standard-compliant. Third-party IJTAG tools might reject the processing of ICL files with such ScanInterface specifications.

ICL106

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that a chain definition of an ICL module scan interface only contains ports of the type ScanInPort and ScanOutPorts

ICL107

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that only scan client and TAP client interfaces can have scan chain definitions. Scan host and TAP host interfaces cannot have scan chain definitions.

ICL108

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that if a client scan interface has more than one ScanInPort/ScanOutPort pair, then each pair shall be declared in a scan chain definition.

ICL109

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that if a scan chain definition is present, there are no ScanInPort, ScanOutPort or DefaultLoadValue statements outside the scan chain definition.

ICL110

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that for every scan chain definition of an ICL module's scan interface, a ScanInPort/ScanOutPort pair is defined. The ports of this chain cannot be used in any other scan chain definition in the same scan interface.

ICL111

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies rules about data storage elements.

Specifically:

- Data storage elements controlling SelectPorts of ScanInterfaces must have ResetValue.
- Data storage elements controlling ToSelectPorts of ScanInterfaces must have ResetValue.

ICL112

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that no binary digits of value 1 are truncated from a sized constant number.

If the number of binary digits of a number's binary representation is larger than the number of binary digits defined by the size constant, then the leftmost digits are truncated until it matches the size constant. Truncating a digit of value 1 generates an error.

ICL113

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies the mutual exclusivity of certain items in a ToClockPort specification.

The use of "Period" is mutually exclusive with the usage of "DifferentialInvOf", "Source", "FreqMultiplier" and "FreqDivider".

The use of "DifferentialInvOf" is mutually exclusive with the usage of "Period", "Source", "FreqMultiplier" and "FreqDivider".

ICL114

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that ports of type AddressPort, ReadEnPort and WriteEnPort are not explicitly connected in an instantiation with an AddressValue specification.

ICL115

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

This check verifies that the appropriate restrictions are fulfilled when an ICL DataMux is under certain circumstances.

If an ICL DataMux is used for the gating of an UpdateEn signal, a CaptureEn signal, a Reset signal, a TMS signal or a TRST signal, the following restrictions apply to the types of the other multiplexer inputs:

If the intercepted signal is of type captureEn signal or updateEn signal, all the other multiplexer inputs must be constant zero values.

If the intercepted signal is of type reset signal, TRST signal or TMS signal, all the other multiplexer inputs must be signals of type data signal.

See also ICL129 for more details on the use of the DataMux construct for the interception of reset signals, TRST signals or TMS signals.

ICL116

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the function _ modifier attribute is used consistently, if an ICL DataMux is used for the gating of an UpdateEn signal, a CaptureEn signal, a Reset signal, a TMS signal or a TRST signal.

ICL117

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that there is no DataRegister involved in the scan path configuration. There must not be any DataRegister in the input cone of the select input of a ScanMux or in the input cone of the EnableSource of a ScanOutPort.

ICL118

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that there is no scan path from the ScanInPort of a Host ScanInterface to the ScanOutPort.

A host ScanInterface with both ScanInPort and ScanOutPort provides scan data through its ScanOutPort to the instrument(s) under its control, and receives scan data through its ScanInPort from the instrument(s) under its control. Therefore there cannot be a scan path between the ScanInPort and the ScanOutPort of a host ScanInterface inside the module containing the ScanInterface.

ICL119

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the instruments which are under control of an ICL host ScanInterface do not bypass the ScanInPort or the ScanOutPort of that ScanInterface.

If a host ScanInterface has both a ScanInPort as well as a ScanOutPort, then the instrument(s) under its control must also use both of them. It is not allowed to connect the instrument(s) to the ScanInPort only and let the ScanOutPort be unused, nor is it allowed to connect the instrument(s) to the ScanOutPort only and let the ScanInPort be unused.

ICL120

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the function_modifier attribute definition of an ICL port is compatible with the function_modifier attribute definition of the source of that ICL port.

ICL121

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the value of the attribute “function_modifier” of an ICL port is one of the following: CaptureShiftClock, CaptureShiftClockInv, tap_fsm_state, tap_fsm_state_delayed.

ICL122

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the DefaultLoadValue specification and the ResetValue specification of a register match at those bits which are non-X in both values.

ICL123

Category: ICL Semantics

Rule Check Type: ICL Primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the source of certain output ports can be unambiguously implied, if it has not been explicitly specified.

If there is a ToTRSTPort without “Source” property, the module must not have more than one input port of type TRSTPort.

If there is a ToTMSPort without “Source” property, the module must not have more than one input port of type TMSPort.

If there is a ToResetPort without “Source” property, the module must not have more than one input port of type ResetPort.

ICL124

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the source of certain instance input ports can be unambiguously implied, if the instance input port binding has not been explicitly specified.

If there is an instance port of type TRSTPort without input port binding, the module that contains the instance must not have more than one input port of type TRSTPort.

If there an instance port of type TMSPort without input port binding, the module that contains the instance must not have more than one input port of type TMSPort.

If there is an instance port of type ResetPort without input port binding, the module that contains the instance must not have more than one input port of type ResetPort.

ICL125

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the module contains the required input ports for the implied sources of certain module output ports.

If there is a ToTMSPort without “Source” property, then the module must also have a TMSPort. The ToTMSPort will then be assumed to be connected to that unique TMSPort. ICL123 ensures there is only one TMSPort in that case.

ICL126

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the module contains the required input ports for the implied sources of certain instance input port bindings.

If there is an instance without explicit input port binding for a port of type TMSPort, then the parent module must also have a TMSPort. The instance input port of type TMSPort will then be assumed to be connected to that unique TMSPort of the parent module. ICL124 ensures there is only one TMSPort in that case.

ICL127

Category: ICL Semantics

Rule Check Type: ICL primitive model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Not supported

Verifies that a module containing registers with ResetValue property has a unique reset signal.

In order to allow the unambiguous association between registers and their local reset source, there must be at most one reset signal in a module containing DataRegisters or ScanRegisters with ResetValue property. The ICL127 check considers module input ports of type ResetPort and instance output ports of type ToResetPort as a “reset signal”.

If the module does not have a reset signal, then the registers with ResetValue property only react to the Global Reset.

ICL128

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that an ICL module with addressable instances and/or addressable data registers also has AddressPort specifications.

Currently, explicit input port bindings of the AddressPorts of an addressable instance are not supported (see ICL114). An addressable instance can only be instantiated in a module with AddressPort specifications, and those specifications are used to provide the address value to the addressable instance. The ultimate source of the address signal (scan register or primary input) must be declared outside of the module that contains the addressable instance.

ICL129

Category: ICL Semantics

Rule Check Type: ICL Primitive Model

Contexts supported: All contexts

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that the multiplexers, which are part of the control logic of reset signals, TRST signals or TMS signals, select the appropriate input after a reset is performed.

The ICL construct DataMux can be used to intercept reset signals, TRST signals and TMS signals. This is required, for example, for the implementation of a Local Reset or for the instantiation of child TAPs. Such a “specialized” DataMux has exactly one data input with a special function (reset, TRST, TMS), while the other inputs are connected to data signals providing, for example, the local reset value. The ultimate sources of the select input(s) of the DataMux must be either primary inputs or registers with ResetValue. If the ResetValues of the registers are chosen such that the DataMux does not select the input with the special function (reset, TRST, TMS), then the selected data signal must evaluate to the active state of the intercepted signal (any of 0 or 1 in case of a TMS signal) after a Global Reset.

This rule ensures that the control logic of Reset signals, TRST signals and TMS signals is always in a defined state, and it ensures that the Global Reset (the event triggered by the iReset command) always affects all parts of the ICL network. When the ICL network complies with this rule, the Local Reset circuitry cannot accidentally block the Global Reset.

ICL130

Category: ICL Semantics

Rule Check Type: ICL Primitive Model

Contexts supported: All contexts

Default Handling: Error

report_drc_rules: Supported

Verifies that there is no reference to an output port from within the ICL module.

Unlike Verilog, the IEEE 1687-2014 standard does not allow the specification of an output port as the source of a signal within the ICL module. Tesson IJTAG can be instructed to tolerate this configuration by setting the handling of this DRC to “warning”, “note” or “ignore”.

ICL131

Category: ICL Semantics

Rule Check Type: ICL Primitive Model

Contexts supported: All contexts

Default Handling: Error

report_drc_rules: Supported

Verifies that each scan register bit serves at most one of the purposes defined below.

These are:

- Scan network reconfiguration
- Local Reset or isolation of embedded TAPs
- Application of the iOverrideScanInterface –capture and iOverrideScanInterface –update specifications for internal scan interfaces (not implemented yet)

ICL132

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Warning

report_drc_rules: Supported

Verifies that vector port specifications with the same base name have consistent port directions.

ICL allows the specification of different port functions for disjoint subsets of the port’s index range. However, all port specifications with the same base name must have either input port functions or output port functions.

ICL133

Category: ICL Semantics

Rule Check Type: Module

Contexts supported: All contexts

Default Handling: Warning

report_drc_rules: Supported

Verifies that vector port specifications with the same base name form a continuous index range.

If the specification of a vector port is split into several parts, the union of the specified index ranges must be a continuous range without gaps. The DRC handling of this rule can be set to error in order to enforce strict standard compliance of the ICL module specification.

ICL134

Category: ICL Semantics

Rule Check Type: ICL Primitive Model

Contexts supported: All contexts

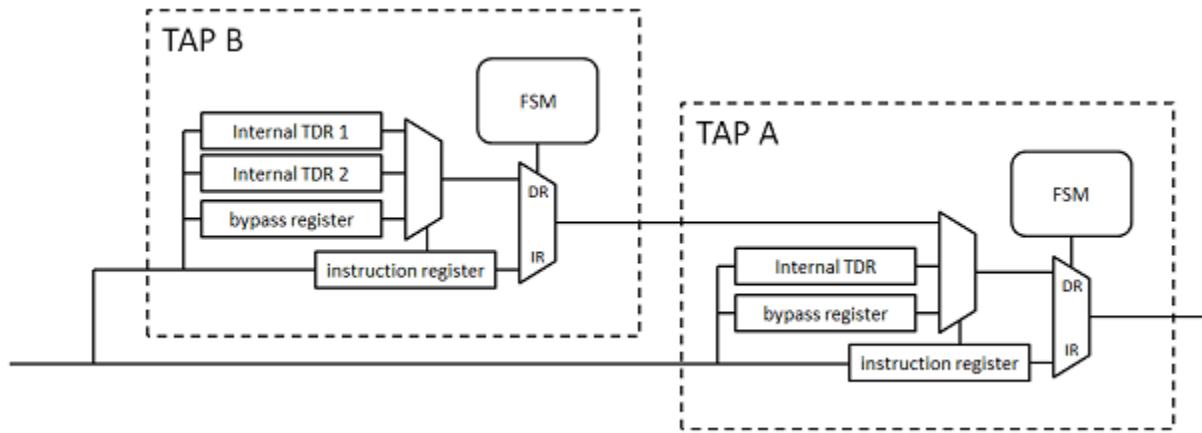

Default Handling: Error

report_drc_rules: Supported

Verifies the accessibility of IR/DR multiplexers in both types of scan loads, IR scan loads as well as DR scan loads.

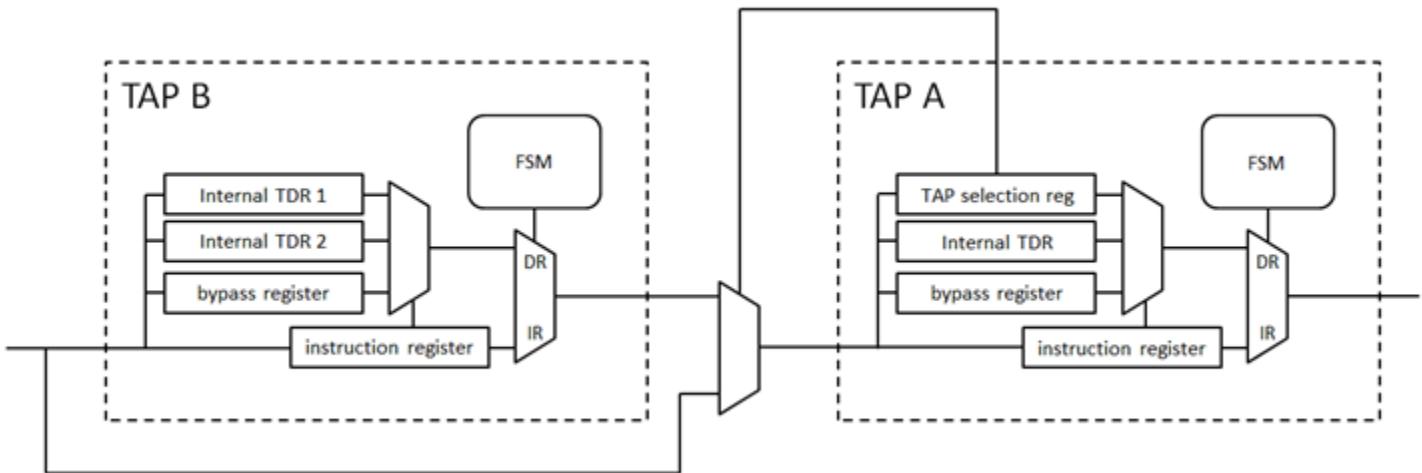

In a design with multiple TAP controllers, the active TAP controllers are controlled simultaneously. All state machines of the active TAP controllers are operated such that they are all in the same TAP state. Consequently, it is not possible to perform, for example, a scan load through the instruction register of an embedded TAP, while the master TAP is in Shift-DR state. This scenario is shown in [Figure 7-46](#). The instruction register of TAP controller “TAP B” is not accessible, because the configuration of the scan path for the access of the register requires the TAP controller “TAP A” to be in a DR state. However, the two TAP controllers cannot be in different states at the same time.

Figure 7-46. Invalid multi-TAP Configuration

To prevent such inaccessible registers, ICL134 verifies that IR/DR multiplexers are not on a pure DR-path or on a pure IR-path of another (superordinate) TAP controller. Each IR/DR multiplexer must be accessible in DR scan loads as well as in IR scan loads. [Figure 7-47](#) shows a valid multi-TAP configuration.

Figure 7-47. Valid multi-TAP Configuration

ICL135

Category: ICL Semantics

Rule Check Type: ICL Primitive Model

Contexts supported: All contexts

Default Handling: Error

report_drc_rules: Supported

Verifies the consistency between the type of a scan interface and the type of the data that is shifted through the scan interface.

There are four types of scan interfaces, which can be identified by the port functions of their controlling ports:

- Client ScanInterface (CaptureEnPort, ShiftEnPort, UpdateEnPort, SelectPort, ResetPort)
- Host ScanInterface (ToCaptureEnPort, ToShiftEnPort, ToUpdateEnPort, ToSelectPort, ToResetPort)
- Client-TAP ScanInterface (TMSPort, TRSTPort)
- Host-TAP ScanInterface (ToTMSPort, ToTRSTPort)

Based on the top level scan interfaces and the IR/DR multiplexers of the TAP controllers, ICL135 verifies the following:

- Each scan interface, which is only accessible during DR scan loads, must be an ordinary (that is, a non-TAP) scan interface. All ordinary (non-TAP) scan interfaces must only be accessible during DR scan loads. (A scan load through an ordinary top level scan interface is automatically considered a DR scan load).
- Each scan interface, which is accessible during DR scan loads as well as during IR scan loads, must be a client-TAP scan interface or a Host-TAP scan interface. All client-TAP scan interfaces and all host-TAP scan interfaces must be accessible during IR scan loads as well as during DR scan loads.
- There are no scan interfaces for the exclusive use with IR scan loads.

ICL136

Category: ICL Semantics

Rule Check Type: Parser

Contexts supported: All contexts

Default Handling: Warning

report_drc_rules: Supported

For backward compatibility reasons, Tessent IJTAG accepts some ICL constructs like LaunchEdge, which are not part of the IEEE 1687-2014 standard, but which have been part of a previous draft version. This check fails if such a deprecated ICL construct is encountered. The DRC handling can be set to “error” in order to ensure strict standard compliance.

ICL137

Category: ICL Semantics

Rule Check Type: ICL Primitive Model

Contexts supported: All contexts

Default Handling: Error

report_drc_rules: Supported

This DRC rules out certain scenarios in which different ScanInterfaces of the same ICL module cannot be activated independently of each other. This check considers only the presence of SelectPorts in client ScanInterface specifications and the presence of ToSelectPorts in host ScanInterface specifications, it does not check if the SelectPorts can actually be controlled in such way that either the one or the other ScanInterface is active.

If two client ScanInterfaces contain SelectPorts, then the set of SelectPorts in one of the ScanInterfaces must not be equal to and must not be a subset of the set of SelectPorts in the other ScanInterface. The same holds for host ScanInterfaces and ToSelectPorts.

EDT Rules (K Rules)

EDT rules only apply to designs that incorporate EDT technology. They are generally performed by Tessent TestKompress when switching from Setup system mode. The tool also performs some checks at other times such as in response to a write_edt_files command or before writing EDT files. These rule checks find EDT design definition inconsistencies.

The following subsections describe each of the EDT rules and the special handling you can set for them.

K1

Category: EDT

Contexts Supported: dft -edt, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Supported

EDT requires a circuit with scan chains. This rule check verifies that the design contains scan chains. The handling for this rule violation is error. You cannot change the handling with the set_drc_handling command.

K2

Category: EDT

Contexts Supported: dft -edt, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Supported

EDT does not support designs with more than one scan group. This rule check verifies that the design defines exactly one scan group. The handling for this rule violation is error. You cannot change the handling with the set_drc_handling command.

K3

Category: EDT

Contexts Supported: dft -edt, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Supported

This rule check verifies that the scan chain input and scan chain output pin of each scan chain are both connected to either top-level ports or to internal pins.

The following are valid ways to connect the scan chains:

- In the IP Creation Phase, all of the scan chains must be connected to primary inputs (PIs) and primary outputs (POs).
- In the Pattern Generation Phase, the scan-in and scan out pin of each chain must be connected either to a PI and PO (for an uncompressed scan chain) or to internal nodes (for a compressed scan chain driven by and observed through the EDT logic).

The handling for this rule violation is error. You cannot change the handling with the set_drc_handling command.

K4

Category: EDT

Contexts Supported: dft -edt

Default Handling: Error

report_drc_rules: Supported

The EDT decompressor provides test patterns through unidirectional outputs to the inputs of the internal scan chains. Similarly, the EDT compactor accepts test responses through unidirectional inputs from the scan chain outputs. This rule check verifies that bidirectional top-level scan chain pins do not exist. The default handling for this rule violation is error.

K5

Category: EDT

Contexts Supported: dft -edt, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

This rule check verifies the existence of all required EDT control and channel pins at the top level of the design. The default handling for this rule violation is error.

If K5 reports as nonexistent an EDT control or channel pin you believe exists, it is typically because the pin does not exist at the *top* level of the design from which the tool can control the pin, or because the pin's current name differs from the pin name the tool expected. This difference could occur, for example, if you manually edited the pin name within the netlist after the IP Creation Phase. Use the [set_edt_pins](#) command to provide the tool with the correct pin name in these cases.

Note

 You can use the [set_edt_pins](#){edt_pin} - option to explicitly tell the tool that an EDT signal is driven internally and does not have an associated top-level pin. Specifying this option prevents the tool from generating a K5 violation for that pin.

K6

Category: EDT

Contexts Supported: dft -edt, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

EDT pins, when shared with a design's functional pins, must be shared with a functional pin of the same type. For example, when an EDT input pin is shared with a functional pin, the functional pin must be an input. Similarly, an EDT output pin must only be shared with a

functional output pin. This rule check verifies that each EDT pin that is shared with a functional pin is of a type consistent with the functional pin. Sharing with bidirectional pins is not allowed, and is covered by other design rule checks.

The K6 rule check also verifies the EDT control and channel pins have valid names. To be consistent with Tessent FastScan and to provide immediate feedback if you change the default pin names, Tessent TestKompress checks the validity of the pin names and pin directions when you enter a [set_edt_pins](#) command. Because the default EDT pin names might also conflict with names of existing pins, the tool performs all checks again when you switch from setup mode to analysis mode. The default handling for this rule violation is error.

The tool performs K6 rule checks at three different times. The items checked at each time by this rule are as follows:

These six requirements are checked immediately after the tool reads an EDT pin name. An error message results if the stated requirement is violated:

1. The pin name must not be hierarchical.
2. If the pin name is shared with a core pin, the directions must match.
3. If the pin is part of a bus, the base name for the pin must not be the same as the name of a core pin.
4. The pin name must not be the same as the base name of a core bus.
5. If the pin name matches a core bus pin name, the index must be within the same range.
6. If a pin name is a bus bit, the bus must exist in the core. Presently, bus-based EDT pins are not supported.

In addition to the preceding six requirements, the K6 rule checks the following requirements during DRC:

1. Each EDT pin must not be shared with either another EDT pin or with a restricted core pin. For information about restricted pins, refer to “[EDT Control and Channel Pins](#)” in the *Tessent TestKompress User’s Manual*.
2. Two EDT pins must not share the same name.
3. An EDT output channel pin must not be shared with a bidi.

Finally, when you write out the files that implement the EDT IP using the [write_edt_files](#) command, the K6 rule results in a warning message for either of the following conditions:

1. The EDT clock pin is shared with a core bus pin.
2. An EDT pin is shared with a core pin that is empty (no fan-ins or fanouts).

K7

Category: EDT

Contexts Supported: dft -edt

Default Handling: Error

report_drc_rules: Supported

EDT does not support either bidirectional or tristate scan channel output pins. This is because Tessent TestKompress includes a multiplexer between the EDT IP and the output pad when a scan channel output pin is shared with a functional output pin. This rule check verifies that neither bidirectional nor tristate scan channel output pins exist. The default handling for this rule violation is error.

K8

Category: EDT

Contexts Supported: dft -edt

Default Handling: Warning

report_drc_rules: Supported

This rule check verifies that neither bidirectional scan channel input pins nor bidirectional EDT control pins exist. This is necessary because the EDT hardware has no control over the signal direction of bidirectional pins, and they might be driven by the core logic during load_unload, resulting in contention problems. The default handling for this rule violation is warning.

K9

Category: EDT

Contexts Supported: dft -edt

Default Handling: Warning

report_drc_rules: Supported

Top-level scan chain pins cannot be shared with a design's functional pins. This is because Tessent TestKompress connects the scan chain pins to the EDT IP and they are no longer available as primary inputs or outputs in the new top level. This rule check verifies that scan chain pins are not used as functional pins. The default handling for this rule violation is warning.

The rule check assumes pin sharing in the following situations:

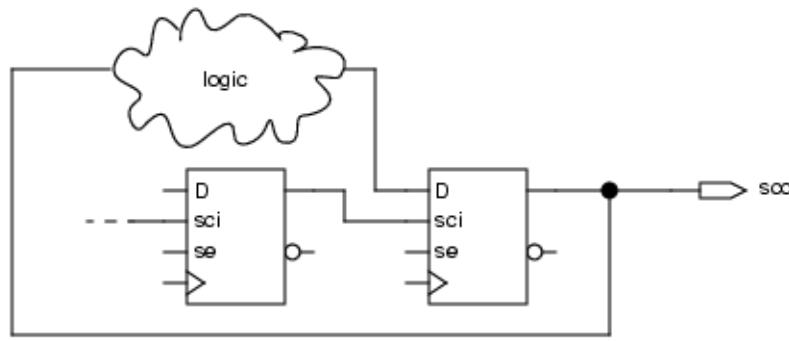

- Scan inputs — If a scan input drives a primary output, drives more than one scan cell, or is a bidirectional pin, pin sharing is assumed.
- Scan outputs — If the last scan cell of a scan chain does not drive other scan cells, and also drives exactly one primary output, pin sharing is assumed.

Note

The K9 rule check will not catch all cases of inappropriate pin sharing (the following discussion describes why this is the case). Therefore, be sure during scan insertion that you insert dedicated scan pins. This is true even if the output of the last scan cell in a scan chain is connected directly to a primary output.

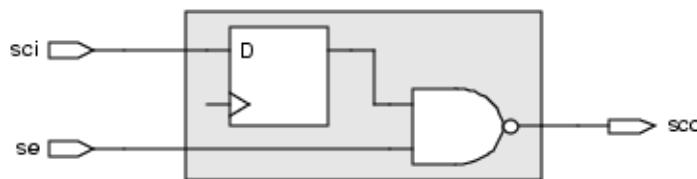

In some cases, a gate-level netlist does not contain the information to enable Tessent TestKompress to determine if there is pin sharing. For example, [Figure 7-48](#) shows a design where the last cell of a scan chain drives functional logic as well as the scan output pin. It is impossible to extract the information from the gate-level netlist about whether the pin was there before scan insertion or has been introduced for scan purposes.

Figure 7-48. Failing identification

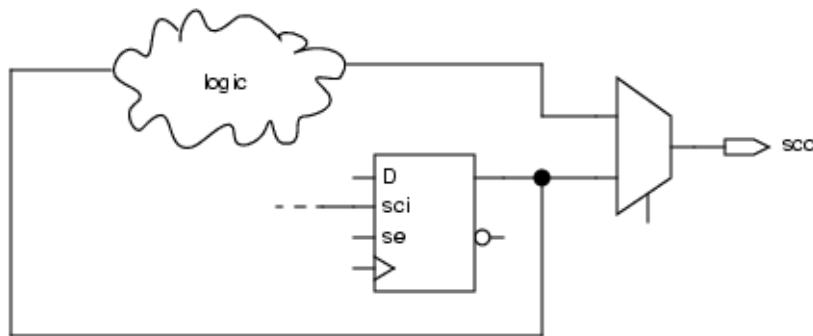

[Figure 7-49](#) shows another case where the K9 rule check cannot determine if pin sharing occurs. The scan cell contains a logic gate that drives the scan output. By examining the netlist, it cannot be determined if the logic gate is part of the scan cell or part of functional logic. Therefore, the design rule check would not detect the sharing.

Figure 7-49. Common cell structure

For the same reason, the design rule check would fail also for the circuit shown in [Figure 7-50](#).

Figure 7-50. Failing identification

K10

Category: EDT

Contexts Supported: dft -edt

Default Handling: Warning

report_drc_rules: Supported

Top-level scan chain pins should not be part of a functional bus. A DRC violation is reported if top-level scan chain pins are part of a functional bus. This DRC does not apply to internal scan pins.

Note

 Top-level scan chain pins can be part of a pure scan bus.

K11

Category: EDT

Contexts Supported: dft -edt

Default Handling: Error

report_drc_rules: Supported

The EDT clock, update, and bypass pins must not be shared with any other clock or RAM control signal.

The reasons for this restriction are as follows:

- If the EDT clock or EDT update are shared with a scan clock, the scan cells would be disturbed during the load_unload procedure.
- If the EDT clock, update or bypass are shared with RAM control signals, RAM sequential patterns and multiple load patterns may not be applicable.

- If the EDT clock or EDT bypass are shared with a non-scan clock, the test coverage might decrease because the EDT clock is constrained to its off state during the capture cycle.

This rule check verifies that the EDT clock, update, and bypass pins are not shared with any other clock or RAM control signal.

K12

Category: EDT

Contexts Supported: dft -edt

Default Handling: Warning

report_drc_rules: Supported

To guarantee that the EDT IP is not disturbed during capture, the EDT clock must be constrained to its off-state during the capture cycle. This rule check verifies that the EDT clock pin does not drive any logic.

Note

 If the EDT clock is shared with a functional pin, the pin constraint may result in lower test coverage.

K13

Category: EDT

Contexts Supported: dft -edt

Default Handling: Note

report_drc_rules: Supported

This rule check reports all pins that will be added to the EDT top-level wrapper in order to implement the EDT hardware.

Note

 The tool reports scan channel and control pins as new pins even if a scan chain pin with the same name exists in the core circuit; otherwise that scan chain pin would not have been connected to the wrapper.

K14

Category: EDT

Contexts Supported: dft -edt, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

In order to prevent EDT from assigning values to the scan chain inputs during the capture cycle, all internal scan chain inputs are automatically constrained to X by EDT. This rule check verifies that there are no user-defined constraints on the scan chain inputs that are different from TIE-X.

K15

Category: EDT

Contexts Supported: dft -edt, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

set_drc_handling: Not supported

This DRC verifies several EDT circuit characteristics.

Specifically:

1. Verifies that all scan channels have the proper top-level pins. All scan channels, except for blocks set up for input channel broadcasting or input channel sharing, require a dedicated top-level pin.
2. Verifies that all EDT control pin sharing is set up properly.
3. Verifies that the internal scan chains driven by the EDT decompressor are not sharing scan inputs.

The tool reports error messages slightly differently depending on whether the EDT block is inside a core. If an EDT block is not inside a core, the tool uses a format that only includes the block name as shown in the following example error messages.

- Verifies that the top-level input port does not connect to different control signals (like clock and update) on the same block. If this is not true, the following error message is reported:

```
// Error: Invalid sharing of port "edt_clock": (K15-1)
//           Block "blk1" EDT clock
//           Block "blk1" EDT update
```

- Verifies that the top-level input port does not connect to different control signals (like clock and update) on different blocks. If this is not true, the following error message is reported:

```
// Error: Invalid sharing of port "edt_clock": (K15-1)
//           Block "blk1" EDT clock
//           Block "blk2" EDT update
```

- Verifies that the top-level input port does not connect to the control signal and channel input of the same block. If this is not true, the following error message is reported:

```
// Error: Invalid sharing of port "edt_a": (K15-1)
//      Block "blk1" EDT update
//      Block "blk1" EDT input channel 1
```

- Verifies that the top-level input port does not connect to the control signal and channel input of different blocks. If this is not true, the following error message is reported:

```
// Error: Invalid sharing of port "edt_a": (K15-1)
//      Block "blk1" EDT update
//      Block "blk2" EDT input channel 1
```

- Verifies that the top-level input port does not connect to different channel inputs on the same block. If this is not true, the following error message is reported:

```
// Error: Invalid sharing of port "edt_channels_in1": (K15-1)
//      Block "blk1" EDT input channel 1
//      Block "blk1" EDT input channel 2
```

- Verifies that the top-level output port does not connect to different channel outputs on the same block. If this is not true, the following error message is reported:

```
// Error: Invalid sharing of port "edt_channels_out1": (K15-1)
//      Block "blk1" EDT output channel 1
//      Block "blk1" EDT output channel 2
```

- Verifies that the top-level output port does not connect to channel outputs on different blocks. If this is not true, the following error message is reported:

```
// Error: Invalid sharing of port "edt_channels_out1": (K15-1)
//      Block "blk1" EDT channel output 1
//      Block "blk2" EDT channel output 1
```

- Verifies that a top-level input port does not broadcast to both compressed and uncompressed blocks. If this is not true, the following error message is reported:

```
// Error: Invalid sharing of port "scan_in1" for EDT channel and
//      uncompressed scan chain: (K15-1)
//      Block "blk1" EDT input channel 1
//      Scan chain "chain1" input
```

- Verifies that two scan chains driven by the EDT decompressor do not share the same scan input pin. If this is not true, the following error message is reported:

```
// Error: Incorrect sharing of pin "/scan_input1": (K15-1)
//           Scan chain "chain1" input
//           Scan chain "chain2" input
```

To support channel sharing between identical and non-identical blocks, this DRC does the following:

- Verifies that the control channels on non-identical blocks do not share the same top-level port. If this is not true, the following error message is reported:

```
// Error: Invalid sharing of port "edt_channels_in1": (K15-1)
//           Block "blk1" EDT input channel 1
//           Block "blk2" EDT input channel 1
//           When broadcasting channels to non-identical blocks, the
//           shared channels at core level cannot include any EDT
//           control registers.
```

- Verifies that if two non-identical EDT blocks have the same input channel, they also have the same “pulse_edt_before_shift_clocks” signal. If this is not true, the following error message is reported:

```
// Error: Invalid sharing of port "edt_channel1" for blocks with
//           inconsistent pulse_edt_before_shift_clocks options:
//           (K15-1)
//           Block "blk1" has pulse_edt_before_shift_clocks set to "on"
//           Block "blk2" has pulse_edt_before_shift_clocks set to
//           "off"
```

- Verifies that if two input channels on two non-identical blocks share the same top-level port, they must have the same number of external pipeline stages. If this is not true, the following error message is reported:

```
// Error: Invalid sharing of port "edt_channel1" for blocks with
//           different number of input pipeline stages: (K15-1)
//           Block "blk1" EDT input channel 1 has 4 pipeline stages
//           Block "blk2" EDT input channel 1 has 5 pipeline stages
```

- Verifies that if two input channels on two non-identical blocks share the same top-level port, they must have the same inversions. If this is not true, the following error message is reported:

```
// Error: Invalid sharing of port "edt_channel1" for blocks of
//           shared input channels with different input channel
//           inversions: (K15-1)
//           Block "blk1" EDT input channel 1 has no inversion
//           Block "blk2" EDT input channel 1 has inversion
```

- If an EDT block is inside a core, the tool includes the parent core name of the EDT block in the error message. This example verifies that if two input channels on two non-identical blocks (either from the top-level, from the same core, or from different cores) share the same top-level port, they must have the same inversions. If this is not true, the following error message is reported:

```
// Error: Invalid sharing of port "edt_channels_in2" for blocks of
// shared input channels with different input channel
// inversions: (K15-1)
// Block "blk1" EDT input channel 2 has no inversion.
// Block "top_core1_unwrapped_blk1" (from core instance
// "top_core1") EDT input channel 2 has inversion.
// Block "top_core2_unwrapped_blk1" (from core instance
// "top_core2") EDT input channel 2 has inversion.
// Block "top_core2_unwrapped_blk2" (from core instance
// "top_core2") EDT input channel 2 has inversion.
```

Identical Block Checks

When checking two blocks that are identical, the K15 DRC separates the conditions into two sets:

- Conditions related to the EDT IP, which include the following:
 - The number of scan chains in each block.
 - The number of input/output channels.
 - The decompressor structure and the connections between decompressor and scan chains.
 - The compactor structure and the connections between scan chains and compactors.
 - The low power controller.
- Conditions related to the embedded logic, which includes everything outside EDT IP, such as scan chain lengths and external pipeline stages.
 - Scan chain lengths.
 - Input /output pipeline stages.
 - Input channel inversions.
 - Input channel port ordering.

If the tool encounters a K15 DRC error sharing channels among non-identical blocks, the tool first checks if the set of conditions related to EDT IP is same or not for two blocks. If they are not the same, then the tool issues the error messages noted above.

If, however, the EDT IPs are identical, then the embedding logic must be different. The intention of users was possibly to use the channel broadcasting rather than channel sharing. In this case, the tool reports the following K15 error messages:

- Two corresponding chains do not have the same lengths.

```
// Error: Invalid sharing of port "B1_edt_channels_in1": (K15-1)
// Block "B1" EDT input channel 1
// Block "B2" EDT input channel 1
// When broadcasting channels to non-identical blocks, control
// channels cannot be shared.
// Broadcasting all input channels including control channels is
// only allowed when the EDT blocks are identical.
// In this case, the two EDT controllers are identical, but they are
// not considered as identical EDT blocks because // they are
// embedded differently in the design. One of the differences is:
// Chain #1 ("chain1") of block "B1" has 5 scan cells while chain #1
// ("chain6") of block "B2" has 4 scan cells.
```

- Two corresponding EDT input channels have different pipeline stages.

```
// Error: Invalid sharing of port "B1_edt_channels_in1": (K15-1)
// Block "B1" EDT input channel 1
// Block "B2" EDT input channel 1
// When broadcasting channels to non-identical blocks, control
// channels cannot be shared. Broadcasting all input channels
// including control channels is
// only allowed when the EDT blocks are identical.
// In this case, the two EDT controllers are identical, but they are
// not considered as identical EDT blocks because they are embedded
// differently in the design. One of the differences is:
// Input channel #1 of block "B1" has 2 pipeline stages while input
// channel #1 of block "B2" has 3 pipeline stages.
```

- Two corresponding EDT output channels have different pipeline stages.

```
// Error: Invalid sharing of port "B1_edt_channels_in1": (K15-1)
// Block "B1" EDT input channel 1
// Block "B2" EDT input channel 1
// When broadcasting channels to non-identical blocks, control
// channels cannot be shared.
// Broadcasting all input channels including control channels is
// only allowed when the EDT blocks are identical.
// In this case, the two EDT controllers are identical, but they are
// not considered as identical EDT blocks because they are embedded
// differently in the design. One of the differences is:
// Output channel #1 of block "B1" has 2 pipeline stages while
// output channel #1 of block "B2" has 3 pipeline stages.
```

- Two corresponding EDT input channels have different inversions.

```
// Error: Invalid sharing of port "B1_edt_channels_in1": (K15-1)
// Block "B1" EDT input channel 1
// Block "B2" EDT input channel 1
// When broadcasting channels to non-identical blocks, control
// channels cannot be shared.
// Broadcasting all input channels including control channels is
// only allowed when the EDT blocks are identical.// In this case,
// the two EDT controllers are identical, but they are not
// considered as identical EDT blocks because they are embedded
// differently in the design. One of the differences is:
// Input channel #1 of block "B1" has inversion while input channel
// #1 of block "B2" has no inversion.
```

- Two blocks share the same set of input channel ports but not in the same order.

```
// Error: Invalid sharing of port "B1_edt_channels_in1": (K15-1)
// Block "B1" EDT input channel 1
// Block "B2" EDT input channel 1
// When broadcasting channels to non-identical blocks, control
// channels cannot be shared.
// Broadcasting all input channels including control channels is
// only allowed when the EDT blocks are identical.
// In this case, the two EDT controllers are identical, but they are
// not considered as identical EDT blocks because they are embedded
// differently in the design. One of the differences is:
// Input channel #1 of block "B1" is driven by port "A" while input
// channel #1 of block "B2" is driven by port "B".
```

K16

Category: EDT

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

This rule check verifies that the EDT clock signal has been added as a clock using the add_clocks command.

K17

Category: EDT

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

This rule check verifies the EDT clock is constrained to its inactive state. This is required in order to avoid disturbing the EDT IP during the capture cycle.

K18

Category: EDT

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

This rule check verifies three required properties of the test procedure file.

Specifically:

1. Analyzes the off states of the EDT control signals.

In the IP Creation Phase, Tessent TestKompress creates the EDT IP such that all the control signals are active high. This check verifies that all control signals are, in fact, active high.

Note

 If a control signal (EDT clock, for example) is inverted between the chip pin and the EDT IP, and you defined the inversion using the “[set_edt_pins](#)” on page 2095 command in the IP Creation Phase, the signal at the chip level may be active-low.

2. Analyzes the EDT update control signal in the load_unload and shift procedures.

In order to operate correctly, the EDT update signal is asserted during load_unload before the leading edge of the EDT clock signal. EDT update must be reset after the leading edge of EDT clock in load_unload and before the leading edge of EDT clock in the first shift procedure. It does not matter if EDT update is reset before or after the trailing edge of EDT clock in load_unload.

3. Analyzes the EDT clock signal in the shift procedure.

This check verifies that the EDT clock is pulsed in the shift procedure in order to decompress vectors provided at the scan channel inputs.

K19

Category: EDT

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

This design rule check simulates the EDT decompressor netlist by applying pseudorandom patterns and compares the results with the emulated values. If a simulation-emulation mismatch occurs, the DRC performs diagnostic checks to narrow down the number of possible problem sources.

This design rule check also detects missing channel input constraints if a pipeline stage is clocked by a non-EDT clock.

How to Debug K19 Violations

For most common K19 debug tasks, such as checking for correct values on EDT control signals as well as sensitized paths from channel pins to the decompressor and from the decompressor to the scan chains during shift, it is typically sufficient to use the `set_gate_report` command to specify Drc_pattern reporting:

`set_gate_report drc_pattern procedure_name`

Then use the `report_gates` command to display simulated values for gates. The positions and values of mismatching monitor gates (certain gates used by the K19 rule check as reference points in its automated analysis of K19 mismatches) are reported as part of the K19 error message and provide clues to where the problem may lie.

When you need to see the specific simulation values applied in each shift cycle, you can view the simulated values for all K19-simulated gates, not just the monitor gates by setting the gate report to K19:

`set_gate_report drc_pattern k19`

This is not commonly required, as most problems are usually due to setup problems such as path sensitization and setting of control signals that are usually not pattern-specific or cycle-specific.

Note

 Use “`set_gate_report drc_pattern k19`” reporting only when necessary. K19 reporting can slow EDT DRC run time and increase memory usage compared to Drc_pattern reporting because the tool has to log simulation data for all simulated setup and shift cycles.

For additional in-depth information on how to reduce the occurrence of K19 violations, refer to the “[K19 through K22 DRC Violations](#)” and “[Understanding K19 Rule Violations](#)” sections of the *Tessent TestKompress User’s Manual*.

K20

Category: EDT

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

This design rule check identifies the number of pipeline stages within the compactors, based on simulation. It also considers channel output pipelines; reporting any discrepancy between the number of identified and specified pipeline stages between the scan chains and pins (including compactor and channel output pipelines).

Note

-  If the K19 rule check that verifies the operation of the decompressor fails, then the K20 rule check will not be able to identify the number of pipeline stages.
-

If this rule check fails, you can still use diagnostic information from the K22 design rule check to help identify a problem. Design rule K22 is checked whether the K20 rule check fails or not.

Note

-  Be sure scan channel output pins that are bidirectional are forced to Z at the beginning of the load_unload procedure. Otherwise, the tool is likely to issue a K20 or K22 rule violation, without indicating the reason for the violation.
-

K21

Category: EDT

Contexts Supported: dft -edt, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

In the IP Creation Phase, this design rule check verifies that lockup cells will be synthesized if there is a scan chain whose first scan cell captures data at, or after, the rising edge of the EDT clock. The rule check also verifies that lockup cells will be synthesized if the output of the last scan cell changes at, or before, the rising edge of the EDT clock. If bypass logic is included, the rule verifies that lockup cells will be synthesized between the last scan cell of one chain and the first scan cell of another chain when they are connected by the bypass logic, and the output of the last scan cell changes before, or at the same time, the first scan cell captures.

In the Pattern Generation Phase, this rule check verifies the first scan cell of each chain does not capture scan data at the same time the corresponding EDT decompressor output changes its signal. If the EDT compactor is pipelined, the rule check also verifies the compactor does not capture at the same time the output of the last scan cell in each chain changes. This could result in clock skew problems, as the EDT and the core circuitry are part of different clock domains. If a violation is reported, you should add lockup cells or modify the timing. The default handling for this rule violation is warning. The K21 rule check will not be able to identify timing problems in the Pattern Generation Phase if the K19 rule check, which verifies the operation of the decompressor, fails.

K22

Category: EDT

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

This design rule check simulates the EDT compactor fed by pseudorandom patterns, and compares the results to the emulated values.

Two different checks are performed, as follows:

1. The tool applies a pseudorandom pattern to the compactor inputs, with all scan chains enabled.
2. The tool tests each compactor input separately. In this case, one pseudo-random pattern is applied to the selected compactor input, and the compactor is programmed to mask all other inputs (scan chains). Decoder problems and scan chain permutations are detected by this test.

If a simulation-emulation mismatch occurs, the tool automatically performs diagnostic checks to eliminate possible sources of the mismatch. Messages regarding K22 violations usually incorporate relevant information from these diagnostic checks to help you find the source of the mismatch.

Note

 Be sure scan channel output pins that are bidirectional are forced to Z at the beginning of the load_unload procedure. Otherwise, the tool is likely to issue a K20 or K22 rule violation, without indicating the reason for the violation.

How to Debug K22 Violations

For most common K22 debug tasks, such as checking for correct values on EDT control signals as well as sensitized paths from the scan chains to the compactor and from the compactor to the channel pins during shift, it is typically sufficient to use the **set_gate_report** command and specify Drc_pattern reporting:

set_gate_report drc_pattern procedure_name

Then use the **report_gates** command to display simulated values for gates. The positions and values of mismatching monitor gates (certain gates used by the K22 rule check as reference points in its automated analysis of K22 mismatches) are reported as part of the K22 error message and provide clues to where the problem may lie.

Note

 In DFTVisualizer, you can press Ctrl + R to execute a report_gates command on selected gates. For more information, see ““[How to Report Gate Data](#)” on page 2648.

When debugging incorrect compactor mask settings for specific patterns simulated by the design rule check, you can view the simulated values for any K22-simulated gate, not just the monitor gates, by setting the gate report to K22:

set_gate_report drc_pattern k22

This is not commonly required, as most problems are usually due to setup problems such as path sensitization and setting of control signals that are usually not pattern-specific or cycle-specific.

Note

-  Use “set_gate_report drc_pattern k22 reporting” only when necessary. K22 reporting can slow EDT DRC run time and increase memory usage compared to Drc_pattern reporting because the tool has to log simulation data for all simulated setup and shift cycles.
-

For additional in-depth information on how to reduce the occurrence of K22 violations, refer to the “[K19 through K22 DRC Violations](#)” and “[Understanding K22 Rule Violations](#)” sections of the *Tessent TestKompress User’s Manual*.

K23

Category: EDT

Contexts Supported: dft -edt

Default Handling: Error

report_drc_rules: Supported

This design rule check verifies (when the tool generates level-sensitive EDT hardware) that there is no scan chain whose first or last scan cell contains edge-triggered flip flops.

Tessent TestKompress can generate EDT IP based on either edge-triggered flip flops or level-sensitive latches. By default, it generates EDT hardware based on flip flops, with a single clock. The edge-triggered EDT hardware can operate with a design that has scan chains based on edge-triggered scan cells or level-sensitive scan cells. Depending on the clocks used by the first and last scan cells in each chain, the tool generates lockup cells when necessary to prevent clock skew problems.

For pure LSSD designs, the tool can optionally generate EDT hardware based on level-sensitive latches with a master clock and a slave clock. But the level-sensitive EDT hardware requires a design that uses only level-sensitive scan cells, with an appropriate clock scheme for the master and slave clocks. Such a scheme ensures there is no clock skew between the EDT hardware and the first and last scan cells, so the tool does not add any lockup cells.

Note

-  If you use level-sensitive EDT hardware with bypass logic, you must make sure that scan chain outputs connected to scan chain inputs via bypass logic do not require lockup cells.
-

K24

Category: EDT

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Note, Warning, and Error

report_drc_rules: Not Supported

This design rule check is performed when EDT Finder is enabled, which it is by default, or when you have enabled the set_edt_mapping command and are reusing block-level dofles for top-level pattern creation. When EDT mapping is enabled, this rule check verifies that the clock, read control, write control, and pin constraint signals specified in the block-level dofles are consistent with the signals specified at the top level.

Note

 K24 does not run when core mapping is used, regardless of whether EDT Finder is on or off.

When core mapping is used, the connections are automatically extracted to the top and connection mapping issues are reported by other DRCs.

The tool performs this verification by tracing connectivity between specified block-level signals (ports) and primary input or output pins. The tool verifies clock off states and pin constraint values while compensating for inversions in the path. During this rule check, all EDT signals that exist as ports on the block, but not as top-level pins, are updated to refer to the top-level input or output pins as determined by the tracing algorithm.

The K24 rule check outputs three different types of messages depending on the severity level of the results:

- **Note** — K24 outputs an informational note in cases such as when an EDT channel pin name is provided and a pin of that name exists at the top-level but not at the block-level or, in the case where the number of traced pipeline stages along the channel I/O do not match user-specified values.
- **Warning** — K24 issues a warning in cases such as when the traced top-level signal is different from the user-specified signal.
- **Error** — K24 issues an error message in cases such as when an I/O pin or clock port cannot be found.

K24 verifies the existence of the specified channels and maps block-level channels to top-level ports (unless EDT Finder has been disabled). K24 severity is set to Error (unless EDT Finder has been disabled) and you cannot override this severity setting.

For detailed information about creating a top-level dofle for the modular Tessent TestKompress flow, see the [Modular Compressed ATPG](#) section of the *Tessent TestKompress User's Manual*.

K25

Category: EDT

Contexts Supported: dft -edt

Default Handling: Error

report_drc_rules: Supported

All block-level EDT pins must be functionally connected in the netlist or have a connection specified during the integration session.

K25 verifies that each block-level EDT pin is either functionally connected in the netlist or has a connection specified. If no connection exists or is specified, an error is returned.

The error message is:

```
// Error: Update pin in block "B1" is not driven in the netlist and does  
not have a defined connection. (K25-2)
```

Procedure Rules (P Rules)

The test procedure file for each scan chain group is checked to ensure adherence to the format rules and accuracy of the test procedure data. All violations of procedure rules are treated as error conditions and cannot be changed—with the exception of rules P30, P31, P32, and P33, which can be ignored.

P1

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

Each statement in the test procedure file must have the proper syntax. A syntax error occurs for a statement if there is an incorrect number of arguments or an incorrect ending character (“=” for procedure statements and “;” for all other statements). You can correct this error condition by editing the indicated line of the test procedure file.

The error message is:

```
Error: syntax error near token (Token). (P1)
```

Where Token represents the token in the input file close to where the error occurred.

P2

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

For statements inside a procedure, the time of the statement must not be less than the time of a preceding statement. You can correct this error condition by editing the time value on the indicated line of the test procedure file.

The error message is:

```
Time value T less than preceding time value. (P2)
```

Where T is the time defined in the specified statement.

P3

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The P3 rule checks if there is any event in the load_unload procedure at the boundary of the apply shift procedure. You can correct this error by editing the time value on the indicated line of the test procedure file.

The error message is:

```
// The following occurred at line L:  
//Error: time value not greater than preceding time value for apply  
procedure. (P3-1)
```

L is the line number in which the failure occurred.

P4

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

All procedures must end with an **end** statement. To correct this error condition, add an **end** statement at the indicated line of the test procedure file.

The error message is:

```
Line number L, P procedure not ended. (P4-1)
```

L is the line number in which the failure occurred, and P is the procedure name.

P5

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

Procedure definitions follow the syntax, procedure proc_type [proc_name] = For most procedures, the procedure name is optional and it is ignored. Procedures of type seq_transparent, clock, and sub_procedure require a name. This error occurs if one of these procedures is missing its name. Also, this error occurs if the user tries to define more than 32 clock or seq_transparent procedures.

```
Incorrect or missing name for procedure of type P. (P5)
```

Where P represents the procedure type that the error occurred on. Unknown procedure types do not cause a P1 violation.

P6

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

You may define a procedure only once in a single test procedure file. You can correct this error condition by deleting the duplicated procedure at the indicated line of the test procedure file.

The error message is:

Duplicate procedure P. Original procedure from file F. (P6)

Where F is the file that the first occurrence of the procedure P was found in.

P7

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

Statements (except the **procedure** statement) can only execute when a procedure definition is still active. To correct this error condition, add a **procedure** statement prior to the indicated line of the test procedure file.

The error message is:

Line number L, no active procedure for S statement. (P7-1)

L is the line number in which the failure occurred, and S is the type of statement.

P8

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The **load_unload** procedure must contain an **apply shift** statement. To correct this error condition, add an **apply shift** statement at the appropriate place in the **load_unload** procedure of the test procedure file.

The error message is:

Line number L, no apply shift in load_unload procedure. (P8-1)

L is the line number of the end of the load_unload procedure.

P9

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The **shift** procedure must contain a **force_sci** statement. To correct this error condition, add a **force_sci** statement at the appropriate place in the **shift** procedure of the test procedure file.

The error message is:

```
Line number L, no force_sci in shift procedure. (P9-1)
```

L is the line number of the end of the shift procedure.

P10

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The **shift** procedure must contain a **measure_sco** statement. To correct this error condition, add a **measure_sco** statement at the appropriate place in the **shift** procedure of the test procedure file.

The error message is:

```
Line number L, no measure_sco in shift procedure. (P10-1)
```

L is the line number of the end of the shift procedure.

P11

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

If you define a period for a procedure, then the period time must not be less than the time of the last procedure event. To correct this error condition, increase the period time for the indicated procedure.

The error message is:

```
Period T for P is less than time of last statement. (P11)
```

T represents the period, and P specifies the name of the procedure or the procedure type if it has no name.

How to Debug P11 Violations

Your test procedure has the following content:

```
set time scale 1.000000 ps ;  
  
timeplate gen_tp1 =  
    force_pi 0 ;  
    measure_po 250 ;  
    pulse clk1 500 750 ;  
    period 1000;  
end;
```

In this case, the tool reports a following message:

```
// The following occurred at line 7 in file test.testproc:  
// Error: Period 1000 for gen_tp1 is less than time of last statement.  
(P11-1)
```

In the timeplate gen_tp1, the clock pulse starts at 500 ps with a width of 750 ps, making the minimum period for the cycle 1250 ps. The period is defined as 1000 ps which ends before the clock pulse returns to its off state at 1250 ps, resulting in the P11 violation.

To resolve the violation, you must either increase the period or decrease the pulse.

P12

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The pin name argument for a **force** or **pulse** statement must be a valid pin name of a primary input or clock signal.

The occurrence message for a **force** statement is:

```
The following occurred at T, incorrect pin name P. (P12-1)
```

Where T represents the token in the input file near to where the error occurred and P is the pin name.

The occurrence message for a **pulse** statement is:

```
Incorrect pin [or path] name, P. (P12-1)
P is not a valid clock pin.
```

Where P is the pin or path name.

How to Debug P12 Violations

Edit the pin or path name on the indicated line of the test procedure file.

If the pin or path name refers to a clock signal, the clock must be defined using the `add_clocks` command.

P13

Category: Procedure

Contexts Supported: `dft -scan`, `patterns -scan`, `patterns -scan_diagnosis`

Default Handling: Error (cannot be changed with the `set_drc_handling` command)

`report_drc_rules`: Not Supported

For the **force** statement, you may only use the force values 0, 1, X, and Z. To correct this error condition, edit the force value on the indicated line of the test procedure file.

The error message is:

```
The following occurred at T, incorrect force value V. (P13-1)
```

Where T represents the token in the input file near to where the error occurred and V is the incorrect value.

P14

Category: Procedure

Contexts Supported: `dft -scan`, `patterns -scan`, `patterns -scan_diagnosis`

Default Handling: Error (cannot be changed with the `set_drc_handling` command)

`report_drc_rules`: Not Supported

You may only use the **force_sci** statement in the **shift** procedure. To correct this error condition, delete the **force_sci** statement on the indicated line of the test procedure file.

The error message is:

```
Line number L, force_sci only allowed in the shift procedure. (P14-1)
```

L is the line number in which the failure occurred.

P15

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

You may only use the **force_sci** statement once in the **shift** procedure. To correct this error condition, delete the **force_sci** statement on the indicated line of the test procedure file.

The error message is:

```
Line number L, duplicate force_sci statement. (P15-1)
```

L is the line number in which the failure occurred.

P16

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

You may only use the **measure_sco** statement in the **shift** procedure. To correct this error condition, delete the **measure_sco** statement on the indicated line of the test procedure file.

The error message is:

```
Line number L, measure_sco only allowed in the shift procedure. (P16-1)
```

L is the line number in which the failure occurred.

P17

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

You may only use the **measure_sco** statement once in the **shift** procedure. To correct this error condition, delete the **measure_sco** statement on the indicated line of the test procedure file.

The error message is:

```
Line number L, duplicate measure_sco statement. (P17-1)
```

L is the line number in which the failure occurred.

P18

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

You may only use the **apply shift** statement in the **load_unload** procedure. To correct this error condition, delete the **apply** statement on the indicated line of the test procedure file. Note that this DRC does not check apply statements used for subprocedures.

The error message is:

```
Line number L, apply only allowed in load_unload procedure. (P18-1)
```

L is the line number in which the failure occurred.

P19

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

You cannot have two **apply shift** statements with a value greater than 1 in the **load_unload** procedure.

The error message is:

```
Line number L, duplicate apply shift statement. (P19-1)
```

L is the line number in which the failure occurred and P19 is the rule ID number.

Note

 You can repeat the **apply shift** statement for as many serial shifts as necessary; however, you must specify 1 for the value in the additional **apply shift** statements.

P20

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

You may only use the **apply shadow_control** statement in the **load_unload** procedure. To correct this error condition, select the **apply shadow_control** statement on the indicated line of the test procedure file.

The error message is:

Line number L, duplicate apply shadow_control statement. (P20-1)

L is the line number in which the failure occurred.

P21

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The **apply shadow_control** statement may only be used immediately after the **apply shift** statement. To correct this error condition, move the **apply shadow_control** statement from its current position on the indicated line of the test procedure file to the position following the **apply shift** statement.

The error message is:

Line number L, apply shift must precede apply shadow_control. (P21-1)

L is the line number in which the failure occurred.

P22

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

You must set the number of repetitions for the **apply shadow_control** statement to 1. To correct this error condition, change the repetition argument of the **apply shadow_control** statement on the indicated line of the test procedure file to the value of 1.

The error message is:

```
Line number L, repetitions for apply shadow_control must be 1. (P22-1)
```

L is the line number in which the failure occurred.

P23

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

You may only use the **apply** statement for the **shift** and **shadow_control** procedures. To correct this error condition, delete the **apply** statement on the indicated line of the test procedure file.

The error message is:

```
Line number L, apply procedure P not allowed. (P23-1)
```

L is the line number in which the failure occurred and P is the procedure name.

P24

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

The timing in a port specific pulse or force statement for a clock must specify the correct number of pulse statements to match the frequency multiplier. Correct this error condition by editing the timing for the clock identified.

The error message is:

```
Specified timing for frequency multiplied clock C in timeplate T only has P pulses where R are required. (P24-1)
```

C is the clock name, T is the timeplate, P is the number of pulses and R are the required number of pulses.

P25

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

You may only use the **initialize** command at time 0 of the **test_setup** procedure. Correct this error condition by moving the statement, on the indicated line of the test procedure file, to the beginning of the **test_setup** procedure.

The error message is:

```
Line number L, initialize command can only be used at time 0  of
test_setup procedure. (P25-1)
```

L is the line number in which the failure occurred.

P26

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The instance name argument for the **initialize** statement must correspond to at least one primitive-level latch or flip-flop gate instance. Correct this error condition by editing the statement on the indicated line of the test procedure file.

The error message is:

```
Line number L, incorrect instance name N. (P26-1)
```

L is the line number in which the failure occurred and N is the instance name.

P27

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

This rule checks two aspects of force values on clock pins.

Specifically:

- The only allowed force values for a clock pin are 0 and 1. Correct this error condition by changing the force value of the statement on the indicated line of the test procedure file.

The error message is:

```
// Error: Line number L, clock C may not be forced to a V. (P27-1)
```

L is the line number in which the failure occurred, C is the clock pin name, and V is the incorrect value.

- The only allowed force state for a clock pin is OFF when pulsed in the timeplate. To fix a P27 error where a clock pin with pulse timing is forced to its ON state, create another timeplate that does not pulse the clock and use this timeplate for the procedure or cycle in question.

The error message is:

```
// The following occurred at line L in file F:
```

```
// Error: Clock C which is pulsed in timeplate T may not be forced  
// to on state. (P27-1)
```

F is the file name, L is the line number in which the failure occurred, C is the clock pin name, and T is the timeplate name.

- The **force_capture_clock_on** and **force_capture_clock_off** procedure file statements are used in a procedure timeplate that contains pulse statements:

```
// The following occurred at line L in file procfile_name.
```

```
// Error: Cannot use force_capture_clock_on in procedure when  
// referenced timeplate timeplate has pulse statements. (P27-1)
```

P28

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The only allowed force value for a write control pin is its defined off-state value, unless it is also defined as a clock. Correct this error condition by changing the force value of the statement on the indicated line of the test procedure file.

The error message is:

```
// The following occurred at line L:  
// Error: Write control W may not be forced to a v. (P28-1)
```

L is the line number in which the failure occurred, W is the write control pin name, and V is the incorrect value.

P29

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

All clocks must be at their off-state prior to any pattern which places a clock line at an on-state. Correct this error condition by changing force statements prior to and including the indicated line of the test procedure file.

Note

 Partially overlapping clocks are not supported.

The error message is:

```
// The following occurred at line L:  
// Error: Clock C not at off-state prior to clock_on pattern. (P29-1)
```

L is the line number in which the failure occurred and C is the clock pin name.

P30

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

A procedure may not place a clock at its on-state at the same time it forces a non-clock pin to a value or place another clock at its off-state. Correct this error condition by changing force statements prior to and including the indicated line of the test procedure file. The rules checker ignores this condition if you set the handling to “ignore” with the set_drc_handling command.

Note

 Partially overlapping clocks are not supported.

The error message is:

```
// The following occurred at line L:  
// Error: Clock C cannot be forced on at this time. (P30-1)
```

L is the line number in which the failure occurred, and C is the clock pin name.

P31

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

A procedure may not force a non-clock pin to a value at the same time it forces a clock pin to a value. Correct this error condition by changing **force** statements prior to and including the indicated line of the test procedure file. The rules checker ignores this condition if you set the handling to “ignore” with the set_drc_handling command.

The error message is:

```
// The followin offured at line L:  
// Error: Non-clock pin N cannot be forced at this time. (P31-1)
```

L is the line number in which the failure occurred, and N is the non-clock pin name.

P32

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

A procedure may not place a clock at its off-state at the same time it places another clock at its on-state. Correct this error condition by changing **force** statements prior to and including the indicated line of the test procedure file. The rules checker ignores this condition if you set the handling to “ignore” with the set_drc_handling command.

The error message is:

```
// Error: Line number L, clock pin C cannot be forced off at this time.  
(P32-1)
```

L is the line number on which the failure occurred, and C is the clock pin name.

P33

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

When a pattern places a clock at its off-state, all clocks must be at their off-state. Correct this error condition by forcing the indicated clock to its off-state at the same time as the indicated line of the test procedure file. The rules checker ignores this condition if you set the handling to “ignore” with the set_drc_handling command.

Note

 Partially overlapping clocks are not supported.

The error message is:

```
// The following occurred at line L:  
// Error: Clock C not at off-state at end of clock_off pattern. (P33-1)
```

L is the line number in which the failure occurred, C is the clock pin name, and P33-1 is the rule and violation ID number.

P34

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

At the end of all test procedures (except **test_setup** procedure), all clocks must be at their off-state. Correct this error condition by forcing the indicated clock to its off-state prior to the indicated line of the test procedure file.

The error message is:

```
// The following occurred at this line L:  
// Error: Clock C not off at end of P procedure. (P34-1)
```

L is the line number in which the failure occurred, C is the clock pin name, and P is the procedure name.

P35

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

At the end of the **master_observe** and **shadow_observe** procedures, all constrained pins must be at their constrained states. The tools assume they are at that state prior to the procedures. Correct this error condition by forcing the indicated pin to its constrained state prior to the indicated line of the test procedure file.

The error message is:

Constrained pin L not at constrained value at end of P procedure. (P35-1)

L is the line number in which the failure occurred, and P is the procedure name.

P36

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The test procedure file must contain a **load_unload** procedure. Correct this error condition by adding a **load_unload** procedure to the test procedure file.

The error message is:

No load_unload procedure in group procedure file. (P36-1)

P37

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The test procedure file must contain a **shift** procedure. Correct this error condition by adding a **shift** procedure to the test procedure file.

The error message is:

No shift procedure in group procedure file. (P37-1)

P38

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

If the test procedure file contains an **apply shadow_control** statement, the test procedure file must contain a **shadow_control** procedure. Correct this error condition by adding a **shadow_control** procedure to the test procedure file or by deleting the **apply shadow_control** statement.

The error message is:

```
No shadow_control procedure in group procedure file. (P38-1)
```

P39

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

If the test procedure file contains a **shadow_control** procedure, the test procedure file must also contain an **apply shadow_control** statement. Correct this error condition by adding an **apply shadow_control** statement or by deleting the **shadow_control** procedure in the test procedure file.

The error message is:

```
Unused shadow_control procedure in group procedure file. (P39-1)
```

P40

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

If you turn on the skew load option, the test procedure file must contain a **skew_load** procedure. Correct this error by adding a **skew_load** procedure to the test procedure file or by turning off the skew load option with the set_skewed_load command.

The error message is:

```
Skewed_load may not be used without a skew_load procedure. (P40-1)
```

P41

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the `set_drc_handling` command)

`report_drc_rules`: Not Supported

The values of all pins at the beginning of the **shift** procedure must be the same as at the end of the **shift** procedure. Correct this error condition by changing force statements in the **shift** or **load_unload** procedures.

The error message is:

```
P initial value different from final value in shift procedure. (P41-1)
```

P is the pin name.

P42

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the `set_drc_handling` command)

`report_drc_rules`: Not Supported

If there are multiple test procedure files, there can be no more than one **test_setup** procedure. Correct this error condition by deleting the extra **test_setup** procedures.

The error message is:

```
Multiple test_setup procedure defined in test procedure files. (P42-1)
```

If there are multiple test procedure files, there can be no more than one **test_end** procedure.

Correct this error condition by deleting the extra **test_end** procedures.

The error message is:

```
Multiple test_end procedure defined in test procedure files. (P42)
```

P43

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the `set_drc_handling` command)

`report_drc_rules`: Not Supported

You must place all write and read control lines at their off-state at time 0 of the **load_unload** procedure. Correct this error condition by adding the appropriate force statements to the test procedure file or by deleting the write or read control lines.

The error message is:

```
T control N not at off-state at time 0 of load_unload procedure. (P43-1)
```

T is the type of control (write or read) and N is the name of the control line.

P44

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

You may only place the **restore_pis** statement at the end of a **seq_transparent** procedure. Correct this error condition by either removing the statement or by placing it at the end of a valid **seq_transparent** procedure.

The error message is:

```
Line number L, restore_pis can only be used at the end of the seq_transparent procedure. (P44-1)
```

L is the test procedure file line number where the error occurred, and P44-1 is the rule and violation ID number.

P45

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

You may only place the **condition** statement at the beginning of a **seq_transparent** procedure. Correct this error condition by either removing the statement or by placing it at the beginning of a valid **seq_transparent** procedure.

The error message is:

```
Line number L, conditions can only be used at time 0 of seq_transparent procedures. (P45-1)
```

L is the test procedure file line number where the error occurred, and P45-1 is the rule and violation ID number.

P46

Category: Procedure

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The **condition** statement must identify a pin pathname that connects to the output of a scan state element. The path between the two points can only contain buffers and inverters. Correct this error condition by either removing the **condition** statement or by correcting the pin pathname

The error message is:

```
Invalid condition for nonscan cell N (G) during procedure P. (P46-1)
```

N is the name of the non-scan cell, G is the gate ID number, P is the **seq_transparent** procedure name, and P46-1 is the rule and violation ID number.

P47

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The statement mentioned is not allowed to be used in the type of procedure that is named. For example, it is not legal to have a measure statement in a load_unload procedure.

The error message is:

```
Statement S cannot be used in P procedure. (P47)
```

Where S is the statement, and P is the name of the procedure.

P48

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The set strobe_window time statement specifies a bad value for the strobe_window time.

For more information, refer to “[Set Statement](#)” in the *Tessent Shell User’s Manual*.

The error message is:

Negative or zero strobe window specified. (P48)

P49

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The set time scale statement specifies a bad time value.

For more information, refer to “[Set Statement](#)” in the *Tessent Shell User’s Manual*.

The error message is:

Negative or zero value specified for the time scale. (P49)

P50

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The pulse width value for the named pulse statement in a named procedure or timeplate is zero or negative. The error message can appear for either timeplates or procedures, and will use either the word “timeplate” or “procedure.”

The error message is:

Negative or zero pulse width for S specified in [timeplate | procedure]
P. (P50)

Where S is the pulse statement, and P is the procedure name.

P51

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The named statement occurs more than once in the named timeplate. For example, forcing the same pin twice in a timeplate is not allowed. Pulsing a clock more than once in a single timeplate is also not allowed.

The error message is:

```
Duplicate S statement in timeplate T. (P51)
```

Where S is the statement that occurs more than once, and T is the timeplate.

P52

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

A pulse statement was used with a pin name which is not a clock pin. This message can also appear for either timeplates or procedures.

The error message is:

```
Non-clock pin P cannot be pulsed in [ timeplate | procedure ] S. (P52)
```

Where P is the pin name, and S is the timeplate or procedure.

P53

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Warning (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The named timeplate does not specify a pulse statement required by one of the procedures which uses this timeplate. For example, if a ram_sequential procedure contains a pulse_read_clock statement, but the timeplate that the procedure uses does not contain a pulse statement for any read clock, this warning will be issued. You can correct this warning by adding pulse statements for all needed clocks in the timeplate definitions.

The error message is:

```
No clock pulse timing in timeplate T which matches event E in procedure P,  
two cycle clock pulses will be used. (P53)
```

Where T is the timeplate statement, E is the pulse event, and P is the procedure.

Note

 A P53 warning will not cause the Vector Interfaces outputs to create incorrect patterns, just larger patterns. During pattern output, if a timeplate does not contain a needed clock pulse statement, the clock pulse will be created by using two cycles and the force_pi time of the timeplate.

How to Debug P53 Violations for analyze_simulation_mismatches

When using the [analyze_simulation_mismatches](#) command for a pattern with a P53 violation, the tool issues an error and stops the DRC checking:

```
// Error: P53 violation may produce incorrect "analyze simulation
// mismatches" result.
// Suggest to fix the test procedure timeplate to avoid P53.
```

The problem of the P53 error is due to an undefined clock waveform in the used timeplate.

This violation can be seen when saving patterns as in the following example:

```
// command: write_pattern testcase_failing_patt.v -verilog -serial -all
// -rep
// Warning: No clock pulse found in timeplate tp_shift which matches
// event /RESETN in procedure used in patterns, two cycle clock pulse
// will be used. (P53)
```

This example shows that the P53 error is issued when saving the Verilog test bench.

The reason for this is the /RESETN is pulsed in some patterns, but the timeplate used for the pattern “tp_shift” does not contain a pulse time for /RESETN, which causes the pattern to expand the capture cycle into two cycles. The P53 rule changes the timing of test patterns and causes an unnecessary increase in test application.

It is recommended you fix any P53 issues first when you want to debug the mismatch issue.

P54

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

Some statement has referenced a name that is not defined. For example, using the “timeplate” statement in a procedure to reference a timeplate that has not yet been defined. Or, using the “force” statement on a pin name that the ATPG tool cannot find.

The error message is:

```
Undefined identifier N referenced by S. (P54)
```

Where N is the undefined name and S is the statement referring to N.

P55

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

This error message indicates that an old procedure type of statement is used within a cycle-based procedure, or that a cycle-based procedure statement is used in an old style procedure. For example, it would be illegal to put a break_repeat statement in a procedure that uses timeplates and cycles; put a force statement with a time value in a cycle-based procedure; or use old procedure statements in a new procedure (for example, the capture procedure).

The error message is:

```
Illegal mix of time based and cycle based statements in procedure P. (P55)
```

Where P is the procedure name.

P56

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The named timeplate or procedure is empty. If it is a procedure, it has no statements, including no timeplate references.

The error message is:

```
[ Timeplate | Procedure ] S has no statements. (P56)
```

Where S is the named timeplate or procedure.

P58

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The time specified for a break_repeat statement is too small to be useful, for example, it is equal to one or less.

The error message is:

```
Break_repeat time value T is too small in procedure P. (P58)
```

Where T is a number, and P is the name of the procedure in which T resides.

P59

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

Checks for incorrect loop values on loop statements in the procedure file.

The error message is:

```
// The following occurred at line N in file <filename>:  
// Error: In <procedure_name>, loop with repetition less than 1 is not  
// allowed. (P59-1)
```

P60

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

Checks if the set tck_ratio is compatible with the timeplate used in the test_setup and/or test_end procedures.

The error message is:

```
// The following occurred at line N in <filename>:  
// Error: IJTAG error for <iCall | iReset | iMerge>: Specified tck_ratio  
// of N does not agree with timing for tck clock in timeplate <name>.  
// (P60-1)
```

For certain conditions, the tool issues optional message continuations for the error. For example:

```
// A tck ratio of 1 requires pulse timing on the tck clock.  
  
// A tck ratio of 4 or greater requires force timing on the tck clock not  
// pulse timing.  
  
// A tck ratio of 4 or greater requires force timing on the tck clock to  
// occur before measure_po time.  
  
// A tck ratio of 2 requires force timing for tck to occur after the  
// measure_po time.
```

P62

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

In a definition statement, the identifier N has already been used in a previous definition. For example, if there is a pin name in the design called “GROUP1” and there is an “alias” statement which tries to define an alias called “GROUP1,” the user will receive the following P62 message, “alias name GROUP1 already in use as pin name.”

The error message is:

```
X name N already in use as Y. (P62)
```

Where X is the type of definition, and Y is the previous definition type.

P63

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

Only one occurrence of a pin is allowed in an alias statement. Pin P occurs more than once in the current alias statement.

The error message is:

```
Duplicate pin P in alias statement. (P63)
```

P64

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

Pin P has a direction (input, output, bidirectional) that is not compatible with statement S.

Direction of pin P is not compatible with S statement. (P64)

For example, the following occurrence message:

Direction of pin Out1 is not compatible with force statement. (P64)

Out1 is an output pin in the netlist that is not compatible with a force statement.

P65

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Warning (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

A duplicate statement S has been found in procedure P. The tool will ignore the first occurrence of this statement. A duplicate statement is one that occurs at the same time and on the same pin (if applicable) as a previous statement.

For example, if a statement in a procedure causes pin A to be forced to a zero at time zero, and then a subsequent statement causes pin A to be forced to a one at time zero, the user will receive a P65 message and the first force statement will be ignored.

The error message is:

Duplicate S statement in procedure P, first statement being ignored. (P65)

S is the either just the event type or the event type and pin name when needed. P is the procedure type.

P66

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The P66 rule is used to check for missing statements within a load_unload_registers procedure. For example, if no Shift block is specified, or if an event statement using the '#' character is not present for each shift_assignment passed to the load_unload_registers procedure, a P66 is issued.

The error message is:

```
Error: Procedure procedure_name is missing required statement_string statement. (P66)
```

See “[Serial Register Load and Unload for LogicBIST and ATPG](#)” for complete information.

P70

Category: Procedure

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Warning (can be changed with the set_drc_handling command)

report_drc_rules: Not Supported

Source clocks defined in clock control definitions cannot be constrained.

The error message is:

```
// Warning: Source clock <name> declared in clock control <name> cannot be constrained. (P70-<occurrence>)
```

P71

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

The pin pathname listed in an internal clock definition must be the pin pathname of an existing clock.

This rule verifies that the pin pathname specified by the CLOCK_CONTROL keyword in the clock definition defines an existing clock. Clocks are added with the [add_clocks](#) command. Internal clocks are added with the add_clocks command.

The error message is:

```
Error: Name "p1" used in clock control is not defined as a clock. (P71)
```

Where P1 is the pin pathname of the clock.

P72

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

The global control conditions and source clocks defined in multiple clock controls of the same or equivalent clocks must be exactly the same.

If the global controls defined in the multiple clock controls are not exactly the same, the following error message is reported.

```
Error: Unable to load clock control for clock "p1" due to multiple clock controls with different global controls defined for the same clock. (P72)
```

If the source clock list defined in the multiple clock controls are not exactly the same, the following error message is reported.

```
Error: Unable to load clock control for clock "p1" due to multiple clock controls with different source clocks defined for the same clock. (P72)
```

Where P1 is the pin pathname of the clock.

P73

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

A FORCE statement cannot be used to force an on value on a clock pin. P73 verifies that no clock pins are forced on in clock control definitions.

The error message is:

```
Error: Cannot force clock "p1" to its on value in clock control for clock "p2". (P73)
```

Where both P1 and P2 are the pin pathnames of the clocks.

P74

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

When multiple clock control definitions are used, compatible conditions must exist to turn off other clock pins while the clock being controlled is pulsed.

Also, a clock pin cannot be forced off when it is defined as a source clock.

This rule check verifies that the clock control conditions defined by multiple clocks are compatible and that the clock being forced to off is not defined as a source clock in the same clock control definition.

If incompatible clock conditions exist, the following error message is reported.

```
Error: Clock "P1" is explicitly forced off in clock control for clock "P2". However, there is no way to force "P1" off while pulsing "P2". (P74)
```

If the clock that is turned off is defined as the source clock in the clock control definition of the equivalent clock, the following error message is reported.

```
Error: Clock "P1" is forced to be off explicitly in clock control for clock "P2" while it is defined as source clock at the same time. (P74)
```

Where P1 and P2 are the pin pathnames of the clocks.

P75

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

Clock control definitions cannot contain conditions that force the clock being controlled or an equivalent clock to an off state.

If a FORCE statement is used to force a controlled clock off, the following error message is reported.

```
Error: Clock "p1" cannot be forced off when defining clock control for the same clock. (P75)
```

If a FORCE statement is used to force an equivalent clock off, the following error message is reported.

```
Error: Clock "p1" cannot be forced off when defining clock control for its equivalent clock "p2". (P75)
```

Where P1 and P2 are the pin pathnames of the clocks.

P76

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Warning (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

At least one of several components must be defined in a clock control definition.

Specifically:

- ATPG_CYCLE #, END block
- ATPG_SEQUENCE, END block
- ATPG_SEQUENCE <N> <M>, END block
- FORCE statement that forces the non-clock pin to off
- CONDITION statement

If none of the statements/procedures listed are present, one of the following warnings display:

Warning: The clock control for clock "P1" is unconditional for ATPG_CYCLE "p2". (P76)

Warning: The clock control for clock "P1" is unconditional for ATPG_SEQUENCE applied to all capture cycles. (P76)

Warning: The clock control for clock "P1" is unconditional for ATPG_SEQUENCE "p1" "p2". (P76)

Where P1 is the pin pathname of a clock and P2 and P3 are capture cycle numbers. The tool assumes that the clock is always pulsed in the specified capture cycles when test patterns are generated.

P77

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

A non-clock pin cannot be defined as a source clock.

This rule check verifies that the pin pathname specified by the SOURCE_CLOCK keyword is a clock pin.

If the pin pathname specified by the SOURCE_CLOCK keyword is not a clock pin, the following error message is reported.

```
Error: Cannot define non-clock pin "p1" as SOURCE_CLOCK. (P77)
```

Where P1 is the pin pathname of the clock.

P78

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

Multiple sequence blocks for a clock must contain local force or condition statements.

If a {ATPG_SEQUENCE, END} or {ATPG_SEQUENCE <N> <M>, END} block is declared without any local force or condition statement, the following error message is reported.

```
Error: Multiple ATPG_SEQUENCE blocks without local condition are defined  
in clock control for clock "P1". (P78)
```

Where P1 is the pin pathname of the clock.

P79

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

A clock control definition containing both sequence and per-cycle blocks must provide mutually exclusive force and/or condition statements to control clock pins.

If an ATPG_SEQUENCE block is declared both with and without force or condition statements, the following error message is reported.

```
Error: ATPG_SEQUENCES with and without local condition are defined in  
clock control for clock "P1". (P79)
```

If an ATPG_SEQUENCE block is declared without force or condition statements and an ATPG_CYCLE block declares force or condition statements, the following error message is reported.

```
Error: Both ATPG_SEQUENCE mode without local condition and per-cycle mode with local condition are defined in clock control for clock "p1". (P79)
```

Where P1 is the pin pathname of the clock.

P80

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

Conditions defined to pulse clocks in multiple clock control block definitions must be mutually exclusive.

This rule check verifies that:

- Sequence clock control conditions that pulse the clock are mutually exclusive with the per-cycle clock control conditions that pulse the same clock.
- Sequence clock control conditions that pulse the clock are mutually exclusive of the clock control condition used to pulse the same clock in another sequence definition.

If the clock control condition to pulse a clock in sequence block is not mutually exclusive with the clock control condition for the same clock in a per-cycle block a P80 violation is reported. Depending on the violation, one of the following error messages is reported.

```
Error: In clock control for clock "P1", the conditions defined in ATPG_SEQUENCE "p2" "p3" are not mutually exclusive with the conditions defined in ATPG_CYCLE P4. (P80)
```

```
Error: In clock control for clock "P1", the conditions defined in ATPG_SEQUENCE "p2" "p3" are not mutually exclusive with the conditions defined in ATPG_SEQUENCE P4 P5. (P80)
```

```
Error: In clock control for clock "P1", the conditions defined in ATPG_SEQUENCE "p2" "p3" are not mutually exclusive with the conditions defined in ATPG_SEQUENCE applied to all capture cycles. (P80)
```

```
Error: In clock control for clock "P1", the conditions defined in ATPG_CYCLE "p2" are not mutually exclusive with the conditions defined in ATPG_SEQUENCE applied to all capture cycles. (P80)
```

Where P1 is pin pathname of the clock and P2, P3, P4, and P5 are capture cycles.

P81

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Warning (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

There must be a disabled condition defined for sequence clock control definitions, either by applying a clock control condition or setting the source clock to the off state.

This rule check verifies that a clock controlled by a sequence block can be disabled.

If there is no way to disable a clock controlled by a sequence block a P81 DRC violation is reported. Depending on the violation, one of the following warning messages is reported:

Warning: No way to disable sequence mode clock control for clock "P1".
(P81)

Warning: No way to disable sequence mode clock control for clock "P1" by disabling clock control condition. (P81)

Where P1 is the pin pathname of the clock.

P82

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Warning (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

There must be a way to disable clocks defined with per-cycle clock control.

If there is no way to disable a clock defined with per-cycle clock control by either applying a condition or setting the source clock to the off state, the following warning message is reported:

Warning: No way to disable cycle mode clock control for "P1". (P82)

If there is no way to disable a clock defined with per-cycle clock control using a condition, but it can be disabled by setting the source clock to the off state, the following warning message is reported:

Warning: No way to disable cycle mode clock control for clock "P1" by disabling clock control condition. (P82)

Where P1 is the pin pathname of the clock.

P83

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Warning (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

When using per-cycle clock control, there must be a way to disable a clock after the capture cycle.

This rule check verifies the on condition for the clock during the capture cycle is mutually exclusive with the off state condition for the same clock after the capture cycle.

If there is no source clock defined or the source clock cannot be suppressed (defined as pulse-always), one of the following warning messages is reported, and the generated test patterns do not include P1 capture cycles while the clock under control is pulsed at P1.

Warning: No way to pulse clock "P1" at capture cycle "p2" while turning off the same clock after the capture cycle "p2" in cycle mode clock control for clock "P1". (P83)
Warning: No way to turn off clock "P1" after capture cycle "p2" in cycle mode clock control for clock "P1". (P83)

If it is possible to suppress the clock under control by turning off the source clock, one of the following warning messages is reported.

Warning: No way to pulse clock "P1" at capture cycle "p2" while turning off the same clock after the capture cycle "p2" in cycle mode clock control for clock "P1" by disabling clock control condition. (P83)

Warning: No way to turn off clock "P1" after capture cycle "p2" in cycle mode clock control for clock "P1" by disabling clock control condition. (P83)

Where P1 is the pin pathname of the clock and P2 is the capture cycle.

P84

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Warning (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

When both sequence mode and cycle mode clock controls are defined for a clock, there must be a way to disable the internal clock for both definitions.

This rule check verifies that a clock running in both sequential and per-cycle mode can be disabled.

If a clock running in both sequence and per-cycle cannot be disabled, the following warning message is reported.

Warning: No way to disable both sequence mode and cycle mode clock control for clock "p1" simultaneously. (P84)

Where P1 is the pin pathname of the clock.

P85

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Warning (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

When clock controls exist for two clocks not defined as equivalent, there must be a way to turn off both clocks simultaneously during a capture cycle.

If both clocks cannot be disabled simultaneously during a capture cycle, the following warning message is reported.

Warning: Clock control is unable to turn off clock "P1" and clock "P2" simultaneously at capture cycle "P3". (P85)

Where P1 and P2 are the pin pathnames of the clocks and P3 is the capture cycle.

P86

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not supported

When clock controls exist for two clocks that are not defined as equivalent and one clock is pulsed during a capture cycle, there must be a way to turn off the other clock during the same capture cycle.

If there is no source clock defined or all source clocks are defined as pulse-always, the following warning message is reported:

Warning: Clock control is unable to turn on clock "P1" while turning off clock "P2" during capture cycle "P3". (P86)

If it is possible to suppress the clock under control by turning off the source clock, one of the following warning messages is reported:

Warning: Clock control is unable to turn on clock "P1" while turning off clock "P2" during capture cycle "P3" by disabling clock control condition. (P86)

Where P1 and P2 are the pin pathnames of the clocks and P3 is the capture cycle.

P87

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

A clock control cannot be defined for a pulse-always clock.

If a clock control is defined for a pulse-always clock, the following error message is reported.

Warning: Cannot define clock control for pulse-always clock "P1". (P87)

Where P1 is the pin pathname of the clock.

P88

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

A CONDITION or FORCE statement cannot assign a value to a non-scan state element.

If a CONDITION or FORCE statement assigns a value to a non-scan state element, the following error message is reported.

Error: Value is forced at non-PI and non-scan cell "P1" in clock control for clock "P2". (P88)

Where P1 is the pin pathname of the gate a value is assigned to and P2 is the name of the clock under control.

P89

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not supported

When you use clock control definitions, all unconstrained internal clocks must have an associated clock control definition.

Clock controls are defined in the test procedure file and can be enabled or disabled using the [set_clock_controls](#) command.

When no clock control is defined for an unconstrained internal clock, the tool displays following error message:

```
Error: Clock control is not defined for the internal clock "P1". (P89)
```

Where P1 is the clock pin pathname.

Note that an unconstrained internal clock does not need a clock control definition and does not cause a P89 error under any of the following circumstances:

- The internal clock is defined as pin-equivalent to other clocks and one of the equivalent clocks has clock control defined.
- The internal clock is a pulse-always or pulse-in-capture clock.
- The internal clock is an asynchronous clock (defined with “add_clocks -period”).
- The internal clock is not driving any observation points (POs or scan cells).

P90

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

Internal clock controls cannot be dependent on source clocks defined by other internal clock controls.

For example, when the clock control for clock clk1 defines clk2 as source clock, the clock control for clock clk2 defines clk1 as source clock.

However, you can define the clock under control as the source clock for itself to unconditionally force itself to an off state.

When no clock control is defined for an unconstrained internal clock, the following warning message is reported.

Error: Clock controls for clocks "P1" and "P2" depend on each other through source clocks. (P90)

Where P1 and P2 are pin pathnames of clocks.

P91

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not supported

Mutually exclusive control conditions cannot exist for different ATPG_CYCLES of the same clock.

If mutually exclusive control conditions are defined in different ATPG_CYCLES for the same clock, the following error message is reported:

Warning: In clock control for clock "P1", the conditions defined in ATPG_CYCLES "P2" and "P3" are mutually exclusive.

Where P1 is the clock pin pathname and P2 and P3 are capture cycles.

P92

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

Verifies that added internal PI (primary input) signals are controlled deterministically.

Specifically, verifies that every internal PI signal satisfies at least one of the following criteria:

- The internal PI has a pin constraint.
- The internal PI has an ATPG constraint.
- The internal PI is a pulse-always or pulse-in-capture clock.
- If NCP are present and enabled, the internal PI must be forced all the time in the internal mode of every enabled NCP.

If none of these criteria is true, the following error message is reported:

```
//Error: Internal primary input /int_clk (42) is not controlled. (P92-1)
```

Note, the following cases are not checked:

- An internal PI that is defined as a scan chain input pin.
- An internal PI that is blocked by pin constraints.
- An internal PI that passes P89 (an internal clock that is controlled by clock control definitions).

You can use the [add_input_constraints](#) and “[add_atpg_constraints](#)” on page 96 commands to properly constrain an internal PI to the right value.

P93

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not supported

The clock under control cannot define itself as the source clock.

If this is the case, the tool issues following error message:

```
//Error: Clock '<clock_pin_pathname>' cannot be defined as source clock  
for itself. (P93)
```

P94

Category: Procedure Rules

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

Verifies a consistent view of the capture window between ATPG settings and external capture procedure options or PLL cycles to avoid generating invalid patterns.

The tool only performs the P94 DRC when you issue the “set_external_capture_procedure -capture_procedure” or “set_external_capture_procedure -PLL_cycles” commands. When you issue either of these commands in SETUP mode, the check is performed during system mode analysis. When you issue either of them in Analysis mode, the check is performed immediately.

The default handling for P94 is Error, but it can be set to Warning, Ignore, or Note. When the handling for P94 is set to warning, the tool automatically adds TX cell constraints to the potential mismatching scan cells.

When the tool forces all pin constraints and constant cell constraints and collects all external PIs and clocks that may reach scan cells directly as candidates for the P94 DRC check, it applies the following checks on each candidate:

- An external clock is pulsed in an external capture procedure.

```
// Error: External clock '/slow_clock' (89) is pulsed in external
capture procedure ext_fast_cap_proc but during pattern generation it
may not be pulsed or may be pulsed for a different number of cycles
than specified in the external capture procedure. This can lead to
simulation mismatches on 7 scan cells, one of which is
'/jn_scell_inst0/' (10297) . (P94-1)

// command: set_drc_handling P94 warn
// Warning: External clock '/slow_clock' (89) is pulsed in external
capture procedure ext_fast_cap_proc but during pattern generation it
may not be pulsed or may be pulsed for a different number of cycles
than specified in the external capture procedure. This can lead to
simulation mismatches on 7 scan cells, one of which is
'/jn_scell_inst0/' (10297) . (P94-1)
// Added 7 TX cell constraints to scan cells due to P94 DRC
violations.
```

Note

 You can fix this violation by blocking this clock from directly reaching a scan cell, or by setting P94 handing to Warning, so that the tool will automatically add TX cell constraints to mask out the affected scan cells.

- An external PI (port) is forced to a known value in an external capture procedure, but does not have a pin constraint or has a constrained value that is inconsistent with the forced value.

```
// Error: Primary input '/SMC' (10) is forced to 1 during external
capture procedure ext_pll_4_pulses but not constrained during
pattern generation. This can lead to simulation mismatches on 1 scan
cell, which is '/sff117/' (561) . (P94-2)c
```

Note

 You can fix this violation by removing the force event from external capture procedure, by adding a consistent pin constraint in ATPG, or by setting P94 to Warning, so that the tool will automatically add a TX cell constraints to mask the affected scan cells.

- An external clock is NOT pulsed in the external capture procedure, and is NOT constrained to Off state in ATPG.

```
// Warning: External clock '/CLK1' (1) is not pulsed in external capture procedure ext_cap_proc but may be pulsed during pattern generation. This can lead to simulation mismatches on 10 scan cells, one of which is '/dff4_pulse_inter/' (369) . (P94-1)
```

Note

You can fix this violation by constraining the clock to off state in ATPG.

- An external clock is pulsed while -pll_cycles is set.

```
// Note: External clock '/RCLK2' (2) is pulsed during external capture when 'set_external_capture_options -pll_cycles' is used but during pattern generation it may not be pulsed or may be pulsed for a different number of cycles than specified by the -pll_cycles switch. This can lead to simulation mismatches on 7 scan cells, one of which is '/dff07/' (248) . (P94-1)
```

- An external clock is not pulsed while -pll_cycles is set.

```
// Warning: External clock '/PHYADRI' (1) is not pulsed during capture when 'set_external_capture_options -pll_cycles' is used but during pattern generation it may not be pulsed or may be pulsed for a different number of cycles than specified by the -pll_cycles switch. This can lead to simulation mismatches on 1 scan cell, which is '/dummy_reg1/' (612) . (P94-1)
// Added 1 TX cell constraints to scan cells due to P94 DRC violations.
```

The summary message issued by “report_drc_rule -summary” command for P94:

```
P94: #fails=0 handling=error (inconsistent view between ATPG settings and external capture options)
```

To debug P94, use the “[set_gate_report](#) drc stable_capture” command to view the values that are constant throughout the capture process for the affected capture.

Core Mapping for ATPG and Scan Pattern Retargeting Rules (R Rules)

Prior to performing core mapping for ATPG or for Scan Pattern Retargeting, Tessent Shell performs rule checks on the design as you switch from setup to analysis mode. This design rule checking phase reads the Tessent core description (TCD) files and core instance information. The tool applies all R rules, except for R7, to the Core mapping for ATPG and Scan Pattern Retargeting functionality.

R1

Category: Core Mapping for ATPG, Core Mapping for Scan Pattern Retargeting, EDT Instruments

Contexts Supported: patterns -scan, patterns -scan_retargeting, patterns -failure_mapping

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that ports defined in the core description match pins at the boundary of core instance(s).

This rule helps detect when a core description is associated with the wrong design module.

R2

Category: Core Mapping for ATPG, Core Mapping for Scan Pattern Retargeting, EDT Instruments

Contexts Supported: patterns -scan, patterns -scan_retargeting

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Extracts connectivity between the core-level scan pins and top-level ports, including extraction of pipelining and inversion. Then, validates the ability to shift from top-level ports to the scan inputs on the core boundary, and from the scan output pins on the core boundary to top-level ports.

How to Debug a R2 Violation

To debug R2 violations, examine the shift simulation values to determine why the scan from the core to the top level is blocked using the following command.

set_gate_report drc shift

You can use the report_gates command and the trace capability in DFTVisualizer to analyze the blockage.

You can use the analyze_drcViolation command to debug a given R2 violation graphically.

R3

Category: Core Mapping for Scan Pattern Retargeting

Contexts Supported: patterns -scan_retargeting

Default Handling: Error (severity cannot be changed)

report_drc_rules: Supported

Verifies that scan input pins of non-identical cores are not shared, unless broadcasting to multiple instances of the same core type.

- When broadcasting to multiple instances of the same core, the pipelining and inversion for each set of equivalent channels must be identical.

- When patterns are loaded from the chip level, if broadcasting to multiple core instances, they must load identical values at the same time.

Verifies that a top-level pin does not drive multiple channels of the same core.

Verifies that the connection from the top-level pin to identical cores connects to the pins of each core in the same order.

R4

Category: Core Mapping for ATPG, Core Mapping for Scan Pattern Retargeting

Contexts Supported: patterns -scan, patterns -scan_retargeting

Default Handling: Error (severity can be changed)

report_drc_rules: Supported

Validates core-level pin constraints against capture-cycle states at the core instance boundary.

The conditions present at the core boundary during core-level pattern generation must be satisfied for each core instance when the core is instantiated in the design. To verify that the same conditions occur, this DRC validates core-level pin constraints against capture-cycle states at the core instance boundary.

Note

 This DRC only validates pin constraints that are specified by the add_input_constraints command.

To perform this validation, the tool simulates the top-level test procedures (test_setup, load_unload, and shift) and input constraints, and compares the stable (constant) values during capture to the pin constraint values at the boundary of each core. The core-level input constraints are stored in the core description file.

You can use the analyze_drcViolation command to debug a given R4 violation graphically.

R5

Category: Core Mapping for ATPG, Core Mapping for Scan Pattern Retargeting

Contexts Supported: patterns -scan, patterns -scan_retargeting

Default Handling: Warning

report_drc_rules: Supported

Validates that the stable values of sequential elements at the end of test_setup at the core level are met after simulating the top-level test_setup procedure. Those are the sequential elements where the "stable_after_setup" value was non-X at the core level.

If the sequential element is no longer present in the design in the retargeting phase due to black boxing or gray boxing of the core, the sequential element's value cannot be validated and will be omitted.

Because the tool cannot determine whether mismatches between the test_setup at the core and the top level matter, this DRC defaults to warning. For example, the state of a core's TAP instruction register may vary after test_setup at the core versus top level, but this may not matter for the core's scan operation.

You can use the analyze_drcViolation command to debug a given R5 violation graphically.

R6

Category: Core Mapping for ATPG, Core Mapping for Scan Pattern Retargeting

Contexts Supported: patterns -scan, patterns -scan_retargeting

Default Handling: Error (severity can be changed)

report_drc_rules: Supported

Verifies the equivalency of the load_unload and shift procedures at the core and top levels.

This DRC validates simulated top-level load_unload and shift procedures against load_unload and shift procedures at the core level.

Pins that are forced in the test_setup procedure are maintained during the load_unload and shift procedures if they are not specifically constrained in the dofile.

You can use the “[report_procedures -core core_name](#)” and the “[report_timeplate -core core_name](#)” commands to debug an R6 violation.

Changing the Default Handling

The R6 DRC can be pessimistic because you may have forced a value, either directly or indirectly, at the core level that is not relevant to the operation of the core. In this case, if you choose to change the default handling for R6 from Error to Warning, the implications of doing that depend on whether the violation was due to over-specification (tool pessimism) or whether the flagged mismatch was needed for correct circuit operation. If the value that is no longer forced from the top is not relevant, downgrading R6 has no impact.

R7

Category: Scan Pattern Retargeting

Contexts Supported: patterns -scan_retargeting

Default Handling: Error (severity can be changed)

report_drc_rules: Supported

Verifies immediately before generation of core-level re-targetable patterns that all primary inputs (PIs) are controlled deterministically.

If any PI (port) was excluded from automatic constraints as a result of applying the `is_excluded_from_isolation_constraints` attribute (found in the Hierarchical Design Data Model [Port](#) attribute table) to it., this DRC verifies that the PI is deterministically controlled and not left for ATPG to justify to different values in different patterns.

Specifically, the tool verifies that every PI signal satisfies at least one of the following criteria:

- The PI has a pin constraint.
- The PI has an ATPG constraint.
- If NCPs are present and enabled, the PI must be forced or pulsed in all cycles of the internal mode of every enabled NCP.

Note, the tool does not check the following PIs:

- An internal PI.
- A PI that is blocked by pins and/or cells whose values are constant during capture.
- A PI that is defined as a pulse-always clock.
- A PI that is defined as an pulse-in-capture clock.

R8

Category: Core Mapping for ATPG, Core Mapping for Scan Pattern Retargeting

Contexts Supported: patterns -scan, patterns -scan_retargeting

Default Handling: Error

report_drc_rules: Supported

Verifies that the core-level load_unload and shift procedures can be correctly retargeted.

In patterns -scan context, when top-level load_unload and shift procedures are present, R8 additionally checks if core-level procedures can be correctly merged with top-level procedures.

The default setting for this rule is an Error. You can change the setting to be either Warning or Note by using the set_drc_handling command.

You can use the analyze_drcViolation command to debug the R8 violations that perform tracing.

The following checks are performed during test procedure retargeting:

- The test procedure is in the core description file. If this is not true, the following error is reported:

```
// Error: load_unload procedure retargeting failed for
// core instance 'coreInstance' (core 'coreName', mode 'coreMode').
// Core-level procedures are missing.
```

- Top-level clock off-states are consistent with those at the core level. If this is not true, the following error is reported:

```
// Error: load_unload procedure retargeting failed for
// core instance 'coreInstance' (core 'coreName', mode 'coreMode').
// Clock pin 'pinName' is driven by top-level port 'portName'. The
// core-level clock pin has an off-state 'value', but the top-level
// clock port has an off-state 'value'.
```

- The path between the core pin and the top-level pin contains only buffers and inverters. If this is not true, the following error is reported:

```
// Error: load_unload procedure retargeting failed for
// core instance 'coreInstance' (core 'coreName', mode 'coreMode').
// Core Pin 'pinName' cannot be traced to the top level. Tracing
// stopped at a gate 'gateName' (gateId).
```

- The core-level clock pin that should be pulsed is instead constantly forced. If this is true, the following error is reported:

```
// Error: load_unload procedure retargeting failed.
// The core-level clock pin 'pinName' (core 'coreName', mode
// 'coreMode') is now constantly forced to 'value'.
```

- The core-level pin that should be forced is constantly forced to an opposite value. If this is true, the following error is reported:

```
// Error: load_unload procedure retargeting failed.
// The core-level pin 'pinName' (core 'coreName', mode 'coreMode')
// is forced to 'value' in the core-level load_unload procedure,
// but it is now constantly forced to 'value'.
```

- The top-level port that is constrained during load_unload can only be forced to the constraint value. If this is true, the following error is reported:

```
// Error: load_unload procedure retargeting failed for
// core instance 'coreInstance' (core 'coreName', mode 'coreMode').
// Core pin 'pinName' is driven by top-level port 'portName'.
// The core-level pin is forced to 'value' in the core-level
// load_unload procedure, but the top-level port is currently
// constrained to 'value' during load_unload.
```

- The top-level port is forced to a different value. If this is true, the following error is reported:

```
// Error: load_unload procedure retargeting failed in
// cycle 'cycleNumber' 1 of the 'procedureName' procedure.
// Top-level port 'portName' has conflicting requirements from the
// existing top-level procedure and the core-level pin(s) it drives:
//
// Top-Level Core-Level Core Pin Inverted Core Mode
// ----- -----
// 'value' 'value' 'corePin' Yes 'coreName' 'modeName'
// 'value' 'value' 'corePin' 'coreName' 'modeName'
```

- A clock pulse definition is missing in the timeplate. If this is true, the following error is reported:

```
// Error: load_unload procedure merging failed.
// Top-level clock port 'portName' which is driving the following
// core-level pin: 'pinName' (core 'coreName', mode 'coreMode')
// has no pulse definition in timeplate 'timeplateName'.
```

- The top-level clock is forced to its on-state. If this is true, the following error is reported:

```
// Error: load_unload procedure merging failed.
// Top-level clock port 'portName' driving the following core-level
// pin: 'pinName' (core 'coreName', mode 'coreMode') is forced to
// its on-state of 'value'.
```

- The top-level clock is pulsed a different number of times in two cores. If this is true, the following error is reported:

```
// Error: load_unload procedure retargeting failed.
// Top-level clock port 'portName' has conflicting pulse
// requirements from the existing top-level procedure and the
// core-level pin(s) it drives:
//
// Clock Pulses Core Pin Core Mode
// ----- -----
// 'pulseCount' 'pinName' 'coreName' 'coreMode'
// 'pulseCount' 'pinName' 'coreName' 'coreMode'
```

- The top-level procedures have conflicting end_measure requirements:

```
// Error: load_unload procedure retargeting failed.  
// Top-level procedures have conflicting end_measure requirements  
// with core-level procedures. (R8-1)
```

- The core-level procedures have conflicting end_measure requirements:

```
// Error: load_unload procedure retargeting failed.  
// Conflicting core-level end_measure requirements. (R8-1)
```

R9

Category: Core Mapping for ATPG, Core Mapping for Scan Pattern Retargeting

Contexts Supported: patterns -scan, patterns -scan_retargeting

Default Handling: Warning (severity can be changed)

report_drc_rules: Supported

Verifies during core extraction that a core-level capture clock connects to a matching top-level clock.

This DRC only checks clocks on the core boundary; clocks internal to the core are not validated.

If a core-level clock is constrained off, and it is not pulsed in the core-level test_setup, load_unload, shift, or test_end procedures, capture validation is not needed because the R4 DRC validates all core-level input constraints. If the core-level clock is constrained off and is pulsed in any of these procedures, the tool performs the following checks:

- Verifies that the core-level clock connects to a top-level pin (either a port or cut point defined by the add_clocks command on an internal pin).
- Verifies that the offstates of the clock and top-level pin match (taking inversion into account).

If a core-level clock is not constrained off and is a pulse-always clock, the tool does the following:

- Verifies that the core-level clock connects to a top-level pin (either port or cut point defined by the add_clocks command on an internal pin).
- Verifies that the top-level pin is defined as a pulse-always clock.
- If a clock is synchronous (not added with “add_clocks -period”), the tool verifies that the off-states match, taking inversion into account. If a clock was added with “add_clocks -period”, the tool does not compare off-states.
- If a clock is synchronous, the tool verifies that it is not connected to a top-level asynchronous free-running clock.

If a core-level clock is not constrained off, is not a pulse-always clock, and is not the capture clock, the tool does not perform any additional R9 checks.

Note

 This DRC considers a clock to be a capture clock if the clock is not blocked, is not an internal primary input, is not constrained during capture, is pulse-always or pulse-in-capture, or if one or more NCPs exists, is pulsed at least once in the active NCPs.

If a core-level clock is not constrained off, is not a pulse-always clock, and is a capture clock, the tool performs the following additional checks:

- Verifies that a core-level clock connects to a top-level pin (either a port or cut point defined by the `add_clocks` command on an internal pin).
- Verifies that the offstates of a clock and top-level pin match (taking inversion into account).

For pattern retargeting when a core-level pin is a pulse-in-capture clock (that is, added with the `add_clocks -pulse_in_capture` command and switch), then the tool performs the following additional checks:

- If top-level clock is `always_pulse` issue, the tool issues an R9 violation.
- If top-level clock is `[async]` free-running, the tool issues an R9 violation.

See “[Scan Pattern Retargeting](#)” in the *Tessent Scan and ATPG User’s Manual*.

For core reuse when a core-level pin is a pulse-in-capture clock (that is, added with the `add_clocks -pulse_in_capture` command switch), then the tool performs the following additional checks:

- If the top-level clock has no special property (that is, `always_capture`, `async_free_running`, and so on), then the tool updates the clock, which means the tool maps and applies the core-level property to the top-level clock.
- In other cases the tool issues an R9 and makes no changes to the top-level clock.

See “[Core Mapping for ATPG Process Overview](#)” in the *Tessent Scan and ATPG User’s Manual*.

R10

Category: Core Mapping for ATPG, Core Mapping for Scan Pattern Retargeting, EDT Instruments

Contexts Supported: patterns -scan, patterns -scan_retargeting

Default Handling: Error (severity can be changed)

report_drc_rules: Supported

Verifies that top-level ICL is available when any of the core instances being retargeted use IJTAG in their test_setup or test_end procedures. This check also applies if any EDT IP instances have been added. If you have disabled IJTAG, then this DRC is not run by the tool.

To correct this error condition, you should use the [extract_icl](#) command to extract top-level ICL.

By default, this violation is an error and can be downgraded to warning or note. If you downgrade this DRC to a lesser violation and the lesser violation occurs, the tool bypasses any remaining IJTAG retargeting.

This DRC reports the following possible error messages:

```
// Error: IJTAG was used in the test_setup and test_end procedures of
//         core 'piccpu_maxlen16' (mode 'internal')
//         but top-level ICL was not extracted or read.
//         Use the 'extract_icl' command to extract top-level ICL or read
//         the top-level ICL model. (R10-1)
// Error: There was 1 R10 violation (Top-level ICL not extracted while
//         IJTAG used in cores).

// Note: IJTAG was used in the test_setup and test_end procedures of
//        core 'piccpu_maxlen16' (mode 'internal')
//        but top-level ICL was not extracted or read.
//        The PDL will not be automatically retargeted and appended to
//        the top-level procedure. (R10-1)
```

R11

Category: Core Mapping for ATPG, Core Mapping for Scan Pattern Retargeting, EDT Instruments

Contexts Supported: patterns -scan, patterns -scan_retargeting

Default Handling: Error (severity can be changed)

report_drc_rules: Supported

Verifies that every core instance that uses IJTAG at the core-level matches an ICL instance at the top-level. This includes design core instances in which IJTAG was used in test_setup and/or test_end, as well as any EDT instrument.

By default, this violation is an error and can be downgraded to warning or note for non-scan instruments. If you downgrade this DRC to a lesser violation and the lesser violation occurs, the IJTAG retargeting capability skips any core instance with IJTAG that does not have a corresponding ICL instance at the top level. If the IJTAG instrument has a scan interface, it cannot be ignored during scan operations and the R11 will be automatically upgraded to an error during the scan identification process.

This DRC reports the following possible error messages:

```
// Error: Current design (mode 'internal', ICL module 'picccpu_maxlen16')
//         is expected to have ICL instance 'tessent_occ_i_clk'
//         in the ICL model, but no such ICL instance was found.
//         Read the missing ICL model and rerun ICL extraction. (R11-1)
// Error: Core 'picccpu_maxlen16' (mode 'internal', ICL module //
//         'picccpu_maxlen16')
//         is expected to have ICL instance 'picccpu_maxlen16_edt_i'
//         in the ICL model, but no such ICL instance was found.
//         Read the missing ICL model and rerun ICL extraction. (R11-2)
// Error: Core instance 'chip_int_1/picccpu_2' (core 'picccpu_maxlen16',
//         mode 'internal') uses IJTAG but has no ICL instance
//         corresponding to it in the ICL model.
//         Rerun ICL extraction and provide the missing ICL model. (R11-3)
// Error: There were 3 R11 violations (Missing ICL instance for core
//         which uses IJTAG).
// Error: Instrument instance 'picccpu_maxlen16_edt_i'
//         (core 'picccpu_maxlen16_edt', instrument type 'edt')
//         uses IJTAG but has no ICL instance corresponding to it in
//         the ICL model. Rerun ICL extraction and provide the missing
//         ICL model. (R11-1)
```

R12

Category: Core Mapping for ATPG, Core Mapping for Scan Pattern Retargeting

Contexts Supported: patterns -scan, patterns -scan_retargeting

Default Handling: Warning (severity can be changed)

report_drc_rules: Supported

Verifies that core-level iCalls are at the end of the test_setup procedure or the start of the test_end procedure.

The tool automatically maps all iCalls located at the end of the test_setup procedure or at the beginning of the test_end procedure; all others are ignored.

By default this violation is a warning and can be changed to error or note. If you downgrade this DRC from error and has a violation, the IJTAG retargeting capability skips all core-level iCalls that have an invalid position.

This DRC reports the following possible error messages:

```
// Error: Core 'piccpu_maxlen16' (mode 'internal', ICL module
//         'piccpu_maxlen16') calls iProc 'setup'
//         of ICL instance 'piccpu_maxlen16_edt_i' (ICL module
//         'piccpu_maxlen16_edt') in test_setup,
//         but not at the end of the test procedure.
//         It will not be automatically retargeted and appended to the
//         top-level procedure. (R12-1)
// Error: Core 'piccpu_maxlen16' (mode 'internal', ICL module
//         'piccpu_maxlen16') calls iProc 'my_proc'
//         in test_end, but not at the beginning of the test procedure.
//         It will not be automatically retargeted and appended to the
//         top-level procedure. (R12-2)
// Error: There were 2 R12 violations (Position of IJTAG in core-level
//         test procedure prohibits automatic retargeting).
```

R13

Category: Core Mapping for ATPG, Core Mapping for Scan Pattern Retargeting, EDT Instruments

Contexts Supported: patterns -scan, patterns -scan_retargeting

Default Handling: Error (severity can be changed)

report_drc_rules: Supported

Verifies that the used core-level iProcs are loaded in memory and are registered against the right ICL instances.

By default, this violation is an error and can be downgraded to warning or note. If this DRC is downgraded from an error and has a violation, the IJTAG retargeting functionality skips all core-level iProc calls that have not been read in at the top-level.

This DRC reports the following possible error messages:

```
// Error: Core 'piccpu_maxlen16' (mode 'internal') calls iProc 'setup'
//         in test_setup, but this iProc is not read for ICL module
//         'piccpu_maxlen16_edt'. (R13-1)

// Error: Core 'piccpu_maxlen16' (mode 'internal') calls iProc 'my_proc'
//         in test_end, but this iProc is not read for ICL module
//         'piccpu_maxlen16'. (R13-2)

// Error: There were 2 R13 violations (Missing iProc used at core level).

// Error: Core 'piccpu_maxlen16_edt' (instrument type 'edt') calls iProc
//         'setup', but this iProc was not read for ICL module
//         'piccpu_maxlen16_edt'. (R13-1)
```

R14

Category: EDT Instruments

Contexts Supported: patterns -scan

Default Handling: Error (severity can be changed to warning)

report_drc_rules: Supported

Validates mapping of static and dynamic control signals.

This DRC validates that static and dynamic EDT IP control signals are properly mapped to the top. Any IJTAG-controlled instruments that do not have a scan interface are also validated.

If the value on the IP boundary is different than what is expected or the signal cannot be traced to the top, the tool issues an R14 violation.

By default, this violation is an error and can be downgraded to warning. When R14 fails and is downgraded to a warning, no automatic procedure updates, clock and constraint adding are performed for the failing pin. You must ensure pin requirements in this case.

This DRC reports the following possible error messages:

```
// Error: Tracing with the stable_shift simulation context from
// core-level control input pin
// 'TOP_DE1_rtl_tessent_occ_elo_inst/slow_clock'
// (core 'TOP_DE1_rtl_tessent_occ', instrument type 'occ')
// to the top level has failed. (R14-1)

// Error: Tracing with the stable_capture simulation context from
// core-level control input pin
// 'TOP_DE1_rtl_tessent_occ_elo_inst/slow_clock'
// (core 'TOP_DE1_rtl_tessent_occ', instrument type 'occ')
// to the top level has failed. (R14-1)

// Error: Core-level control input pin
// 'TOP_DE1_rtl_tessent_occ_elo_inst/capture_cycle_width[1]'
// (core 'TOP_DE1_rtl_tessent_occ', instrument type 'occ')
// is not driven to the expected value of '0'
// or tracing with the stable_shift simulation context to the
// top level has failed.
// Simulated pin value is '1'. (R14-2)

// Error: Tracing with the stable_shift simulation context from
// core-level control input pin
// 'cba9_gate_tessent_lpct_i/scan_en'
// (core 'cba9_gate_tessent_lpct', instrument type 'lpct')
// to the top level has failed.
// Multiple potential drivers found:
//   'tie_high' (31.0),
//   'CS' (5.0).
// Use 'set_attribute_value -name constraint_value_during_load_unload' /
// command to constrain ports and guide the tracer. (R14-1)

// Error: Tracing with the stable_capture simulation context from
// core-level control input pin
// 'cba9_gate_tessent_lpct_i/scan_en'
// (core 'cba9_gate_tessent_lpct', instrument type 'lpct')
// to the top level has failed.
// Multiple potential drivers found:
//   'tie_high' (31.0),
//   'CS' (5.0).
// Use the 'add_input_constraints' command to constrain ports
// and guide the tracer. (R14-1)
```

R15

Category: EDT Instruments

Contexts Supported: patterns -scan

Default Handling: Error

report_drc_rules: Supported

Validates consistency of static and dynamic signals.

This DRC validates that static and dynamic EDT IP signals have consistent requirements properly mapped to the top.

The R15 rules checks if any top-level ports have the same requirements between multiple instruments and already specified values (clock-off state, constrain value).

This DRC checks the following properties:

- Is clock port offstate is correct
- Is the capture constraint value correct
- Is the load_unload force value correct
- Is the shift force value correct

All channel sharing rules are validated by the existing K15 rule.

By default R15 handling is set to error and cannot be downgraded.

This DRC reports the following possible error messages:

```
// Error: Conflicting top-level clock 'edt_clock' clock-off values
// between core instances and user defined clock. (R15-1)
// The clock-off value defined at the top-level is '1'.
//
//      Core Pin     Instance     Core      Type   Top Level   Core Level
//      -----  -----  -----  -----  -----

```

R16

Category: EDT Instruments

Contexts Supported: patterns -scan

Default Handling: Error

report_drc_rules: Supported

Validates EDT IP core scan chain binding.

This DRC validates if the scan chain binding is correct for the newly added EDT IP cores. This DRC is executed after automatic scan chain binding will be executed.

The tool attempts to bind EDT instruments with the following user-defined scan chains:

- Direct access chains
- User added internal chains that are not bound to an EDT block

Direct access chains can be bound with an EDT instrument in bypass or single bypass mode.

This DRC reports the following possible error messages similar to the following:

If corresponding EDT instance scan pins are connected to different chains:

```
// Error: Core instance 'core_1/picccpu_maxlen16_1_edt_i'  
// (core 'picccpu_maxlen16_1_edt', instrument type 'edt') (R16-1)  
// EDT instance scan pins corresponding to chain index 1 are connected to two  
// different scan chains:  
// EDT scan pin 'core_1/picccpu_maxlen16_1_edt_i/edt_scan_out[0]'  
// connects to scan chain input 'core_1/input56' of 'chain56'  
// EDT scan pin 'core_1/picccpu_maxlen16_1_edt_i/edt_scan_in[0]'  
// connects to scan chain output 'core_1/output57' of 'chain57'
```

If one side of the chain is bound, and the pin specified for the other side does not exist in the design (so not a connectivity issue):

```
// Error: Core instance 'core_1/picccpu_maxlen16_1_edt_i'  
// (core 'picccpu_maxlen16_1_edt', instrument type 'edt') (R16-1)  
// One of the scan pins of the following scan chains does not exist in the  
// design:  
// chain56 (the scan output 'core_1/picccpu_maxlen16_1_edt_i/edt_scan_out1[1]'  
// does not exist in the design),  
// chain57 (the scan input 'core_1/foo' does not exist in the design).
```

If one side of the chain is bound, and the other side has a valid pin with no binding:

```
// Error: Core instance 'core_1/picccpu_maxlen16_1_edt_i'  
// (core 'picccpu_maxlen16_1_edt', instrument type 'edt') (R16-1)  
// One of the scan pins of the following scan chains is not connected to the EDT  
// instance:  
// chain56 (no connection found from scan chain outputABC' to the EDT  
// instance pin 'core_1/picccpu_maxlen16_1_edt_i/edt_scan_out[1]'),  
// chain57 (no connection found from EDT instance pin  
// 'core_1/picccpu_maxlen16_1_edt_i/edt_scan_in[3]' to scan chain input  
// 'core_1/foo').
```

If neither side is bound, and both scan pins do not exist in the design:

```
// Error: The scan pins of the following scan chains do not exist in the design.  
// (R16-1)  
// edt_chain0 (input = 'foo1', output = 'bar1'),  
// edt_chain1 (input = 'foo2', output = 'bar2').
```

If neither side is bound, and SCI exists in the design but SCO does not:

```
// Error: The scan output pins of the following scan chains do not exist in the  
// design and their scan input pins do not connect to any EDT instance. (R16-1)  
// edt_chain0 (input = 'input1', output = 'foo'),  
// edt_chain1 (input = 'input2', output = 'bar').
```

If neither side is bound, and SCO exists in the design but SCI does not:

```
// Error: The scan input pins of the following scan chains do not exist
// in the design and their scan output pins do not connect to any EDT
// instance. (R16-1)
//   edt_chain0 (input = 'foo', output = 'output1'),
//   edt_chain1 (input = 'bar', output = 'output2').
```

If neither side is bound, but both SCI and SCO exist in the design:

```
// Error: The scan pins of the following scan chains do not connect to any EDT
// instance. (R16-1)
//   edt_chain0 (input = 'input1', output = 'output1'),
//   edt_chain1 (input = 'input2', output = 'output2').
```

R17

Category: EDT Instruments

Contexts Supported: patterns -scan

Default Handling: Error

report_drc_rules: Supported

Validates if EDT IP unused channels are tied off.

Accessible input channel number selection requires that unused channels are feeding constant '0' values into the decompressor.

By default R17 handling is set to error and cannot be downgraded.

This DRC reports the following possible error messages:

```
// Error: Core instance 'core_1/picccpu_maxlen16_1_edt_i' (core
//        'picccpu_maxlen16_1_edt', instrument type 'edt') (R17-1)
//        has inaccessible input channels that are not tied off:
//        core_1/picccpu_maxlen16_1_edt_i/edt_channels_in[2],
//        core_1/picccpu_maxlen16_1_edt_i/edt_channels_in[3].
// Error: Core instance 'core_1/picccpu_maxlen16_1_edt_i' (core
//        'picccpu_maxlen16_1_edt', instrument type 'edt') (R17-2)
//        has an inaccessible input channel that is not tied off:
//        core_1/picccpu_maxlen16_1_edt_i/edt_channels_in[3].
// Error: There were 2 R17 violations (Inaccessible input channels
// not tied off).
```

R18

Category: Tessent OCC

Contexts Supported: patterns -scan

Default Handling: Error

report_drc_rules: Supported

Verifies after scan chain tracing that the Tessent OCC registers are part of the scan chains.

Applies only when using the Tessent OCC in a mode where it is controllable by scan.

This DRC reports the following possible error messages:

```
// Error: OCC configuration registers of core instance
// 'top_gates_tessent_occ_NX1_inst' (core 'top_gates_tessent_occ',
// instrument type 'occ') are not part of active scan chains. (R18-1)
// The following OCC configuration registers exist in the design but
// are not part of any active scan chain.
//   'top_gates_tessent_occ_NX1_inst/occ_control/ShiftReg/FF_reg_0_',
//   'top_gates_tessent_occ_NX1_inst/occ_control/ShiftReg/FF_reg_1_',
//   'top_gates_tessent_occ_NX1_inst/occ_control/ShiftReg/FF_reg_2_',
//   'top_gates_tessent_occ_NX1_inst/occ_control/ShiftReg/FF_reg_3_'.
// Please make sure all configuration registers of OCCs that are active
// in this mode are stitched into scan chains that are active in this
// mode and all EDT instances active in this mode were added using the
// 'add_core_instances' command.
// Error: There was 1 R18 violation (OCC configuration registers are not
// part of any active scan chains).

// Error: OCC configuration register of core instance
// 'top_gates_tessent_occ_NX1_inst' (core 'top_gates_tessent_occ',
// instrument type 'occ') does not exist in the design. (R18-1)
// Please make sure the hierarchy inside the OCC IP is preserved during
// synthesis, and that design object names are not changed.
//   'top_gates_tessent_occ_NX1_inst/occ_control/ShiftReg/KUKU[0]'.
// Error: There was 1 R18 violation (OCC configuration registers are not
// part of any active scan chains).
```

R19

Category: Tessent OCC

Contexts Supported: patterns -scan

Default Handling: Error

report_drc_rules: Supported

Verifies if Tessent OCC's internal nodes exist in the design.

This DRC reports the following possible error message:

```
// Error: Core '<OCC IP instance>' (core '<OCC IP core name>', instrument
type 'occ') (R19-1)
// The following OCC internal paths do not exist in the design.
// /top_gates_tessent_occ_NX1_inst/dummy_path1,
// /top_gates_tessent_occ_NX1_inst/dummy_path2.
```

R20

Category: EDT Instruments

Contexts Supported: patterns -scan

Default Handling: Error

report_drc_rules: Supported

Validates that if an iCall is retargeted from one level to the next, then this iCall is for an iProc and not an iTopProc.

Detects if an iTopProc was used at the core level. It is not triggered for core instances added with -current_design switch.

By default R20 handling is set to error and can be downgraded to a warning or a note. If the DRC is downgraded, those iCalls are not mapped.

This DRC reports the following possible error messages:

```
// Error: Core 'piccpu_maxlen16' (mode 'internal') calls iTopProc
//         'my_proc' in the test_end procedure.
//         iTopProc can only be defined for the top level and therefore
//         cannot be retargeted from a lower-level instance. (R20-1)
// Error: There was 1 R20 violation (iTopProc used at core level).
```

R22

Category: EDT Instruments

Contexts Supported: patterns -scan, patterns -scan_retargeting

Default Handling: Warning (severity can be changed)

report_drc_rules: Supported

Verifies instrument IJTAG requirements for instruments without a scan interface.

This DRC can be changed to error or note. R22 typically applies to scan instruments like the EDT controller where static control signals like edt_bypass are declared as DataIn ports.

This DRC reports the following possible error messages:

```
// Error: Core 'piccpu_maxlen16_1_edt' (instrument type 'edt') is an
// IJTAG instrument with no scan interface, but top-level ICL was not
// extracted or read.
// Use the 'extract_icl' command to extract top-level ICL or read the
// top-level ICL model. (R21-2)
// Error: There was 1 R22 violation (Top-level ICL not extracted while
// IJTAG instruments with no scan interfaces present in the design).

// Warning: Core 'piccpu_maxlen16_1_edt' (instrument type 'edt') is
// an IJTAG instrument with no scan interface, but top-level ICL was not
// extracted or read.
// The PDL will not be automatically appended to the top-level
// procedure. (R22-1)
// Warning: There was 1 R22 violation (Top-level ICL not extracted
// while IJTAG instruments with no scan interfaces present in the design).
```

R23

Category: EDT Instruments

Contexts Supported: patterns -scan, patterns -scan_retargeting

Default Handling: Error (severity can be changed to a Warning or Note)

report_drc_rules: Supported

Verifies scan instrument IJTAG requirements.

This DRC can be downgraded to a Warning or Note.

This DRC reports the following possible error messages:

```
// Error: Core 'piccpu_maxlen16_1_edt' (instrument type 'edt') is an
// IJTAG instrument with scan interface, but top-level ICL was not
// extracted or read.
// Use the 'extract_icl' command to extract top-level ICL or read the
// top-level ICL model. (R23-1)
// Error: There was 1 R23 violation (Top-level ICL not extracted
// while IJTAG instruments with scan interfaces present in the design).
```

R27

Category: OCC Instruments

Contexts Supported: patterns -scan, patterns -scan_retargeting

Default Handling: Error (severity can be changed)

report_drc_rules: Supported

Verifies that the active OCCs are not driven by the outputs of other active OCCs during capture.

Cascading of OCCs can lead to incorrect capture clock sequences and cause mismatches. Active OCCs in the parent mode driving active child OCCs will not cause a R27 violation. This DRC will be executed during ATPG and pattern retargeting step.

This DRC reports the following error message:

```
// Error: Capture clock 'corec_i1/corec_rtl2_tessent_occ_clka_inst/fast_clock'
//          (20442.1) of OCC instance 'corec_i1/corec_rtl2_tessent_occ_clka_inst'
//          (core 'corec_rtl2_tessent_occ') is driven by OCC instance
//          'coreb_i1/corea_i1/corea_rtl2_tessent_occ_clka_inst'
//          (core 'corea_rtl2_tessent_occ') output clock 'coreb_i1/corea_i1/
//          corea_rtl2_tessent_occ_clka_inst/clock_out' (19140.0).
//          An active OCC cannot be driven by another active OCC unless the driven
//          OCC is a child OCC and the driving OCC is operating in parent mode.
//          This may lead to incorrect OCC capture clock sequences and result in
//          mismatches. (R27-1)
```

R28

Category: OCC Instruments

Contexts Supported: patterns -scan, patterns -scan_retargeting, and patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

Verifies that, in fast_capture mode, the fast_clock ports of OCC instances are driven by a pulse-always, pulse-in-capture, or an asynchronous clock.

This DRC performs the following checks:

1. The OCC fast clock port must be driven by a port or a pseudo-port.

Example:

```
// Warning: Fast clock pin 'coreb_rtl2_tessent_occ_clka_inst/
fast_clock' (1990.1)
//          of OCC instance 'coreb_rtl2_tessent_occ_clka_inst'
(core 'coreb_rtl2_tessent_occ')
//          is not driven by a clock.
//          This may result in incorrect patterns. (R28-1)
```

2. The OCC fast clock port driver, which is a port or pseudo-port, must be defined as a clock.

```
// Warning: Fast clock pin 'coreb_rtl2_tessent_occ_clkc_inst/fast_clock' (1992.1)
//          of OCC instance 'coreb_rtl2_tessent_occ_clkc_inst' (core
'coreb_rtl2_tessent_occ')
//          is driven by port 'clkc' (3.0) which is not defined as a clock.
//          This may result in incorrect patterns. (R28-2)
```

3. The OCC fast clock driver must be a clock that is pulse-always, pulse-in-capture, or an asynchronous clock.

```
// Warning: Fast clock pin 'coreb_rtl2_tessent_occ_clkb_inst/
fast_clock' (1991.1)
//          of OCC instance 'coreb_rtl2_tessent_occ_clkb_inst' (core
'coreb_rtl2_tessent_occ')
//          is driven by clock 'clkb' (2.0) which is not pulse-
always,
pulse-in-capture, or asynchronous (defined with a period).
//          This may result in incorrect patterns. (R28-3)
```

Use the [set_drc_handling](#) command to change the handling of this DRC to error or note.

Scannability Rules (S Rules)

Scan substitution and stitching is done with respect to library cells and pre-existing scan segments. For library cells, a simple cell may just contain a single memory element (_dff primitive in the Tessent cell library) that exists in both the non-scan version and the scan equivalent. In this case, S-rule checking must be performed on that memory element. A more complex library cell may contain some memory elements that will not become part of the scan path after the non-scan model has been replaced with the scan model. S-rules are only run on those memory elements that will become part of the scan path. The scan model for a complex library cell may contain multiple scan input and scan output pins. In this case, the tool will identify the clocks that control these embedded scan segments, and target only those clocks during S-rule analysis. Finally, you can specify pre-stitched scan segments on arbitrary Verilog modules. In this case, S-rules are once again performed with respect to the clock and set/reset pins that you specified as part of the add_scan_segments command. The specific memory elements (dff primitives) that will become part of the scan path after scan chain stitching is complete will be referred to as scan path memory elements.

For each sequential element in the design, the tool performs two main checks. The first check, S1, ensures that when all defined clocks — including sets and resets — are at their off-states, the sequential elements remain stable and inactive. The second check, S2, ensures that for each defined clock, sequential elements can capture data when all the other defined clocks are off. These scannability checks determine if the tool can turn off all set and reset lines, and turn on and off all clock inputs of sequential cells from the design's primary input pins. Without this controllability, the tool will not allow a sequential element to pass scannability checks, which is a requirement to be considered for scan identification.

This checking is similar to the C1 (S1) and C7 (S2) rules checks, which the tool performs to determine the stability of defined scan chains. The C1 and C7 rules perform these same checks on sequential elements that are already converted to scan. For more information on C1 and C7, refer to “[Clock Rules \(C Rules\)](#)” on page 2240.

Once these scannability rules pass, the elements are considered “scannable” and the DRC process treats the non-scan elements as though they were scan elements for the remainder of the DRC rules.

The default handling for S1 and S2 rules is “error”. This identifies the flops that cannot be used for scan insertion due to clock controllability issues and aborts the system mode transition. This allows you to debug your design at this stage instead of discovering it later during ATPG. The default handling can be changed to “warning” with the set_drc_handling command, in which case the flops will remain non-scan and may lead to poor ATPG results.

The default handling for the S3 rule is “warning” which causes the tool to add the necessary pin constraints to allow activating the clock during scan shifting. The handling can be changed to “error”, but this does not abort the system mode transition. Instead, the flops will be inserted into scan chains, but no extra pin constraints will be added.

Tip

i In DFTVisualizer, you can press Ctrl + R to execute a report_gates command on selected gates. For more information, see “[How to Report Gate Data](#)” on page 2648 on page 2215.

S6	2990
S7	2991
S8	2992

S1

Category: Scannability

Contexts Supported: dft -scan, dft -test_points

Default Handling: Error

report_drc_rules: Supported

Scannability rule S1 checks all the clock inputs (including sets and resets) of each scannable non-scan memory element to ensure that these inputs can be turned off. This rule ensures that non-scan elements that may be converted to scan can be controlled to hold their current data. You can use “report_drc_rules s1” to get a listing of all the violations. This report will include the pin-path and gate-id of the flop with the violation (for scan segments it will report the segment name instead).

To debug an S1 DRC violation without DFTVisualizer, use the command “[analyze_drcViolation <violation_number>](#)”. This will run the DRC analysis for the specific violation and allow the simulation data to be displayed. In the following example, the failure is due to the clock pin “CP” being set to X. To pass the S1 DRC, the clock must be set to its off state of 0. The command sequence noted will work with or without DFTVisualizer.

```
analyze_drcViolation viol S1-2
// Gate report now set to display_sim_data.
// Creating schematic for 3 instances (0 were compacted).
report_drc_rules s1-2
// Warning: Unstable nonscan cell /AA/OUT_2_reg(32) when all clocks are
off. (S1-2)
report_gates 32
// /AA/OUT_2_reg (32) TIEX
// "I0" I (0) 10-
// "I1" I (0) 27-
// CP I (X) 22-/AA/I_1/out
// "I3" I (X) 13-
// "OUT" O (X) 15-
```

Scannability rule S1 is a modified version of the C1 clock rule, in that it performs the same type of checking on nonscan sequential elements that C1 performs on scan elements. For additional information on the C1 clock rule, refer to “[C1](#)” on page 2692.

You can specify how these potential scan cells are handled by setting S1 to one of the following handling options:

- **Error** — identifies cells with constant data inputs, and stops after identifying all the DRC violations.
- **Warning** — identifies cells, reports violations, and marks these cells as non-scan.

Note

 Clocks that are defined as pulse-always cannot be turned off during testing. Therefore, flops driven by pulse-always clocks fail the S1-rule checking.
Note that Tessent Scan does not use pulse-always clocks as test-clocks to repair the clock signals of the flops that fail with any S-rules.”

Here are some examples of S1 DRC violation error messages:

- For flop based violation:

```
// Error: Unstable nonscan cell because clock input '/dff1_inst/
CLK' (552.3) is set to X when all clocks are off. (S1-1)
```

- For subchain based violation:

```
// Error: Unstable nonscan cell because clock input (subchain:
'lff_subchain_1/lff2_u2/SO2', pin: 'CLK') is driven by a pulse-
always clock. (S1-122)
```

S2

Category: Scannability

Contexts Supported: dft -scan, dft -test_points

Default Handling: Error

report_drc_rules: Supported

Scannability rule S2 checks all clock inputs (not including sets and resets) of each scan path memory element to see whether they can capture data. This rules ensures that a non-scan cell can capture data using one of the defined clocks. In order to be converted to scan, a non-scan cell must be able to capture data when a single clock is on. You can use “report_drc_rules s2” to get a listing of all the violations. This report will include the pin-path and gate-id of the flop with the violation (for scan segments it will report the segment name instead)

Scannability rule S2 is a modified version of the C7 clock rule, in that it performs the same type of checking on non-scan sequential elements that C7 performs on scan elements. For additional information on the C7 clock rule, refer to “[C7](#)” on page 2716.

You can specify how these potential scan cells are handled by setting S2 to one of the following handling options:

- **Error** — identifies cells with constant data inputs, and stops after identifying all the DRC violations.
- **Warning** — identifies cells, reports violations, and marks these cells as non-scan.

Here is an example of an S2 DRC violation error message:

```
// Error: Clock capture ability check failed at clock input '/dff1_inst/CLK' (553.3) (S2-1)
```

S3

Category: Scannability

Contexts Supported: dft -scan, dft -test_points

Default Handling: Warning

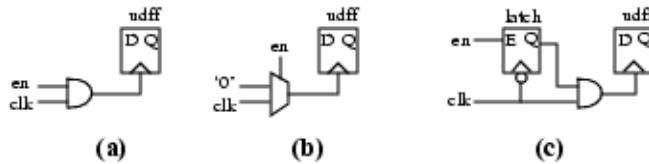

report_drc_rules: Supported

All non-clock primary input pins in the clock cone of scan path memory elements must be constrained. If these pins are unconstrained and made scannable, trace violations may occur.

Non-clock primary input pins in the clock cone of non-scan memory elements should be constrained in the ATPG dofile or load_unload procedure to correctly sensitize the clock path.

[Figure 7-51](#) illustrates S3 violations where the pin ‘clk’ is defined as the shift clock with an off state value of ‘0’. The non-clock pin ‘en’ causes the violation if it is left un-constrained.

Figure 7-51. Example S3 Rule Violation

The total number of S3 violations are reported in the session transcript during the DRC rule checking. Individual S3 violations can be reported with the report_drc_rules and report_scan_elements commands.

The default DRC handling of the S3 rule is “Warning,” which means that memory elements with S3 violations are kept in the pool of scannable candidates. The handling can be changed to “Error” using the set_drc_handling command, in which case the memory elements with S3 violations are excluded from the pool of scannable candidates automatically.

If you want to include some of those memory elements back in scan insertion, you can issue delete_nonscan_instances commands on them. Similarly, if the S3 rule handling is “Warning” (the default), you can obtain the list of the violations using the report_scan_elements or report_drc_rules commands and issue add_nonscan_instances commands on a subset of the list explicitly.

Although the handling of the S3 DRC violation can be changed to “Error,” the effect of the violation is different from that of the S1 and S2 rules. The tool does not insert_test_logic on the clock pins to correct an S3 violation even if the user turns on the test logic insertion using the set_test_logic command.

Here is an example of an S3 DRC violation error message:

```
// Warning: Un-initialized non-clock input detected for clock port aa/udff2/CLK
// Primary input pin "d" must be set to 0 (S3-1)
```

S4

Category: Scannability

Contexts Supported: dft -scan, dft -test_points

Default Handling: Note

report_drc_rules: Supported

Scannability rule S4 identifies and determines the handling of non-scan memory elements that satisfy certain conditions.

These conditions are:

- Meet requirements for use as scan elements.
- Maintain constant output values during the shift and capture cycles.

- Are in the clock and set/reset paths of other flip-flops/latches, RAMs, and ROMs.
- Contribute to the data lines of the memory elements in the clock and set/reset paths of other flip-flops/latches, RAMs, and ROMs.

Note

 Flip-flop/latch elements that maintain constant output values during shift and capture cycles can potentially disturb the clock and set/reset signals of other flip-flops/latches, RAMs, and ROMs if their constant output values are not maintained.

If non-scan cells that maintain constant output values and are associated with clock and set/reset signals are converted to scan cells, they can prevent the clock and set/reset signal paths from being sensitized properly. When this occurs, more test logic may be required to sensitize the clock path.

You can specify how these non-scan cells are handled by setting S4 to one of the following handling options:

- **Note** — reports the non-scan cells to the log file and leaves them as non-scan cells. Default handling.
- **Warning** — reports the non-scan cells to the log file and converts them to scan cells. The resulting scan cells will have an unknown value (TIEX) for the output during the remainder of the DRC.
- **Ignore** — allows non-scan cells to be converted to scan cells; no reporting is done.

You can report on the S4 results with the `report_drc_rules` command.

Here is an example of an S4 DRC violation error message:

```
// Note: Non-scan cell /dff1(14) that maintains a constant value during capture and shift phases will remain non-scan. (S4-1)
```

S5

Category: Scannability

Contexts Supported: dft -scan, dft -test_points

Default Handling: Error

report_drc_rules: Supported

Scannability rule S5 identifies clock sources that drive set/reset ports as well as clock ports.

When a clock source (a top-level pin or an internally defined clock net) drives the set/reset port of one or more flip-flops while also driving the clock port of one or more flip-flops, the set/reset port driven by this signal is reported as an S5 violation.

You can optionally fix S5 violations by adding test logic at the set/reset ports driven by the clock. The tool will then treat the set/reset ports as uncontrollable and insert the same test logic that is used to fix the set/reset ports of flip-flops with an S1 violation.

You can specify how these potential scan cells are handled by setting S5 to one of the following handling options:

- **Error** — identifies cells with constant data inputs, and stops after identifying all the DRC violations.
- **Warning** — identifies cells, reports violations, and marks these cells as non-scan.

Here is an example of an S5 DRC violation error message:

```
// Error: Set/reset port (subchain: '/my_inst/TEST__SOUT[4]', pin: 'R0') is driven by clock
// '/test_TEST__SHIFT_CLK1' (36)

// This signal also drives clock port (subchain: '/my_inst/TEST__SOUT[0]', pin:
// 'TEST__SHIFT_CLK[1]') which must pulse during shift (S5-1)
```

S6

Category: Scannability

Contexts Supported: dft -scan, dft -test_points

Default Handling: Error (in dft -scan context); Note (in dft -test_points context)

report_drc_rules: Supported

Scannability rule S6 identifies both subchains and pre-existing scan cells (that are not part of declared scan chains or subchains) that have driven scan-in ports and reports them as an S6 violation.

Subchain instances with driven scan-in ports are deleted. That is, they are no longer considered subchains.

By default, an S6 violation is reported as an Error, the system mode remains as setup, and the following error message displays:

```
// Error: There were <int> scannability rule S6 fails (driven scan-in pin
of a sub chain or of a scan cell in unspecified scan chain).
```

You can optionally choose to change the handling of this rule to Warning. In this case, the tool allows the system mode to change to analysis, but deletes subchain instances that violate the S6 rule and ignores scan cells that violate the S6 rule when stitching into scan chains during the scan chain generation process. The following warning message displays:

```
// Warning: There were <int> scannability rule S6 fails (driven scan-in
pin of a sub chain or of a scan cell in unspecified scan chain).
```

You can optionally choose to change the handling of this rule to Note. In this case, the tool allows the system mode to change to analysis, but deletes subchain instances that violate the S6 rule; however, scan cells that violate the S6 rule will still be treated as scannable cells. The following warning message displays:

```
// Note: There were <int> scannability rule S6 fails (driven scan-in pin of a sub chain or of a scan cell in unspecified scan chain).
```

You can use the [report_drc_rules](#) command to list the details of an S6 rule violation.

When scan cells produce S6 violations, you can optionally fix them by explicitly declaring the scan chains or subchains that the identified scan cells belong to using the [add_scan_chains](#) command. The tool will use this information to validate the traceability of declared scan chains or subchains when a test procedure file containing `load_unload` and `shift` procedures is present.

You can optionally declare the scan cells violating the S6 rule to be non-scan instances using the [add_nonscan_instances](#) command. In this case, the tool ignores these cells when stitching scan chains during the scan chains generation process.

S7

Category: Scannability

Contexts Supported: dft -scan, dft -test_points

Default Handling: Note

report_drc_rules: Supported

Scannability rule S7 identifies potential scan cells with a constant data input.

During scan insertion, memory elements with input signals tied to 0 or 1 are treated as scannable cells, which improves stuck-at fault coverage. However, these paths may not be optimized for timing, and are not used in functional mode. By default, all cells with constant input values are identified but are not excluded from scan insertion unless the constant value is in the clock control logic (that is, the output of the flop is in the fan-in cone of a clock or set/reset port of another flop).

Only the data inputs are checked for a constant 1 or 0 value. Cells that are “constant” because the set/reset signal is forced active are not considered, but those gates would already be marked as non-scan because of the implied S1 rule violation.

Note that tied values do not propagate through sequential elements unless a `test_setup` procedure is used to pulse the relevant clocks.

You can specify how these potential scan cells are handled by setting S7 to one of the following handling options:

- **Error** — identifies cells with constant data inputs, and stops after identifying all DRC violations.
- **Warning** — identifies cells, reports violations, and marks these cells as non-scan.
- **Note** — identifies cells, reports violations, but allows these cells to become scan cells. This is the default DRC handling of rule S7. Maintains backward compatibility.
- **Ignore** — does not check for constant data input.

For each DRC violation, the instance name of the scan cell, the affected data-input pin, and the constant value that was identified will be reported. You may use the analyze_drcViolation command to graphically display the failing gate along with the sensitization values that led to the violation. This can be used to trace backward from the data input pin of the flop and identify the source of the constant value that triggered this violation.

S8

Category: Scannability

Contexts Supported: dft -scan

Default Handling: Error

report_drc_rules: Supported

Scannability rule S8 identifies the OCC circuits that control the clocks for all of the scan elements in any scan mode, and then it verifies that the OCC control scan segments that are needed to operate the clocks for the scan elements within in each scan mode are also part of the population for that mode.

When an OCC segment is omitted from a scan mode population that also includes some of scan elements clocked by its OCC, it is reported as an S8 violation. By default, an S8 violation is reported as an Error, and the following error message displays:

```
// Error: There was 1 S8 violation (OCC scan segment not included in a
scan mode's population that contains scan elements clocked by its OCC).
```

You can optionally choose to change the handling of this rule to Warning using the set_drc_handling command. In this case, the following warning message displays:

```
// command: set_drc_handling s8 warn
// command: analyze_scan_chains
.....
.....
.....
// Warning: There was 1 S8 violation (OCC scan segment not included in a
scan mode's population that contains scan elements clocked by its OCC)
....
```

If the OCC segment is not part of the population because it marked as is_non_scannable, then this is reported in the error message:

```
// Error: OCC scan segment '/corea_rtl_tessent_sib_sti_inst/ltest_so' is
not included in the population of the unwrapped scan mode 'unwrapped'
which contains scan elements clocked by its OCC.
// Note that the OCC scan segment '/corea_rtl_tessent_sib_sti_inst/
ltest_so' is non scannable for this reason: user_specified. (S8-1)
```

Scan Chain Trace Rules (T Rules)

Using the information in the test procedure files, the rules checker traces the scan chains to identify the scan cells and all memory elements associated with the scan cells. It then classifies the scannable memory elements as either MASTER, SLAVE, SHADOW, COPY, or EXTRA. Violations of scan chain trace rules are error or warning conditions, and you cannot change the handling of these rules—with the exception of rule T18, which you can set to ignore.

The following subsections describe each of the trace rules.

Tip In DFTVisualizer, you can press Ctrl + R to execute a report_gates command on selected gates.

T1

Category: Trace

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported

All defined scan chains must contain at least one scan cell. Correct this error condition by deleting the indicated scan chains.

The error message is:

```
No scan cells identified in scan chain C. (T1-1)
```

C is the scan chain name.

T2

Category: Trace

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Supported

A scannable memory element can reside in more than one scan chain unless you have issued the “set_drc_handling -ALLOW_COMMON_SCAN_CELLS_IN_MULTIPLE_CHAIN OFF” command.

However, there are some restrictions on scan cell sharing, which result in a T2 violation when not observed:

- Scan cell sharing is not allowed for compressed chains driven by a decompressor.
- The shared scan cells must be at the logical scan cell boundary. A library model with multiple scan cells cannot be partially shared. In other words, you cannot have the merged point within the state elements of a logical scan cell.
- The shared scan cells must not end at a master segment of a master/slave combination.

You can display the complete paths of the scan chains by using the set_trace_report command by turning trace reporting on and then repeating the rules checking. If you use all scan chains, you may need to make netlist modifications to correct this error condition.

The T2 DRC will flag a violation when the split point drives scan cells with different clock edges. The split point and the driven point need to be at the same clock edge, for example leading edge to leading edge, trailing edge to leading edge, or trailing edge to trailing; never leading edge to trailing edge.

The T2 rule has three possible error messages, in which N is an instance name, and G is its gate ID number:

- You have issued the “set_drc_handling -ALLOW_COMMON_SCAN_CELLS_IN_MULTIPLE_CHAIN OFF” command, and the scan cell exists in more than one scan chain:

N (G) already used in chain trace. (T2-1)

- Two scan chains share a merge point that is within a single library model:

Chain N and N split at N (G) which is not a logical cell boundary.
(T2-1)

- The scan cell exists in more than one scan chain, and at least one of the chains is compressed:

Scan cell N (G) is shared by compressed chains N and N. (T2-1)

T3

Category: Trace

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The **shift** procedure must create a sensitizable path from the scan chain output back to the scan chain input. An improperly sensitized gate in the scan path will cause an error condition, which the tool reports as a T3 DRC violation.

The occurrence message is:

Scan chain S blocked at gate N (G) after tracing C cells. (T3-1)

S is the scan chain name, N is the instance name, G is its gate ID number, and C is the number of scan cells traced in the scan chain.

The summary message is:

T3 : #fails=N handling=error (scan path blocked)

N is the number of T3 rule violations.

How to Debug T3 Violations in DFTVisualizer

You can also debug T3 violations in the DFT visualizer. When the tool encounters the error, it will report this message:

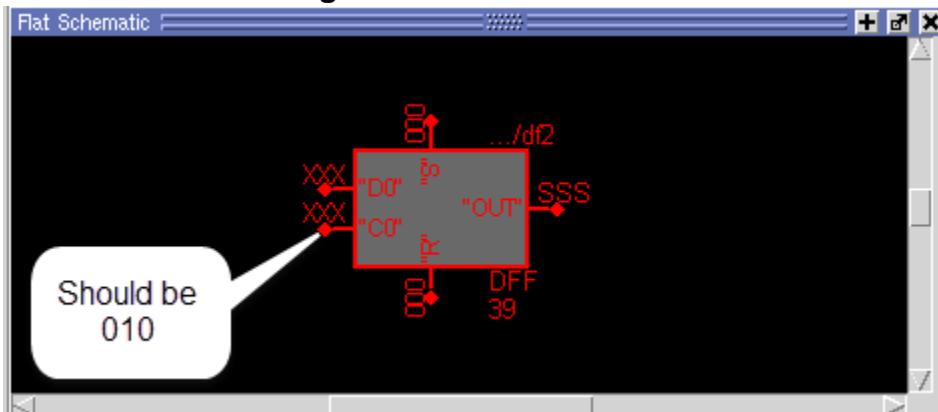

```
// Error: Scan chain chain1 blocked at gate /reg2/df2 (39) after tracing  
1 cells. (T3-1)  
// Error: Rules checking unsuccessful, cannot exit SETUP mode.
```

You can now analyze the drc error in DFTVisualizer using this command:

analyze_drcViolation T3-1

DFTVisualizer starts and will display /reg2/df2 in the Flat Schematic window as shown in [Figure 7-52](#).

Figure 7-52. T3 Violation

The clock “C0” should be 010, not XXX. Trace backwards by clicking on the pin for “C0”.

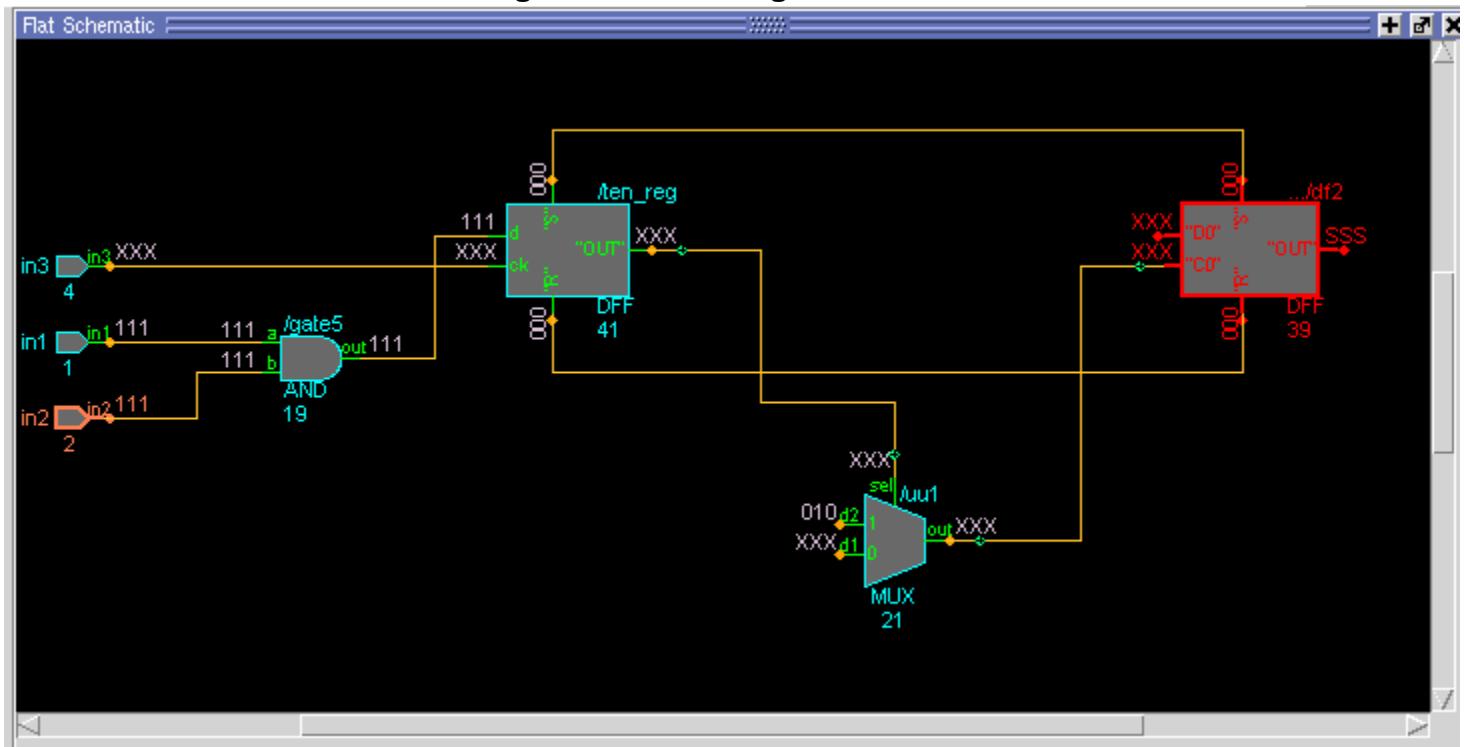

Note

When a T3 violation occurs, and you use the “analyze_drc_violation” command, the gate report is set to trace and the report will show an SSS on some paths. The S distinguishes scan path “don’t cares” from non-scan path “don’t cares”, which are shown as X.

The same happens when you used the “set_gate_report drc shift” command.

The results of tracing backwards from “C0” is shown in [Figure 7-53](#).

Figure 7-53. Tracing T3 Violation

The “C0” pin is driven by the output of MUX whose “sel” pin is XXX. That pin is driven by the output of DFF (a flop) whose clock pin, “ck” is driven by a primary input “in3” which is XXX.

The solution is to provide a correct test_setup procedure that initializes the device to the correct mode. In this example, add the the primary input “in3” as a clock and constrain “in1” and “in2”:

```
add_clock 0 in3
add_input_constraint in1 -c1
add_input_constraint in2 -c1
```

Modify the test procedure to pulse “in3”:

```
timeplate gen_tp1 =
    offstate "in3" 0 ;
    force_pi 0 ;
    measure_po 100 ;
    pulse in3 200 100 ;
    pulse clock 200 100 ;
    period 400 ;
end;
...
procedure test_setup =
    timeplate gen_tp1 ;
    cycle =
        force oe 1 ;
        force in1 1 ;
        force in2 1 ;
        force in3 0 ;
        pulse in3;
    end ;
end;
```

How to Debug T3 Violations Without DFTVisualizer

Correct this error condition by accessing the simulated values of all time periods of the **shift** procedure. To do this, set the gate reporting to trace, and use the **report_gates** command for the gate ID number displayed in the error message. This can help you to identify where the blockage occurs; tracing back from the inputs helps you identify how to correct the problem.

The error message is:

```
Error: Scan chain chain1 blocked at gate /reg2/df2 (39) after tracing 1
cells. (T3-1)
```

The message tells you that the scan chain, “chain1”, is blocked at the gate /reg2/df2. The tool stays in SETUP mode. To proceed to debug, set up the tool to be in trace mode. If you have not already done so, issue the following commands:

```
set_trace_report on
set_gate_level primitive
set_gate_report trace
```

Re-run the DRC rule checks by going back into ANALYSIS mode and then report the gate that is identified as having a T3 error.

```
set_system_mode analysis
report_gate /reg2/df2

//  /reg2/df2 (39)  DFF
//      "S"      I  (000)  10-
//      "R"      I  (000)  9-
//      "C0"     I  (XXX)  26-
//      "D0"     I  (XXX)  23-
//      "OUT"    O  (SSS)  13-  14-
```

When you run report_gate with trace on, you expect the scan clock to show “010”, the constrained pins to be at their constrained values, scan enable to be active, and all sets and resets to be inactive. Scan out and scan in (on scan elements) should all be “X”. On all the combinational elements, in the scan chain, you should see “X” on the output and “X” on one of the inputs. When you have “X” on two inputs, the chain is blocked.

In this example, the blocked gate is a flop. Pins “S” and “R” are both inactive, which is okay, but the clock “C0” and data “D0”pins have a problem. “C0” is not shifting, and since this is a flop, it should show (010). Do a backwards trace to find out what drives the clock. In this example, we will set the gate level to be design.

```
set_gate_level design
report_gate /reg2/df2

//  /reg2  dfsc
//    ck    I  (XXX)  /uu1/out
//    d0    I  (XXX)  /gate2/out
//    d1    I  (XXX)  /reg3/qbar
//    sc    I  (111)  /scan_en
//    q     O  (XXX)  /gate3/a
//    qbar  O  (SSS)  /reg1/d1
```

The clock, “ck”, is driven by /uu1/out, so report that gate.

```
report_gates /uu1

//  /uu1  mux21
//    d1    I  (XXX)  /reg1/q
//    d2    I  (010)  /clock
//    sel   I  (XXX)  /ten_reg/q
//    out   O  (XXX)  /reg2/ck  /reg3/ck
```

Gate /uu1 is a mux with an unknown driver, One of the pins, “d2”, looks like our clock, so the “sel” signal should have been “111”, but it is “XXX”. Trace /ten_reg.

```
report_gates /ten_reg

//  /ten_reg dff
//    ck    I  (XXX)  /in3
//    d     I  (111)  /gate5/out
//    q     O  (XXX)  /uu1sel
//    qbar  O  (XXX)
```

The gate /ten_reg is a dflop that controls the mux. In this design, this control signals is actually an internally generated “test_enable” signal. The flop needs to be initialized to hold a “111” on the output. Modify test_setup sequence as needed to put the device into a state so there is a sensitizable path from the scan chain output back to the scan chain input.

T4

Category: Trace

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

A memory element in the scan path must have an active clock during some time period of the **shift** procedure. Correct this error condition by accessing the simulated values of all time periods of the **shift** procedure. You do this by setting the gate reporting to trace and using the report_gates command for the gate ID number displayed in the error message. This can help you identify where the problem occurred; tracing back from the inputs helps you identify how to correct the problem.

The error message is:

```
Clock inputs of N (G) never set active during shift procedure. (T4-1)
```

N is the instance name and G is its gate ID number.

The summary message is:

```
T4: #fails=F handling=error (scan cell without active clock event during shift)
```

F is the number of T4 violations.

How to Debug T4 Violations in DFTVisualizer

You can debug T4 violations in the DFT visualizer. When the tool encounters the error, it will report a message:

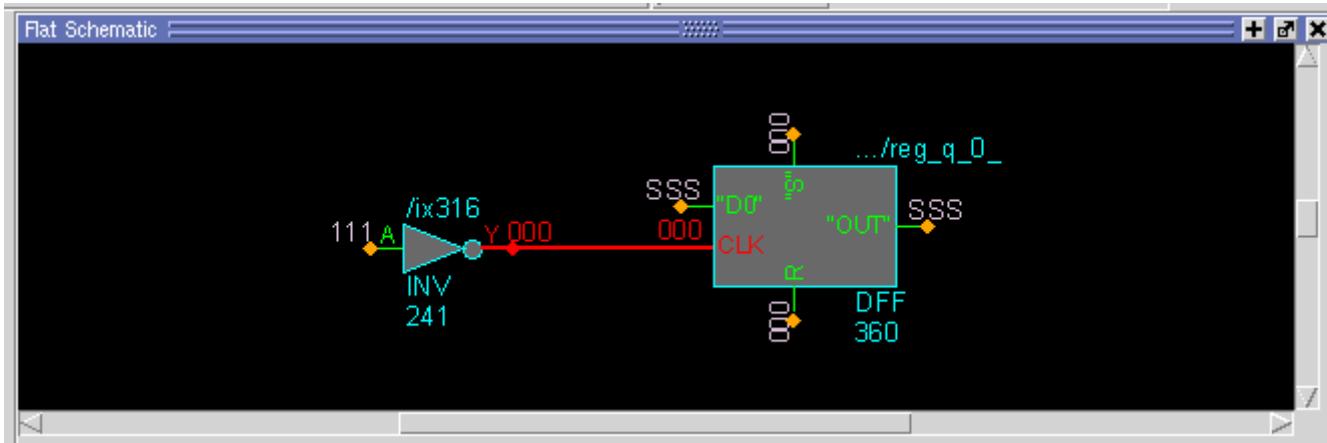

```
// Error: Clock inputs of /data0/reg_q_0_ (360) never set active during shift procedure. (T4-1)
```

Issue these commands:

```
set_gate_report trace
set_trace_report on
set_gate_level primitive
analyze_drcViolation T4-1
```

Since T4 and T3 DRCs occur in pairs, you can analyze T3-1. DFTVisualizer starts and displays the instance with the violation. [Figure 7-54](#) shows the signal driving CLK of /reg_q_0_ violates the T4 DRC. That clock must be active at some point.

Figure 7-54. T4 Violation

Trace back from the A input of the INV /ix316, and continue until you find the problem origin.

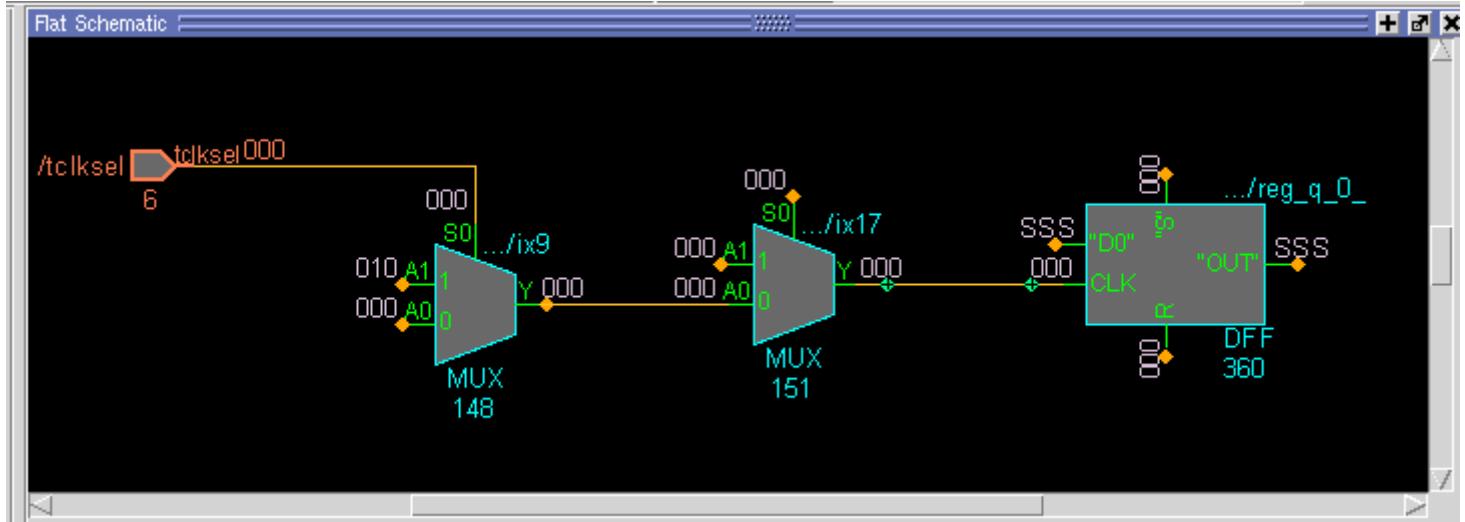

Note

When a T4 violation occurs, and you use the “analyze_drcViolation” command, the gate report is set to trace and the report will show an SSS on some paths. The S distinguishes scan path “don’t cares” from non-scan path “don’t cares”, which are shown as X.

The same happens when you have used the “set_gate_report drc shift” command.

Figure 7-55 shows the traceback. The control signal for a MUX, /ix17, is set to select input A0. It is driven by a MUX, /ix9, whose control signal, tclkSEL, is selecting A0 as well. However, the input A1 has the pulse that is required to fix the problem CLK. So we need to have tclkSEL go high.

Figure 7-55. T4 Violation Traced Back

You need to find when to pulse the offending clock high by forcing tclksel high at some point. You can determine when by setting the gate report to see the states of all the signals. This can be done with the command:

```
set_gate_report drc state
```

Figure 7-56 shows the offending /reg_q_0_ instance and the states of the signals. CLK is fine until the last shift, when it is 0.

Figure 7-56. T4 Violation Showing States

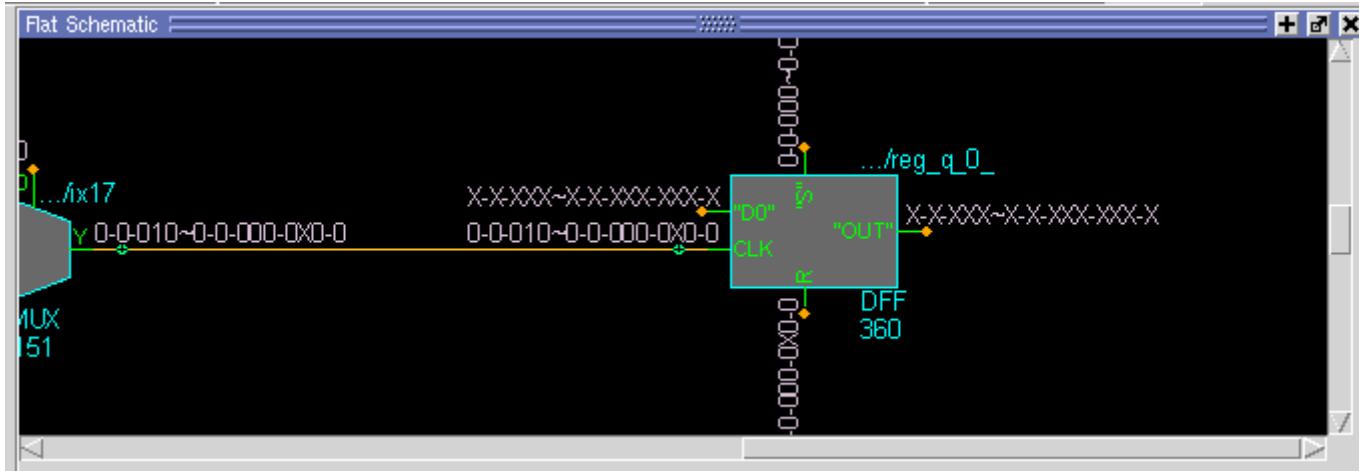

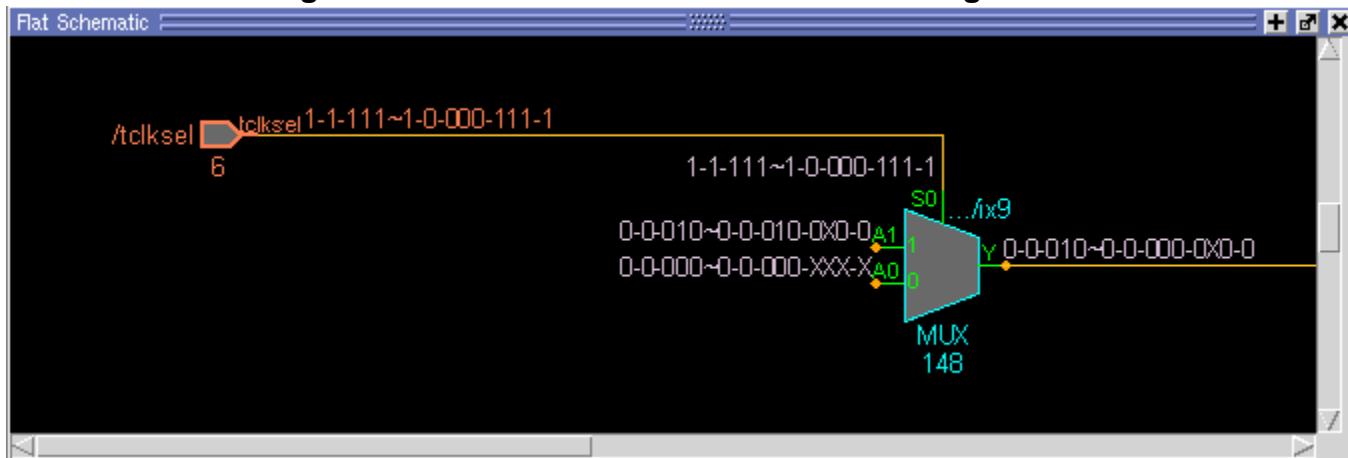

Figure 7-57 shows the result of tracing back to tclkSEL. The tclkSEL signal is 000 in the last shift and needs to be forced to 1 in the load_unload procedure.

Figure 7-57. T4 Violation Traced Back Showing States

The load_unload procedure in the test procedure file should look like this:

```
rocedure load_unload =
    scan_group grp1 ;
    timeplate gen_tp2 ;
    cycle =
        force tclkSEL 1 ;
        force clear 0 ;
        force scan_en 1 ;
        force tclk 0 ;
        force clka 0 ;
        force clkB 0 ;
        force clkr 0 ;
        force clock 0 ;
    end ;
    apply shift 12;
    cycle =
        force tclkSEL 1 ;
    end ;
    apply shift 1;
end;
```

How to Debug T4 Violations Without DFTVisualizer

You correct T4 violations by making certain that there is an active clock during some time period of the shift procedure. Correct this error condition by accessing the simulated values of all the time periods of the shift procedure.

For simple cases set the gate reporting style to trace:

set_gate_report trace

Use the "report_gate" command to help you know where to trace back on the blocking path and then sensitize the path correctly.

For more complex cases set the gate report style to state:

set_gate_report drc state

Go back into analysis mode:

set_system_mode analysis

Use the “report_gate” command to help you know where to trace back on the blocking path.

Make the necessary changes to sensitize the path correctly.

There could be several causes for T4 violations, these are the most common issues

- The shift clock is defined incorrectly in the shift procedure
- A missing or incorrect pin constraint
- The TAP controller is in the wrong state

T5

Category: Trace

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

During the **shift** procedure, you must never place an X value on a clock input or an active (X or 1) value on a set or reset input of a memory element in the scan path. The T5 DRC reports such issues.

Correct this error condition by accessing the simulated values of all time periods of the **shift** procedure. You do this by setting the gate reporting to trace and using the report_gates command for the gate ID number displayed in the error message. This can help you identify where the problem occurred; tracing back from the indicated input helps you identify how to correct the problem.

The error message is:

```
T input of N (G) set to V. (T5-1)
```

T is the type of input (clock, set, or reset), N is the instance name, G is its gate ID number, and V is the invalid state.

The summary message is:

```
T5: #fails=F handling=error (scan cell with unexpected clock event)
```

F is the number of fails for this DRC violation.

How to Debug T5 Violations in DFTVisualizer

You can debug T5 violations in the DFT visualizer. When the tool encounters the error, it will report a message:

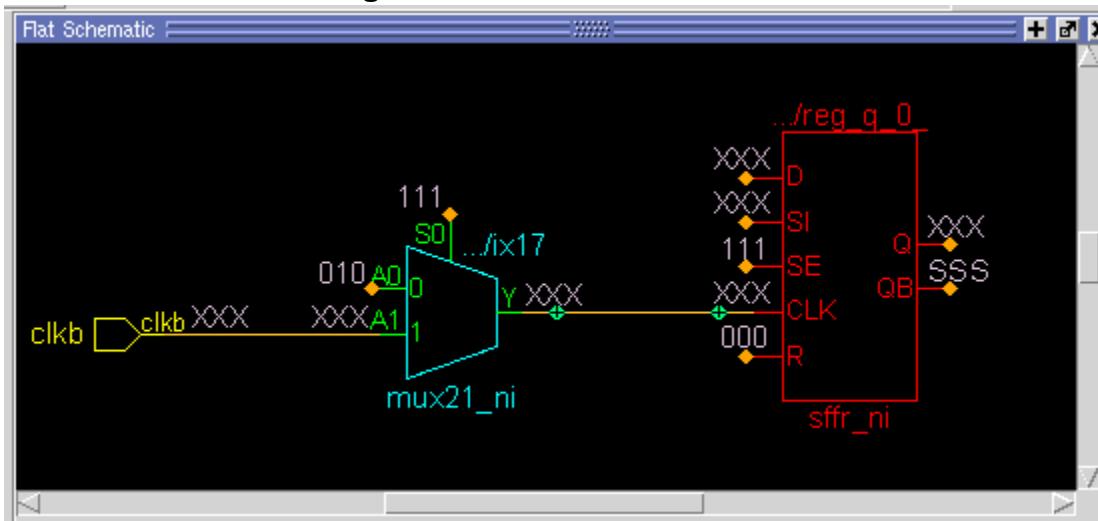

```
// Error: clock input of /data0/reg_q_0_ (360) set to X. (T5-1)
// Error: Scan chain chain1 blocked at gate /data0/reg_q_0_ (360) after
tracing 0 cells. (T3-1)
```

T5 and T3 DRC violations occur in pairs. Resolving one corrects the other. This debugging example begins with this command:

analyze_drcViolation T5-1

The DFTVisualizer opens displaying the instance with the T5 (and T3) violation as shown in [Figure 7-58](#)

Figure 7-58. T5 DRC Violation

The clock input, CLK, of the /datao/reg_q_0_ is set to XXX. That is the cause of both the T5 and T3 violations. The S0 pin of the MUX appears to be constrained to 1, which selects the A1 input of the MUX. The desired input is A0, which has a pulse 010.

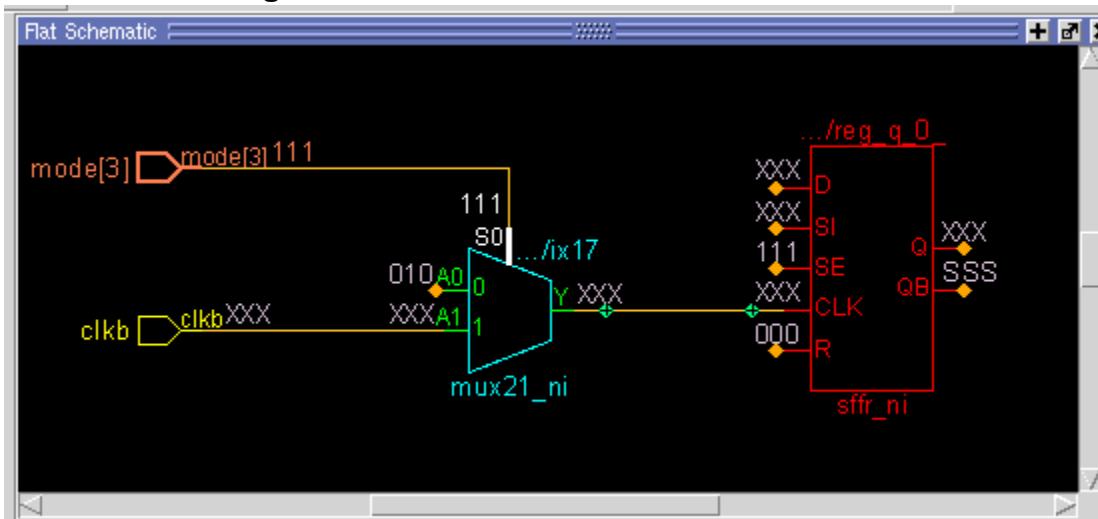

Note

When a T5 violation occurs, and you use the “analyze_drcViolation” command, the gate report is set to trace and the report will show an SSS on some paths. The S distinguishes scan path “don’t cares” from non-scan path “don’t cares”, which are shown as X.

The same happens when you have used the “set_gate_report drc shift” command.

Figure 7-59, shows S0 is driven by a primary input, mode[3].

Figure 7-59. T5 DRC Violation Traced Back

Use the command “report_input_constraints” to verify mode[3] is constrained. The solution for this would be to constrain the input S0 to 0.

This can be done temporarily in the visualizer with these commands:

```
delete_input_constraint mode[3]
add_input_constraint mode[3] -C0
set_system_mode analysis
```

You could also make certain the primary input is correctly constrained in a dofile.

How to Debug T5 DRC Violations Without DFTVisualizer

You correct T5 violations by making certain that during the shift procedure, you must never place an X value on a clock input or an active (X or 1) value on a set or reset input of a memory element in the scan path. Correct this error condition by accessing the simulated values of all the time periods of the shift procedure.

Set the gate reporting style to trace:

```
set_gate_report trace
```

Use the "report_gate" command to trace back on the blocking path to find the path that corrected.

T6

Category: Trace

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

During any time period of the **shift** procedure, a memory element in the scan path must never have more than one clock input turned on. Correct this error condition by accessing the simulated values of all time periods of the **shift** procedure. You do this by setting the gate reporting to trace and using the report_gates command for the gate ID number displayed in the error message. This can help you identify where the problem occurred; tracing back from the indicated input helps you identify how to correct the problem.

The error message is:

```
Multiple clock inputs of N (G) set active. (T6-1)
```

N is the instance name and G is the gate ID number.

T8

Category: Trace

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The **measure_sco** statement in the **shift** procedure must follow the successful observation of the scan cells.

To guarantee the observation is successful, the time of the **measure_sco** statement must meet the following conditions:

- It must not occur after exercising the first clock on the memory element closest to the scan chain output.
- It cannot be at time 0 if you capture the data into the last memory element at the end of the **shift** procedure.
- The states on all inputs at the **measure_sco** time must be the same as at the end of the **shift** procedure.

To correct the error condition, you must modify the **shift** procedure to meet the above conditions for the **measure_sco** statement.

The error message is:

```
Invalid measure_sco time. (T8-1)
```

T9

Category: Trace

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The traced scan chain input pin must be the same as the scan chain input pin specified with the add_scan_chains command. You can correct this error condition by redefining the scan chain input to be the traced pin.

The error message is:

```
Chain input P1 doesn't match entered value P2. (T9-1)
```

P1 is the name of the traced scan chain input pin, and P2 is the name of the entered scan chain input pin.

T10

Category: Trace

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The time of the **force_sci** statement in the **shift** procedure must occur before a clock input of the memory element (closest to the scan chain input) turns on. Correct this error condition by changing the time of the **force_sci** statement to a value less than or equal to the indicated time.

The error message is:

```
Force_sci must occur on or before time T. (T10-1)
```

T is the maximum time.

T11

Category: Trace

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

A clock input of the memory element (closest to the scan chain input) must not turn on during the **shift** procedure prior to the time of the **force_sci** statement. Correct this error condition by changing the times of the **force_sci** statement or **force** statements.

The error message is:

```
Incorrect propagation of force_sci value to scan cell. (T11-1)
```

T12

Category: Trace

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

If a scan cell contains a SLAVE element, the MASTER element is not directly observable.

The error message is:

```
MASTER not observable, a master_observe procedure is required by scan group G. (T12-1)
```

G is the scan group.

When the handling is set to other than error, the tool automatically makes the necessary MASTER unobservable to prevent a potential simulation mismatch. This applies only to the MASTER of the scan cell containing a SLAVE. The scan cell without a SLAVE retains its original observability. Due to the loss of observability on some MASTERS, test coverage may be reduced. To correct this violation, you can define a master_observe procedure to propagate the MASTER value to the SLAVE.

T13

Category: Trace

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

If you define and try to use a **master_observe** procedure, there must be at least one scan cell that contains a SLAVE. If there is no such cell, Correct this error condition by deleting the **master_observe** procedure.

The error message is:

```
Master_observe procedure defined but not used. (T13-1)
```

T14

Category: Trace

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

If you define and try to use a **shadow_control** procedure, there must be at least one identified SHADOW memory element. Correct this error condition by either changing or deleting the **shadow_control** procedure.

The error message is:

```
No SHADOWs identified using shadow_control procedure. (T14-1)
```

T15

Category: Trace

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported

If you define and try to use a **shadow_observe** procedure, the procedure must observe at least one SHADOW. You can correct this error condition by changing or deleting the **shadow_observe** procedure.

The error message is:

```
No observable SHADOWs identified using shadow_observe procedure. (T15-1)
```

T16

Category: Trace

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

When clocks and write control lines are off and pin constraints are set, the gate that connects to the input of a reconvergent pulse generator sink gate (PGS) in the long path must be at the non-controlling value of the PGS gate.

To correct this error condition, access the simulated values by setting the gate reporting to error_pattern and using the report_gates command. You can also avoid this error by setting the pulse generators to off, but that results in no pulse generator support.

The error message is:

```
Input of pulse generator N (G) not at correct value when clocks are off.  
(T16-1)
```

N is the pulse generator instance name, and G is its gate ID number.

T17

Category: Trace

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

Reconvergent pulse generator sink gates (PGS) cannot connect to any of the following: primary outputs, non-clock inputs of scan memory elements, ROM gates, non-write inputs of RAMs, or transparent latches. To avoid this error, set the pulse generators to off, however note that this results in no pulse generator support.

The error message is:

```
Pulse generator N1 (G1) connected to T N2. (T17-1)
```

N1 is the pulse generator instance name, and G1 is its gate ID number.

T18

Category: Trace

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Ignore

report_drc_rules: Not Supported

The maximum number of traced cells in the longest scan chain of a group must equal the entered number of repetitions in the **apply shift** statement in the **load_unload** procedure. The default setting for this DRC is “Ignore.”

You can enable this check with the [set_drc_handling](#) command.

You can correct this condition by changing the repetition number on the **apply shift** statement. This rules violation has no adverse effects because the tool recalculates the actual number of necessary shifts based on the number of scan cells it encounters.

The warning message is:

```
Traced number of shifts (N1) doesn't match entered value (N2). (T18-1)
```

N1 is the traced number of shifts, and N2 is the entered number of shifts.

T19

Category: Trace

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported

If one scan cell has a SLAVE, then all scan cells must have a SLAVE. You must correct this warning by changing the netlist of the scan chains.

The warning message is:

```
N scan cells do not have a SLAVE when some do. (T19-1)
```

N is the number of non-slave scan cells.

T20

Category: Trace

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The number of shifts specified using the set_number_shifts command must be at least equal to the length of the longest scan chain. To correct this error set a valid value using the set_number_shifts command.

The error message is:

Entered number of shifts N is too small. (T20-1)

N is the entered number of shifts, and T20 is the rule ID number.

T21

Category: Trace

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The number of independent **shift** applications in the **load_unload** procedure must be less than the scan chain length. Correct this error by removing a sufficient number of independent **shift** applications from the **load_unload** procedure or by deleting the short scan chain.

The error message is:

Number of independent shifts N must be less than scan chain length L.
(T21-1)

N is the number of independent **shift** applications, L is the scan chain length, and T21 is the rule ID number.

T22

Category: Trace

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

If the rules checker traces a scan cell during the application of an independent **shift**, it must also trace that cell during the application of its associated general **shift**. Correct this error by

changing the sensitization for either the independent or general **shift**, so that they are sensitizing the same scan cells.

The error message is:

```
N (G) was not used in general chain trace. (T22-1)
```

N is the scan cell instance name, G is its gate ID number, and T22 is the rule ID number.

T23

Category: Trace

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The chain length calculated for an independent **shift** must be the same as that calculated for its associated general **shift**. Correct this error by changing the sensitization for either the independent or general **shift**, so that they are sensitizing the same scan cells.

The error message is:

```
Chain length (L1) using independent shift not equal to chain length (L2).  
(T23-1)
```

L1 is the independent shift chain length, L2 is the general shift chain length, and T23 is the rule ID number.

T24

Category: Trace

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

When two adjacent memory elements (source and sink) in a scan chain path are clocked by different shift clocks, the sink must not capture data from the source at the same time the source changes its value. Failure to satisfy this rule can result in unwanted shoot-through during scan chain shifting when clock skew exists between the different shift clocks.

The warning message is:

```
A lockup latch may be required between N1 (G1) of cell M1 and N2 (G2) of  
cell M2 in scan chain S. (T24-1)
```

N1 and N2 are the instance names of the adjacent elements clocked by different clocks. G1 and G2 are the corresponding gate IDs. M1(M2) is the cell ID of the scan cell in which N1(N2) is located. S is the name of the scan chain.

Note

If N1(N2) is not within a scan cell, M1(M2) is the cell ID of the scan cell that is driven by N1(N2).

You can correct the violation by inserting a lockup latch between the adjacent memory elements reported in the violation message. To find out which clocks are involved, use the command, [report_scan_cells -Range cell_id1 cell_id2](#).

T25

Category: Trace

Contexts Supported: patterns -scan, patterns -scan_diagnosis

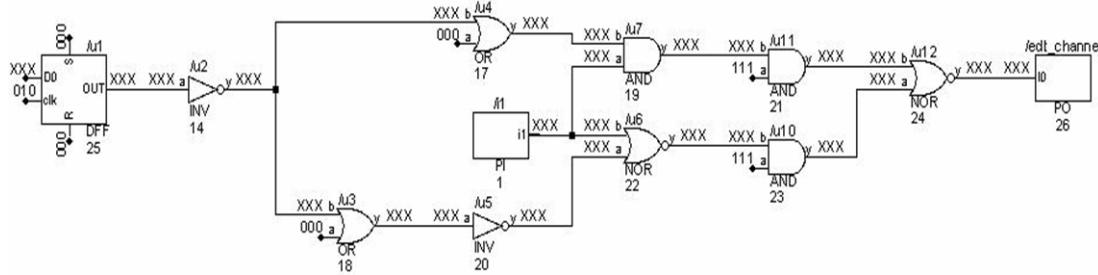

Default Handling: Warning

report_drc_rules: Supported

Scan chain tracing must be independent of whether or not a gate with an X value is initialized to a known value (either 0 or 1).

[Figure 7-60](#) is an example of a T25 violation.

Figure 7-60. Example of T25 Violation

In [Figure 7-60](#), the scan path is from DFF gate 25 to PO gate 26. If PI gate 1 is initialized to 1, then the actual scan path is the upper path from gate 25 to gate 26. If PI gate 1 is initialized to 0, then the actual scan path is the lower path from gate 25 to gate 26. In either case, the scan shifting is successful; however, a simulation mismatch could occur in Verilog if PI gate 1 is not initialized (remains an X value). The warning message is:

There is a T25 violation. Scan chain tracing has assumed that some gates with X values are initialized to any non-X values. This is not a problem in silicon but may cause Verilog simulation mismatches. For more conservative scan chain tracing, please use the command: "set_drc_handling -scan_chain_tracing conservative".

You can display the T25 violation using the “report drc rule T25” command as shown in the following example:

rep drc rule T25

```
Warning: Scan chain tracing between scan output and scan cell 0
(from gate 24 back to gate 14) in scan chain 0 assumes that some gates
with X values are initialized to any non-X values. (T25-1)
```

You can debug T25 violations by displaying the gate value in scan shift. To do this, use the [set_gate_report](#) command to set gate reporting to drc shift and use the [report_gates](#) command with the gate ID number displayed in the message.

The default handling for this rule violation is warning. If you do not want scan chain tracing to pass with a T25 violation, use the “set_drc_handling -scan_chain_tracing conservative” command. For more information, see the [set_drc_handling](#) command.

T26

Category: Trace

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

The shift procedure must create a sensitizable path through bidirectional pins at the scan chain output or EDT channel output. The improperly sensitized bidirectional pin causes an error condition.

For scan chain output, the tool issues the following error message:

```
Scan chain tracing failed at bidirectional scan chain output pin N in
chain "C". The pin is not forced to Z during measure_sco. (T26-1)
```

For EDT channel output, the tool issues the following error message:

```
Scan chain tracing failed at bidirectional channel output pin N in block
"B". The pin is not forced to Z during measure_sco. (T26-2)
```

N is the pin name, C is the corresponding chain name, and B is the corresponding EDT block name.

You can avoid this rule violation by adding a force to Z for the reported pins at the beginning of the load_unload procedure. Alternatively, you can force all bidirectional pins with a ‘force _ALL_BIDI Z’ at the beginning of the load_unload procedure. The _ALL_BIDI is a macro that selects all primary bidirectional pins.

You can also define the pin as an output pin instead of as an inout pin in your Verilog file. By doing this, then there is no need to force this pin to Z anymore.

Power-Aware Rules (V Rules)

Power-aware designs rely on DRC rules that are designed specifically for that application.

You must load power data using the `read_cpf` or `read_upf` commands before using the `report_drc_rules` command for the V DRC rules.

When using the power-aware DRC rules, the following conditions apply:

- **Rule V1 to V7** — Checked after reading a power data file.
- **Rule V8 to V21** — Checked when switching from setup mode to a non-Setup mode.

The tool displays a summary of the V rules when you load power data into the tool without any parsing errors as shown here:

```
read_upf my_design.upf
report_drc_rules -summary

...
T26: #fails=0 handling=error (bidirectional chain / channel outputs not
forced to Z during chain tracing)
V1: #fails=0 handling=ignore/verbose (no power modes are defined)
V2: #fails=0 handling=ignore/verbose (no default power modes are defined)
V3: #fails=0 handling=error (multiple default power modes are defined)
V4: #fails=0 handling=error (no default power domains are defined)
V5: #fails=0 handling=error (multiple default power domains are defined)
V6: #fails=0 handling=warning (no restore_edge or default_restore_edge is
defined)
V7: #fails=0 handling=warning (power mode is not reachable)
V8: #fails=0 handling=error (scan data path is in a power-off domain)
V9: #fails=0 handling=error (scan control path is in a power-off domain)
V10: #fails=0 handling=error (power start/end/shutoff condition is X
during the scan shift period)
V11: #fails=0 handling=error (active power mode has changed during the
scan shift period)
V12: #fails=0 handling=warning (active power mode may change during the
capture cycle)
V13: #fails=0 handling=warning (path crosses power domains without a
level-shifter cell)
V14: #fails=0 handling=warning (path crosses power domains without an
isolation cell)
V15: #fails=0 handling=note (scan chain contains both retention and
regular cells)
V16: #fails=0 handling=note (scan chain contains both always-on and
other types of cells)
V17: #fails=0 handling=note (EDT channel contains both retention and
regular cells)
V18: #fails=0 handling=warning (power control signals are in a domain
that could be powered-off)
V19: #fails=0 handling=warning (retention save signal is not off during
shift)
V20: #fails=0 handling=note (non-scan retention cells are identified in
the design)
V21: #fails=0 handling=error (power data assertions are detected)
```

V1

Category: Power Aware

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Supported

No power modes are defined when there are multiple power domains. You cannot change the handling.

The violation message is:

At least one power mode is required when multiple power domains are defined (V1).

Because power modes in UPF are implicitly learned through power switches control logic, the V1 rule is ignored in UPF format.

When you issue the [analyze_drcViolation](#) command on an occurrence of this violation, DFTVisualizer opens the CPF file in a Text Editor window.

V2

Category: Power Aware

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Supported

No default power modes are defined when there are multiple power modes. You cannot change the handling.

The violation message is:

```
A default power mode is required when multiple power modes are defined  
(V2) .
```

The V2 rule is ignored for UPF format.

When you issue the [analyze_drcViolation](#) command on an occurrence of this violation, DFTVisualizer opens the CPF file in a Text Editor window.

V3

Category: Power Aware

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Supported

Multiple default power modes are defined. You cannot change the handling.

The violation message is:

```
Multiple default power modes are defined (V3) .
```

When you issue the [analyze_drcViolation](#) command on an occurrence of this violation, DFTVisualizer opens the CPF file in a Text Editor window and highlights the line containing the error.

V4

Category: Power Aware

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Supported

No default power domain is defined when there are multiple power domains. You cannot change the handling.

The violation message is:

A default power domain is required when multiple power domains are defined (V4) .

When you issue the [analyze_drcViolation](#) command on an occurrence of this violation, DFTVisualizer opens the CPF file in a Text Editor window.

V5

Category: Power Aware

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Supported

Multiple default power domains are defined. You cannot change the handling.

The violation message is:

Multiple default power domains are defined (V5) .

When you issue the [analyze_drcViolation](#) command on an occurrence of this violation, DFTVisualizer opens the CPF file in a Text Editor window and highlights the line containing the error.

V6

Category: Power Aware

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

Either restore_edge or default_restore_edge must be defined if the design contains any retention cells; if this rule is violated, the state retention rule is ignored and no retention value is restored.

Note that missing both save_edge and default_save_edge is allowed on CPF as long as restore_edge or default_restore_edge is defined. In this case, the inversion of restore_edge (or default_restore_edge when restore_edge is missing) will be used as save_edge.

The violation message is:

No restore_edge is defined for the state retention rule name. (V6-n) .

When you issue the [analyze_drcViolation](#) command on an occurrence of this violation, DFTVisualizer opens the CPF file in a Text Editor window and highlights the retention definition lines.

V7

Category: Power Aware

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

A defined power mode is not reachable from the default power mode with the defined power transition rules.

The violation message is:

```
Power mode name1 is not reachable from the default power mode name2 using  
any defined power transition rule (V7-n).
```

The V7 rule is ignored for UPF format.

When you issue the [analyze_drcViolation](#) command on an occurrence of this violation, DFTVisualizer opens the CPF file in a Text Editor window and highlights the line defining the power mode.

V8

Category: Power Aware

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

The scan tracing should not propagate to a scan cell in a power domain that is in the shutoff state.

Note

 Scan insertion in the dft -scan contexts supports this rule if the design contains pre-existing scan chains and a valid test procedure file.

Note that the number of power OFF gates in a given scan chain can be large, so only one V8 violation is recorded per scan chain and the first scan path gate from the sco pin is reported. Violation of the V8 rule can be due to at least one of the following reasons:

- The power mode definition is incorrect.
- The shutoff condition of the power domain is defined incorrectly.

- The test procedures (for example, load_unload or shift) for the scan chain operation are defined incorrectly.
- The inserted scan logic of the design does not consider the power mode properly.

The violation message is:

The scan path of chain chain-name is in power off domain domain-name (the first power off scan path gate is N1 (G1) after tracing C cells) (V8-n)

When you issue the [analyze_drcViolation](#) command on an occurrence of this violation, DFTVisualizer displays the scan cell in the Flat Schematic window with a callout box attached containing the following message:

Power Domain: < name>, Power Mode (CPF) or Power State: <name>

V9

Category: Power Aware

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

All control logic for the scan operation must be in a power ON domain during the entire scan shift operation.

Note

 Scan insertion in the dft -scan context supports this rule if the design contains pre-existing scan chains and a valid test procedure file.

Some popular control logic examples are listed below:

- If EDT logic exists in the design, it should stay at power ON mode during the scan test when the compression mode is used; otherwise the scan operation will fail.
- If the scan_enable signal is derived from a JTAG controller, the JTAG controller should stay at power ON mode during the scan test.
- The shift clock control logic should remain at power ON mode during the scan test. The tool performs the check by monitoring all test procedures except test_setup and ensures that the power domains where the scan control logic are located remain at the power ON mode after test_setup procedure.

The violation message is:

The scan chain chain-name is blocked at N1 (G1) after tracing C cells due to the control gate N2 (G2) in power off domain domain_name (V9-n).

When you issue the [analyze_drcViolation](#) command on an occurrence of this violation, DFTVisualizer displays the control gates in the Flat Schematic window with a callout box attached containing the following message:

```
Power Domain: < name>, Power Mode (CPF) or Power State: <name>
```

V10

Category: Power Aware

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

The expression used by mode_transition rule and shutoff condition should not be X during the scan shift period. The tool performs the rule by checking all events to ensure that no expression can be X during the scan shift operation. The expressions to be checked include the shutoff condition of every power domain and the start and end conditions of every mode_transition rule.

Note

 Scan insertion in the dft -scan contexts supports this rule if the design contains pre-existing scan chains and a valid test procedure file.

The violation messages are:

Case 1 — When shutoff condition of a power domain is X:

```
The shutoff condition of power domain name is X at time t of procedure
procedure-name (V10-n).
```

Case 2 — When the start condition of a mode_transition rule is X:

```
The start condition of mode transition rule name is X at time t of
procedure procedure-name (V10-n).
```

Case 3 — When the end condition of a mode_transition rule is X:

```
The end condition of mode transition rule name is X at time t of procedure
procedure-name (V10-n).
```

The handling of X is different based on the handling of the V10 DRC rule. When the handling of the rule is set to warning, the condition of X will be treated as HI as if the condition is satisfied. When the handling is Note, the condition of X will be treated as LO as if the condition is not satisfied. Note, the violation of this rule may cause the design to be in the wrong power mode and thereby cause a simulation mismatch.

When you issue the analyze_drcViolation command on an occurrence of this violation, DFTVisualizer opens the CPF file and the test procedure files (if applicable) in a Text Editor window. DFTVisualizer highlights the line in the CPF file that defines the power domain (if applicable) and also the line in the test procedure file that defines the procedure name.

V11

Category: Power Aware

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

During scan chain shift operation, the design should not change power modes because this can cause some power domains to be switched between power OFF mode and power ON mode. This occurs because changing active power domains during the shift period may cause the scan chain configuration to be changed. The tool performs the rule by checking the shutoff expressions of all power domains to ensure they remain false during the scan shift period.

Note

 Scan insertion in the dft -scan context supports this rule if the design contains pre-existing scan chains and a valid test procedure file.

The violation messages are:

Case 1 — When mode transition rules are defined:

```
Active power mode changed from mode1 to mode2 at time t of procedure
procedure_name (V11-n).
```

Case 2 — When mode transition rules are not defined:

```
The power domain name changed from state-1 to state-2 at time t of
procedure procedure_name (V11-n).
```

When the handling of the violation is not error, the scan shift operation may be unreliable and this can result in a simulation mismatch. Note that a mismatch may not be seen in the parallel test bench and this can make the debugging process more complicated.

When you issue the analyze_drcViolation command on an occurrence of this violation, DFTVisualizer opens the CPF file and the test procedure files (if applicable) in a Text Editor window. DFTVisualizer highlights the line in the CPF file that defines the power domain (if applicable) and also the line in the test procedure file that defines the procedure name.

V12

Category: Power Aware

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

ATPG should not create_patterns that can turn off an active power domain during the capture cycle; turning off an active power domain during the capture period changes the scan chain configuration. The tool performs the rule by checking on active power domains with shutoff expressions and ensuring they cannot be true during the capture period.

Note

 Scan insertion in the dft -scan context supports this rule if the design contains pre-existing scan chains and a valid test procedure file.

The violation messages are:

Case 1 — When mode transition rules are defined:

The power mode may change from name1 to name1 during the capture cycle (V12-n) .

Case 2 — When mode transition rules are not defined:

The power domain name may change state during the capture cycle (V12-n) .

When the shutoff condition is true and the handling of the violation is not error, the capture value of the scan cells in the shutoff power domain remains the same as if the power domain is still active. This may cause some test patterns to fail in silicon that may not be detected during the logic simulation phase.

When you issue the analyze_drcViolation command on an occurrence of this violation, DFTVisualizer opens the CPF file and the test procedure files (if applicable) in a Text Editor window. DFTVisualizer highlights the line in the CPF file that defines the power domain (if applicable) and also the line in the test procedure file that defines the procedure name.

V13

Category: Power Aware

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

A path should not cross different power domains without a level-shifter cell if the power domains can operate in different operation voltages.

The following situations can cause a V13 DRC violation:

- An instance is driven by another instance of a different voltage power domain.

- The scan_in pin or the EDT decompressor to the first scan cell crosses different voltage domains.
- The last scan cell to the scan_out pin or EDT compactor crosses different voltage domains.
- The scan cell (i+1) to scan cell i crosses different voltage domains.

The violation messages are:

Case 1 — When violation is on a non-scan path:

Path from gate N1 (G1) to gate N2 (G2) crosses different voltage domains without a level-shifter cell (V13-n).

Case 2 — When violation is on a scan path:

Scan path from gate N1 (G1) of cell (i+1) to gate N2 (G2) of cell i of scan chain chain-name crosses different voltage domains without a level-shifter cell (V13-n).

When you issue the analyze_drcViolation command on an occurrence of this violation, DFTVisualizer displays the path between the two gates reported in the message in the Flat Schematic window and displays the simulation data as a DRC in the Flat Schematic window. If possible, a callout box for the DRC is attached to the source and the sink containing the power domain names.

V14

Category: Power Aware

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

If a path crosses two power domains and the driving power domain contains the shutoff condition, the path must include an isolation cell. Similar to rule V13, there are four situations to be considered for this rule.

The violation messages are:

Case 1 — When violation is on a non-scan path:

Path from gate N1 (G1) to gate N2 (G2) crosses different power domains without an isolation cell (V14-n).

Case 2 — When violation is on a scan path:

Scan path from gate N1 (G1) of cell (i+1) to gate N2 (G2) of cell i of scan chain chain-name crosses different power domains without an isolation cell (V14-n).

When you issue the analyze_drcViolation command on an occurrence of this violation, DFTVisualizer displays the path between the two gates reported in the message in the Flat Schematic window and displays the simulation data as a DRC in the Flat Schematic window. If possible, a callout box for the DRC is attached to the source and the sink containing the power domain names.

V15

Category: Power Aware

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Note

report_drc_rules: Supported

A scan chain should not include both retention cells and regular scan cells. A violation of this rule will make retention test less efficient.

The violation message is:

```
Scan chain chain-name contains both retention cells and regular cells  
(V15-n) .
```

This violation is not supported in DFTVisualizer.

V16

Category: Power Aware

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Note

report_drc_rules: Supported

Typically, always-on cells are used to program power mode and retention mode. To make the control of the power mode more efficient, a scan chain should not include both always-on cells and other types of scan cells.

The violation message is:

```
Scan chain chain-name contains both always-on cells and other type of  
cells (V16-n) .
```

This violation is not supported in DFTVisualizer.

V17

Category: Power Aware

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Note

report_drc_rules: Supported

An EDT scan channel should try to prevent the mix of scan chain with retention cells and, regular scan chain without retention cells. This rule prevents the retention cells from being masked by regular cells when the circuit is restored from the retention mode.

The violation message is:

```
Scan channel channel-name contains both retention scan chain and regular  
scan chain (V17-n) .
```

This violation is not supported in DFTVisualizer.

V18

Category: Power Aware

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

All power control signals, including retention save, retention restore, isolation_enable, and power-domain shutoff conditions should be from always-on power domains that cannot be turned off.

By default, the V18 violation handling is Warning. The tool starts with an all power-off state, except for the always-on power domains.

The violation message is:

```
Shutoff condition 'condition_expression' for domain domain_name is in non-  
always-on power domain (V18-n) .
```

When the V18 violation handling is set to Note, the tool assumes it is in an all power-on state at the beginning of test_setup.

When you issue the [analyze_drcViolation](#) command on an occurrence of this violation, DFTVisualizer opens the CPF file and highlights the line that defines the power domain.

V19

Category: Power Aware

Contexts Supported: patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

Retention save signals should be off during the scan shift period to prevent the loading value from being overridden by the retention saved state.

The violation message is:

```
Save signal 'condition_expression' for retention rule rule_name is not off  
during the scan shift period (V19-n) .
```

When you issue the [analyze_drcViolation](#) command on an occurrence of this violation, DFTVisualizer opens the CPF file and highlights the line that defines the rule name.

V20

Category: Power Aware

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Note

report_drc_rules: Supported

Only scanned retention cells are supported by the retention test to test the retention functionality. So this rule checks if there are any non-scan retention cells.

The violation message is:

```
Retention cell cell_name is a non-scan cell (V20-n) .
```

This violation is not supported in DFTVisualizer.

V21

Category: Power Aware

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

The design should never enter any illegal power configurations specified in CPF command assert_illegal_domain_configurations during any test cycle.

The violation message is:

```
The active power mode violates assert_illegal_domain_configurations name  
at time t of procedure proc_name (V21-n) .
```

Note

 CPF and UPF power data parsers support the Tcl scripting mechanism. The violation of the Tcl format results in an error. Note, the format of the error message is not described in this document.

When you issue the [analyze_drcViolation](#) command on an occurrence of this violation, DFTVisualizer opens the CPF file and the test procedure files (if applicable) in a Text Editor window. In the CPF file, DFTVisualizer highlights the assert_illegal_domain_configurations command (if applicable).

Timing Rules (W Rules)

These rules apply to timeplates and the mapping of timeplates to procedures. This includes making sure that the order of events in a procedure is not changed after leaving setup mode.

For timing rules specific to the enhanced procedure file, see “[Test Procedure File](#)” in the *Tessent Shell User’s Manual*.

W1

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

This message can only occur when not in setup mode. After leaving setup mode, it is possible to load an enhanced procedure file using the read_procfile command. It is also possible for the enhanced procedure file to load a new procedure which overwrites a procedure already loaded. This is fine as long as the event order in the new procedure matches that of the old procedure.

If the new procedure has additional events, the tool will issue this error message:

```
New procedure P has more events than existing procedure. (W1)
```

P is the name of the new procedure.

W2

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

Similar to rule W1, but this rule is violated if the new procedure has less events than the old procedure.

The error message is:

```
New procedure P has fewer events than existing procedure. (W2)
```

P is the name of the new procedure.

W3

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

Similar to rule W1, this rule is violated if the new procedure has a different event order than the old procedure.

The error message is:

```
New procedure P has a different event order than existing procedure. (W3)
```

P is the name of the new procedure.

W4

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

This message is similar to rule W1. Instead of an entire new procedure being loaded, the enhanced procedure file only specifies that a new timeplate is applied to an existing procedure. This is done by specifying a new procedure in the enhanced procedure file with only a timeplate reference statement.

If that new timeplate causes the event order in the old procedure to change, the tool will issue this error message:

```
New timeplate T changes event order in procedure. (W4)
```

T is the name of the new timeplate.

W5

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

A new non-scan procedure has an event statement that either occurs in the wrong order, or is not allowed in that type of procedure.

All non-scan procedures must conform to the event order that is stated for them in “Non-Scan Procedures” in the *Tessent Shell User’s Manual*. An example of this would be a capture procedure that has a “measure_po” statement before the “force_pi” statement.

The error message is:

```
Procedure P has an illegal event statement or event order S. (W5)
```

P is the procedure name and S is the illegal statement or event order.

W6

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

If one shift procedure has the “measure_sco” statement occurring after the pulse of the shift clock, then all shift procedures must place the “measure_sco” statement after the pulse of the shift clock, and all load_unload procedures must have a “measure_sco” statement occurring at the end of the cycle right before the “apply shift” statement. Placing the “measure_sco” statement after the pulse statement enables end measure mode which affects the way the Vector Interfaces code writes out parallel load scan patterns.

See the “[Creating Test Procedure Files for End Measure Mode](#)” section of the *Tessent Shell User’s Manual*.

The error message is:

```
Shift procedure P [does | does not] use end measure, while previous ones [do | do not]. (W6)
```

P is the procedure name.

W7

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

No timing information has been specified for the named procedure. Either the procedure needs to reference a timeplate, or time values must be associated with the event statements.

The error message is:

No timeplate or times specified for procedure P. (W7)

P is the procedure name.

W8

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

A scan procedure (shift, load_unload, ...) has been read in by the read_procfile command, but no “scan_group” statement is in the procedure.

The error message is:

No scan group specified for procedure P. (W8)

P is the procedure name.

W9

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The named procedure has no event statements, no apply statements, and no timeplate references.

The error message is:

No events in procedure P. (W9)

P is the procedure name.

W10

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

This warning is issued during DRC checking. It indicates that none of the procedure files specified in the add_scan_groups commands have any procedures in them.

The warning message is:

```
No test procedures have been loaded. (W10)
```

W11

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

A cycle in a procedure that needs to be split into two cycles in order to use the timeplate that is specified for that procedure. This could occur, for example, if the test_setup procedure contains a pulse statement on a specific clock pin, and yet the timeplate used referenced by this procedure does not contain a pulse statement for the clock. The user will receive a P53 rule message and then a W11 rule message to indicate that the cycle (where the pulse statement is) was split into two cycles in order to create the clock pulse.

The warning message is:

```
Cycle S being split in procedure P. (W11)
```

S in the cycle and P is the procedure name.

W12

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

A timeplate was loaded that is missing a required statement. For example, a timeplate must have a “force_pi” statement. If a required clock pulse statement is missing from the loaded timeplate, you will receive a P53 rule message.

The error message is:

```
No S statement in timeplate T. (W12)
```

S is the statement name and T is the timeplate.

W13

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

The event order for the name procedure has changed while parsing an procedure file, but since the tool is still in setup mode, this change of event order is acceptable. This could happen if two procedure files in two different add_scan_groups commands both have the same procedure (test_setup, for example), but one specifies a different event order than the other. The last one loaded is what will be used.

The warning message is:

```
Event order has changed in procedure P. (W13)
```

P is the procedure name.

W14

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Note

report_drc_rules: Not Supported

This message indicates that a procedure has been replaced by a new procedure with the same name, same type, and same scan group if applicable. This message indicates that the replacement did not violate any rules. Both procedures have the exact same event order, but they might use different timeplates.

The warning message is:

```
Procedure P replaces same procedure from file S. (W14)
```

P is the procedure name and S is the filename.

W15

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

End measure mode is enabled but an illegal force or pulse statement occurs between the measure_sco statement and the end of the procedure in a shift procedure, or the illegal statement

occurs between the measure_sco statement and the apply shift statement in a load_unload procedure.

See the “[Creating Test Procedure Files for End Measure Mode](#)” section of the *Tessent Shell User’s Manual*.

The error message is:

```
Statement S cannot follow measure_sco in end measure procedure P. (W15)
```

S is the illegal statement and P is the procedure name.

W17

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

Clock_po procedures are used to hold clock pins at certain values. In order to obtain the correct fault coverage, it is important that the timeplates used in a clock_po procedure do not pulse the clock pins, but only force them. If this is not corrected before patterns are saved, the Vector Interfaces code places X values on the output pins for the clock_po procedure and fault coverage decreases.

The error message is:

```
Timeplate T has clock pulses but is used in a clock_po procedure. (W17)
```

T specifies which timeplate has the clock pulses. To correct this, make sure you define a different timeplate that does not have clock pulses and use this in the clock_po procedure.

W18

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning (can be changed to Note or Ignore)

report_drc_rules: Supported

Many ASIC vendors require that shift procedures only be one cycle in length, and it is very unusual to encounter a multiple cycle shift procedure. This warning alerts the user that something might not be specified correctly in the shift procedure, such as forcing the same pin with more than one value, or pulsing a clock twice.

The warning message is:

Shift procedure has more than one cycle, please check if shift clocks are defined properly. (W18)

W19

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Not Supported

This message occurs when using the offstate option improperly. The offstate option is only supported when using the Enhanced Vector Interfaces. Also, the pin referenced with the offstate option cannot be used in a capture, ram_sequential, or clock_sequential procedure. These are considered non-scan procedures.

Any timeplate that uses the offstate statement will be treated as a complex timeplate and will not be allowed to be used in a non-scan procedure. Complex timeplates are most useful in shift procedures where a non-clock pin needs to be pulsed while still maintaining a single cycle in the shift procedure. If you attempt to pulse a signal specified with an offstate option in a capture or other non-scan procedure, you will encounter the following error message.

Timeplate gen_tp1 with complex waveforms cannot be used in non-scan procedure capture. (W19)

W20

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

This error occurs if, in a capture procedure, a force_pi event does not occur before the first clock pulse.

The error message is:

A force_pi statement does not exist before the first clock pulse in Procedure P. (W20)

P is the procedure name.

To correct this violation, add a force_pi statement to the beginning cycle of the procedure, before the first clock pulse. For a named capture procedure with internal and external modes, add a force_pi statement to the beginning cycle in each mode.

W21

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

In a named capture procedure, a measure_po statement is allowed only in the last cycle of the internal mode. This error occurs if a measure_po statement is found in a cycle where it is not permitted.

The error message is:

Procedure P has one or more measure_po statements which do not occur in the cycle before the last clock pulse. (W21)

P is the procedure name.

To correct this violation, remove the measure_po statements from the cycles where they are not allowed.

W22

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

In a named capture procedure, a measure_po statement is allowed only in the last “cyclized” ATPG cycle of the internal mode—before the last clock pulse. This warning alerts you that the tool did not find a measure_po statement in this location. A capture procedure with this warning will not use any PO as a capture point.

The warning message is:

Procedure P has no measure_po statement in the cycle before the last clock pulse. (W22)

P is the procedure name.

To view the cyclized information for the procedure, use the report_capture_procedures command.

W23

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

In a named capture procedure, the total period of the external mode must match the total period of the internal mode. This warning alerts you that the external mode's period is longer than the internal mode's period.

The warning message is:

The total period for the external mode is longer than the total period for internal mode in procedure P. (W23)

P is the procedure name.

To eliminate this warning, modify the timeplate(s) so that the external mode period matches the internal mode period.

W24

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Supported

In a named capture procedure, the total period of the external mode must match the total period of the internal mode. This error occurs if the internal mode's period is longer than the external mode's period.

The error message is:

The total period for the internal mode is longer than the total period for external mode in procedure P. (W24)

P is the procedure name.

To correct this violation, modify the timeplate(s) so that the external mode period matches the internal mode period.

W25

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

Event times in the external and internal modes of a named capture procedure should match. This warning alerts you that an event in the external mode does not have a matching event in the internal mode.

The warning message is:

```
// Warning: External event pulse S at time T needs to have a matching
internal event in procedure P or the signal needs to be disconnected from
internal sequential elements or observe points. (W25-1)
```

Where S is the signal name, T is the time of the event, and P is the procedure name.

In Tessent Diagnosis, these violations if uncorrected can cause pattern verification errors in the tool. See the *Tessent Diagnosis User's Manual* for more information.

W26

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

Event times in the external and internal modes of a named capture procedure must match. This error occurs if an event (other than an internal pin event) in the internal mode does not have a matching event in the external mode.

The error message is:

```
Event E N at time T in internal mode does not have matching event in
external mode in procedure P. (W26)
```

E is the type of event, N is the name of the pin to which the event applies, T is the time of the event, and P is the procedure name.

To correct this violation, you need to do two things:

- Add the missing event to the external mode.
- Modify the timeplate(s) so that the event added to the external mode occurs at the same time as in the internal mode.

W27

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Supported

In a named capture procedure, the start time for the scan load cycle in the internal mode must have a match in the external mode. This error occurs if there is not a match in the external mode.

The error message is:

```
Start time for scan load cycle in internal mode does not have a match in  
external mode in procedure P. (W27)
```

P is the procedure name.

To correct this violation, adjust the timeplate(s) or procedure so that the internal scan load cycle has a corresponding external cycle starting at the same time.

W28

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

In a named capture procedure, the measure_po time in the external mode must match the internal mode. This error occurs if the measure_po time in the external mode does not match the internal mode.

The error message is:

```
Measure_po time in external mode does not match internal mode in procedure  
P. (W28)
```

P is the procedure name.

To troubleshoot this violation, check that there is a measure_po statement in both the internal mode and the external mode. If a measure_po exists in both modes, adjust the timeplate(s) to ensure the measure_po occurs at the same time in both modes.

W29

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

In a named capture procedure, the force_pi time in the external mode must match the internal mode. This error occurs if the force_pi time in the external mode does not match the internal mode.

The error message is:

```
Force_pi time in external mode does not match internal mode in procedure  
P. (W29)
```

P is the procedure name.

To troubleshoot this violation, check that there is a force_pi statement in both the internal mode and the external mode. If a force_pi exists in both modes, adjust the timeplate(s) to ensure the force occurs at the same time in both modes.

W30

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Supported

In a named capture procedure, an event on an internal pin is not allowed in the external mode. This warning alerts you that there is an internal pin event in the external mode of the procedure.

The warning message is:

```
Event E N on internal pin is not allowed in external mode of procedure P.  
(W30)
```

E is the type of event, N is the name of the pin to which the event applies, and P is the procedure name.

The tool will ignore the internal pin event in the external mode; however, you can avoid the violation by removing the internal pin event from the external mode.

W31

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

A named capture procedure that has an external mode must also have an internal mode. This error occurs when an external mode exists without an accompanying internal mode.

The error message is:

```
Procedure P has an external mode but is missing an internal mode. (W31)
```

P is the procedure name.

To correct this violation, do one of the following:

- Add an internal mode definition to the named capture procedure, or
- Remove the “mode external =” statement and its corresponding “end;” statement from the named capture procedure.

W32

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Not Supported

A force_pi in a named capture procedure must not occur when a clock is in an on state.

W32 ensures the procedure file is valid.

This DRC checks the force_pi statement in named capture procedures in the procedure file when loading a new procedure file, which can occur during DRC, when the read_procfile command is used, or when the write_patterns command is used with a new procedure file specified on the write_patterns command line.

Messaging

If the procedure file fails W32, the following message displays:

```
A force_pi statement occurs while a clock or control is active in
procedure P (W32).
```

Where P is the name of the procedure file.

Troubleshooting

To correct this violation, edit the procedure file so the force_pi statement does not occur during the time that a clock is in its on state.

W33

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Warning

report_drc_rules: Not Supported

The named capture procedure in the procedure file cannot be loaded using the -Append_or_timing_update switch in the read_procfile command.

W33 ensures the procedure file is valid.

This DRC checks a new procedure file when it is loaded with the `read_procfile` or `write_patterns` command. A W33 violation occurs when the new procedure file contains a new scan procedure (`load_unload`, `alternate shift`, `master_observe`, and so on) or a new named capture procedure. W33 is only issued for new named capture procedures if the `-Append_or_timing_update` switch is specified with the `read_procfile` command.

Messaging

If the `test_setup` procedure file fails W33, the following message displays:

```
Cannot add new procedure P, procedure ignored (W33)
```

Where P is the procedure name.

Troubleshooting

To correct this violation, do one of the following:

- If the violation is for a named capture procedure, either change the `read_procfile` command option from `-Append_or_timing_update` to `-Replace` or edit the procedure file to remove the named capture procedure.
- If the violation is for a scan procedure, edit the procedure file to remove the scan procedure.
- For both cases, you can return to setup mode and load the procedure file with the `add_scan_groups` command.

W34

Category: Timing

Contexts Supported: `dft -scan`, `patterns -scan`, `patterns -scan_diagnosis`

Default Handling: Error

`report_drc_rules`: Supported

This error occurs when saving patterns if a force event in the external mode conflicts with a pin constraint in a named capture procedure.

The error message is:

```
//Error: Event E N at time T in external mode conflicts with pin  
constraint on same pin in procedure P. (W34)
```

Where E is the event type, N is the name of the event pin, T is the time at which the conflict occurs, and P is the name of the procedure that contains the conflicting pin constraint.

To resolve this issue, either the pin constraint or the named capture procedure must be changed. If this error is ignored, you will not be able to load external mode STIL or WGL patterns back into the tool because the pattern data (using the force event) will not match the pin constraint.

W35

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error (cannot be changed with the set_drc_handling command)

report_drc_rules: Supported

This error occurs when a pulse-always clock needs to be added to a cycle, and that cycle uses a timeplate that has no pulse timing for the clock.

The error message is:

```
//Error: The following occurred at line N in file F
Pulse-always clock C is not pulsed in T. (W35)
```

Where N is the line number, F is the filename, C is the clock name, and T is the timeplate name.

The W35 rule is an error, and the handling cannot be changed.

W36

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

This error occurs when “offstate” statements in the timeplates used by a named capture procedure are defined for a pin that has already been defined as a clock in the dofile. The unnecessary “offstate” statements cause extra pulses in a cycle.

The error message is:

```
// Error: Offstate cannot be used with pin N already defined as a clock
(W36)
```

Where N is the name of the clock pin.

To resolve this error, remove the unnecessary “offstate” statements from the timeplates.

W37

Category: Timing

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

Each load cycle of a named capture procedure must include a **force_pi** event. The ATPG tools require a **force_pi** event after each scan load. If there is no **force_pi** event in the load cycle of a named capture procedure, the generated test patterns may be incorrect and produce errors when read back into the ATPG tools.

The W37 violation does not override or mask a [W20](#) violation. Therefore, if this error occurs in the first cycle and there is no force_pi event before the first clock pulse, then both a W37 and W20 violation are issued.

The W37 rule can be reduced to a warning or note only if every signal having a force event in a load_unload procedure has a pin constraint defined with a matching value.

The occurrence message is:

```
//Error: A force_pi statement does not exist in a scan load cycle in
Procedure P. (W37-1)
```

Where P is the name of the procedure.

Troubleshooting

Edit the load cycle(s) of the named capture procedure to include a force_pi event.

W38

Contexts Supported: dft -scan, patterns -scan, patterns -scan_diagnosis

Default Handling: Error

report_drc_rules: Supported

This rule checks whether pulse-always clocks that are pulsed in the external mode of a named capture procedure and are internally connected also pulse in the internal mode of the named capture procedure at the same time.

The error message is:

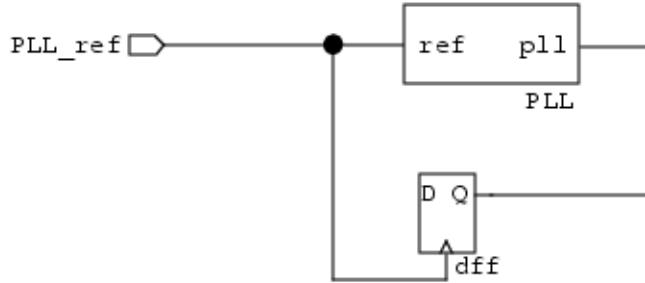

```
// Error: External event E on pulse-always clock at time T needs to have
// matching internal event in procedure P or clock be disconnected from
// internal sequential elements or observe points.
```

Where E is a combination of the event type command and the signal in question. For example, if MyClock was the pulse-always clock, E would be “pulse MyClock”. T is the time at which the conflict occurs, and P is the name of the procedure that contains the unmatched external event.

A PLL clock connected to a sequential cell can also produce a W38 violation. Figure 7-61 shows the type of circuit that would cause a W38 error if there is no matching internal event. For this example, assume that the clock is defined with the following command:

```
> add_clocks 0 PLL_ref -pulse_always
```

Figure 7-61. W38 Reference Circuit

How to Correct W38 Violations

You can correct a W30 violation by either adding a matching internal event for every external mode event, or adding a cut point to disconnect the clock from sequential elements and observe points.

This rule defaults to error handling. If you set the rule to warning handling, the tool attempts to auto-correct the W38 problem by copying external mode event(s) to the appropriate time in the internal mode. If the auto-correct fails (for example, a W35 violation in the internal mode), then the W38 rule's handling is changed to an error by the tool.

W39

Contexts Supported: All contexts

Default Handling: Error

report_drc_rules: Supported

This rule ensures that all test clocks (TCKs) defined in ICL have consistent timing.

When you have an elaborated ICL, regardless of context, W39 is checked during system mode transition, after the read_procfile command. This ensures that the waveforms of all TCK ports, in each timeplate, adhere to these conditions:

- All TCK ports must have the same off state.
- The TCK ports cannot have more than one pulse.
- The waveforms of all TCK ports must either have one pulse or no pulse.

If there is no specific timing for the clock, the tool uses the pulse_clock timing. By default, the W39 DRC triggers an error, but may be set to trigger a warning.

W39 can report three error conditions. The error messages are:

```
// Error: The waveform of TCK port C has multiple pulses. TCK waveform  
cannot have more than one pulse. (W39-1)
```

Where C is the TCK port name.

```
// Error: Inconsistent TCK timings between the 2 TCK ports: C1 and C2.  
All TCK portss must have the same off state. (W39-1)
```

Where C1 and C2 are the TCK port names.

```
// Error: Inconsistent TCK timings between the 2 TCK ports: C1 and C2.  
The waveforms of all TCK ports must either have one pulse or no pulse at  
all. (W39-1)
```

Where C1 and C2 are the TCK port names.

W41

Contexts Supported: All contexts

Default Handling: Error

report_drc_rules: supported

Flags the improper use of timeplates that pulse frequency divided clocks within capture procedures.

The W41 rule check defaults to an error, but its handling can be changed to warning, note, or ignore. The message has the following format:

```
// The following occurred at line 53 in file  
// ..../data/design_with_chains_modified_error.testproc:  
// Error: Event 'pulse user_added_clk_1' at time 100 conflicts with  
// frequency divided clock in procedure my_ncp_proc. (W41-1)
```

Other DRC Messages

DRC generates various messages to indicate the status of various processes and state elements.

Some of them are discussed here.

Transparent Capture Handling Analysis	3052
Oscillation Limitation	3053
RAM Summary Results and Test Capability	3053

Transparent Capture Handling Analysis

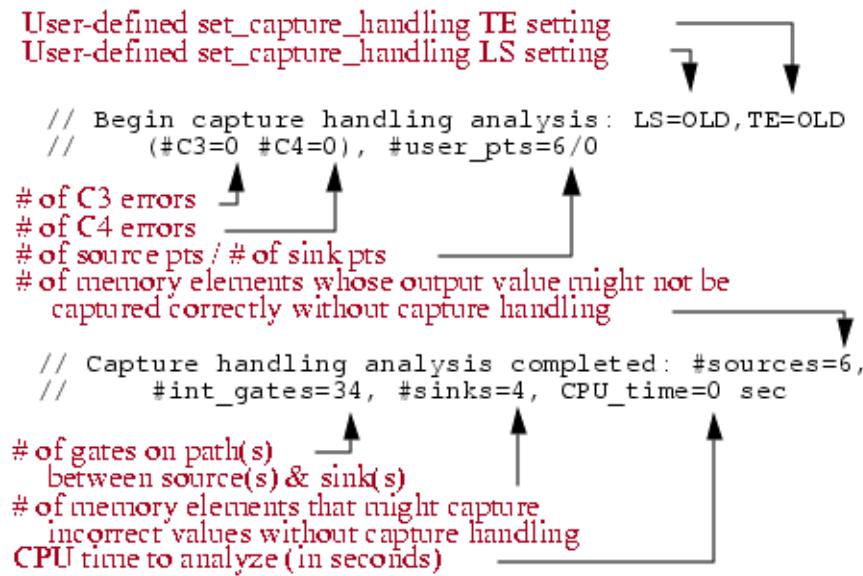

If you issue the set_capture_handling command before running DRC, an analysis message displays upon completion of DRC.

Example

```
// Begin capture handling analysis: LS=OLD, TE=OLD
//      (#C3=0 #C4=0), #user_pts=6/0
// Capture handling analysis completed: #sources=6,
//      #int_gates=34, #sinks=4, CPU_time=0 sec
```

Figure 7-62 describes each component of the messages.

Figure 7-62. Transparent Capture Handling Analysis Messages

Oscillation Limitation

The DRC simulator limits the maximum number of iterations performed to 500 while stabilizing state changes. If state elements continue to change after the maximum number of iterations is reached, the tool displays a message warning that the limit was reached. Additionally, the message reports each state element set to X to limit the iterations. State elements include latches, flip-flops, and feedback buffers.

The warning message is:

```
S forced to X in procedure P at time T due to iteration limit.
```

Where S is the state element, P is the procedure type, and T is the time.

Example

```
// latch1/Q (151) forced to X in procedure load_unload at
//      time 25 due to iteration limit.
```

RAM Summary Results and Test Capability

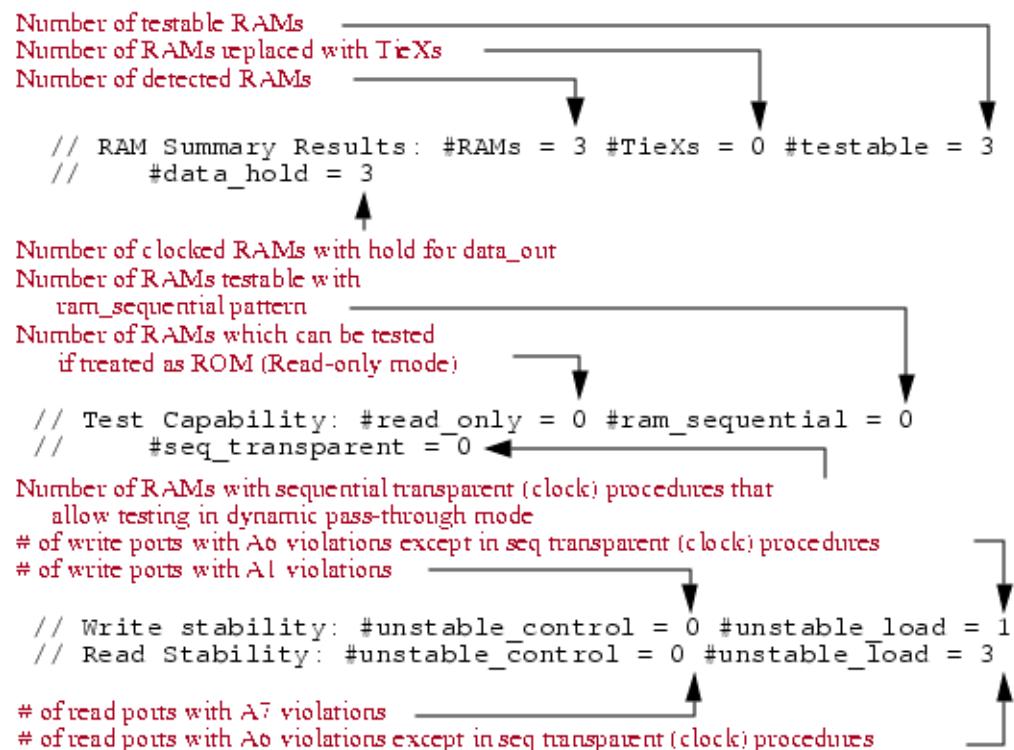

Upon completion of RAM rules checking, DRC displays summary result information as well as test capability information.

Example

```
// RAM Summary Results: #RAMs = 3 #TieXs = 0 #testable = 3
//      #data_hold = 3
// Test Capability: #read_only = 0 #ram_sequential = 0
//      #seq_transparent = 0
// Write stability: #unstable_control = 0 #unstable_load = 1
// Read stability:  #unstable_control = 0 #unstable_load = 3
```

Figure 7-63 describes the information displayed after running RAM rules checking.

Figure 7-63. RAM Summary Results and Test Capability Messages

Chapter 8

Data Models

Tessent Shell has an internal database that is organized into data models which are broad categories of design information (such as hierarchical design data). Each of the data models contains one or more types of design objects (such as pins and modules), and each design object has a list of attributes (such as an ID or bit-width of a bus).

For additional information about the design data models and how to work with them, refer to “[Design Data Model, Attributes, and Introspection](#)” in the *Tessent Shell User’s Manual*.

You can access the pre-defined attributes on those design objects using the *_attribute* tool commands listed in [Table 9-1](#) on page 3159. Those commands also provide a way for you to register new user-defined attributes for those design objects in the database.

The following sections describe the various data models, the types of objects they can contain, and the attributes associated to the objects:

Hierarchical Design Data Model	3056
Module	3058
Instance	3069
Port	3080
Pin	3094
Net	3099
Pseudo_port	3104
Flat Design Data Model.....	3107
Flat Design Object Types	3108
ICL Data Model.....	3118
ICL Object Types	3119
Scan Data Model	3144
Scan Element Object Type	3144
Scan Chain Family Object Type	3150
Scan Mode Object Type	3151
Test Point Data Model.....	3151
Configuration Data Model	3153
config_csv_wrapper	3153
config_data_wrapper	3154
config_property	3155
config_repeatable_property	3155
config_wrapper	3156

Hierarchical Design Data Model

The hierarchical design data model contains six different object types: module, instance, port, pin, net, and pseudo_port.

As suggested by [Figure 8-1](#), instances, pins, and nets are hierarchical objects that exist relative to the current design. Ports and modules, shown in [Figure 8-2](#), are non-hierarchical objects.

The figures also show the attributes that can be associated with the design objects.

The *current design* is the design specified by the set_current_design command.

Figure 8-1. Tessent Shell Hierarchical Design Objects

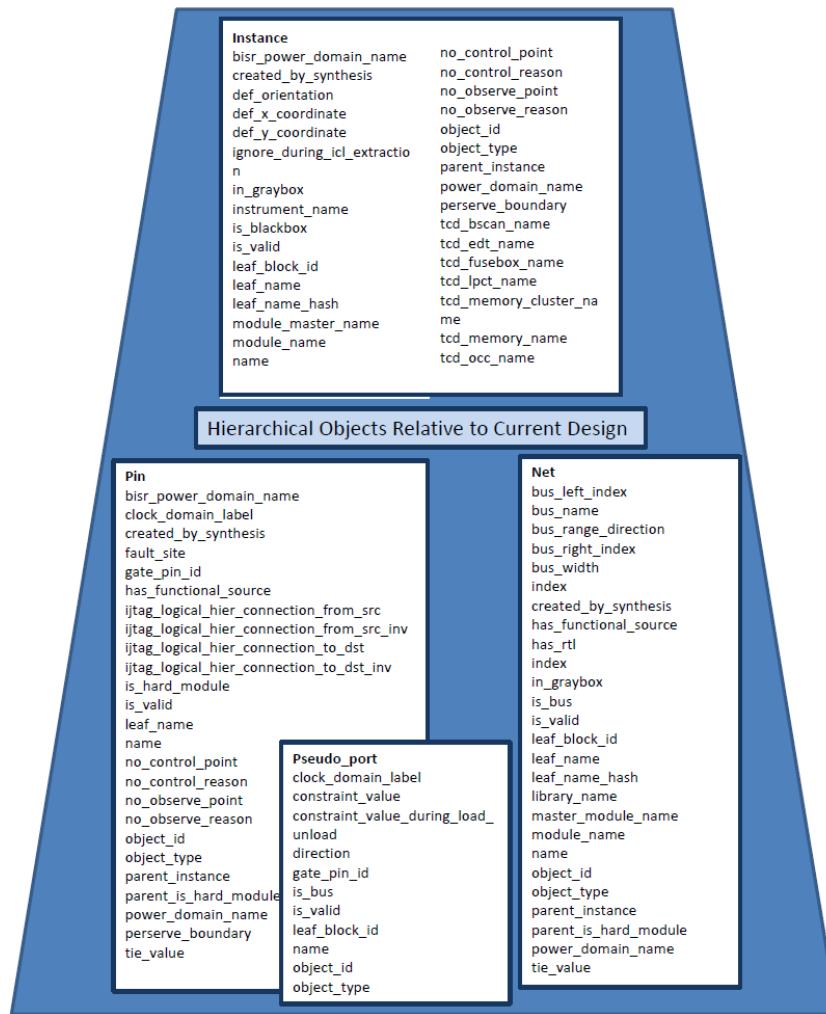

Figure 8-2. Tessent Shell Non-Hierarchical Design Objects

The six hierarchical design object types are described on the following reference pages:

[Module](#), [Instance](#), [Port](#), [Pin](#), [Net](#), and [Pseudo_port](#).

Reference information about attributes is provided in section “[Attributes](#)” on page 3159.

Module	3058
Instance	3069
Port	3080
Pin	3094

Net	3099
Pseudo_port	3104

Module

A module definition can come from a Verilog module, a VHDL entity, a Tessent library model, or it can be a built-in primitive. A module has a simple non-hierarchical name.

The module object type interacts with attributes as follows:

- Attributes are automatically visible as read-only attributes on instances if the same attribute is not also registered on the instance object type. Such attributes remain stored on the module definition and not on the instance itself
- Attributes with the `applies_to_child_instances` option set to On are visible to all child instances below the module.

Built-In Attributes

The module object type has the following attributes:

active_child_scan_mode	<p>When a child core exposes scan chain segments from several scan modes, this attribute makes the existing segments from a specific child scan mode active. During DRC, these active segments are the ones that get traced if tracing is enabled.</p> <p>Scan segments of the “active” child scan mode get the “state” attribute “usable”, while segments from other child scan modes are attributed with the “state” “unusable_child_mode”.</p> <p>Accordingly, during analysis, when creating scan chain families and/or adding scan modes, this attribute is also used to control their populations. If the tool cannot uniquely resolve the active scan mode for an instance by using the rules below, then the “state” attribute is set to “unresolved_child_mode”.</p> <p>The tool determines the effective “active_child_scan_mode” attribute for scan segments of a multi-mode instance using the following rule sequence:</p> <ol style="list-style-type: none">1. The mode corresponding to the “active_child_scan_mode” if it is set for the instance and matches one of its child modes.2. The mode of type “external” if “active_child_scan_mode” is not set for the instance and a unique child mode of type “external” exists.3. The mode of type “unwrapped” if “active_child_scan_mode” is not set for the instance and a unique child mode of type “unwrapped” exists.
------------------------	---

cell_type	String that reports characteristics of the cell. This attribute is initially null and is populated by the set_current_design command with information extracted from the cell library files. For example, any cell described as a pad in the library will have cell_type set to “pad”. If your cell library includes the scan mapping information, the non-scan flip-flop will be identified with a nonscan_dff type and the scan equivalent flip-flops will have mux_scan_dff type. See the read_cell_library command description for information on how the cell_type information can be loaded. Note that the LogicVision scang.lib, pad.lib and cell.lib format are natively supported by the read_cell_library command if your cell library file only includes the ATPG cell modeling information. <i>Tessent Cell Library Manual</i> .
def_x_coordinate_list	For the top module of the current design, this attribute is a list of all the x coordinates from a specified def file when you execute the read_def command.
def_y_coordinate_list	For the top module of the current design, this attribute is a list of all the corresponding y coordinates of the die from a specified def file when you execute the read_def command.
def_xl_coordinate	For the top module of the current design, the lower left x coordinate from a specified def file when you execute the read_def command. For other modules, the lower left x coordinate from a specified LEF file when you execute the read_lef command.
def_yl_coordinate	For the top module of the current design, the lower left y coordinate from a specified def file when you execute the read_def command. For other modules, the lower left y coordinate from a specified LEF file when you execute the read_lef command.
def_xh_coordinate	For the top module of the current design, the upper right x coordinate from a specified def file when you execute the read_def command. For other modules, the upper right x coordinate from a specified LEF file when you execute the read_lef command.
def_yh_coordinate	For the top module of the current design, the upper right y coordinate from a specified def file when you execute the read_def command. For other modules, the upper right y coordinate from a specified LEF file when you execute the read_lef command.
design_id	A string attribute that is set to reflect its design_id. It is set by read_design when reading a design. It also gets set after elaboration on the current design to the value returned by get_context -design_id when the value is not null.

design_level	A string attribute that is set to reflect its design_level. It is set by read_design when reading a design. It also gets set on the current design when the set_design_level command is run. The value is set to one of the following: <ul style="list-style-type: none">• chip• physical_block• sub_block
exclude_from_concatenated_netlist	Boolean that specifies that the given module is a hard macro and should not be included in the concatenated netlist.
exclude_from_synthesis	Boolean that specifies that the given module is excluded from any synthesis. During ICL extraction and other tasks, the combinational path between the IJTAG port of the modules having a corresponding ICL module is traced and any module encountered along the way is synthesized. The pre-tracing step that does the synthesis performs a structural tracing of the input or output cone of a port. In the opposite case, following the flat model tracing only follows the controllable paths. Therefore in some cases the synthesis on the modules is not required and may take a long time, for example, for large memories that were not defined as memories. The exclude_from_synthesis attribute can be used to shorten the pre tracing time in that case.
file_path_name	String that specifies the pathname to the file where a given module is defined. This attribute is null for created modules or modules without a definition.
format	Contains the value of the -format option as it was specified by the read_verilog or read_vhdl command when the module was read in. This value is only defined for modules with the “language” attribute set to “verilog” or “vhdl”; if the language attribute is set to “tessent_lib”, an empty string is returned. See the “language” attribute for more information. For no_rtl and created modules, “2001” is the value for “verilog”.
has_async_set_reset	Boolean that is true when a module has an asynchronous set port (port with active_high_set or active_low_set pin function) and/or an asynchronous reset port (port with active_high_reset or active_low_reset pin function).
has_def	Boolean that indicates whether or not the DEF file of the module was read in.
has_no_definition	Boolean that is true when a module does not have a definition, but a blackbox model was created during elaboration from its instantiation. You cannot have this type of module before creating the flat module unless you identify the module as a blackbox using the add_black_boxes command.

ijtag_is_icl_module	Boolean that identifies a design module as an ICL module. This attribute is only set in the patterns -ijtag context.
instrument_name	String that is set to the ICL module name it matches when its ijtag_is_icl_module attribute is true. The default is null.
is_blackbox	Boolean that returns true if the module was blackboxed in one of the following manners: <ul style="list-style-type: none">• The add_black_boxes -module command was issued on the module• The add_black_boxes -auto switch is used• The module was read using read_verilog -interface_only or read_vhdl -interface_only A false value is returned otherwise.
is_created	Boolean that specifies whether the module was created using the create_module command in insertion mode. In -rtl mode, this attribute is set as soon as the module is created and remains set until the insertion state is left. In -no_rtl mode, this attribute is set once when the module is created and never reset.
is_elaborated	Boolean that specifies whether the module is part of an elaborated design. When set to true, the module is part of the elaborated design, that is, it is either the current design module or there is at least one instance of this module.
is_graybox	Boolean that is set to true for the top module loaded with read_design -view graybox. When reading a graybox module of a child physical block, the exclude_from_concatenated_netlist attribute is set on the module such that if you call the write_design command, the child physical graybox netlist is not concatenated within the parent physical netlist. When using the write_design -graybox command, elements that the tool finds within the child physical graybox may need to be preserved in the parent physical region's graybox. This typically happens when a clock is sourced from a PLL found inside the child physical region. The is_graybox attribute set on that module is used by the write_design -graybox command to ignore the exclude_from_concatenated_netlist attribute for that module.

is_hard_module	<p>Boolean that specifies the module cannot be edited when set to true. This attribute is automatically set to true for all modules with type = “cell” or “primitive”. This attribute is set for design modules in the dofile using the following command:</p> <pre>set_attribute_value -name is_hard_module.</pre> <p>This property has applies_to_child_instances set to On by default. The setting of this attribute also has an effect on the is_non_editable instance attribute.</p>
is_incomplete	<p>Boolean that specifies that the module cannot be edited and/or written out when set to true. This attribute is set to true when the module was read with the read_verilog or read_vhdl -interface_only commands, or when the module includes RTL constructs that are not supported by the set_context -no_rtl option. The is_hard_module attribute automatically returns true for any module with the is_incomplete attribute set to true. To write out a module with only its port and parameter definition, read it in normally and write it back out using the write_design -interface option.</p>
is_internal_scan_only	Boolean that specifies that the module is internal scan only.
is_internal_scan_only_reason	<p>String that specifies the reason the instance is internal scan only as follows:</p> <ul style="list-style-type: none"> • imported_from_tcd_scan — The object was inferred to be internal scan only because it has a Core/ScanTCD description and the property internal_scan_only is equal to 1. • user_specified — The instance is internal scan only because the specified_internal_scan attribute was set to true on this instance or the instance inherited the true value from an instance in its ancestry. <p>The values are reported only when is_internal_scan_only is true.</p>
is_modified	<p>Boolean that specifies that a module read in from a file was edited during the insertion mode.</p> <p>In -rtl mode, this attribute is set as soon as the module is modified and remains set until the insertion state is left.</p> <p>In -no_rtl mode, the attribute is set once when the module is edited and never reset.</p> <p>See the get_modules command description for usage examples.</p>
is_non_scannable	Boolean that specifies that the module is non-scannable.

is_physical_module	Boolean that specifies that the module is a physical block. It gets set during design elaboration if the module is found in an open TSDB and its level was defined as chip or physical_block when its TSDB was created.
is_power_always_on_cell	Boolean that is set to true when the module is specified as an always_on cell when power data is read using the read_upf or read_cpf commands. By default, this attribute is false.
is_power_isolation_cell	Boolean that is set to true when the module is specified as an isolation cell when power data is read using the read_upf or read_cpf commands. By default, this attribute is false.
is_power_level_shifter_cell	Boolean that is set to true when the module is specified as a level shifter cell when power data is read using the read_upf or read_cpf commands. By default, this attribute is false.
is_power_retention_cell	Boolean that is set to true when the module is specified as a retention cell when power data is read using the read_upf or read_cpf commands. By default, this attribute is false.
is_synthesized	Boolean that specifies that the given module was synthesized when going to analysis mode by the quick synthesis engine.
is_unsaved	Boolean that specifies that a module that was either modified or created within the insertion mode of the dft context was not yet written out. This attribute is set as soon as the module is modified or created and is reset as soon as the module is saved using the write_design command. See the get_modules command description for examples of its usage.
is_valid	Boolean that specifies whether the object still exists. This Boolean attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
language	String that specifies the supported library language. Set to “tessent_lib” for Tessent library models. Set to “verilog” for Verilog modules and Verilog primitives. Set to “vhdl” for VHDL entities.
library_name	String that specifies the logic name of the library containing the module definition. All commands that accept a module name look for the module in the default library as specified by the set_logical_design_libraries command. You can use the get_modules command to access modules from different libraries. Libraries are only supported in -rtl sub-contexts. In -no_rtl contexts, one library exists and it is named “work”.
line_number	Integer that specifies a line number in the file where a given module is defined. This number is 0 for created modules and for modules without a definition.

master_name	String that specifies the real name of the module as it was defined independently of the parameterized view.
master_object_id	An attribute that returns the object_id of the master module associated with this parameterized module. If this module is not a parameterized view, it returns the object_id of this module.
name	<p>String that specifies the name of the module. Modules are defined from the following sources:</p> <ul style="list-style-type: none">• read_verilog files• read_vhdl files• create_design and copy_design commands• read_cell_library files• primitives have built-in names <p>For parameterized modules, a unique name is created for each parameterized view by appending to the master_name the string @PV# where # is an integer starting from 1 and incremented for each parameterized view. Use the get_module_parameter_list and get_module_parameter_value commands to introspect the parameter values.</p>
no_control_point	An attribute that specifies that no control point can be inserted on any pin, port or instance in the specified module when the attribute value is set to true. Possible values are true, false and unspecified. The default value is unspecified which means that control points will be allowed unless the attribute is set to false in one of its parent modules or instances.

no_control_reason	<p>String that specifies why no control point can be inserted at the specified location. The possible values fall in two categories, tool identified and user specified.</p> <p>The no control point locations identified by the tools during analysis have the highest priority and you cannot overwrite or change them. These locations are deleted when you transition back to setup mode.</p> <p>The possible values for the tool identified locations are:</p> <ul style="list-style-type: none">• cell_internal - all the gate pins inside the library cells.• clock_cone - including set and reset line.• power-aware - input pins of power cells (isolation cell, level shifter)• scan_path - including sub_chain, shift_register and any logic between scan in and scan out.• tristate_enable - including tristate logic and bidirectional gates.• constant_value_during_capture - including all the gates that have constant value during capture. This can be determined either by the add_input_constraints command or test procedure. <p>The possible values for the user-specified locations are:</p> <ul style="list-style-type: none">• explicitly_specified - can be specified using the “add_nptest_point” command or “set_attribute_value” command for and no_observe_point attributes.• cross_clock_domain - can be specified using “set_test_point_analysis_option -exclude_cross_domain_paths” command.• xbounding - can be specified using “set_test_point_analysis_options -allow_in_xbounding_regions” command or “analyze_xbounding” command in dft –scan context.• multicycle_path - can be specified by reading SDC file .• false_path - can be specified by reading SDC file.• excluded_clock_domain - can be specified using “set_test_point_analysis_option -exclude_clock_domains” command.
no_observe_point	An attribute that specifies that no observe point can be inserted on any pin, port or instance in the specified module when the attribute value is set to true. Possible values are true, false and unspecified. The default value is unspecified which means that control points will be allowed unless the attribute is set to false in one of its parent modules or instances.

no.observe_reason	<p>String that specifies why no observe point can be inserted at the specified location. The possible values fall in two categories, tool identified and user specified.</p> <p>The no observe point locations identified by the tools during analysis have the highest priority and you cannot overwrite or change them. These locations are deleted when you transition back to setup mode.</p> <p>The possible values for the tool identified locations are:</p> <ul style="list-style-type: none"> • cell_internal — All the gate pins inside the library cells. • clock_cone — Including set and reset line. • power-aware — Output pins of power cells (isolation cell, level shifter) • scan_path — Including sub_chain, shift_register and any logic between scan in and scan out. • tristate_enable — Including tristate logic and bidirectional gates. • constant_value_during_capture — Including all the gates that have constant value during capture. This can be determined either by the add_input_constraints command or test procedure. <p>The possible values for the user-specified locations are:</p> <ul style="list-style-type: none"> • explicitly_specified — Can be specified using the “add_notest_point” command or “set_attribute_value” command for and no.observe_point attributes. • cross_clock_domain — Can be specified using “set_test_point_analysis_option -exclude_cross_domain_paths” command. • xbounding — Can be specified using “set_test_point_analysis_options -allow_in_xbounding_regions” command or “analyze_xbounding” command in dft –scan context. • multicycle_path — Can be specified by reading SDC file. • false_path — Can be specified by reading SDC file. • excluded_clock_domain — Can be specified using “set_test_point_analysis_option -exclude_clock_domains” command.
object_id	The object_id attribute is a unique id for the object that remains valid while the design is in memory. This attribute is useful to identify the object in a Tcl dictionary. The object_id is only valid within one tool invocation. Once you terminate the tool or delete the design, the object_id is no longer valid. The object_id has the form "module: <i>integer</i> "
object_type	Returns the object data type “module”.

power_domain_island	Returns the name of the power domain island associated to the current design. This attribute is null for all other modules. This attribute is populated when going from setup to analysis system mode if a UPF or CPF file has been read in. For a definition of Power Domain Island , refer to the <i>Tessent Glossary</i> .
power_domain_name	Returns the name of the power domain associated to the current design. This attribute is null for all other modules. This attribute is populated when going from setup to analysis system mode if a UPF or CPF file has been read in. For a definition of Power Domain , refer to the <i>Tessent Glossary</i> .
preserve_boundary	Boolean that specifies whether to preserve the boundary in the flat model. When set to true, all pins on all instances of the module will have an inferred buffer created in the flat model to preserve the separation of nets inside and outside the module. Any attribute stored on the hierarchical pin will be visible in the flat model. If you set this attribute on a pin of the design, the flat model will need to be reconstructed. The attribute is not lost during flattening.
simulation_function	String that specifies the function as learned by simulation. Refer to “ Model-Level Attribute Descriptions ” in the <i>Tessent Cell Library Manual</i> for complete information.
specified_internal_scan_only	An attribute used to specify that the instance of the module are to be forced to remain internal during wrapper analysis. Dedicated isolation wrapper cells will be inferred to isolate the input and output pins of the instances if any interacts with the primary input and output ports.
sync_cell_length	For posedge and negedge synchronizer cells, this attribute is an integer that specifies the number of DFFs in the cell. For all other cell types, this attribute is an empty string.

synthesize_before_analysis	<p>Boolean that specifies that the given module is to be synthesized when going to analysis mode.</p> <p>During ICL extraction, the combinational path between the IJTAG port of the modules having a corresponding ICL module is traced and any module encountered along the way is synthesized. If you use a test_setup procedure during ICL extraction, you must set this attribute on all RTL modules which must be synthesized in order for the test setup simulation to propagate its value to the entire ICL network as the pretracer does not traverse sequential cells. The quick synthesis engine uses a cell library defined in the build tree at the given location “\$TESSENT_HOME/lnx-x86/lib64/hdleng/lib”. Both Tessent and Verilog cell library models are supplied, namely “dft_sim.atpg” and “dft_sim.v”. The tessent libraries are automatically loaded when synthesis is used.</p>
tcd_bscan_name	<p>A string attribute that gets set on every module for which there is a matched TCD BoundaryScan description (see “Tessent Core Description” on page 3755).</p> <p>See “set_design_sources -format tcd_bscan” and set_module_matching_options commands for more information about this matching process.</p>
tcd_fusebox_name	<p>A string attribute that gets set on every module for which there is a matched TCD FuseBoxInterface description (see “Tessent Core Description” on page 3755).</p> <p>See “set_design_sources -format tcd_memory” and set_module_matching_options commands for more information about this matching process.</p>
tcd_memory_cluster_name	<p>A string attribute that gets set on every module for which there is a matched TCD MemoryCluster description (see “Tessent Core Description” on page 3755).</p> <p>See “set_design_sources -format tcd_memory_cluster” and set_module_matching_options commands for more information about this matching process.</p>
tcd_memory_name	<p>A string attribute that gets set on every module for which there is a matched TCD Memory description (see “Tessent Core Description” on page 3755). This attribute is also set on memory modules that are <i>inside</i> another memory.</p> <p>See “set_design_sources -format tcd_memory” and set_module_matching_options commands for more information about this matching process.</p>

type	<p>Set to “cell” for the following modules:</p> <ul style="list-style-type: none"> • Models read in with <code>read_cell_library</code>. • Verilog modules surrounded by the <code>`celldefine</code>/ <code>`endcelldefine</code> directives and read in with <code>read_verilog</code>. <p>Set to “primitive” for the following modules:</p> <ul style="list-style-type: none"> • Verilog primitives used in the design. <p>Set to “design” for all other modules.</p>
vhdl_architecture	<p>String that reports the architecture of vhdl modules. It is null for modules of other languages. All commands that accept a module name return the vhdl entity associated with the default architecture which is the last compiled version. Use get_modules to access modules with the non default architecture.</p>

Inheritance

Built-in inherited attributes:

- None

User-defined attributes are inherited. See “[Attribute Inheritance Behavior](#)” on page 3170.

Module Specification

A module object (`module_object`) is specified by a module name which is a string. For example: “modA”.

Instance

An instance is a single instantiation of a module. No instance object exists until the `set_current_design` command is executed.

The instance object type interacts with attributes as follows:

- **Module** attributes are automatically visible as read-only attributes on corresponding instances if the instance object type does not have the same attribute registered.
- Attributes defined with the `applies_to_child_instances` option set to On automatically become visible to all child instances of the instance object.

Built-In Attributes

active_child_scan_mode	<p>When a child core exposes scan chain segments from several scan modes, this attribute makes the existing segments from a specific child scan mode active. During DRC, these active segments are the ones that get traced if tracing is enabled.</p> <p>Scan segments of the “active” child scan mode get the “state” attribute “usable”, while segments from other child scan modes are attributed with the “state” “unusable_child_mode”. Accordingly, during analysis, when creating scan chain families and/or adding scan modes, this attribute is also used to control their populations. If the tool cannot uniquely resolve the active scan mode for an instance by using the rules below, then the “state” attribute is set to “unresolved_child_mode”.</p> <p>The tool determines the effective “active_child_scan_mode” attribute for scan segments of a multi-mode instance using the following rule sequence:</p> <ol style="list-style-type: none">1. The mode corresponding to the “active_child_scan_mode” if it is set for the instance and matches one of its child modes.2. The mode of type “external” if “active_child_scan_mode” is not set for the instance and a unique child mode of type “external” exists.3. The mode of type “unwrapped” if “active_child_scan_mode” is not set for the instance and a unique child mode of type “unwrapped” exists.
bisr_power_domain_name	An attribute that can be set on memory instance to associate a BISR power domain name to a memory. You typically do not need to use this attribute when you read in a UPF or CPF file as the <code>power_domain_name</code> attribute will be used to infer the power domain of the memories. You use the <code>bisr_power_domain_name</code> attribute if you want to have more BISR power than those described in the UPF/CPF file. You use this attribute on Pins to map specific BISR chains on subblock to power domain at the current level as documented in the <code>bisr_segment_order_file</code> section.

created_by_synthesis	Boolean that indicates that the instance was created by quick synthesis. When an instance has this attribute set to true, it does not exist in the original RTL and cannot be used for design edits. See the set_quick_synthesis_options command.
def_orientation	Contains the DEF orientation of the flip-flop, memory, or sub-physical region extracted by the read_def command. The attribute can have the following values: N, S, E, W, FN, FS, FW, FN.
def_x_coordinate	The x coordinate of an instance extracted from a specified def file when you execute the read_def command.
def_y_coordinate	The y coordinate of an instance extracted from a specified def file when you execute the read_def command.
ignore_during_icl_extraction	When set to true, even if the instance has an associated ICL module during ICL extraction, the instance is ignored and not reported in the extracted ICL. This attribute is useful to allow extracting the ICL for the portion of the network that is correct while other instances still have issues to resolve. The generated ICL module will have the <code>tessent_ignored_design_instances</code> attribute defined referencing all design instances that were ignored.
in_graybox	Set to true when the instance is included in the graybox netlist. Set to false when the instance is excluded from the graybox netlist, which is the default for all the instances in the design. You can change the attribute value with the analyze_graybox or set_attribute_value command. For more information about this attribute, refer to the analyze_graybox command description.
instrument_name	A string attribute that is set on instances of modules for which there is a matched TCD instruments description. If a TCD instruments instance is instantiated below another TCD instruments instance, the attribute is only set on the higher instance. See set_design_sources -format icl and set_module_matching_options commands for more information about this matching process.
is_blackbox	Boolean that specifies that the instance was black boxed with add_black_boxes -instance or that the module of the instance was black boxed as described for the <code>is_blackbox</code> attribute of the module object type. The default is false.
is_internal_scan_only	Boolean that specifies that the instance is internal scan only.

is_internal_scan_only_reason	<p>String that specifies the reason the instance is internal scan only as follows:</p> <ul style="list-style-type: none"> • imported_from_tcd_scan — The object was inferred to be internal scan only because it has a Core/Scan TCD description and the property internal_scan_only is equal to 1. • user_specified — The instance is internal scan only because the specified_internal_scan attribute is set to true on this instance or the instance inherited the true value from an instance in its ancestry. • user_specified_from_net — The instance is internal scan only because the specified_internal_scan attribute was set on a net which happens to be an RTL register. The instances happen to be the flop-flop instance that the tool created during quick synthesis for that RTL register. <p>The values are reported only when is_internal_scan_only is true.</p>
is_non_editable	Boolean that specifies that the instance is non-editable.
is_non_editable_reason	<p>A string that specifies why the instance is non-editable as follows:</p> <ul style="list-style-type: none"> • below_hard_module — The instance is below an instance which has is_hard_module equal to 1 • hard_module — The instance has is_hard_module equal to 1 • created_by_quick_synthesis — The instance was created by quick synthesis • matched_icl_module — The module of the instance has a matched ICL module • below_matched_icl_module — The instance is below a module that has a matched ICL module
is_non_scannable	Boolean that specifies that the instance is non-scannable.

is_non_scannable_reason	A string that specifies why the instance is non-scannable as follows: <ul style="list-style-type: none">• inferred_from_drc — The object was inferred to be non-scannable during DRC either because it had an S-rule violation or it is part of a hard_module yet excluded from the traced scan chains.• imported_from_tcd_scan — The object was inferred to be non-scannable because it has a Core/Scan TCD description and the property drc_from_boundary_only is equal to 1.• imported_from_icl — The instance was inferred to be non-scannable because it has a matched ICL description and the attribute keep_active_during_scan_test is not specified as false.• imported_from_bscan — The instance was inferred to be non-scannable because it is part of the boundary scan chain.• missing_scan_model — The instance was inferred to be non-scannable because it does not have a scan flop equivalent mapping. This is only happening in dft –scan context.• user_specified — The instance was specified to be non-scannable using the add_nonscan_instances command.• user_specified_from_net — The instance is non scannable because the add_nonscan_instances -rtl_reg command was used on a net which happens to be an RTL register. The instances happens to be the flop-flop instance that the tool created during quick synthesis for that RTL register. If is_non_scannable is false, then is_nonscannable_reason returns an empty string.
is_power_always_on_cell	Boolean that is set to true when the instance is specified as an always_on cell when power data is read using the read_upf or read_cpf commands. By default, this attribute is false.
is_power_isolation_cell	Boolean that is set to true when the instance is specified as an isolation cell when power data is read using the read_upf or read_cpf commands. By default, this attribute is false.
is_power_level_shifter_cell	Boolean that is set to true when the instance is specified as a level shifter cell when power data is read using the read_upf or read_cpf commands. By default, this attribute is false.
is_power_retention_cell	Boolean that is set to true when the instance is specified as a retention cell when power data is read using the read_upf or read_cpf commands. By default, this attribute is false.
is_valid	Boolean that specifies whether the object still exists. This Boolean attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.

leaf_block_id	The leaf_name of instances located inside generate blocks have the generate block ids joined by periods prepended to their instantiation name. This attribute returns the block_id part of the leaf_name. It is null for instances that are not inside generate blocks.
leaf_name	String that specifies the name of the instance (value of the name attribute) without the hierarchical path. After leaving insertion mode in the tool, this attribute will show the value of the unrolled_leaf_name attribute.
leaf_name_hash	This attribute is normally identical to the leaf_name attribute except when the leaf instance is located inside a generate loop construct inside an RTL file. The leaf_name includes the block id with the loop index such as in loopA[4].u2. The leaf_name_hash attribute is the same except that the loop index is replaced by a hash sign as shown here: loopA[#].u2. You use this attribute if you are editing the content of generate loops and you have not enabled auto uniquification. For the delete_connections and move_connections commands, you must use a lookup table with <i>parent_module.leaf_name_hash.pin_leaf_name</i> entries to know if you have already processed that pin. See the examples in the move_connections and get_dft_cell command descriptions for examples of such usage. Note that the value of this attribute always refer to the pre_synthesis_name just like the pre_synthesis_leaf_name attribute.
master_module_name	String that specifies the value of the master_name on the module object associated with the instance.
module_name	String that specifies the value of the name of the module object associated with the instance.
name	String that specifies the hierarchical name of the instance relative to the current design. The name of every instance is unique. After leaving insertion mode in the tool, this attribute will show the value of the unrolled_name attribute.
no_control_point	An attribute that specifies that no control point can be inserted on any pin or instance in the specified instance when the attribute value is set to true. Possible values are true, false and unspecified. The default value is unspecified which means that control points will be allowed unless the attribute is set to false in one of its parent instances.

no_control_reason	<p>String that specifies why no control point can be inserted at the specified location. The possible values fall in two categories, tool identified and user specified.</p> <p>The no control point locations identified by the tools during analysis have the highest priority and you cannot overwrite or change them. These locations are deleted when you transition back to setup mode.</p> <p>For possible values for the tool identified locations and the user-specified locations, refer to no_control_reason in the Module attribute section.</p>
no_observe_point	<p>An attribute that specifies that no observe point can be inserted on any pin or instance in the specified instance when the attribute value is set to true. Possible values are true, false and unspecified. The default value is unspecified which means that control points will be allowed unless the attribute is set to false in one of its parent instances.</p>
no_observe_reason	<p>String that specifies why no observe point can be inserted at the specified location. The possible values fall in two categories, tool identified and user specified.</p> <p>The no observe point locations identified by the tools during analysis have the highest priority and you cannot overwrite or change them. These locations are deleted when you transition back to setup mode.</p> <p>For possible values for the tool identified locations and the user-specified locations, refer to no_observe_reason in the Module attribute section.</p>
object_id	<p>The object_id attribute is a unique id for the object that remains valid while the design is in memory. This attribute is useful to identify the object in a Tcl dictionary. The object_id is only valid within one tool invocation. Once you terminate the tool or delete the design, the object_id is no longer valid. The object_id has the form "instance: <i>integer</i>"</p>
object_type	Returns the object data type "instance".
parent_instance	String that specifies the instance name in which the instance exists. This attribute automatically handles the escaped identifier and returns the instance path of the instance without the /<leaf_name> part of the path.
power_domain_island	Returns the name of the power domain island associated to the instance. This attribute is populated when going from setup to analysis system mode if a UPF or CPF file has been read in. For a definition of Power Domain Island , refer to the Tessent Glossary .

power_domain_name	Returns the name of the power domain associated to the instance. This attribute is populated when going from setup to analysis system mode if a UPF or CPF file has been read in. For a definition of Power Domain , refer to the <i>Tessent Glossary</i> .
pre_synthesis_leaf_name	String that specifies the original RTL leaf name of the object even when the quick synthesis view of the design is currently in memory. When the quick synthesis view of the design is not in memory, then the value of this attribute equals the value of the leaf_name attribute. If the object is created by the synthesis (created_by_synthesis attribute is true which means the object did not exist before the synthesis), then the string is empty. The pre_synthesis_leaf_name will only ever be different from the leaf_name when the instance is inside a generate block that the tool synthesized during quick synthesis.
pre_synthesis_leaf_block_id	String that shows which generated block instantiation is the current focus of the tool. This attribute is used to detect and compute instances that are from generated blocks.
pre_synthesis_leaf_name_hash	String that shows where the parameter of the generated block is located. This attribute is used to detect and compute instances that are from generated blocks.
pre_synthesis_name	String that specifies the original RTL name of the object even when the quick synthesis view of the design is currently in memory. When the quick synthesis view of the design is not in memory, then the value of this attribute equals the value of the name attribute. If the object is created by the synthesis (created_by_synthesis attribute is true which means the object did not exist before the synthesis), then the string is empty. The pre_synthesis_name will only ever be different from the name when the instance has one or more generate block in its ancestry that the tool synthesized during quick synthesis
preserve_boundary	Boolean that specifies whether to preserve the boundary in the flat model. When set to true, all pins on the instance will have an inferred buffer created in the flat model to preserve the separation of nets inside and outside the instance. Any attribute stored on the hierarchical pin will be visible in the flat model. If you set this attribute on a pin of the design, the flat model will need to be reconstructed. The attribute is not lost during flattening.

specified_internal_scan_only	An attribute used to specify that the instance is to be forced to remain internal during wrapper analysis. Dedicated isolation wrapper cells will be inferred to isolate the input and output pins of the instances if any interacts with the primary input and output ports. When the attribute is not specified on an instance it inherits its value from its associated module when the attribute is specified on the module. If it is not specified on the module, it inherits its value from its parent instance.
specified_wrapper_type	An attribute that forces the wrapper type of a flop or clock gater instance. Available values are: off, input, output, and generic. The default is off. When set or left to default to off, the wrapper_type value of each flop and clock gater instance is computed by the analyze_wrapper_cells command. Special treatment is performed on instances of OCCs. See the inferred_from_clock_source value in the wrapper_type_reason attribute description below. When you set the specified_wrapper_type attribute to input, output, or generic, the specification is kept during the analysis. If you used the input value, the analyze_wrapper_cells command will automatically find all flip-flops fanning out from the instance you forced to input type and infer them as output wrapper type. The result of the analyze_wrapper_cells command, which combines the specified_wrapper_type values with the inferred values, are reflected in the wrapper_type and wrapper_type_reason attributes described below.
tcd_bscan_name	A string attribute that is set on instances of modules for which there is a matched TCD BoundaryScan description (see “ Tesson Core Description ” on page 3755). If a tcd BoundaryScan instance is instantiated below another tcd BoundaryScan instance, the attribute is only set on the higher instance. See set_design_sources -format tcd_bscan and set_module_matching_options commands for more information about this matching process.
tcd_edt_name	A string attribute that is set to the name of a core instance when the EDT instrument core instance is associated with a design instance. This ensures boundary preservation during flattening.
tcd_fusebox_name	A string attribute that is set on instances of modules for which there is a matched TCD FuseBoxInterface description (see “ Tesson Core Description ” on page 3755). If a tcd FuseBoxInterface instance is instantiated below another tcd FuseBoxInterface instance, the attribute is only set on the higher instance. See set_design_sources -format tcd_fusebox and set_module_matching_options commands for more information about this matching process.
tcd_lpct_name	A string attribute that is set to the name of a core instance when the LPCT core instance is associated with a design instance. This ensures boundary preservation during flattening.

tcd_memory_cluster_name	A string attribute that is set on instances of modules for which there is a matched TCD MemoryCluster description (see “ Tessent Core Description ” on page 3755). If a TCD Memory or MemoryCluster instance is instantiated below another TCD MemoryCluster instance, the attribute is only set on the higher instance. See set_design_sources -format tcd_memory_cluster and set_module_matching_options commands for more information about this matching process.
tcd_memory_name	A string attribute that is set on instances of modules for which there is a matched TCD Memory description (see “ Tessent Core Description ” on page 3755). If a TCD Memory instance is instantiated below another TCD Memory instance, the attribute is only set on the higher instance. See set_design_sources -format tcd_memory and set_module_matching_options commands for more information about this matching process.
tcd_occ_name	A string attribute that is set to the name of a core instance when the OCC core instance is associated with a design instance. This ensures boundary preservation during flattening.
unrolled_leaf_name	An attribute that indicates whether the tool performed loop unrolling. In insertion mode and if the tool unrolled loops, then this attribute will show the name the object will have when written with the write_design command. When there is no loop or the loop is not unrolled, this attribute is the same value as the leaf_name attribute.
unrolled_name	An attribute that indicates whether the tool performed loop unrolling. In insertion mode and if the tool unrolled loops, then this attribute will show the name the object will have when written with the write_design command. When there is no loop or the loop is not unrolled, this attribute is the same value as the name attribute.
wrapper_type	An attribute used to reflect the resulting wrapper type of flop and clock gater instances based on the specified_wrapper_type attribute value you set, special processing of the OCC modules, and the result of the analysis after the analyze_wrapper_cells command is issued. See the specified_wrapper_type attribute description above for more information. The instances of type input have their scan enable held on during the input test modes. The cells of type output have their scan enable held on during the output test modes. The cells of type generic do not have their scan enable held on during any mode type. The allowed values of this attribute are input, output, generic, or an empty string.

wrapper_type_reason	An attribute that describes why the wrapper has a given type. <ul style="list-style-type: none">• inferred_from_analysis — Indicates the type was inferred by the analyze_wrapper_cells command.• inferred_from_clock_source — Means the instance is an OCC, the fast_clock port of the OCC is not directly sourced by a PI (that is, a PLL or clock divider), and the OCC drives at least one flop of type input or output wrapper. The wrapper_type is always generic when wrapper_type_reason is inferred_from_clock_source.• user_specified — Indicates the specified_wrapper_type attribute was explicitly set on the flop or clock gater instances.
---------------------	---

Inheritance

Built-in attribute inheritance from associated module objects:

- cell_type
- has_no_definition
- ijtag_is_icl_module
- is_created
- is_hard_module
- is_incomplete
- is_modified
- is_synthesized
- is_unsaved
- language
- library_name
- preserve_boundary
- type
- vhdl_architecture

User-defined attributes are inherited. See “[Attribute Inheritance Behavior](#)” on page 3170.

Instance Specification

An instance object (instance_object) is specified by a complete hierarchical instance pathname. For example: “/u1/u2/u3”.

Port

A port is an object on a module and can have an input, output or inout direction. Ports have a simple non-hierarchical name.

One port object exists for each bit of a bussed port so every bit of a bussed port can be attributed independently.

The port object type interacts with attributes as follows:

- Attributes defined on ports are automatically visible as read-only attributes on the associated pin objects unless the attribute is also registered for the pin object type. This is the case for the name attribute which is defined for both port and pin object types. These attributes are stored on the associated port of the pins and not on the pin object itself.

Built-In Attributes

active_clock_edge	A string attribute that reflects the value of the gate_pin attribute having the same name when the gate_pin maps to a net object. See the description of the Gate_pin attribute description for the meaning of its value.
active_polarity	A string attribute that reflects the value of the gate_pin attribute having the same name when the gate_pin maps to a net object. See the description of the Gate_pin attribute description for the meaning of its value.
bisr_function	String that reflects the function of the design port for Tessent MemoryBIST's BISR. Legal values for this attribute are: Reset, MemoryDisable, Select.
bus_left_index	Integer that specifies the left index of the complete bus. Null for scalar ports.

bus_name	String that specifies the name of the bus without the index. $\langle \text{name} \rangle = \text{bus_name} [\text{index}]$ when <code>is_bus</code> is true; otherwise, <code>bus_name</code> is null.
bus_range_direction	String set to “up” or “down” that reflects the bus range direction. This attribute follows the <code>to</code> and <code>downto</code> <code>BIT_VECTOR</code> types in VHDL.
bus_right_index	Integer that specifies the right index of the complete bus. Null for scalar ports.
bus_width	Integer that specifies the number of bits independent of whether <code>left_index</code> is smaller, larger than, or equal to <code>right_index</code> .
clock_domain_inversion	A string attribute that specifies whether there is an inversion between the clock domain base and the node. When 1, then the inversion exists.
clock_domain_label	A string attribute that is populated when running the <code>DFT_C1</code> , <code>DFT_C2</code> , and <code>DFT_C3</code> DRC rules. It is attached to every port on which a clock was defined. The string contains the label associated to the clock defined on the port. It is also set by <code>DFT_C6</code> on every node between the clock and the sequential elements.
constraint_value	String that specifies that the port’s primary input was set to a constant with the <code>add_input_constraints</code> command. When set to <code>C0</code> , <code>CT0</code> , <code>Cl</code> , <code>CT1</code> , <code>CX</code> , or <code>Cz</code> , this attribute displays <code>0</code> , <code>0</code> , <code>1</code> , <code>1</code> , <code>x</code> , or <code>z</code> , respectively. The default is null.
constraint_value_during_load_unload	String that specifies a constant value for a top-level port during <code>load_unload</code> test procedure retargeting. Possible values are: <code>0</code> , <code>1</code> , <code>X</code> , or <code>Z</code> . Constraining the value of the top-level port enables tracing of signals from the core level to the chip level.
created_by_synthesis	Boolean that indicates that the port was created by synthesis. When a port has this attribute set to true, it does not exist in the original RTL and cannot be used for design edits. See the set_quick_synthesis_options command.
def_x_coordinate	The x coordinate of a top-level port extracted from a specified def file when you execute the <code>read_def</code> command.

def_y_coordinate	The y coordinate of a top-level port extracted from a specified def file when you execute the read_def command.
direction	String that specifies the direction of the port. Possible values are as follows: <ul style="list-style-type: none">• buffer (VHDL)• inout (Verilog and VHDL)• input (Verilog and VHDL)• linkage (VHDL)• output (Verilog and VHDL)
dynamic_dft_signal	A string attribute that is set on the node where a dynamic DFT signal is defined. The value of the attribute is the name of the dynamic DFT signal. This attribute has the <code>-display_in_gui</code> option set to on such that when the node is displayed in the GUI, a callout box is shown letting you know that it is the location of the dynamic DFT signal.

function	<p>String that either reports the function of the port on cell modules or reports the presence of the power or ground attributes on ports of the current_design. For a list of possible values, see “Function Attribute Values” on page 3090.</p> <p>For cell modules, this attribute is initially null and is set by the set_current_design command from information extracted from the cell library files. For information about how cell_type information can be loaded, refer to the read_cell_library command. Note that the LogicVision scang.lib, pad.lib and cell.lib format are natively supported by the read_cell_library command in case your cell library file only includes the ATPG cell modeling information. See the table in the Pin Attributes section of the <i>Tessent Cell Library Manual</i> for a complete list of available function values.</p> <p>For a top-level module, this attribute is initially null and you can set one of the following values on an input/inout port with the set_attribute_value command:</p> <ul style="list-style-type: none">• power — Constrains power input/inout ports during circuit setup and DRC.• ground — Constrains ground input/inout ports during circuit setup and DRC. <p>For more information about using these values, refer to “Power and Ground Ports Exclusion from the Pattern Set” in the <i>Tessent Scan and ATPG User’s Manual</i>.</p>
gate_pin_id	Returns the id of a gate_pin when the pin has an associated gate_pin inside the flat model. Exists for cell pins associated to fault sites and for hierarchical pins that have an attribute that is set to a non-default value and whose -preserve_boundary_in_flat_model option is set to true.
has_functional_source	Returns true unless the port is of direction output and the port net is undriven or tied.

ignore_during_icl_extraction	Ports of the current design with this attribute set to true are ignored during ICL extraction. This is useful, for example, if an ICL instance has connections to primary ports as well as to other ICL instances, but the ICL shall contain only the connections between the instances. This attribute does not have any effect on ports of other modules besides the current design.
ignore_for_graybox	Set to true when an output port is to be excluded from graybox analysis. By default, this attribute is set to false for all output ports (considered by the graybox analysis backtracing). Setting this attribute on an input port has no effect on the analyze_graybox command. You need to exclude the scan_out ports of the core chains (or channel outputs if it's a design containing EDT hardware) from graybox analysis using this attribute because the tool has no way of knowing which outputs are core chain scan output ports. For more information about this attribute, refer to the analyze_graybox command description.
ijtag_c0	Boolean attribute that is set on the design ports of a module that has a corresponding ICL module, if the port name is listed in the forced_low_output_port_list attribute on the ICL module.
ijtag_c1	Boolean attribute that is set on the design ports of a module that has a corresponding ICL module, if the port name is listed in the forced_high_output_port_list attribute on the ICL module.
ijtag_connection_rule_option	An attribute that reflects the connection_rule_option attribute of the ICL port of the ICL module associated to the design module during ICL extraction.
ijtag_forced_high_dft_signal_list	An attribute that reflects the forced_high_dft_signal_list attribute of the ICL port of the ICL module associated to the design module during ICL extraction.
ijtag_forced_low_dft_signal_list	An attribute that reflects the forced_low_dft_signal_list attribute of the ICL port of the ICL module associated to the design module during ICL extraction.

ijtag_forced_high_output_port_list	An attribute that reflects the force_high_output_port_list attribute of the ICL port of the ICL module associated to the design module during ICL extraction.
ijtag_forced_low_output_port_list	An attribute that reflects the force_low_output_port_list attribute of the ICL port of the ICL module associated to the design module during ICL extraction.
ijtag_function	String that reflects the port function of the ports as described in the ICL module. Its value, which is populated in the ICL extraction mode of the patterns -ijtag context, is the port function with an underscore separating the words. For example, a ScanInPort in ICL has icl_function equal to scan_in.
ijtag_function_modifier	An attribute that reflects the function_modifier attribute of the ICL port of the ICL module associated to the design module during ICL extraction.
ijtag_logical_hier_connection_from_src	An attribute that is set on output ports and contains the port on the module that is the logical source of the output port. It is extracted from the associated ICL module attribute ijtag_logical_connection = “{port1 port2} {port3 port4} ...”
ijtag_logical_hier_connection_from_src_inv	An attribute that is set on output ports and contains the port on the module that is the inverted logical source of the output port. It is extracted from the associated ICL module attribute ijtag_logical_connection_inv = “{port1 port2} {port3 port4} ...”
ijtag_logical_hier_connection_to_dst	This attribute is set on input ports and contains the ports on the module that are the logical destinations of the input port. It is extracted from the associated ICL module attribute ijtag_logical_connection = “{port1 port2} {port3 port4} ...”

ijtag_logical_hier_connection_to_dst_inv	This attribute is set on input ports and contains the ports on the module that are the inverted logical destinations of the input port. It is extracted from the associated ICL module attribute ijtag_logical_connection_inv = “{port1 port2} {port3 port4} ...”
index	Integer that specifies the index of the port that is already part of the name when the port is part of a bus.
is_bus	Boolean that specifies whether the port is part of a bus. This attribute is set to true when the port is part of a bus.
is_excluded_from_isolation_constraints	Boolean that specifies if the port should be excluded from CX constraints (input ports) or masking (output ports) when set to true. During core-level pattern generation, the tool automatically adds X constraints on most input ports and adds output masks on all output ports so that generated patterns can be mapped to the chip level for retargeting. Pulse-always clocks, pulse-in-capture clocks, constrained ports and internal primary inputs are excluded from these X constraints. You can exclude additional primary inputs from X constraints by setting this attribute to true; this is necessary if the ports are controlled by a Named Capture Procedure (NCP) that models chip-level constraints such as a clock controller located outside of the core. If a port is not a pulse-always or pulse-in-capture clock, is not constrained, and is excluded from isolation constraints (that is, the attribute is set to true on the port), the create_patterns command checks that the port is controlled (for example, by NCPs or clock control definitions). If the port is not controlled, the tool issues an R7 DRC violation. The default is false.
is_valid	Boolean that specifies whether the object still exists. This attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
library_name	String that specifies the library the port belongs to.

loadboard_pad_decay	Specifies the leakage time of a pin. The attribute value must be a valid time value and time unit.
loadboard_pull_resistor	Specifies whether the port is a pullup or pulldown. Possible values are zero for pulldown, one for pullup, and an <EMPTY_STRING> for a normal port.
master_module_name	String that specifies the value of the master_name on the module object the port belongs to.
module_name	String that specifies the name of the module object the port belongs to.
name	String that specifies the name of the port object. One port object exists for each bit of a bused port and the name includes the index of the port. For example: A[3]
no_control_point	An attribute that specifies that no control point can be inserted on any top-level pin or a pin in any module when the attribute value is set to true. Possible values are true, false and unspecified. The default value is unspecified which means that control points will be allowed unless the attribute is set to false in one of its parent modules or instances.
no_control_reason	String that specifies why no control point can be inserted at the specified location. The possible values fall in two categories, tool identified and user specified. The no control point locations identified by the tools during analysis have the highest priority and you cannot overwrite or change them. These locations are deleted when you transition back to setup mode. For possible values for the tool identified locations and the user-specified locations, refer to no_control_reason in the Module attribute section.

no.observe_point	An attribute that specifies that no observe point can be inserted on any top-level pin or a pin in any module when the attribute value is set to true. Possible values are true, false and unspecified. The default value is unspecified which means that control points will be allowed unless the attribute is set to false in one of its parent modules or instances.
no.observe_reason	<p>String that specifies why no observe point can be inserted at the specified location. The possible values fall in two categories, tool identified and user specified.</p> <p>The no observe point locations identified by the tools during analysis have the highest priority and you cannot overwrite or change them. These locations are deleted when you transition back to setup mode.</p> <p>For possible values for the tool identified locations and the user-specified locations, refer to no.observe_reason in the Module attribute section.</p>
object_id	The object_id attribute is a unique id for the object that remains valid while the design is in memory. This attribute is useful to identify the object in a Tcl dictionary. The object_id is only valid within one tool invocation. Once you terminate the tool or delete the elaboration tree, the object_id is no longer valid. The object_id has the form "port: <i>integer</i> "
object_type	Returns the object data type "port".
power_domain_name	Returns the name of the power domain of the current design. This attribute is populated when going from setup to analysis system mode if a UPF or CPF file has been read in. For a definition of Power Domain , refer to the <i>Tessent Glossary</i> .

preserve_boundary	Boolean that specifies whether to preserve the boundary in the flat model. When set to true, all pins of the port will have an inferred buffer created in the flat model to preserve the separation of nets inside and outside the module. Any attribute stored on the hierarchical pin will be visible in the flat model. If you set this attribute on a pin of the design, the flat model will need to be reconstructed. The attribute is not lost during flattening.
special_drive	String value extracted from the cell library data. See the read_cell_library command for information on how cell_type information can be loaded. Note that the LogicVision scang.lib, pad.lib and cell.lib format are natively supported by the read_cell_library command in case your cell library file only includes the ATPG cell modeling information. Possible values are: open_drain open_source.
pull_drive	String value extracted from the cell library data. See the read_cell_library command for information on how cell_type information can be loaded. Note that the LogicVision scang.lib, pad.lib and cell.lib format are natively supported by the read_cell_library command in case your cell library file only includes the ATPG cell modeling information. Possible values are: pull0 pull1.
static_dft_signal	A sting attribute that is set on the node where a static DFT signal is defined. The value of the attribute is the name of the static DFT signal. This attribute has the -display_in_gui option set to on such that when the node is displayed in the GUI, a callout box is shown letting you know that it is the location of the static DFT signal.
tcd_bscan_function	A string attribute that reflects on the port the function the given port has within the matched TCD BoundaryScan description (see “ Tessent Core Description ” on page 3755). Only module which has the tcd_bscan_name attribute defined will have ports with the tcd_bscan_function defined. The property names found in the Interface wrapper gets transferred to the port they map to.

tcd_memory_function	A string attribute that reflects on the port the function the given port has within the matched TCD Memory description (see “ Tessent Core Description ” on page 3755). Only module which has the tcd_memory_name attribute defined will have ports with the tcd_memory_function defined. The function name found in the Core/Memory/Port wrapper gets transferred to the port they map to.
tie_value	String that indicates the value to which the port is tied. Possible values are: 0, 1, X, Z, or “” (empty string). The default is the empty string which means the port is not tied to a value.

Inheritance

Built-in attribute inheritance from associated objects:

- None

User-defined attributes are inherited. See “[Attribute Inheritance Behavior](#)” on page 3170.

Port Specification

A port object (port_object) is an input, output, or inout interface of a module, which is specified by a string. Examples of port names can be “In1”, “ClkA”, and “Out3”.

Function Attribute Values

The following list shows the possible values for the function attribute. See the table in the [Pin Attributes](#) section of the *Tessent Cell Library Manual* for a complete list of available function values.

- active_high_clock
- active_high_reset
- active_high_set
- active_low_clock
- active_low_reset
- active_low_set
- asynch_disable
- asynch_disable_inv
- asynch_enable

Pin

A pin is an object on an instance that can be connected to other pins or ports with net objects. No pin object exists until the set_current_design command is executed.

The pin object type interacts with attributes as follows:

- Attributes defined on ports are automatically visible as read-only attributes on the associated pin objects unless the attribute is also registered for the pin object type. This is the case for the name attribute which is defined for both port and pin object types.
- Port attributes are stored on the associated port of the pin and not on the pin object itself.
- Attributes defined on a net are automatically visible by a pin having the exact same name unless the attribute is also defined on the pin object type. The reverse is also true. Attributes defined on a pin are automatically visible by a net having the exact same name unless the attribute is also defined on the net object type. This behavior enables you to register an attribute for net object types and have the attribute fully visible from the root-level ports and the hierarchical pins.

Built-In Attributes

active_clock_edge	A string attribute that reflects the value of the gate_pin attribute having the same name when the gate_pin maps to a net object. See the description of the Gate_pin attribute description for the meaning of its value.
active_polarity	A string attribute that reflects the value of the gate_pin attribute having the same name when the gate_pin maps to a net object. See the description of the Gate_pin attribute description for the meaning of its value.
base_name	String that specifies the name of the pin without the leaf name.
bisr_power_domain_name	An attribute that can be set on BIST_SI pins of sub modules to associate a BISR chain to a power domain defined in the current level. You typically do not need to use this attribute if you have used consistent power domain name in your bottom-up flow but you can use this attribute on pins to map specific BISR chains on sub modules to power domain at the current level if they are different as documented in the bisr_segment_order_file section.
clock_domain_inversion	A string attribute that specifies whether there is an inversion between the clock domain base and the node. When 1, then the inversion exists.

clock_domain_label	A string attribute that is populated when running the DFT_C1, DFT_C2, and DFT_C3 DRC rules. It is attached to every pin found between the clock source and the memory and other clock in its fanout. The string contains the label associated to the clock defined at the source. It is also set by DFT_C6 on every node between the clock and the sequential elements.
created_by_synthesis	Boolean that indicates that the pin was created by synthesis. When a pin has this attribute set to true, it does not exist in the original RTL and cannot be used for design edits. See the set_quick_synthesis_options command.
direction	<p>String that specifies the direction of the pin. Possible values are as follows:</p> <ul style="list-style-type: none"> • buffer (VHDL) • inout (Verilog and VHDL) • input (Verilog and VHDL) • linkage (VHDL) • output (Verilog and VHDL)
dynamic_dft_signal	A sting attribute that is set on the node where a dynamic DFT signal is defined. The value of the attribute is the name of the dynamic DFT signal. This attribute has the -display_in_gui option set to on such that when the node is displayed in the GUI, a callout box is shown letting you know that it is the location of the dynamic DFT signal.
fault_site	String that is populated in the analysis mode of the patterns -scan context and reports if the pin is a fault site for 0, 1, or both fault polarity types. The attribute is null on pins that are not a fault site for both polarities.
gate_pin_id	Returns a gate_pin id when the pin has an associated gate_pin inside the flat model. Set to true for cell pins associated to fault sites and for hierarchical pins that have an attribute that is set to a non-default value and whose -preserve_boundary_in_flat_model option is set to true.
has_functional_source	Returns true unless the pin is of direction input and the pin is not connected, is connected to an undriven or tied net or is connected to a constant.
ijtag_logical_hier_connectio_n_from_src	Reflects the result of the add_ijtag_logical_connection commands. Each destination points back to its logical source.
ijtag_logical_hier_connectio_n_from_src_inv	Reflects the result of the add_ijtag_logical_connection commands. Each destination points back to its inverted logical source.
ijtag_logical_hier_connectio_n_to_dst	Reflects the result of the add_ijtag_logical_connection commands. Each source points forward to its logical destinations.
ijtag_logical_hier_connectio_n_to_dst_inv	Reflects the result of the add_ijtag_logical_connection commands. Each source points forward to its inverted logical destinations.

is_hard_module	Boolean that reports the state of the is_hard_module attribute on the instance on which the pin exists.
is_non_editable	Boolean that specifies that the pin is non-editable.
is_non_editable_reason	A string that specifies why the pin is non-editable as follows: <ul style="list-style-type: none"> • below_hard_module — The pin is on an instance that is inside an instance that has is_hard_module equal to 1 • created_by_quick_synthesis — The pin is on an instance that was created by quick synthesis • below_matched_icl_module — The pin is on an instance that is below a module that has a matched ICL module
is_valid	Boolean that specifies whether the object still exists. This attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
leaf_name	String that specifies the name of the pin (value of the name attribute) without the hierarchical path. After leaving insertion mode in the tool, this attribute will show the value of the unrolled_leaf_name attribute.
name	String that specifies the hierarchical name of the pin object relative to the current design. One pin object exists for each bit of a bused port; the name includes the index of the port appended to its associated instance name. For example: u1/u2/A[3]. After leaving insertion mode in the tool, this attribute will show the value of the unrolled_name attribute.
no_control_point	An attribute that specifies that no control point can be inserted on a pin in a specific instance when the attribute value is set to true. Possible values are true, false and unspecified. The default value is unspecified which means that control points will be allowed unless the attribute is set to false in one of its parent modules or instances.
no_control_reason	String that specifies why no control point can be inserted at the specified location. The possible values fall in two categories, tool identified and user specified. The no control point locations identified by the tools during analysis have the highest priority and you cannot overwrite or change them. These locations are deleted when you transition back to setup mode. For possible values for the tool identified locations and the user-specified locations, refer to no_control_reason in the Module attribute section.
no_observe_point	An attribute that specifies that no observe point can be inserted on a pin in a specific instance when the attribute value is set to true. Possible values are true, false and unspecified. The default value is unspecified which means that control points will be allowed unless the attribute is set to false in one of its parent modules or instances.

no.observe.reason	<p>String that specifies why no observe point can be inserted at the specified location. The possible values fall in two categories, tool identified and user specified.</p> <p>The no observe point locations identified by the tools during analysis have the highest priority and you cannot overwrite or change them. These locations are deleted when you transition back to setup mode.</p> <p>For possible values for the tool identified locations and the user-specified locations, refer to no.observe.reason in the Module attribute section.</p>
object_id	The object_id attribute is a unique id for the object that remains valid while the design is in memory. This attribute is useful to identify the object in a Tcl dictionary. The object_id is only valid within one tool invocation. Once you terminate the tool or delete the elaboration tree, the object_id is no longer valid. The object_id has the form "pin:integer"
object_type	Returns the object data type “pin”.
parent_instance	<p>String that specifies the instance name of the instance on which the pin is instantiated. This attribute automatically handles the escaped identifier and returns the instance path of the instance without the <leaf_instance_name>/<leaf_pin_name> part of the path.</p> <p>For example:</p> <p>parent_instance of pin (u2/u7/a) is u2 parent_instance of pin (u2/b) is null</p>
parent_is_hard_module	Boolean that specifies whether the is_hard_module attribute on the pin’s parent instance is set to true. This attribute is set to true if the is_hard_module attribute on the pin’s parent instance is set to true. The default is false.
power_domain_name	Returns the name of the power domain of the instance to which this pin belongs. This attribute is populated when going from setup to analysis system mode if a UPF or CPF file has been read in. For a definition of Power Domain , refer to the <i>Tessent Glossary</i> .
pre_synthesis_name	<p>String that specifies the original RTL name of the object even when the quick synthesis view of the design is currently in memory. When the quick synthesis view of the design is not in memory, then the value of this attribute equals the value of the name attribute. If the object is created by the synthesis (created_by_synthesis attribute is true which means the object did not exist before the synthesis), then the string is empty. The pre_synthesis_name will only ever be different from the name when the pin has one or more generate block in its ancestry that the tool synthesized during quick synthesis.</p>

preserve_boundary	Boolean that specifies whether to preserve the boundary in the flat model. When set to true, the hierarchical pin will have an inferred buffer created in the flat model to preserve the separation of nets inside and outside the instance. Any attribute stored on the hierarchical pin will be visible in the flat model. If you enable this attribute on a pin of the design, the flat model will need to be reconstructed. The attribute is not lost during flattening.
static_dft_signal	A string attribute that is set on the node where a static DFT signal is defined. The value of the attribute is the name of the static DFT signal. This attribute has the -display_in_gui option set to on such that when the node is displayed in the GUI, a callout box is shown letting you know that it is the location of the static DFT signal.
tie_value	String that indicates the value to which the pin is tied. Possible values are: 0, 1, X, Z, or "" (empty string). The default is the empty string which means the pin is not tied to a value.
unrolled_leaf_name	An attribute that indicates whether the tool performed loop unrolling. In insertion mode and if the tool unrolled loops, then this attribute will show the name the object will have when written with the write_design command. When there is no loop or the loop is not unrolled, this attribute is the same value as the leaf_name attribute.
unrolled_name	An attribute that indicates whether the tool performed loop unrolling. In insertion mode and if the tool unrolled loops, then this attribute will show the name the object will have when written with the write_design command. When there is no loop or the loop is not unrolled, this attribute is the same value as the name attribute.

Inheritance

Built-in attribute inheritance from associated port objects:

- bus_left_index
- bus_name
- bus_range_direction
- bus_right_index
- bus_width
- direction
- function
- ijtag_function
- index
- is_bus

- library_name
- master_module_name
- module_name
- preserve_boundary
- special_drive
- pull_drive

User-defined attributes are inherited. See “[Attribute Inheritance Behavior](#)” on page 3170.

Pin Specification

A pin object (pin_object) is specified by a complete hierarchical pin pathname including the pin. For example: /u1/u2/u3/Y refers to pin Y of the hierarchical instance /u1/u2/u3.

Net

For every port and pin object, a net object with the same name exists. No net objects exist until the set_current_design command is executed.

When objects are referenced by name in the editing and attribute commands, if a specified name exists as both a pin and a net or a port and a net, the pin or port is selected. If you want to force the selection of the net object that has the same name as a pin or port, use the [get_nets](#) introspection command. For examples of this usage, see the examples shown on the [move_connections](#) command reference page.

Attributes defined on a net are automatically visible by a pin or port having the exact same name unless the attribute is also defined on the pin object type. The reverse is also true. Attributes defined on a pin or port are automatically visible by a net having the exact same name unless the attribute is also defined on the net object type. This is true for attributes on pins inherited from their associated port. This behavior enables you to register an attribute for the net object type

and have the attribute fully visible from the hierarchical pins and from the ports of the current design.

Built-In Attributes

active_clock_edge	A string attribute that reflects the value of the gate_pin attribute having the same name when the gate_pin maps to a net object. See the description of the Gate_pin attribute description for the meaning of its value.
active_polarity	A string attribute that reflects the value of the gate_pin attribute having the same name when the gate_pin maps to a net object. See the description of the Gate_pin attribute description for the meaning of its value.
bus_left_index	Integer that specifies the left index of the complete bus. Null for scalar ports.
bus_name	String that specifies the name of the bus without the index. <name> = bus_name [index] when is_bus is true; otherwise, bus_name is null.
bus_range_direction	String set to “up” or “down” that reflects the bus range direction. This attribute follows the to and downto BIT_VECTOR types in VHDL.
bus_right_index	Integer that specifies the right index of the complete bus. Null for scalar ports.
bus_width	Integer that specifies the number of bits independent of whether left_index is smaller, larger than, or equal to right_index.
clock_domain_inversion	A string attribute that specifies whether there is an inversion between the clock domain base and the node. When 1, then the inversion exists.
clock_domain_label	A string attribute that is populated when running the DFT_C1, DFT_C2, and DFT_C3 DRC rules. It is attached to every net found between the clock source and the memory and other clock in its fanout. The string contains the label associated to the clock defined at the source. It is also set by DFT_C6 on every node between the clock and the sequential elements.
created_by_synthesis	Boolean that indicates that the net was created by synthesis. When a net has this attribute set to true, it does not exist in the original RTL and cannot be used for design edits. See the set_quick_synthesis_options command.
dynamic_dft_signal	A sting attribute that is set on the node where a dynamic DFT signal is defined. The value of the attribute is the name of the dynamic DFT signal. This attribute has the -display_in_gui option set to on such that when the node is displayed in the GUI, a callout box is shown letting you know that it is the location of the dynamic DFT signal.

has_functional_source	Returns true unless the net is undriven or tied.
has_rtl	Boolean that indicates whether the net is connected to an RTL construct, such as an always block. Also indicates when the driver of the net is an RTL construct. The attribute is true under the following circumstances: <ul style="list-style-type: none">• The net is used in an RTL expression.• The net is directly connected to a complex pin (not via an assign). The attribute is always false in the -no_rtl flow.
has_rtl_fanin	Boolean that indicates whether the net is connected to a driver embedded inside an RTL construct, such as an always block.
has_rtl_fanout	Boolean that indicates whether the net is connected to one or more sinks embedded inside an RTL construct, such as an always block.
index	Integer that specifies the index of the net that is already part of the name when the net is part of a bus.
in_graybox	Set to true when the net is included in the graybox netlist. Set to false when the net is excluded from the graybox netlist, which is the default for all the nets in the design. The attribute value can be changed by the analyze_graybox or set_attribute_value command. For more information about this attribute, refer to the analyze_graybox command description.
is_bus	Boolean that specifies whether the net is a part of a bus. This attribute is set to true when the net is part of a bus.
is_non_editable	Boolean that specifies that the net is non-editable.
is_non_editable_reason	A string that specifies why the net is non-editable as follows: <ul style="list-style-type: none">• below_hard_module — The net is inside an instance that has is_hard_module equal to 1• created_by_quick_synthesis — The net was created by quick synthesis• below_matched_icl_module — The net is below a module that has a matched ICL module
is_valid	Boolean that specifies whether the object still exists. This attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
leaf_block_id	The leaf_name of nets located inside generate blocks have the generate block ids joined by periods prepended to their local name. This attribute returns the block_id part of the leaf_name. It is null for nets that are not inside generate blocks.
leaf_name	String that specifies the name of the net (value of the name attribute) without the hierarchical path. After leaving insertion mode in the tool, this attribute will show the value of the unrolled_leaf_name attribute.

leaf_name_hash	<p>This attribute is normally identical to the leaf_name attribute except when the leaf instance is located inside a generate loop construct inside an RTL file. The leaf_name includes the block id with the loop index such as in loopA[4].u2.</p> <p>The leaf_name_hash attribute is the same except that the loop index is replaced by a hash sign as shown here: loopA[#].u2. You use this attribute if you are editing the content of generate loops and you have not enabled auto uniquification. For the delete_connections and move_connections commands, you must use a lookup table with <i>parent_module.leaf_name_hash.pin_leaf_name</i> entries to know if you have already processed that pin. See the examples in the move_connections and get_dft_cell command descriptions for examples of such usage. Note that the value of this attribute always refer to the pre_synthesis_name just like the pre_synthesis_leaf_name attribute.</p>
library_name	String that specifies the library of the module in which the leaf net resides.
master_module_name	String that specifies the value of the master_name in which the leaf net resides.
module_name	String that specifies the name of the module object in which the leaf net resides.
name	String that specifies the hierarchical name of the net object relative to current design. One net object exists for each bit of a bused net; the name includes the index of the net appended to its associated instance name. For example: u1/u2/A[3]. After leaving insertion mode in the tool, this attribute will show the value of the unrolled_name attribute.
object_id	The object_id attribute is a unique id for the object that remains valid while the design is in memory. This attribute is useful to identify the object in a Tcl dictionary. The object_id is only valid within one tool invocation. Once you terminate the tool or delete the elaboration tree, the object_id is no longer valid. The object_id has the form "net:integer"
object_type	Returns the object data type "net".
parent_instance	String that specifies the instance name in which the net exists. This attribute automatically handles the escaped identifier and returns the instance path of the instance without the /<leaf_name> part of the path.
parent_is_hard_module	Boolean that specifies whether the module containing the net has the is_hard_module attribute set to true. This attribute is set to true if the module containing the net has the is_hard_module attribute set to true. The default is false.

pre_synthesis_leaf_name	String that specifies the original RTL leaf name of the object even when the quick synthesis view of the design is currently in memory. When the quick synthesis view of the design is not in memory, then the value of this attribute equals the value of the leaf_name attribute. If the object is created by the synthesis (created_by_synthesis attribute is true which means the object did not exist before the synthesis), then the string is empty. The pre_synthesis_leaf_name will only ever be different from the leaf_name when the net is inside a generate block that the tool synthesized during quick synthesis.
pre_synthesis_name	String that specifies the original RTL name of the object even when the quick synthesis view of the design is currently in memory. When the quick synthesis view of the design is not in memory, then the value of this attribute equals the value of the name attribute. If the object is created by the synthesis (created_by_synthesis attribute is true which means the object did not exist before the synthesis), then the string is empty. The pre_synthesis_name will only ever be different from the name when the net has one or more generate block in its ancestry that the tool synthesized during quick synthesis.
power_domain_name	Returns the name of the power domain of the instance in which this net exists. This attribute is populated when going from setup to analysis system mode if a UPF or CPF file has been read in.
preserve_boundary	Boolean that specifies whether to preserve the boundary in the flat model. When set to true, the net will have an inferred buffer created in the flat model to preserve the net name. If you set this attribute on a net of the design, the flat model will need to be reconstructed. The attribute is not lost during flattening.
specified_internal_scan_only	An attribute used to specify that the flip-flop instance inferred from the given net during quick synthesis is to remain internal during wrapper analysis. Dedicated isolation wrapper cells will be inferred to isolate the input and output pins of the instances if any interacts with the primary input and output ports.
static_dft_signal	A sting attribute that is set on the node where a static DFT signal is defined. The value of the attribute is the name of the static DFT signal. This attribute has the -display_in_gui option set to on such that when the node is displayed in the GUI, a callout box is shown letting you know that it is the location of the static DFT signal.
tie_value	String that indicates the value to which the net is tied. Possible values are: 0, 1, X, Z, or "" (empty string). The default is the empty string which means the net is not tied to a value.
unrolled_leaf_name	An attribute that indicates whether the tool performed loop unrolling. In insertion mode and if the tool unrolled loops, then this attribute will show the name the object will have when written with the write_design command. When there is no loop or the loop is not unrolled, this attribute is the same value as the leaf_name attribute.

unrolled_name	An attribute that indicates whether the tool performed loop unrolling. In insertion mode and if the tool unrolled loops, then this attribute will show the name the object will have when written with the write_design command. When there is no loop or the loop is not unrolled, this attribute is the same value as the name attribute.
---------------	---

Inheritance

Built-in attribute inheritance from associated pin objects:

- Attributes defined on pins or ports having the same name as the net, if the attribute is not also registered on the net object type.

User-defined attributes are inherited. See “[Attribute Inheritance Behavior](#)” on page 3170.

Net Specification

A net object (net_object), sometimes called just a net, is a wire that connects the pins of instances in the design. A net is specified by a hierarchical net pathname. In the following example, u5/u2/Q is a pin that drives the net u5/u2_Q. This example is based on the example design presented in the “[Hierarchical Design Data Model](#)” section of the *Tessent Shell User’s Manual*.

```
SETUP> get_fanouts u5/u2/Q
{u5/u1/A0 u5/u3/A0}

SETUP> get_fanouts u5/u2/Q -stop_on net
{u5/u2_Q}
```

Pseudo_port

A pseudo_port represents a user-added primary input or primary output.

A pseudo_port object enables the introspection of user-added primary inputs and outputs such as those created using the commands [add_primary_inputs](#), [add_primary_outputs](#), and [add_clocks](#).

A pseudo_port is not a real port in that it is not present in the original design, it cannot be used for design editing, and it is not reflected in designs written out using the write_design command. However, the pseudo_port is reflected in the flat model and it is used for analysis operations that use the flat model such as ATPG and simulation.

A pseudo_port shares some of the same attributes as the port object. Pseudo ports have a simple non-hierarchical name which may be the same as the pin's hierarchical name (for non-grouped pseudo_ports).

Pseudo_ports can be introspected with the [get_ports](#) command. The “real” pins that underlie a pseudo_port can be introspected with the “[get_pins -of_pseudo_ports pseudo_port_objects](#)” command.

The pseudo_port object type does not support attribute inheritance to the real underlying objects (pins/nets) associated to it. That is, the real design object behind the pseudo_port does not see the attributes set on this type of port.

Built-In Attributes

active_clock_edge	A string attribute that reflects the value of the gate_pin attribute having the same name when the gate_pin maps to a net object. See the description of the Gate_pin attribute description for the meaning of its value.
active_polarity	A string attribute that reflects the value of the gate_pin attribute having the same name when the gate_pin maps to a net object. See the description of the Gate_pin attribute description for the meaning of its value.
clock_domain_inversion	A string attribute that specifies whether there is an inversion between the clock domain base and the node. When 1, then the inversion exists.
clock_domain_label	A string attribute that is populated when running the DFT_C1, DFT_C2, and DFT_C3 DRC rules. It is attached to every pseudo_port on which a clock was defined. The string contains the label associated to the clock defined on the pseudo_port. It is also set by DFT_C6 on every node between the clock and the sequential elements.
constraint_value	String that specifies that the port’s primary input was set to a constant with the add_input_constraints command. When set to C0, CT0, C1, CT1, CX, or Cz, this attribute displays 0, 0, 1, 1, x, or z, respectively. The default is null.
constraint_value_during_load_unload	String that specifies a constant value for a top-level pseudo_port during load_unload test procedure retargeting. Possible values are: 0, 1, X, and Z. Constraining the value of the top-level pseudo_port enables tracing of signals from the core level to the chip level.

direction	String that specifies the direction of the pseudo_port. Possible values are as follows: <ul style="list-style-type: none">• input• output
gate_pin_id	Returns the id of the gate_pin associated with the pseudo_port inside the flat model.
is_bus	Boolean that specifies whether the pseudo_port is part of a bus. This attribute is always set to false. The pseudo_port object type does not support busses.
is_valid	Boolean that specifies whether the object still exists.
name	String that specifies the name of the pseudo_port object.
object_id	The object_id attribute is a unique id for the object that remains valid while the design is in memory. This attribute is useful to identify the object in a tcl dictionary. The object_id is only valid within one tool invocation. Once you terminate the tool or delete the design, the object_id is no longer valid. The object_id has the form "pseudo_port: integer"
object_type	Returns the object data type "pseudo_port".

Inheritance

Built-in attribute inheritance from associated objects:

- None

User-defined attributes are inherited. See “[Attribute Inheritance Behavior](#)” on page 3170.

Flat Design Data Model

The flat design data model is an internal, flattened representation of the hierarchical design that is produced when exiting setup mode.

You can also explicitly create the flat model using the `create_flat_model` command.

The flat design data model consists of gates that are connected together. A gate is an instance of a primitive module, and a `gate_pin` object represents a pin on a gate instance. Gates and `gate_pins` have no unique instance name, instead having a unique ID that is available to differentiate one from another. The format of the ID is two integers separated by a period character. The first integer represents the gate and the second integer represents the `gate_pin`. However, this ID does not remain in place from one netlist version to the next or from one Tesson Shell invocation to the next. For that reason, you should avoid hardcoding a gate ID into a script.

Flat Design Object Types	3108
<code>Gate_pin</code>	3108

Flat Design Object Types

The `gate_pin` is the only object type in the flat model.

Gate_pin 3108

Gate_pin

A `gate_pin` represents a pin on a gate instance in a flattened design.

Built-In Attributes

The `gate_pin` object type has the following attributes:

active_clock_edge	A string attribute having the value “trailing” or “leading” which is set on the <code>gate_pins</code> of the DFF primitives. The attribute is set on the CK input <code>gate_pin</code> and its associated D input <code>gate_pin</code> . The attribute is also visible on the Q <code>gate_pin</code> . For multi clock DFF primitive, the value seen on the Q <code>gate_pin</code> is the list of all values present on all CK <code>gate_pins</code> . The value of the attribute is “leading” when the clock source has an off state of 0 and there is no inversion between the source and the DFF CK pin or when the clock source has an off state of 1 and there is an inversion between the source and the DFF CK pin. In the other two situations, the value is “trailing”.
active_polarity	A string attribute having the value “on_state” or “off_state” which is set on the <code>gate_pins</code> of the DLAT primitives. The attribute is set on the CK input <code>gate_pin</code> and its associated D input <code>gate_pin</code> . The attribute is also visible on the Q <code>gate_pin</code> . For multi clock DLAT primitive, the value seen on the Q <code>gate_pin</code> is the list of all values present on all CK <code>gate_pins</code> . The value of the attribute is “on_state” when the latch is open when the clock source is set to it its on state. The value of the attribute is “off_state” when the latch is open when the clock source is set to it its off state.
base_name	String that specifies the name of the instance in which the primitive module of the <code>gate_pin</code> is instantiated.
clock_domain_inversion	A string attribute that specifies whether there is an inversion between the clock domain base and the node. When 1, then the inversion exists.
clock_domain_label	A string attribute that is populated when running the DFT_C1, DFT_C2, and DFT_C3 DRC rules. It is attached to every <code>gate_pin</code> found between the clock source and the memory and other clocks in its fanout. The string contains the label associated to the clock defined at the source. It is also set by DFT_C6 on every node between the clock and the sequential elements.

default_fault_classification_0	<p>String that provides an initial fault classification for the gate_pin on which it is set. This attribute corresponds to stuck-at-0 or slow-to-rise. You use the “set_attribute_value” command to set the desired default fault classification. During the flow, when the “add_faults” and “load_faults” commands are called, or when the tool internally adds faults for scan-based test pattern generation, the fault sites marked with this attribute will be initialized with the specified default fault classification, instead of UC. This attribute only applies to the stuck fault model and transition fault model. It also applies to the UDFM fault model with no condition (for example, port faults) so that UDFM continues to work as a superset of stuck/transition. If this is set on a pin that is no-faulted or a non-fault site, it will be ignored.</p> <p>This attribute is useful to identify gate_pins which are AU during scan-based test generation, but tested by some other test mode. You identify those faults using DI.<label>, where label identifies the test mode in which those faults are covered. For example, Tessent memory BIST uses the DI.mbisr value to identify the fault in the BISR register which are not testable by scan-based test generation, but covered in the memory BIST test.</p> <p>See Example 4 in the set_attributes_value command for a typical use model</p>
default_fault_classification_1	<p>String that provides an initial fault classification for the gate_pin on which it is set. This attribute corresponds to stuck-at-1 or slow-to-fall. You use the “set_attribute_value” command to set the desired default fault classification. During the flow, when the “add_faults” and “load_faults” commands are called, or when the tool internally adds faults for scan-based test generation, the fault sites marked with this attribute will be initialized with the specified default fault classification, instead of UC. This attribute only applies to the stuck fault model and transition fault model. It also applies to the UDFM fault model with no condition (for example, port faults) so that UDFM continues to work as a superset of stuck/transition. If this is set on a pin that is no-faulted or a non-fault site, it will be ignored.</p> <p>This attribute is useful to identify gate_pins which are AU during scan-based test generation, but tested by some other test mode. You identify those faults using DI.<label>, where label identifies the test mode in which those faults are covered. For example, Tessent memory BIST uses the DI.mbisr value to identify the fault in the BISR register which are not testable by scan-based test generation, but covered in the memory BIST test.</p> <p>See Example 4 in the set_attributes_value command for a typical use model</p>

direction	<p>String that specifies the direction of the gate_pin object.</p> <p>Possible values are as follows:</p> <ul style="list-style-type: none"> • input • output
dynamic_dft_signal	A string attribute that is set on the node where a dynamic DFT signal is defined. The value of the attribute is the name of the dynamic DFT signal. This attribute has the -display_in_gui option set to on such that when the node is displayed in the GUI, a callout box is shown letting you know that it is the location of the dynamic DFT signal.
fault_site	String that is populated in the analysis mode of the patterns -scan context and reports if the pin is a fault site for 0, 1, or both fault polarity types. The attribute is null on pins that are not a fault site for both polarities.
gate_id	Integer that specifies the unique ID of the gate to which the gate_pin belongs. This integer is identical to the first integer in the gate_pin's id attribute. This value is not persistent and changes every time you create a flat model.
gate_input_count	Integer that specifies the number of inputs on the gate associated with gate_pin. Use this attribute to filter a collection of gate_pins and quickly separate single input gates from multi-input gates. For example, to find all multi-input gates along the clock tree: <code>get_gate_pins -filter "clock_domain_label && direction == output && primitive_name != DFF && primitive_name != DLAT && gate_input_count > 1"</code>
hier_pin_name	String that specifies a hierarchical pin name when the gate_pin is associated to a hierarchical pin. This attribute is null when the gate pin is not associated to a hierarchical pin. Pins on hierarchical instances of type cells and pins on design modules that have an attribute that is set to a non-default value and whose -preserve_boundary_in_flat_model option is set to true are the only hierarchical pins with a corresponding gate_pin.
id	Specifies a unique ID for each gate_pin that consists of two integers separated by a period: <i>gate_id.pin_index</i>
is_internal_scan_only	Boolean that specifies whether the gate_pin object is internal scan only.
is_non_scannable	Boolean that specifies that the gate_pin object is non-scannable. Default is false.
is_valid	Boolean that specifies whether the gate_pin object still exists. This attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.

leaf_name	String that specifies the hierarchical pin name without the hierarchical path when the gate_pin is associated to a hierarchical pin. This is null by default.
name	String that specifies name of the gate_pin object. The value is the same as the hier_pin_name attribute when not empty; otherwise, the value is the same as the id attribute of the gate_pin object. Pins on hierarchical instances of type cells and pins on design modules that have an attribute that is set to a non-default value and whose -preserve_boundary_in_flat_model option is set to true are the only hierarchical pins with a corresponding gate_pin.
no_control_point	An attribute that specifies that no control point can be inserted on a gate_pin in a specific instance when the attribute value is set to true. Possible values are true, false and unspecified. The default value is unspecified which means that control points will be allowed unless the attribute is set to false in one of its parent modules or instances.
no_control_reason	<p>String that specifies why no control point can be inserted at the specified location. The possible values fall in two categories, tool identified and user specified.</p> <p>The no control point locations identified by the tools during analysis have the highest priority and you cannot overwrite or change them. These locations are deleted when you transition back to setup mode.</p> <p>For possible values for the tool identified locations and the user-specified locations, refer to no_control_reason in the Module attribute section.</p>
no_observe_point	An attribute that specifies that no observe point can be inserted on a gate_pin in a specific instance when the attribute value is set to true. Possible values are true, false and unspecified. The default value is unspecified which means that control points will be allowed unless the attribute is set to false in one of its parent modules or instances.
no_observe_reason	<p>String that specifies why no observe point can be inserted at the specified location. The possible values fall in two categories, tool identified and user specified.</p> <p>The no observe point locations identified by the tools during analysis have the highest priority and you cannot overwrite or change them. These locations are deleted when you transition back to setup mode.</p> <p>For possible values for the tool identified locations and the user-specified locations, refer to no_observe_reason in the Module attribute section.</p>
object_type	Returns the object data type “gate_pin”.

parent_instance	If the gate_pin is associated to a hierarchical pin, this string specifies the name of the instance on which the hierarchical pin is instantiated. If the gate_pin isn't associated to any hierarchical pin, this attribute specifies the name of the instance on which the primitive module is instantiated.
parent_is_hard_module	Boolean that specifies whether the is_hard_module attribute is set to true on the parent module of the gate_pin. This attribute is false if the parent module of the gate_pin does not have the is_hard_module attribute set to true. This attribute is true for primitives instantiated directly into a design module which does not have is_hard_module set to true. This attribute can also be true for a gate_pin that has the hier_pin_name pointing to a pin on a module instantiated into a non-hard design module.
pin_index	Integer that specifies the <i>id</i> of the pin. This integer is identical to the second integer of the gate_pin's <i>id</i> attribute. The pin index is persistent. The pin_index is the index of the gate_pin on the primitive module, where 0 is the index of the single output and integers larger than 0 correspond to the inputs.
primitive_name	Name of the primitive module associated with the gate on which the gate_pin exists. The primitive_name attribute values for all primitive types are listed in Table 8-1 .
primitive_port_name	Name of the port on the primitive module. The primitive_port_name attribute values for all primitive types are listed in Table 8-1 .
power_domain_name	Returns the name of the power domain in which the gate (instance) to which this gate_pin is attached exists. This attribute is inherited from the instance.
simulation_force_value	String that contains the simulation force value that is specified for a gate_pin with the add_simulation_forces command.
simulation_value	String that contains the simulation value on a gate_pin.
static_dft_signal	A sting attribute that is set on the node where a static DFT signal is defined. The value of the attribute is the name of the static DFT signal. This attribute has the -display_in_gui option set to on such that when the node is displayed in the GUI, a callout box is shown letting you know that it is the location of the static DFT signal.

Built-In Primitives and Primitive Port Names

Table 8-1. Built-in Primitives and Primitive Port Names

Primitive Name	Functional Description	Primitive Port Names	
		Inputs	Outputs
BUF	Buffer	I	O
INV	Inverter	I	O
AND	AND gate	I0, I1, ..., In	O
NAND	Negated AND	I0, I1, ..., In	O
OR	OR gate	I0, I1, ..., In	O
NOR	Negated OR gate	I0, I1, ..., In	O
XOR	Exclusive OR	I0, I1, ..., In	O
NXOR	Negated Exclusive OR	I0, I1, ..., In	O
DFF	D Flip-flop	S, R, CK (CK0, CK1, ... CKn in case of multiple clock/data input pairs), D (D0, D1, ..., Dn in case of multiple clock/data input pairs)	Q
DLAT	D latch	S, R, CK (CK0, CK1, ... CKn in case of multiple clock/data input pairs), D (D0, D1, ..., Dn in case of multiple clock/data input pairs)	Q
PI	Primary input	-	O
PO	Primary output	I	-
TIE0	Tie-0	I	O
TIE1	Tie-1	I	O
TIEX	Tie-X	I	O
TSD	Tri-state driver with active high at control input.	EN, D	O

Table 8-1. Built-in Primitives and Primitive Port Names (cont.)

Primitive Name	Functional Description	Primitive Port Names	
		Inputs	Outputs
BUS	Bus primitive. Drivers must include at least one TSH or switch gate.	I0, I1, ..., In	O
ZVAL	Z converter gate, converts Z to X: dummy gate inserted between output of the gate taking Z and the binary gate input.	I	O
WIRE	Wire	I0, I1, ..., In	O
MUX	Multiplexer	S, D0, D1	O
TIEZ	Tie-Z	I0, I1, ..., In	O
NMOS	Switch gate	G (gate), S (source)	D (drain)
ZHOLD	Z-hold allows modeling of tri-state nets such that they can retain the previous state when the net goes to a Z value.	I	O
PBUS	Pull-bus gate. Used when combining strong (ZW) bus and weak bus signals (e.g. TIE0) together. The strong value (input 1) always goes to the output, unless the value is Z, in which case the weak value (input 2) propagates to the output.	I0, I1	O

Table 8-1. Built-in Primitives and Primitive Port Names (cont.)

Primitive Name	Functional Description	Primitive Port Names	
		Inputs	Outputs
WBUS	Weak bus primitive	I0, I1, ..., In	O
BUFZ	Buffer allowing Z value at input.	I	O
XDET	X-detector gate: input 'X' results in output value '1'; otherwise output is '0'.	I	O
ZDET	Z-detector gate: input 'Z' results in output value '1'; otherwise output is '0'.	I	O
RAM	Read-write memory	S, R, WCK (WCK0, WCK1, ... WCKw in case of multiple write ports), WEN (WEN0, WEN1, ... WENw in case of multiple write ports), WADDR[0...i] (WADDR0[0...i], WADDR1[0...i], ... WADDRw[0...i] in case of multiple write ports), WDIN[0...j] (WDIN0[0...j], WDIN1[0...j], ... WDIN w[0...j] in case of multiple write ports), RCK, REN, RADDR[0...i] (RADDR0[0...i], RADDR1[0...i], ... RADDRr[0...i] in case of multiple read ports)	Q
ROM	Read-only memory	CK, EN, ADDR[0...i] (ADDR0[0...i], ADDR1[0...i], ... ADDRr[0...i] in case of multiple read ports)	Q

Table 8-1. Built-in Primitives and Primitive Port Names (cont.)

Primitive Name	Functional Description	Primitive Port Names	
		Inputs	Outputs
RAM_OUT	Output of a memory, place holder for multiple data outputs of memories in the flat model.	I0, I1, ..., In	O
ROM_OUT	Output of a memory, place holder for multiple data outputs of memories in the flat model.	I0, I1, ..., In	O
FB_BUF	Feedback buffer: internal gate type to break combinational loops in the design.	I	O
PGEN	Pulse generator: circuitry that creates a pulse at its output when active.	I	O
CORE	Core (obsolete)	I0, I1, ..., In	O
CORE_OUT	Output of core, place holder for multiple core outputs in the flat model (obsolete).	I0, I1, ..., In	O

Inheritance

Built-in inherited attributes:

- During flattening, attributes defined on hierarchical pins (cell or design) are copied to the gate_pin objects when there is a gate_pin associated to the hierarchical pin. Those are fault sites on cell pins, and those pins that have an attribute that is set to a non-default value and whose -preserve_boundary_in_flat_model option is set to true.

User-defined attributes are inherited. See “[Attribute Inheritance Behavior](#)” on page 3170.

get_attribute_value_list	get_pins
report_attributes	get_name_list

Gate_pin Specification

A gate_pin object (gate_pin_object) is assigned a number ID rather than having an actual name. The number ID is a unique gate pin object id of the format “gate_id.gate_pin_id”. For example an output of an AND gate in the flattened design might have an ID of “1325.0”.

ICL Data Model

The ICL data model defines objects as one of the following four data types: `icl_module`, `icl_instance`, `icl_port`, and `icl_pin`. The `icl_module` and the `icl_port` object types are created as soon as ICL modules are read in using the `read_icl` command.

Each `icl_module` object has its list of `icl_port` objects. Once the current design is set using the `set_current_design` command, the ICL data model is elaborated downward from the current design and `icl_instance` objects are created for each instance of `icl_module`, and `icl_pin` objects are created for each port of the modules associated to the `icl_instances`. The `icl_instance` and `icl_pin` objects are hierarchical objects and therefore only exist after the current design is set.

The purpose of the Instrument Connectivity Language (ICL) is to describe the elements that comprise the IJTAG network as well as their logical (though not necessarily physical) connections to each other and to the instruments at the endpoints of the network. ICL bears a loose resemblance to a hierarchical netlist such as Verilog; it is organized by modules that may contain instances of other modules, and it describes the connections between the pins of the instances. However, it is important to note that ICL is not a complete netlist; connections are port-to-port rather than through nets, and ICL freely uses abstraction in order to omit the detailed physical construction of the circuitry — only the behavioral operation of the network is represented.

Beyond merely documenting the structure of the network, the purpose of ICL is to enable an operation called “test pattern retargeting.” With test pattern retargeting, the sequences of test patterns, written in PDL, that are to be applied at the instrument boundaries are mapped through the IJTAG network to a higher level of hierarchy and ultimately to chip level pins. Tesson Shell reads and stores ICL information in a data structure and uses that information to retarget the instrument-level test patterns into test patterns that can then be applied at a higher level.

If a Verilog or VHDL representation has also been read prior to issuing the `set_current_design` command, the port list on the design and the ICL module corresponding to the current design is compared to make sure that all ports declared in the ICL module also exist on the design module. The design module is allowed to have more ports than the ICL module. In fact, it is very likely the design module will have more ports because the ICL module only include the ports with an IJTAG function while the design module includes all ports on the physical module. The test bench created for the current design uses the complete port list read in from the design view when it is supplied.

ICL Object Types.....	3119
<code>icl_module</code>	3119
<code>icl_port</code>	3126
<code>icl_instance</code>	3139
<code>icl_pin</code>	3141

ICL Object Types

The `icl_module`, `icl_instance`, `icl_port`, and `icl_pin` object types are described on the following reference pages.

<code>icl_module</code>	3119
<code>icl_port</code>	3126
<code>icl_instance</code>	3139
<code>icl_pin</code>	3141

icl_module

One module is designated as the target module using the `set_current_design` command. Instances and pins are hierarchical objects defined relative to the current module.

The following properties apply to the `icl_module` object type:

- An `icl_module` object has a simple non-hierarchical name. Only one `icl_module` with a given name is allowed within a given namespace. Currently there is only one global namespace for ICL in Tessent Shell.
- An `icl_module` can be parameterized and its parameters can be overridden during instantiation. For each combination of parameter overrides, an `icl_module` object corresponding to the parameterized view exists. The name of the parameterized view is unqualified with a `@PV#` suffix where # is a unique integer starting from 1 and incrementing per unique parameterized view.
- One master `icl_module` exists for each module definition in the input files. The master `icl_module` is the one that contains the ICL module definition with default parameter values.
- Attributes defined on `icl_modules` are automatically visible as read-only attributes on the instance objects when the same attribute name is not also registered on the `icl_instance` object type.
- Attributes defined with the `set_attribute_options -applies_to_child_instances` switch set to On automatically become visible to all child instances of each instance of the `icl_module`.
- `icl_module` attributes are stored on all parameterized views of an `icl_module`. When an attribute value is set on an `icl_module` object, the attribute value is set on all `icl_module` objects having the same `master_name` within a name space.

For more information on attributes, see “[Attributes](#)” on page 3159.

Built-In Attributes

The `icl_module` object type has the following attributes:

<code>bsdl_file</code>	An attribute that is attached to the ICL module by Tessent Shell, if the ICL module contains an AccessLink statement and the <code>-bsdl_file</code> option of the <code>read_icl</code> command has been used. The presence of the AccessLink statement in the ICL module instructs the tool to create ICL for the TAP controller and to integrate it into the IJTAG network. The BSDL file is required for the details of the TAP controller, such as instruction names and opcodes. The attribute <code>bsdl_file</code> holds the information about the BSDL file that provided those TAP controller specifications.
<code>file_path_name</code>	String that specifies the pathname to the file where a given module was read from. This attribute is null for modules created by ICL extract until they have been saved and read back in.
<code>forced_high_input_port_list</code>	Lists all input ports that were constrained to 1 during ICL extraction. Those constraints are automatically re-applied in the generated patterns. They are also verified to be properly simulated when running ICL extract at the next level. An I5 DRC violation is generated if the simulated value on any of those pins is not 1.
<code>forced_high_internal_input_port_list</code>	Lists all internal pins that were constrained to 1 during ICL extraction. Those constraints are reported in this attribute for debugging and serve no other purpose.
<code>forced_high_output_port_list</code>	Lists output ports of IJTAG instruments that must be forced high during ICL extraction in order to see all the connections between the instruments. You must use this attribute with care and typically use it for logictest testmode signals sourced by the ICL network itself. For example, if you have a TDR bit driving a TM signal and this TM signal puts the circuit in scan mode, you may need to force this signal to its inactive value for the rest of the ICL network to be traceable.
<code>forced_low_input_port_list</code>	Lists all input ports that were constrained to 0 during ICL extraction. Those constraints are automatically re-applied in the generated patterns. They are also verified to be properly simulated when running ICL extract at the next level. An I5 DRC violation is generated if the simulated value on any of those pins is not 0.
<code>forced_low_internal_input_port_list</code>	Lists all internal pins that were constrained to 0 during ICL extraction. Those constraints are reported in this attribute for debugging and serve no other purpose.

forced_low_output_port_list	List output ports of IJTAG instruments that must be forced low during ICL extraction in order to see all the connections between the instruments. You must use this attribute with care and typically use it for logictest testmode signals sourced by the ICL network itself. For example, if you have a TDR bit driving a TM signal and this TM signal puts the circuit in scan mode, you may need to force this signal to its inactive value for the rest of the ICL network to be traceable.
icl_extraction_date	Reports the date and time when the ICL module was extracted. It is defined in the ICL module and created by ICL extraction.
ijtag_logical_connection	An attribute that creates a logical connection between source and destination ports. These attributes are transferred to the <code>ijtag_logical_hier_connection_from_src</code> and <code>ijtag_logical_hier_connection_to_dst</code> attributes on the matching module object. ICL extraction traces through those connections as if there was a buffer between the two ports. The syntax is <code>attribute ijtag_logical_connection = "{src1 dst1} {src2 dst2} ...";</code> The source and destination ports may or may not be declared as ports in the ICL module but they must be declared with the proper direction in the design module object. To create a logical connection that is not between an input and output port of a module having an associated ICL module, use the <code>add_ijtag_logical_connection</code> command.
ijtag_logical_connection_inv	An attribute that creates an inverted logical connection between source and destination ports. These attributes are transferred to the <code>ijtag_logical_hier_connection_from_src_inv</code> and <code>ijtag_logical_hier_connection_to_dst_inv</code> attributes on the matching module object. ICL extraction traces through those connections as if there was a buffer between the two ports. The syntax is <code>attribute ijtag_logical_connection_inv = "{src1 dst1} {src2 dst2} ...";</code> The source and destination ports may or may not be declared as ports in the ICL module but they must be declared with the proper direction in the design module object. To create a logical connection that is not between an input and output port of a module having an associated ICL module, use the <code>add_ijtag_logical_connection</code> command.
is_created	Boolean that specifies whether the module was created by ICL extraction. This attribute is set to true for modules created by ICL extraction. This attribute is not exported to the ICL file. Once the ICL module is re-read, this attribute is false.

is_modified	Boolean that specifies whether an ICL module contains attributes that have been added or modified after the module was read in.
is_valid	Boolean that specifies whether the ICL module is deleted or still valid. This Boolean attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
keep_active_during_scan_test	Boolean that specifies that the given ICL module is a node that must remain active during scan test so as not to be disturbed and be usable for scan test_setup. See the create_dft_specification command description for more information on how it is used. The default is “true”.
line_number	Integer that specifies a line number in the file where a given module was read from. This attribute is null for modules created by ICL extract until they have been saved and read back in.
master_name	String that specifies the name of the icl_module without the optional parameterized view suffix.
name	String that specifies the name of the icl_module with an optional parameterized view suffix @PV#. ICL modules are defined from files read into the ICL database with the read_icl command. For example, the name of a parameterized view of the master icl_module ModA is: ModA@PV1
object_type	Returns the object data type “icl_module”.
partially_forced_input_port_list	Lists all bus ports with at least one element in the forced_low_input_port_list and forced_high_input_port_list. This attribute is useful when creating the testbench using the ICL port list in order to get the complete bus range of the constrained bused ports. This attribute is not used when the Verilog or VHDL design module is read before setting the current design in the patterns -ijtag context because the top-level port list is then extracted from the design module.
scan_interface_list	Lists all ScanInterface names defined within the ICL module.
tessent_boundary_scan_reg	A string attribute that identifies a ScanRegister inside the ICL module as the BOUNDARY register described in the BSDL file. See the section “Requirements on a TAP to be usable for BoundaryScan” in “ BoundaryScan ” on page 3593 for more information.
tessent_bypass_reg	A string attribute that identifies a ScanRegister inside the ICL module as the BYPASS register described in the BSDL file. See the section “Requirements on a TAP to be usable for BoundaryScan” in “ BoundaryScan ” on page 3593 for more information.

tessent_design_id	A string attribute that is set on the current ICL module when it is created during ICL extraction to reflect the design_identifier associated with the current design. See the “ set_context -design_identifier ” command and switch for more information about this identifier.
tessent_design_level	A string attribute that is set on the current ICL module when it is created during ICL extraction to reflect the design_level associated with the current design. See the set_design_level command for more information about this value.
tessent_device_id_reg	A string attribute that identifies a ScanRegister inside the ICL module as the DEVID register described in the BSDL file. See the section “Requirements on a TAP to be usable for BoundaryScan” in “ BoundaryScan ” on page 3593 for more information.
tessent_dft_function	A string attribute used to identify an ICL module having special meaning during DFT. For example, the create_dft_specification command uses this attribute to identify the Sib(sti) and Sib(sri) so that they can be found again during the next insertion pass.
tessent_ignore_during_icl_verification	A string attribute used to identify an ICL module that is to be automatically excluded from the ICLNetworkVerify patterns or from the patterns created using the create_icl_verification_patterns command.
tessent_ignored_design_instances	A string attribute reported by ICL extract to reflect the list of design instances ignored during ICL extraction. These are the design instances with an ICL module for which the Boolean attribute ignore_during_icl_extraction has been set. The format of this attribute is a list of 3-element lists as shown here: { {<IclModuleName>} {<DesignModuleName>} {<DesignInstancePath>} ... }
tessent_instruction_reg	A string attribute that identifies a ScanRegister inside the ICL module as the INSTRUCTION register described in the BSDL file. See the section “Requirements on a TAP to be usable for BoundaryScan” in “ BoundaryScan ” on page 3593 for more information.
tessent_instrument_container	String that specifies the base name of the directory that contains the Tessent Instrument Description (TID) file and any other IP-specific data. This attribute is required for any ICL module that has IP-specific data.
tessent_instrument_subtype	String that identifies the sub-type of the ICL module for one of the known instrument types. The value of this attribute is only used when the tessent_instrument_type attribute is also set.

tessent_instrument_type	String that identifies the ICL module as one of the known instrument types within the tool. When this attribute is set, the tessent_signature attribute must also be set with a valid signature string.
tessent_is_physical_module	Boolean that is set on the top ICL module when the extract_icl command runs and the level was set to chip or physical_block using the set_design_level command.
tessent_repair_word_size	Used for physical blocks with BISR chains. This value reports the maximal repair word size used in the block. The repair word size is the number of bits read from the fuse box. This value is used to generate the compression hardware in the fuse box controller.
tessent rtl pre trace stop port_list	Lists the names of ports on which the tool stops the ICL tracing during the ICL extraction pre-trace phase. This is useful to prevent the unnecessary synthesis of module during ICL extraction.
tessent_signature	A string that is used to identify that an ICL module has not been modified after its creation. An ICL module can be read in without a tessent_signature or with a valid tessent_signature but a module with an invalid signature generates an error and is rejected during the read_icl command.
test_setup_procfile	Reports the filename of the procfile that contained the optional test_setup procedure used during ICL extraction. It currently is only informational to remind the user to reuse the same test_setup file during IJTAG pattern retargeting.
tessent_use_in_dft_specification	String that you can set on an ICL module in its ICL file to force the create_dft_specification command to ignore instances of this module. The legal value is auto or false.
use_in_icl_extraction	<p>String that specifies if the instances of the corresponding design modules are unconditionally used in ICL Extraction or if they are used only on-demand (corresponding design modules: design modules that have been mapped to the ICL module which owns this attribute)</p> <p>The attribute can have the following values:</p> <ul style="list-style-type: none"> • always — All instances of the corresponding design modules are used as starting points for ICL Extraction (default) • when_reached_by_other_modules — An instance of a corresponding design module is used in ICL Extraction only if it has been reached by tracing from another instance or top module port.

icl_port

Several properties apply to the icl_port object type.

- An icl_port object has a simple non-hierarchical name.
- An icl_port is an object on an icl_module and can have an input or output direction.
- One port object exists for each bit of a bussed port so every bit of a bussed port can be attributed independently.
- Attributes defined on icl_port objects are automatically visible as read-only attributes on the associated [icl_pin](#) objects unless the attribute is also registered for the [icl_pin](#) object type.
- Attributes set on an icl_port of one icl_module are set on the same port of each icl_module having a common master_name. Because different parameterized views can have more or less icl_port objects when the size of a bussed icl_port is parameterized, attributes on the other icl_module having the common master_name are only copies if the port object actually exists on the given parameterized view.

For more information on attributes, see “[Attributes](#)” on page 3159.

Built-In Attributes

The icl_port object type has the following attributes

active_polarity	An integer attribute defined on the ResetPort and ToResetPort ICL port objects which reflects the value of the ActivePolarity property in the ICL definition.
bus_left_index	Integer that specifies the left index of the complete bus. Null for scalar ports.
bus_name	String that specifies the name of the bus without the index. <name> = bus_name [index] when is_bus is true; otherwise, bus_name is null.
bus_range_direction	String set to “up” or “down” that reflects the bus range direction.
bus_right_index	Integer that specifies the right index of the complete bus. Null for scalar ports.
bus_width	Integer that specifies the number of bits independent of whether left_index is smaller, larger than, or equal to right_index.

compliance_value	<p>This attribute specifies the compliance value of the ICL port and as such represents the COMPLIANCE_PATTERNS specification of an IEEE 1149.1 BSDL file. The attribute value can be specified as a sized or unsized binary number using legal ICL digits 0, 1 and X. If the attribute value is specified as a sized number, the size must match the size of the object. If the attribute value is specified as an unsized number, it is padded with 0s or Xs if necessary, dependent on the leftmost specified bit. The right-most bit (the least significant bit) of the attribute value represents the right-most bit of the port, the second right-most bit of the value refers to the second right-most bit of the port, and so on.</p> <p>This attribute is set automatically on all compliance enable ports, if the ICL top module contains an AccessLink statement of type STD_1149_1_2001 or STD_1149_1_2013. If the corresponding BSDL file contains more than one compliance pattern, the first compliance pattern is used to derive the attribute values.</p> <p>The compliance_value attribute determines the values that are applied to the ICL ports at the beginning of an IJTAG pattern set, see open_pattern_set.</p>
------------------	--

connection_rule_option	<p>Specified inside the Port wrappers of the ICL modules and used to modify the connection rules for the corresponding port. You use one of the following values to achieve the described behavior.</p> <ul style="list-style-type: none">• allowed_no_source — Allowed on input ports of an ICL instrument to indicate that this input port is allowed not to be connected to a valid source. You typically use this for DataInPort and ScanInPorts of host ports which are not always used in all instantiations.• allowed_tied — Allowed on input ports of an ICL instrument to indicate that this input port is allowed not to be connected to a valid source as long as the port is tied high or low. You typically use this for DataInPort and ScanInPorts of host ports which are not always used in all instantiations.• allowed_tied_low — Allowed on input ports of an ICL instrument to indicate that this input port is allowed not to be connected to a valid source as long as the port is tied low. You typically use this for DataInPort and ScanInPorts of host ports which are not always used in all instantiations.• allowed_tied_high — Allowed on input ports of an ICL instrument to indicate that this input port is allowed not to be connected to a valid source as long as the port is tied high. You typically use this for DataInPort and ScanInPorts of host ports which are not always used in all instantiations.• allowed_no_destination — Allowed on output ports of an ICL instrument to indicate that this output port is allowed not to be connected to a valid destination. You typically use this for DataOutPort and ScanOutPorts of host ports which are not always used in all instantiations.• auxiliary_data — Identifies the DataOutPort as an active-high auxiliary data pin. When tracing from a port with connection rule option “auxiliary_data”, ICL Extraction asserts all ports on all instances declared as an auxiliary_data or auxiliary_data_inverse to their inactive values, except for the current port which is not forced. This enables ICL Extraction to trace through OR-like combinational logic that combines several active-high auxiliary data pins into one single data signal. Please note that this logic will be represented by a OneHotDataGroup in the generated ICL. Therefore, the involved DataOutPorts must have the “Enable” property or an equivalent enabling condition to pass the ICL75 check.
------------------------	--

connection_rule_option (continued...)	<ul style="list-style-type: none">auxiliary_data_inverse — Identifies the DataOutPort as an active-low auxiliary data pin. When tracing from a port with connection rule option “auxiliary_data_inverse”, ICL Extraction asserts all ports on all instances declared as an auxiliary_data or auxiliary_data_inverse to their inactive values, except for the current port which is not forced. This enables ICL Extraction to trace through AND-like combinational logic that combines several active-low auxiliary data pins into one single data signal. Please note that this logic will be represented by a OneHotDataGroup in the generated ICL. Therefore, the involved DataOutPorts must have the “Enable” property or an equivalent enabling condition to pass the ICL75 check.auxiliary_data_enable — Identifies the DataOutPort as an auxiliary data enable pin. When tracing a port with a forced_low_output_port_list or a forced_high_output_port_list attribute pointing to a port declared as an auxiliary_data_enable or auxiliary_data_enable_inverse, ICL extract asserts all ports on all instances declared as an auxiliary_data_enable or auxiliary_data_enable_inverse to their inactive values, except for the ones referenced by the current port which are forced to their active values instead. This enables ICL extract to extract DataOut ports connected through an AND OR mux like this: (d1 & en1) (d2 & en2) (d3 & en3);auxiliary_data_enable_inverse — Identifies the DataOutPort as an auxiliary data enable inverse pin.must_connect_to_top_port — Allowed on input and output ports of an ICL instrument to indicate that this input or output port is only allowed to be connected to a primary input or output pin of the current design. For example, a ScanInPort is allowed to be sourced by a ScanOutPort of another instance. If this attribute is set to must_connect_to_top_port, it is only allowed to be sourced by a primary input port.
default_load_value	This attribute corresponds to the DefaultLoadValue that is specified on DataIn ports in the ICL. Possible values are: 0, 1, or X, where X is specified when the DataIn port does not have a specified default load value.
differential_inv_of	An icl_port attribute that specifies a functional clock. The value is computed from the optional DifferentialInvOf keyword of the ClockPort or ToClockPort statement.

direction	<p>Direction of the icl_port.</p> <p>Possible values are as follows:</p> <ul style="list-style-type: none"> • input • output
exclude_from_sdc	<p>An attribute that is used to exclude ICL feedthrough clocks that the tool identifies as reference clocks. When set to true, the extract_sdc command ignores the ICL port when tracing functional clocks and does not add a generated clock.</p> <p>The default is false.</p>
explicit_iwrite_only	<p>An attribute that is used to specify that the value of an ICL data object cannot be changed by the retargeter unless it is the target of an explicit iWrite command. In the ICL, the attribute can be specified inside DataInPort, DataOutPort, ScanRegister and DataRegister elements. The attribute value can be specified as a sized or unsized binary number using legal ICL numbers 0 and 1, where a 1 activates the described functionality on the corresponding port bit, while 0 represents ordinary behavior. If the attribute value is specified as a sized number, the size must match the size of the object. If the attribute value is specified as an unsized number, it is padded with 0s if necessary. The right-most bit (the least significant bit) of the attribute value represents the right-most bit of the port, the second right-most bit of the value refers to the second right-most bit of the port, and so on. You can also specify the attribute value using string values that are simply binary, decimal or hexadecimal numbers. Complex expressions are not allowed if the attribute is specified as a string, but concatenation is allowed. You can use this attribute to have full control over parts of the scan path configuration and prevent the retargeter from always using the shortest path.</p>
forced_high_dft_signal_list	<p>This attribute is specified inside the Port wrappers of the ICL modules and is used to list Dft signals that must be forced high during the tracing of the current port. The pins or ports that correspond to the listed Dft signals are simulated high and appended to the stable_after_setup simulation condition when tracing the associated port.</p>
forced_low_dft_signal_list	<p>This attribute is specified inside the Port wrappers of the ICL modules and is used to list Dft signals that must be forced low during the tracing of the current port. The pins or ports that correspond to the listed Dft signals are simulated low and appended to the stable_after_setup simulation condition when tracing the associated port.</p>

forced_low_output_port_list	This attribute is specified inside the Port wrappers of the ICL modules and is used to list output ports on the IJTAG instrument that must be force low during the tracing of the current output port. The listed ports are simulated low and appended to the stable_after_setup simulation condition when tracing the associated output port. For example, tdoEnable typically needs to be forced active when tracing the tdo port of a TAP controller.
forced_high_output_port_list	This attribute is specified inside the Port wrappers of the ICL modules and is used to list output ports on the IJTAG instrument that must be force high during the tracing of the current output port. The listed ports are simulated high and appended to the stable_after_setup simulation condition when tracing the associated output port. For example, tdoEnable typically needs to be forced active when tracing the tdo port of a TAP controller.
freq_multiplier	A positive integer value attribute at the icl_port. The value is computed from the optional FreqMultiplier keyword of the ICL ToClockPort statement. The default value is 0.
freq_divider	A positive integer value attribute at the icl_port. The value is computed from the optional FreqDivider keyword of the ICL ToClockPort statement. The default value is 0.
function_modifier	A string with value CaptureShiftClock or CaptureShiftClockInv that can be specified on a ToCaptureEnPort and a CaptureEnPort in ICL. When specified to CaptureShiftClock or CaptureShiftClockInv on a CaptureEnPort, the port can only trace to ToCaptureEnablePort or a CaptureEnPort with function_modifier also set to CaptureShiftClock or CaptureShiftClockInv. When generating patterns for an ICL module and this module has a CaptureEnPort with function_modifier equal to CaptureShiftClock, the port is driven by a gated version of TCK that is only active during the capture and shift cycles. When generating patterns for an ICL module and this module has a CaptureEnPort with function_modifier equal to CaptureShiftClockInv, the port is driven by a gated version of inverted TCK that is only active during the capture and shift cycles. The function_modifier attribute value sync_tester_clock can be applied to Clock ports and ToClock ports to indicate that the clock will be in sync with the tester clock.

icl_extraction_port_trigger_list	String that contains a list of ports that must be present in the same ICL module. An ICL port with this attribute does not serve as a starting point for ICL Extraction tracing from the very beginning. This port is used as starting point only if one of the ports listed in the attribute value has been reached by tracing from another instance or top module port.
ijtag_function	String that specifies the function of the icl_port; for example, "scan_in". This is the ICL port function string converted to lowercase and the words connected with underscores.
index	Integer that specifies the index of the icl_port that is already part of the name when the icl_port is part of a bus.
is_bus	Boolean that specifies whether the icl_port is part of a bus. This attribute is set to true when the icl_port is part of a bus.
is_valid	Boolean that specifies whether the ICL port still exists. This attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
launch_edge	String attribute that is defined on a port with function ScanOut to reflect the LaunchEdge of the ScanOutPort in ICL.
master_module_name	String that specifies the master_name of the icl_module object the icl_port belongs to.
module_name	String that specifies the name of the icl_module object the icl_port belongs to.
name	String that specifies the name of the icl_port including its bus index when it is an element of a bus.
object_type	Returns the object data type "icl_port".
period	A string provides access to the "Period" specification of the ToClockPort in the ICL file.

read_latency	<p>An attribute that can be specified inside a DataRegister element. If present, the IJTAG retargeting engine will insert the specified latency as a delay before the corresponding DataRegister is read through an iRead operation. The delay is inserted right before the operation that captures value of the DataRegister. When an operation captures the value of multiple DataRegisters with the read_latency attribute, the delays are merged into a single delay. Use one of the following values for the read_latency attribute:</p> <ul style="list-style-type: none"> • tck <delay> : Indicates that the delay should last for <delay> cycles of the tester clock (TCK). • sck <icl_clock_port> <delay>: Indicates that the delay should last for <delay> cycles of the clock <icl_clock_port>. The clock has to be defined in the same module as the DataRegister with the read_latency attribute. The clock has to be previously traced with the iClock command. • time <time value>: Indicates that the delay should last for <time value>. The <time value> consists of a value and a time unit (s, ms, us, ns, fs or as), for example: 5us. When TCK is OFF, <delay> is converted to <delay>/tester_period TCK cycles rounded up to the next integer. If TCK is asynchronous free-running, TCK is ON and the <delay>/tester_period must be a multiple of the TCK ratio.
scan_interface_list	Lists all ScanInterface names that the port belongs to.
tessent_bisr_function	String that reflects the function of the ICL port for Tessent MemoryBIST's BISR ICL module. Legal values for this attribute are: Reset, MemoryDisable, Select.
tessent_clock_domain_labels	String that reports the label of clocks that were added prior to ICL extraction. The value is a list of label design pin/port. The attribute is added to ICL ports that represent asynchronous clocks, reference clocks, and branch clocks.
tessent_clock_periods	A string attribute that is set on ports of the current ICL design during ICL extraction. It reports the period that was set on the clock port with the “add_clocks -period” command prior to running ICL extraction. The value of this attribute is the “all” keyword followed by the period. The “all” keyword is used to reflect the fact that the period is used for all test modes. In the future, we may allow different periods to be specified for different test modes on the same pin, and this attribute will be able to reflect different periods for different modes by using the test mode name as the keyword.

tessent_common_tdr_source	An attribute that can be defined in any DataInPort wrapper inside the ICL Module wrapper to specify an arbitrary common source name for the DataInPorts. During the execution of the <code>create_dft_specification</code> command, one Tdr will be created with one DataOutPort for each unique source name such that all ports with the same common source name can be controlled by a single IJTAG signal. If "tessent_enable_group" is also specified, a separate Tdr will be created for each unique group.
tessent_default_procedure_name	An attribute that you can define inside a <code>ToClockPort</code> element of an ICL module to describe the name of an iProc that should be called by default to initialize the PLL or clock divider modeled by the ICL module. As you can see in Example 2 of the <code>ProcedureStep</code> section, the <code>create_icl_verification_patterns</code> command automatically detects that the memory BIST controller makes use of a clock that goes through the <code>ToClockPort</code> and automatically infers a <code>ProcedureStep</code> wrapper to initialize the PLL or clock divider associated to the <code>ToClockPort</code> . The <code>ProcedureStep</code> will include the <code>iProcArguments</code> wrapper if you also defined the <code>tessent_default_procedure_parameters</code> attribute.
tessent_default_procedure_parameters	An attribute that can be defined inside a <code>ToClockPort</code> element of an ICL module to describe the arguments that should be passed to the proc referenced by the <code>tessent_default_procedure_name</code> attribute
tessent_dft_function	A string attribute used to identify ICL ports having special meaning during DFT.
tessent_dft_signal_default_value_in_all_test	String attribute that defines the value the DFT signal is to have in all test modes. Its value is "1", or "0". See the description of the <code>register_static_dft_signal_names</code> command for more information. This attribute is mandatory when the <code>tessent_dft_signal_usage</code> attribute is set to <code>global_dft_control</code> and illegal otherwise.
tessent_dft_signal_name	A string attribute that defines the name of the DFT signal the ICL port corresponds to. This attribute is set on ports of the TDR created by <code>process_dft_specification</code> when the <code>add_dft_signals dft_signal_name -create_with_tdr</code> command is used. It is set on port of the current design when the <code>add_dft_signals dft_signal_name -source_node port_name -make_icl_port</code> command is used. If you want to have the output ports of your own TDR be automatically identified as the source of DFT signals, you must identify them with this attribute and three more attributes described below. See Example 2 in the <code>add_dft_signals</code> command for a complete example.

tessent_dft_signal_reset_value	A string attribute that defines the value the DFT signal is to have in functional mode. Its value is “1”, or “0”. See the description of the register_static_dft_signal_names command for more information. This attribute is mandatory when the tessent_dft_signal_name attribute is set on an ICL port.
tessent_dft_signal_scan_mode_type	A string attribute that defines the scan mode type of the DFT signal when the tessent_dft_signal_usage is set to scan_mode. See the description of the register_static_dft_signal_names command for more information. This attribute is mandatory when the tessent_dft_signal_usage attribute is set to scan_mode and illegal otherwise.
tessent_dft_signal_usage	A string attribute that defines the usage of the DFT signal. Its value is global_dft_control, logic_test_control and scan_mode. See the description of the register_static_dft_signal_names command for the meaning of each usage. This attribute is mandatory when the tessent_dft_signal_name attribute is set on an ICL port.
tessent_dft_signal_value_in_pre_scan_drc	A string attribute that defines the value the DFT signal is to be forced to during pre-DFT/pre-Scan DRC. Its value is “1”, “0”, or “x”. See the description of the register_static_dft_signal_names command for more information. This attribute is mandatory when the tessent_dft_signal_usage attribute is set to global_dft_control or logic_test_control.
tessent_enable_group	An attribute that can be defined in any DataInPort wrapper inside the ICL Module wrapper to specify arbitrary group names for the DataInPorts. During the execution of the create_dft_specification command, one Tdr will be created for each group of DataInPorts such that the group of ports can be controlled by IJTAG while leaving the ports in the other groups under functional control.

tessent_ignore_during_e14_drc	<p>This attribute controls the handling of ICL ports during the E14 check.</p> <p>If the test_setup procedure contains iCall commands, E14 also verifies the effect of the processed iRead and iWrite commands on the design. This verification can be suppressed by means of the “tessent_ignore_during_e14_drc” attribute.</p> <p>The attribute value can be specified as a sized or unsized binary number using legal ICL digits 0, 1 and X. If the attribute value is specified as a sized number, the size must match the size of the object. If the attribute value is specified as an unsized number, it is padded with 0s or Xs if necessary, dependent on the leftmost specified bit. The right-most bit (the least significant bit) of the attribute value refers to the right-most bit of the port, the second right-most bit of the value refers to the second right-most bit of the port, and so on. The value ‘1’ instructs Tessent Shell to ignore the bit of the port during the E14 check, the values ‘0’ and ‘X’ represent the default behavior.</p>
tessent_ignore_during_icl_verification	A string attribute used to identify an ICL module that is to be automatically excluded from the ICLNetworkVerify patterns or from the patterns created using the create_icl_verification_patterns command.
tessent_memory_bist_function	String that reflects the function of the ICL port for Tessent MemoryBIST’s ICL module of the memory module.
tessent_no_input_constraints	An attribute that affects only ICL ports of type DataInPort. If this attribute is not set on an ICL port with port function DataInPort or if it is set to “off”, then the port is automatically constrained to C0 or C1 at the end of the test_setup procedure, according to the last value that has been assigned to it during the IJTAG retargeting of the iCall and iMerge commands in the test_setup procedure. If the attribute is set to “on”, this behavior is suppressed.

tessent_use_in_dft_specification	<p>String attribute that you can set to off on an ICL Port to force the create_dft_specification command to ignore this DataIn or DataOut port. The attribute can be added in the ICL source description or set using the set_attribute_value command. The legal values for this attribute are: auto, false, auto_no_pi.</p> <p>When set or left to default to auto, the DataInPort will be driven by a TDR DataOutPort if it is not seen to be already sourced by a DataOutPort or a primary input of the current design. The DataOutPorts will be observed by a TDR DataInPort if it is not seen to be already observed by a DataInPort or a Primary output of the current design. See the description of the tessent_enable_group and tessent_common_tdr_source attributes above for a method to control the TDR assignment. The complete algorithm on how this works is described in the create_dft_specification command description. To have create_dft_specification ignore a complete ICL instance, use the “set_ijtag_instance_options -use_in_dft_specification off” command.</p> <p>When set to “auto_no_pi”, the DataInPort will be equipped with a local IJTAG control even if it is seen to already be sourced by a primary input. You want to use the “auto_no_pi” value for ports like the reset port of a PLL because they are often sourced by a system level reset port. Even though it is possible to toggle the system reset to reset the PLL, the effect of the reset pulse will be felt by the entire system and you may affect already running parts of the circuit. When you provide local controllability, it becomes possible to reset the PLL without affecting the rest of the chip. See the description of create_dft_specification for more information about how DataInPorts are handled during the creation of the DFT specification.</p>
write_latency	<p>An attribute that can be specified inside a DataRegister element. If present, the IJTAG retargeting engine will insert the specified latency as a delay after each iApply that contained an iWrite operation to the DataRegister. When the iApply contains write operations to multiple DataRegisters with the write_latency attribute, the delays are merged into a single delay.</p> <p>For details on the possible values of the write_latency attribute, see the documentation of the values for the read_latency attribute.</p>

Inheritance

Built-in attribute inheritance from associated icl_module objects:

- None

User-defined attributes are inherited. See “[Attribute Inheritance Behavior](#)” on page 3170.

icl_instance

An icl_instance is a single instantiation of an icl_module. No icl_instance object exists until the set_current_design command is executed.

The icl_instance object type interacts with attributes as follows:

- The icl_instance attributes are automatically visible as read-only attributes on corresponding icl_instances if the icl_instance object type does not have the same attribute registered.
- Attributes defined with the applies_to_child_instances option set to On automatically become visible to all child instances of the icl_instance object.
- The object type icl_instance treats different physical instances as different objects, even if they are associated with the same “[Instance](#)” construct in the ICL file (this can happen if the instances have the same parent module, but the parent module is instantiated several times). This introduces ambiguity during [write_icl](#), if an attribute is set to different values on different icl_instance objects associated with the same “Instance” construct. In case of ambiguity, the most recent usage of the commands [set_attribute_value](#) or [reset_attribute_value](#) determines the value of the attribute in the written ICL file.

For more information on attributes, see “[Attributes](#)” on page 3159.

Built-In Attributes

The icl_instance object type has the following attributes:

is_valid	Boolean that specifies whether the ICL instance still exists. This attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
leaf_name	String that specifies the name of the icl_instance (value of the name attribute) without the hierarchical path.
master_module_name	String that specifies the value of the master_name on the icl_module object associated with the icl_instance.
module_name	String that specifies the name of the ICL module associated to the icl_instance with the @PV# suffix when the instantiation uses parameter overrides.
name	String that specifies the full hierarchical instance path of the icl_instance with '.' as a hierarchy separator.
object_type	Returns the object data type “icl_instance”.
parent_instance	String that specifies the instance name of the ICL instance in which the pin is instantiated. It is null for pins on icl_instances found within the current design.

tessent_clock_domain_labels	String that reports the label of clocks that were added prior to ICL extraction. The value is a list of <i>label design pin/port</i> . The attribute is added to ICL instances that represent asynchronous clocks, reference clocks, and branch clocks.
tessent_design_instance	An attribute populated by ICL extract when extracting the top level ICL module. The attribute reflects the hierarchical instance path of the design instance corresponding to the ICL instance at the time of ICL extraction. The design instance path is relative to the current design at the time the ICL module was extracted which is always the parent ICL module of the ICL Instance. To get the complete design instance path of an ICL instance, use the <code>hierarchical_design_instance</code> attribute. ICL Extraction sets the <code>tessent_design_instance</code> attribute to the pre-synthesis instance names whenever those names are available.
hierarchical_design_instance	A string attribute that returns the complete hierarchical instance path of a design instance to the top. Unlike <code>tessent_design_instance</code> , <code>hierarchical_design_instance</code> is a read-only attribute that is computed internally and contains the complete instance path of a design instance. The path is computed only if the <code>tessent_design_instance</code> attribute is set for each instance in the hierarchy, otherwise an empty string is returned. The <code>tessent_design_instance</code> attribute, on the other hand, is an ICL attribute that is either user-specified or inserted by ICL extraction, and contains only the relative portion of the instance path between a design instance and the design module which matches the ICL module in which the ICL instance is instantiated.
tessent_ignore_during_icl_verification	A string attribute used to identify an ICL instance that is to be automatically excluded from the ICLNetworkVerify patterns or from the patterns created using the create_icl_verification_patterns command.

Inheritance

Built-in attribute inheritance from associated `icl_module` objects:

- `c0_constrained_internal_pin_list`
- `c0_constrained_pin_list`
- `c1_constrained_internal_pin_list`
- `c1_constrained_pin_list`
- `icl_extraction_time`
- `is_created`
- `partially_constrained_bus_pin_list`

- port_group_list
- tesson_instrument_type
- test_setup_procfile

User-defined attributes are inherited. See “[Attribute Inheritance Behavior](#)” on page 3170.

icl_pin

An `icl_pin` is an object on an `icl_instance` that can be connected to other `icl_pin` or `icl_port` objects. No `icl_pin` object exists until the `set_current_design` command is executed.

The `icl_pin` object type interacts with attributes as follows:

- Attributes defined on `icl_port` objects are automatically visible as read-only attributes on the associated `icl_pin` objects unless the attribute is also registered for the `icl_pin` object type. This is the case for the `name` attribute which is defined for both `icl_port` and `icl_pin` object types.

For more information on attributes, see “[Attributes](#)” on page 3159.

Built-In Attributes

The icl_pin object type has the following attributes

base_name	String that specifies the name of the pin without the leaf name.
freq_multiplier	A positive integer value attribute at the icl_pin. The value is computed from the optional FreqMultiplier keyword of the ICL ToClockPort statement. The default value is 0.
freq_divider	A positive integer value attribute at the icl_pin. The value is computed from the optional FreqDivider keyword of the ICL ToClockPort statement. The default value is 0.
is_valid	Boolean that specifies whether the icl_pin still exists. This attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
leaf_name	String that specifies the name of the ICL pin (value of the name attribute) without the hierarchical path.
name	String that specifies the full hierarchical name of the icl_pin with '.' as a hierarchy separator.
object_type	Returns the object data type "icl_pin".
parent_instance	String that specifies the name of the parent icl_instance of the icl_instance on which the icl_pin is on.
tessent_bisr_power_domain_name	This attribute is only specified for ICL pins of the fuse box controller, which is part of the memory repair technology of Tessent MemoryBIST. The attribute is used to identify the power domain group label for each pin.
tessent_ignore_during_icl_verification	A string attribute used to identify an ICL module that is to be automatically excluded from the ICLNetworkVerify patterns or from the patterns created using the create_icl_verification_patterns command.
tie_value	String that indicates the value to which the port is tied. Possible values are: 0, 1, X, or "" (empty string). The default is the empty string which means the port is not tied to a value.

Inheritance

Built-in attribute inheritance from associated icl_port objects:

- bus_left_index
- bus_name
- bus_range_direction
- bus_right_index

- bus_width
- direction
- ijtag_function
- index
- is_bus
- master_module_name
- module_name
- period
- port_group_list

User-defined attributes are inherited. See “[Attribute Inheritance Behavior](#)” on page 3170.

Pin Specification

An ICL pin object is specified by a complete hierarchical ICL pin pathname including the ICL pin. For example: /u1/u2/u3/Y refers to pin Y of the hierarchical instance /u1/u2/u3.

Scan Data Model

This section describes the scan models used for Hierarchical Scan Insertion and their built-in attributes.

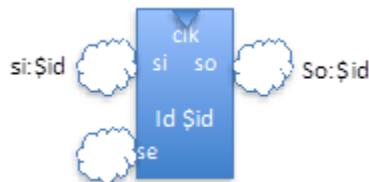

Scan Element Object Type	3144
Scan Chain Family Object Type.....	3150
Scan Mode Object Type	3151

Scan Element Object Type

The Scan Element object type is used to represent all scan path objects making up the scan segments and the scan chains.

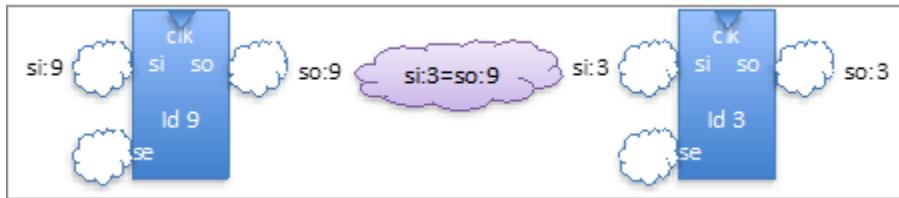

A scan element is either hierarchical (for example, scan chain, scan segment, shift register) or a leaf node, which models a single scan path of a cell or blackbox. The most common leaf scan element model is a single-bit scan cell, but multi-bit leaves like a flop-tray or a multi-chain cell can be modeled with one or more scan elements respectively. After DRC, there is one “active” scan element per scannable path of each cell, per declared scan segment and per scan chain. Most scan element leaves are populated from DRC results, but some get inferred by the planned insertion of certain types of modules like dedicated wrapper cells; these scan elements are deemed “virtual” as they do not exist yet but are assumed to exist for analysis and planning purposes.

The figure below is a simplified graphical representation of a scan_element. \$id in si:\$id and so:\$id means that the group is taken from the id (node group) of the associated element. Other signals are classified into three different groups: at_speed_control, static_control, and clock. The scan element object holds a unique value for each of those group IDs.

The si:\$id of one scan element connects to the si signal of its parent scan element when it is the first child element. It connects to the so of the previous element when it is not the first element. The so:\$id of a hierarchical scan element connects to the so of its last child. The next figure

illustrates how the scan path equation “si:3 = so:9” is used to create a scan path between scan elements 9 and 3. Similarly, equations are used to control the scan enable of each scan element.

If specified, the si equation must include the signal type "si" as one of its inputs; similarly, the so equation must include the signal type "so" as one of its input. If specified, the clk equation must include the signal type "clk" or the operator <src> as one of its inputs.

Table 8-2. Built in attributes on Scan Element (SE) Object Type

Attribute name	Default	Description
class		standard, core, wrapper
clock_domains		The clock domain name(s) of this element.
cluster_name		The value of the cluster_name attribute, if any.
exists		Indicates if the scan element exists in the design netlist; a false value signifies that the element has not been implemented yet
has_children		Indicates if a hierarchical scan element has sub-scan elements defining it.
id		This is a unique integer that uniquely identifies a “scan_element” object. This id is only persistent within one run while in the analysis or insertion state.
is_non_scannable	False	Boolean that specifies that the scan element is non-scannable. Default is false.

Table 8-2. Built in attributes on Scan Element (SE) Object Type (cont.)

Attribute name	Default	Description
is_non_scannable_reason		<p>A string that specifies why the scan_element is non-scannable, as follows:</p> <ul style="list-style-type: none">• user_specified — The object was specified to be non-scannable using the add_nonscan_instances command.• inferred_from_drc — The object was inferred to be non-scannable during DRC either because it had an S-rule violation or it is part of a hard_module yet excluded from the traced scan chains.• imported_from_tcd_scan — The object was inferred to be nonscannable because it has a Core/Scan TCD description and the property drc_from_boundary_only is equal to 1.• imported_from_icl — The instance was inferred to be nonscannable because it has a matched ICL description and the attribute keep_active_during_scan_test is not specified as false.• imported_from_bscan — The instance was inferred to be nonscannable because it is part of the boundary scan chain.

Table 8-2. Built in attributes on Scan Element (SE) Object Type (cont.)

Attribute name	Default	Description
is_non_scannable_reason (continued)		<ul style="list-style-type: none"> • missing_scan_model <ul style="list-style-type: none"> — The instance was inferred to be nonscannable because it does not have a scan flop equivalent mapping. This only happens in dft-scan context. • user_specified_from_net <ul style="list-style-type: none"> — The instance is non scannable because the add_nonscan_instances -rtl_reg command was used on a net which happens to be an RTL register. The instance happens to be the flip-flop instance that the tool created during quick synthesis for that RTL register. • If is_non_scannable is false, then is_nonscannable_reason returns an empty string. The scan_element also inherits is_non_scannable_reason values from its associated instance (see instance attributes).
length		This is the length of the scan element object (number of master sequential cells recursively found down the hierarchy).
name		This is an optional name that was given when defining the “scan_element” object. This name is not necessarily unique and may be null.
no_si_pipeline		Boolean indicating that no pipelining element would get inserted at the beginning of a new scan chain if this element is the first element in the chain.

Table 8-2. Built in attributes on Scan Element (SE) Object Type (cont.)

Attribute name	Default	Description
no_si_pipelining_reason		A string that specifies why no_si_pipelining is set for a scan_element, as follows: <ul style="list-style-type: none">• imported_from_tcd_scan<ul style="list-style-type: none">— A .tcd_scan file specified no_si_pipelining on this scan_element.• user_specified<ul style="list-style-type: none">— The object specified no_si_pipelining by setting the specified_no_si_pipelining attribute.• If no_si_pipelining is false, then is_nonscannable_reason returns an empty string.
power_domain_island		Returns the name of the power domain island associated to the scan_element. This attribute is inherited for its parent design object if a UPF or CPF file has been read in. For a definition of Power Domain Island , refer to the <i>Tessent Glossary</i> .
power_domain_name		The value of the power_domain_name attribute, if any. For a definition of Power Domain , refer to the <i>Tessent Glossary</i> .
si_clock_domain		Clock domain for the first scan cell.
si_clock_edge		Capture edge for the first scan cell.
so_clock_domain		Clock domain for the last scan cell.
so_clock_edge		Capture edge for the last scan cell.
specified_no_si_pipelining		An attribute that prevents a pipelining element to get inserted at the beginning of a new scan chain if this element is the first element in the chain, even if the scan insertion options specifies -si_pipelining for that chain.

Table 8-2. Built in attributes on Scan Element (SE) Object Type (cont.)

Attribute name	Default	Description
specified_wrapper_type	Off	<p>An attribute that forces the wrapper type of a scan_element. Available values are: off, input, output, and generic. The default is off.</p> <ul style="list-style-type: none"> The result of the analyze_wrapper_cells command, which combines the specified_wrapper_type values with the inferred values, are reflected in the wrapper_type and wrapper_type_reason attributes described below. When set or left to default to off, the wrapper_type value of each scan_element object is computed by the analyze_wrapper_cells command. When you set the specified_wrapper_type attribute to input, output, or generic, the specification is kept during the analysis. If you used the input value, the analyze_wrapper_cells command will automatically find all flip-flops fanning out to the scan_element you forced to input type and infer them as output wrapper type.
state		ignored unusable unusable_child_mode unresolved_child_mode usable usable_indirectly. Only “usable” scan elements can be specified as part of a population when defining a chain/segment using the “-include_...” option.
type		chain segment leaf_cell shift_register transparent_leaf_cell inferred
used		Indicates if the scan element is used in at least one mode

Table 8-2. Built in attributes on Scan Element (SE) Object Type (cont.)

Attribute name	Default	Description
wrapper_type		input output generic ""
wrapper_type_reason		An attribute that describes why the wrapper has a given type. <ul style="list-style-type: none"> • inferred_from_analysis <ul style="list-style-type: none"> — Indicates the type was inferred by the analyze_wrapper_cells command. • inferred_from_clock_source <ul style="list-style-type: none"> — Means the instance is an OCC, the fast_clock port of the OCC is not directly sourced by a PI (that is, a PLL or clock divider), and the OCC drives at least one flop of type input or output wrapper. The wrapper_type is always generic when wrapper_type_reason is inferred_from_clock_source. • user_specified <ul style="list-style-type: none"> — Indicates the specified_wrapper_type attribute was explicitly set on the flop or clock gater instances.

Scan Chain Family Object Type

The scan_chain_family is an intelligent container that controls the allocation of new scan chains from a specific population of scan element.

The command create_scan_chain_family is used to generate new chain families; the related commands delete_scan_chain_families and get_scan_chain_families are also available. The current introspection is currently very limited, but will eventually include the various scan insertion options specified for this particular population sample.

Table 8-3. Built in Attributes on Scan Chain Family Object Type

Attribute name	Default	Description
name		This is an optional name than was given when defining the “scan_chain_family” object. This name is not necessarily unique and may be null.

Table 8-3. Built in Attributes on Scan Chain Family Object Type (cont.)

Attribute name	Default	Description
id		This is a unique integer that uniquely identifies a “scan_chain_family” object. This id is only persistent within one run while in the analysis or insertion state.

Scan Mode Object Type

The scan_mode object controls the allocation of scan chains for a specific scan mode. The scan_mode object controls the allocation of scan chains for a specific scan mode.

The hierarchical scan engine allows you to specify any number of scan modes. A mode typically applies to an entire scan element population or a large subset (for example, wrapper elements), and is typically populated by including scan_element objects directly and/or scan_chain_family objects.

Table 8-4. Built-in Attributes on Scan Mode Object Type

Attribute Name	Default	Description
name		This is an optional name than was given when defining the “scan_mode” object. This name is not necessarily unique and may be null.
id		This is a unique integer that uniquely identifies a “scan_mode” object. This id is only persistent within one run while in the analysis or insertion state.

Test Point Data Model

This section describes the Test Point data model and its built-in attributes.

Test points are inserted into the design to increase controllability and/or observability of otherwise hard to reach locations. For more information, see “[What are Test Points?](#)” in the *Tessent Scan and ATPG User’s Manual*.

Table 8-5. Built in Attributes on Test Point Object Type

Attribute name	Default	Description
name		A unique name that was given when defining the “test point” object.
id		A unique integer that uniquely identifies a “test_point” object. This id is only persistent within one run while in the analysis or insertion state.
location		A string representing the full design path to the observed/controlled gate.
shared_id		An integer indicating the test points that are driven by the same flop. This integer is unique per sharing group.
type		A string that specifies the type of test point. The possible values are: <ul style="list-style-type: none"> • control point • observe point
control_point_gate_type		A string that specifies the type of control point. The possible values are: <ul style="list-style-type: none"> • AND Control Point • OR Control Point
origin		A string that specifies how the test point was created. The possible values are: <ul style="list-style-type: none"> • user_specified — created by the user or imported from an external tool/script • design_analysis — created by the tool with the analyze_test_points command
power_domain_name		A string representing the power domain name of the test point location.
power_domain_island		A string representing the power domain island in which the test point is placed.
clock_connection_name		A string representing the full design path to the clock that is driving the test point flop.
enable_connection_name		A string representing the full design path to the connection that enables the test point.
flop_location		A string representing the full design path to the observed/controlled flop instance.

Configuration Data Model

This section describes the Configuration data model and its built-in attributes.

config_csv_wrapper	3153
config_data_wrapper	3154
config_property	3155
config_repeatable_property	3155
config_wrapper	3156

config_csv_wrapper

This section describes the built-in attributes for the config_csv_wrapper object type.

You use this metadata syntax to define a config_csv_wrapper in the [CsvWrapper](#) that contains comma separated value lists.

Built-In Attributes

expanded_tree_node	If you use the add_config_tab command to display a configuration data tree in the GUI, then you can open the nodes as if you clicked the [+] sign in the GUI. If you click the [+] in the GUI and you query the value of this attribute, it will reflect that the node is open with a true value. If you save the configuration data to file using write_config_data , you will see a +{ for all wrappers that were open at the time you issue the command. Reading this configuration data back using read_config_data will restore the value of this attribute where the wrapper starting with +{ will have this attribute true and those open with { will have it false.
file_path_name	String attribute that specifies the pathname to the file where a given object was read using the read_config_data command. When the configuration is created in memory using commands such as add_config_element , the value of this attribute is null.
is_valid	Boolean that specifies whether the object still exists. This Boolean attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
leaf_name	String that specifies the leaf name of the object. Refer to the get_config_value command for a precise description of what is the leaf name of a configuration object.
line_number	String that specifies a line number in the file where a given object was read from using the read_config_data command. When the configuration is created in memory using commands such as add_config_element , the value of this attribute is null.

name	String that specifies the name of the object. Refer to the get_config_value command for a precise description of what is the leaf name of a configuration object.
object_type	Returns the object type of the configuration element, namely 'config_csv_wrapper' for this object type.

config_data_wrapper

This section describes the built-in attributes for the config_data_wrapper object.

You use this metadata syntax to define a config_data_wrapper in the [DataWrapper](#) that contains comma separated value lists.

Built-In Attributes

expanded_tree_node	If you use the add_config_tab command to display a configuration data tree in the GUI, then you can open the nodes as if you clicked the [+] sign in the GUI. If you click the [+] in the GUI and you query the value of this attribute, it will reflect that the node is open with a true value. If you save the configuration data to file using write_config_data , you will see a +{ for all wrappers that were open at the time you issue the command. Reading this configuration data back using read_config_data will restore the value of this attribute where the wrapper starting with +{ will have this attribute true and those open with { will have it false.
file_path_name	String attribute that specifies the pathname to the file where a given object was read from using the read_config_data command. When the configuration is created in memory using commands such as add_config_element , the value of this attribute is null.
is_valid	Boolean that specifies whether the object still exists. This Boolean attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
leaf_name	String that specifies the leaf name of the object. Refer to the get_config_value command for a precise description of what is the leaf name of a configuration object.
line_number	String that specifies a line number in the file where a given object was read from using the read_config_data command. When the configuration is created in memory using commands such as add_config_element , the value of this attribute is null.
name	String that specifies the name of the object. Refer to the get_config_value command for a precise description of what is the leaf name of a configuration object.

object_type	Returns the object type of the configuration element, namely 'config_data_wrapper' for this object type.
-------------	--

config_property

This section describes the built-in attributes of the config_property object.

You use this metadata syntax to define a config_property wrapper in the [Property](#) wrapper that contains comma separated value lists.

Built-In Attributes

file_path_name	String attribute that specifies the pathname to the file where a given object was read from using the read_config_data command. When the configuration is created in memory using commands such as add_config_element , the value of this attribute is null.
is_valid	Boolean that specifies whether the object still exists. This Boolean attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
leaf_name	String that specifies the leaf name of the object. Refer to the get_config_value command for a precise description of what is the leaf name of a configuration object.
line_number	String that specifies a line number in the file where a given object was read from using the read_config_data command. When the configuration is created in memory using commands such as add_config_element , the value of this attribute is null.
name	String that specifies the name of the object. Refer to the get_config_value command for a precise description of what is the leaf name of a configuration object.
object_type	Returns the object type of the configuration element, namely 'config_property' for this object type.
value	String that returns the value of the property the same way get_config_value does. The value attribute is useful when you want to filter a collection of config property objects based on their current values.

config_repeatable_property

The section describes the built-in attributes for the config_repeatable_property object.

You use this metadata syntax to define a config_repeatable_property wrapper in the [RepeatableProperty](#) wrapper that contains comma separated value lists.

Built-In Attributes

file_path_name	String attribute that specifies the pathname to the file where a given object was read from using the read_config_data command. When the configuration is created in memory using commands such as add_config_element , the value of this attribute is null.
is_valid	Boolean that specifies whether the object still exists. This Boolean attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
leaf_name	String that specifies the leaf name of the object. Refer to the get_config_value command for a precise description of what is the leaf name of a configuration object.
line_number	String that specifies a line number in the file where a given object was read from using the read_config_data command. When the configuration is created in memory using commands such as add_config_element , the value of this attribute is null.
name	String that specifies the name of the object. Refer to the get_config_value command for a precise description of what is the leaf name of a configuration object.
object_type	Returns the object type of the configuration element, namely 'config_repeatable_property' for this object type.
value	String that returns the value of the property the same way get_config_value does. The value attribute is useful when you want to filter a collection of config property objects based on their current values.

config_wrapper

This section describes the built-in attributes for the config_wrapper object.

You use this metadata syntax to define a config_wrapper in the [Wrapper](#) that contains comma separated value lists.

Built-In Attributes

expanded_tree_node	If you use the add_config_tab command to display a configuration data tree in the GUI, then you can open the nodes as if you clicked the [+] sign in the GUI. If you click the [+] in the GUI and you query the value of this attribute, it will reflect that the node is open with a true value. If you save the configuration data to file using write_config_data , you will see a +{ for all wrappers that were open at the time you issue the command. Reading this configuration data back using read_config_data will restore the value of this attribute where the wrapper starting with +{ will have this attribute true and those open with { will have it false.
file_path_name	String attribute that specifies the pathname to the file where a given object was read from using the read_config_data command. When the configuration is created in memory using commands such as add_config_element , the value of this attribute is null.
is_valid	Boolean that specifies whether the object still exists. This Boolean attribute is set to true unless the object is deleted, in which case the is_valid attribute becomes false.
leaf_name	String that specifies the leaf name of the object. Refer to the get_config_value command for a precise description of what is the leaf name of a configuration object.
line_number	String that specifies a line number in the file where a given object was read from using the read_config_data command. When the configuration is created in memory using commands such as add_config_element , the value of this attribute is null.
name	String that specifies the name of the object. Refer to the get_config_value command for a precise description of what is the leaf name of a configuration object.
object_type	Returns the object type of the configuration element, namely 'config_wrapper' for this object type.
tree_node_state	String that specifies the tree node state. Possible values are as follows: <ul style="list-style-type: none">• default• pass• maybe• fail

Chapter 9

Attributes

Attributes are properties assigned to any object type. Attributes have names and values to associate relevant data with those objects. Attribute names may only include alphanumeric and underscore characters.

This section provides information on the following topics:

For detailed information on the attributes associated with each object type, see “[Data Models](#)” on page 3055.

Attribute-Related Commands	3159
Attribute Types	3161
Pre-Defined Attributes	3161
User-Defined Attributes	3161
Attribute Value Types	3161
Attribute Filtering Equation Syntax	3162
Glob and Regular Expression Pattern Matching Syntax	3164
Hierarchical Name Matching With Escaped Identifiers	3167
Attribute Inheritance Behavior	3170
Inheritance Rules	3170
DFT Test Logic Related Attributes (no_control_point and no_observe_point)	3171

Attribute-Related Commands

You use the attribute-related Tesson Shell commands to create, manipulate, and query objects' attributes.

Table 9-1. Commands for Manipulating Attributes

Command	Description
get_attribute_list	Returns an alphabetically sorted Tcl list of attribute names.
get_attribute_option	Retrieves the current setting of an attribute's option.
get_attribute_value_list	Retrieves the value of an attribute on the specified design objects.
get_name_list	Returns the name(s) of the specified object(s).
register_attribute	Registers a new user-defined attribute.

Table 9-1. Commands for Manipulating Attributes (cont.)

Command	Description
report_attributes	Creates a human readable report for the set of attributes based on the usage options.
reset_attribute_value	Resets an attribute to its default value for the design objects specified in obj_spec.
set_attribute_options	Modifies options of any registered user-defined attribute.
set_attribute_value	Sets an attribute's value for the objects specified in object_spec.
unregister_attribute	Unregisters a user-defined attribute that was registered using the register_attribute command.

Attribute Types

Tessent Shell supports two types of attributes: pre-defined attributes and user-defined attributes. Different object types have different pre-defined attributes. You can also create and specify user-defined attributes.

Pre-Defined Attributes	3161
User-Defined Attributes	3161

Pre-Defined Attributes

Pre-defined attributes exist on the object itself in the internal database. Because of this, pre-defined attributes do not need to be registered. Different object types have different pre-defined attributes. By default, these attributes are read-only.

Each data model has a list of pre-defined attributes that are described in sections “[Hierarchical Design Data Model](#)”, “[Flat Design Data Model](#)”, and “[ICL Data Model](#)”.

User-Defined Attributes

User-defined attributes are registered with the `register_attribute` command before they can be used. The registration operation defines the attribute’s value type and its default value and determines which design object type the attribute belongs to.

Attribute Value Types

Both pre-defined and user-defined attributes have an attribute value type.

Table 9-2. Attribute Value Types

Type	Description
Boolean	Case-insensitive. A Boolean. <ul style="list-style-type: none">Accepts any of the following for true: 1, true, yes, on.Accepts any of the following for false: 0, false, no, off
Integer	Case-insensitive. An integer.
Double	Case-insensitive. Double-precision floating-point number.
String	Case-insensitive. A sequence of alphanumeric characters.

Attribute Filtering Equation Syntax

An attribute filtering equation is a series of relations joined together with the `&&` (AND) and `||` (OR) operators. Parentheses are also supported. A basic relation compares or matches the value of an attribute with a constant expression through a relational operator.

Relational Operators

The relational operators are as follows:

<code>==</code>	Equal
<code>!=</code>	Not equal
<code>></code>	Greater than
<code><</code>	Less than
<code>>=</code>	Greater than or equal to
<code><=</code>	Less than or equal to
<code>=~</code>	Matches pattern
<code>!~</code>	Does not match pattern

Basic Relational Rules

The basic relational rules are as follows:

- Compare string attributes using any operator.
- Do not compare numeric attributes using pattern matching operators (`=~` or `!~`).
- Compare Boolean attributes using only `==` and `!=`. The only possible value is true or false.
- Using an attribute without a relational operator in an equation is equivalent to saying `att == true` for a Boolean attribute or `att != <defaultValue>` for other types. You can also invert this default behavior by putting a `!` in front of the attribute name. For example:

```
is_something && !is_something_else
```

translates to:

```
is_something != <default> && is_something_else == <default>
```

which mean the following when the attributes are of Boolean type:

```
is_something == true && is_something_else == false
```

Pattern Matching in the Filtering Attribute Equation

By default, the `=~` and `!~` filter operators use simple wildcard pattern matching (glob) with the `“*”` and `“?”` wildcards. When the `-regexp` option is specified for any command, the complete Posix Extended Regular Expression syntax is supported.

When you use the `-regexp` option, you should pay special attention to how you quote filter expressions. We recommend using rigid quoting with braces around regular expressions.

Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `“.*”` to the beginning or end of the expression as necessary.

Refer to “[Glob and Regular Expression Pattern Matching Syntax](#)” for a complete description of the Tesseract Shell pattern matching mechanism and a detailed description of the regular expression syntax.

Filter Equation Examples

This example shows different filtering attribute equations used to filter instance objects:

```
register_attribute -name Att1 -value_type boolean -object_types instance
register_attribute -name Att2 -value_type integer -default -1
register_attribute -name Att3 -value_type string -default ""

set_attribute_value u1 -name Att1
set_attribute_value u1 -name Att2 -value 3
set_attribute_value u1 -name Att3 -value "aba"

set_attribute_value u2 -name Att1
set_attribute_value u2 -name Att3 -value "abb"

#Matches only u1 because Att2 has default value on u2 so Att2 returns
#false

get_instance -filter {Att1 && Att2}
{u1}

#Matches both because Att3 starts with a in both

get_instance -filter {Att1 && Att3 =~ "a*”}
{u1 u2}

#Matches u2 because Att2 defaults to -1.

get_instances -filter {Att2 < 2}
{u2}
```

Glob and Regular Expression Pattern Matching Syntax

The introspection commands perform pattern matching in two distinct ways with subtle usage differences. The first way is with the *name_patterns* argument and it is specified as a list of patterns to match against object names. The second one is the use of the `=~` and `~!` operators within a filter attribute equation.

When specifying *name_patterns*, the hierarchy separator (`/`) is used to automatically split the matching patterns so that each pattern can be matched against the leaf name of each level of hierarchy separately. For example, the command “`get_instance a*/b*`” means to match the leaf instance starting with `b` in each instance whose name starts with `a`. Refer to section “[Hierarchical Name Matching With Escaped Identifiers](#)” for ways to deal with that in the presence of escape identifiers, especially when the escaped identifiers contains slashes.

When specifying the filter attribute equation, the `/` is treated as a literal within the pattern and the entire value of the attribute is searched by the entire pattern. For example, the command “`get_instance -filter {name =~ "a*/b*"}`” would match instance `a1/b1` as well as `a1/c1/b1` because `a*` matches “`1/c1`” as the `/` is just another literal character to match.

In regular expressions syntax, most characters are treated as literals. That is, they match only themselves (for example, `a` matches “`a`”). The exceptions are called meta characters and are listed in [Table 9-3](#)

Table 9-3. Posix Extended Regular Expression Metacharacters

Meta Character	Description
.	The dot matches any single character. Within bracket expressions, the dot character matches a literal dot. For example: <code>a.c</code> matches “ <code>abc</code> ” and so on but <code>[a.c]</code> matches only “ <code>a</code> ”, “ <code>.</code> ”, or “ <code>c</code> ”.
[]	A bracket expression. Matches a single character that is contained within the brackets. For example, <code>[abc]</code> matches “ <code>a</code> ”, “ <code>b</code> ”, or “ <code>c</code> ”. <code>[a-z]</code> specifies a range which matches any lowercase letter from “ <code>a</code> ” to “ <code>z</code> ”. These forms can be mixed: <code>[abcx-z]</code> matches “ <code>a</code> ”, “ <code>b</code> ”, “ <code>c</code> ”, “ <code>x</code> ”, “ <code>y</code> ”, or “ <code>z</code> ”, as does <code>[a-cx-z]</code> . The <code>-</code> character is treated as a literal character if it is the last or the first character within the brackets: <code>[abc-]</code> , <code>[-abc]</code> . Note that backslash escapes are not allowed. The <code>]</code> character can be included in a bracket expression if they are the first character: <code>[]abc</code> . The <code>[</code> character can appear anywhere.
[^]	Matches a single character that is not contained within the brackets. For example, <code>[^abc]</code> matches any character other than “ <code>a</code> ”, “ <code>b</code> ”, or “ <code>c</code> ”. <code>[^a-z]</code> matches any single character that is not a lowercase letter from “ <code>a</code> ” to “ <code>z</code> ”. As above, literal characters and ranges can be mixed.

Table 9-3. Posix Extended Regular Expression Metacharacters (cont.)

Meta Character	Description
^	Matches the starting position of the string. In Tesson shell, all matching is rooted which means the ^ character is inferred at the beginning of every expression when it is not already specified. For example, abc.* is equivalent to ^abc.* and both mean to match any string starting with abc.
\$	Matches the ending position of the string. In Tesson shell, all matching are rooted which means that the \$ character is inferred at the end of every expression when it is not already specified. For example, .*abc is equivalent to .*abc\$ and both mean to match any string ending with abc.
()	Defines a marked expression. The string matched within the parentheses can be recalled later (see next entry, \n). A marked expression can also be used to specify a sequence of characters that must be matched some number of times by following it by a *, + or {m.n} sequence. For example, (ab)* matches "", "ab", "abab", "ababab", and so on.
\n	Matches what the nth marked expression matched, where n is a digit from 1 to 9. For example (ab).*\1 matches any string that starts and ends with either a or b, such as aa, aca, aba, or bab but not acb and bca. A second example (ab)(cd).*\2\1 matches acffca but not acffaa because the second marked expression matched c and the first matched a.
*	Matches the preceding element zero or more times. For example: ab*c matches "ac", "abc", "abbbc", and so on. [xyz]* matches "", "x", "y", "z", "zx", "zyx", "xyzzy", and so on. (ab)* matches "", "ab", "abab", "ababab", and so on.
?	Matches the preceding element zero or one time. For example: ba? matches "b" or "ba".
+	Matches the preceding element one or more times. For example: ba+ matches "ba", "baa", "baaa", and so on.
	The choice operator matches either the expression before or the expression after the operator. For example: abc def matches "abc" or "def".
{m,n}	Matches the preceding element at least m and not more than n times. For example: a\{3,5\} matches only "aaa", "aaaa", and "aaaaa". (ab){2,3} matches "abab" and "ababab".

Table 9-4 the escapes character that have special meaning in Posix regular expression syntax:

Table 9-4. Special Characters in Regular Expressions

Escaped character	Description
\f	Form Feed
\n	New Line
\r	Carriage Return
\t	Tab

Table 9-5 lists the pre-defined special character sets that can be used in regular expressions:

Table 9-5. Special Characters Set in Regular Expression

Symbol	Content	Description
[:alnum:]	[A-Za-z0-9]	Alphanumeric characters
[:alpha:]	[A-Za-z]	Alphabetic characters
[:blank:]	[\t]	Space and tab
[:cntrl:]	[\x00-\x1F\x7F]	Control characters
[:digit:]	[0-9]	Digits
[:graph:]	[\x21-\x7E]	Visible characters
[:lower:]	[a-z]	Lowercase letters
[:print:]	[\x20-\x7E]	Visible characters and space character
[:punct:]	[!#\$%&'()*+,.:/;<=>?@^\`{ }~-]	Punctuation characters
[:space:]	[\t\r\n\f]	Whitespace characters
[:upper:]	[A-Z]	Uppercase letters
[:xdigit:]	[A-Fa-f0-9]	Hexadecimal digits

Example 1

The following list of examples illustrates the use of meta characters in matching expressions:

- .at matches any three-character string ending with “at”, including “hat”, “cat”, “bat”.
- [hc]at matches “hat” and “cat”.
- [^b]at matches all strings matched by .at except “bat”.
- ^[hc]at matches “hat” and “cat”, but only at the beginning of the string or line.
- [hc]at\$ matches “hat” and “cat”, but only at the end of the string or line.

- `\[\]` matches any single character surrounded by “[” and “]” since the brackets are escaped. For example: “[a]” and “[b]”.
- `[hc]+at` matches “hat”, “cat”, “hhat”, “chat”, “hcat”, “ccchat”, and so on, but not “at”.
- `[hc]?at` matches “hat”, “cat”, and “at”.
- `[hc]*at` matches “hat”, “cat”, “hhat”, “chat”, “hcat”, “ccchat”, “at”, and so on.
- `cat|dog` matches “cat” or “dog”.
- `[:digit:]]+ matches “1”, and “32” but not “a1”.`

Example 2

The following example matches all leaf instance names between 3 and 4 characters in length.

```
get_instances -filter { leaf_name =~ "[[:alnum:]]{3,4}" } -regexp
{u1/u2/abc u1/u3/ab_1}
```

Example 3

The following example matches all instances having a leaf instance name with a prefix matching the value within a Tcl variable followed by 1 or many digits. In the example, the attribute equation cannot be enclosed in braces because it would prevent the Tcl shell from replacing the Tcl variable. Instead, the attribute equation is enclosed in double quotes and all special characters within the expression are escaped.

```
set prefix "MyString_"
get_instances -filter "leaf_name =~ \"$${prefix}\[[:digit:]\]+\\" -regexp
{u1/u3/MyString_1 u1/u2/MyString_75}
```

Example 4

The following example looks for all leaf instances with a prefix equal to abc inside all instances starting with u or U followed by one or more digits. Notice that the / is automatically inferred as a hierarchy separator causing the expression to be split in two and applied to each level of hierarchy separately.

```
get_instance {[Uu][[:digit:]]+/abc.*} -regexp
{u3/abcd U43/abc}
```

Hierarchical Name Matching With Escaped Identifiers

The slashes inside a name_patterns argument have special meaning; they are interpreted as hierarchy separators unless they are within escaped identifiers. For example, consider an instance whose name has two escaped identifiers as part of its hierarchical name: “u1/u2/u3 /

u4/u5 /insta". In Tessent Shell, all attribute, introspection, and editing commands can reference such a name with and without the escape characters and trailing spaces.

For more information, refer to "[Glob and Regular Expression Pattern Matching Syntax](#)" on page 3164.

Note

 Legacy commands (commands that existed prior to v9.6) only support names from which the escape characters and trailing spaces have been removed. However, the legacy commands are upgraded to accept collections of objects instead of a simple list of names so you can pass in directly the output of commands such as get_pins and get_instances.

When the escape identifier and trailing spaces are removed, the example path "u1\|u2/u3 \|u4/u5 /insta" becomes "u1/u2/u3/u4/u5/insta". As you can see, the four levels of hierarchy appear as six levels because the leaf instance names \u2/u3 and \u4/u5 look like two levels each.

Matching "u1/u2/u3/u4/u5/insta" against "u1\|u2/u3 \|u4/u5 /insta" requires searching for u1\|u2/u3 if no matches are found for u1/u2. You must apply this guessing approach recursively which can be expensive when the escaped identifiers contain many slashes. More importantly, pattern matching on these names is difficult because the / is interpreted as a hierarchy separator which incorrectly splits the name_patterns into the wrong patterns to match against the level of hierarchies. For these reasons, we recommend you keep the escape identifiers in the name_patterns argument to prevent escaped slashes from being interpreted as hierarchy separators.

The following two examples both successfully match the instance with name "u1\|u2/u3 \|u4/u5 /insta":

```
get_instances {{u1\|u2/u3 \|u4/u5 /insta}}
get_instances {{u1\|u[0-9]+/u[0-9]+ \|u[0-9]+/u[0-9]+ /insta}} -regexp
```

Because the get_instances command accepts a list of pattern names as input, two sets of braces are used to enclose the name_patterns argument. The Tcl shell performs a first evaluation to get the list items and consumes one set of braces; it performs a second evaluation on each item and consumes the second set of braces. Without two sets of braces, you would need to escape both bracket characters "[" and "]" to keep them as part of the regular expression and prevent them from being interpreted as a Tcl command. Notice how the \ that is part of the escaped identifier is escaped by a second \ when the -regexp option is used. This is because the \ is a special character in Posix regular expression syntax and it must be escaped to be treated as a literal.

In the second example, "get_instances {{u1\|u[0-9]+/u[0-9]+ \|u[0-9]+/u[0-9]+ /insta}} -regexp", the *leaf instance* matching insta, inside leaf instances matching "\u[0-9]+/u[0-9]+", inside leaf instances matching "\u[0-9]+/u[0-9]+", inside leaf instance matching u1 is returned. Notice how the slashes within the escaped identifiers were not interpreted as hierarchy separators but as literals within the patterns.

The parser terminates the escape identifier string when it encounters a white space. For this reason, your patterns must not include any spaces; there is no reason to include spaces when matching instance path names.

If you need the Tcl shell to replace the Tcl variable within the regular expression, as in the example below, you must use double quotes instead of the inner set of braces and escape every special character. The `\` became `\\\` because the Tcl interpreter will replace `\\\` by `\`, and the `\` will be interpreted as a `\` literal by the regexp parser.

Having to escape all special characters is very error prone. We recommend that you use the double sets of braces as shown above unless your pattern contains Tcl variables that must be replaced by the shell as shown below.

```
set range "0-9"
get_instances {"u1\\\\\\u\\[$range]+/u\\[$range]+ /\\\\u\\[$range]+/u\\[$range]+ /insta"} \
-regexp
```

Attribute Inheritance Behavior

By default, attributes with the applies_to_child_instances option set to On are visible to all child instances below the current module. When you query the attribute value, the tool first looks to see if it is explicitly set for the specified instance. If the attribute is not set, it then traverses up the hierarchy and checks to see if the attribute is set in any of the parent instances. The first explicitly specified attribute value found will be returned to you. The default value will be returned if you did not explicitly set it at any level of the hierarchy.

Inheritance Rules [3170](#)

DFT Test Logic Related Attributes (no_control_point and no_observe_point) [3171](#)

Inheritance Rules

Attribute inheritance follows specific rules.

Normal Attribute Inheritance Rule

If the attribute is not registered for the current object type, the attribute can be inherited from a different object type. The individual data model descriptions (such as, Module, Instance, Port, and so on) provide an “Inheritance” section that lists the build-in inherited attributes.

Special Boolean Inheritance Rule

If a boolean attribute value is not specified for the current object, the attribute value can be inherited from an object of a different object type. To determine if a given attribute is specified for the current object, use the “[get_attribute_value_list -is_specified](#)” command and switch.

The following example demonstrates the boolean inheritance with a pin and a port, specifically the pin inheriting the attribute from its port:

```
register_attribute -name myboolattr -value_type boolean -object_types [list port pin]
set pin [get_pins i1/a]
set port [get_ports -of_pins $pin]
set_attribute_value $port -name myboolattr -value true // value is set to true on the port
set_attribute_value $pin -name myboolattr -value false // value is set to false on the pin
puts [get_attribute_value_list $pin -name myboolattr]
// no inheritance since the value is specified on the pin
false

report_attributes $pin
Attributes defined for object 'i1/a':
Name          Value  Inheritance
...
myboolattr    false  -
...
```

```

puts [get_attribute_value_list $pin -name myboolattr -is_specified]
1

reset_attribute_value $pin -name myboolattr // unspecified the value on the pin
puts [get_attribute_value_list $pin -name myboolattr] // value is inherited from the port
true

puts [get_attribute_value_list $pin -name myboolattr -is_specified]
0

report_attributes $pin

Attributes defined for object 'i1/a':
Name          Value   Inheritance
-----
...
myboolattr    true    port
...

```

Attribute Inheritance Reporting

Using the `report_attributes` command with a collection of objects lists an Inheritance column that shows if the value is set on the current object, or if the value is inherited from another object type. For example:

```

report_attributes [get_scan_elements -class wrapper]

Attribute Definition Report
Attributes defined for object '/\cnt_s_reg[0] ':
Name          Value   Inheritance
-----
at_speed_control_group 2
cell_type      scan_cell

```

Attributes defined with the `applies_to_child_instances` option set to “on” show the value that is inherited from a parent instance or `icl_instance`.

DFT Test Logic Related Attributes (no_control_point and no_observe_point)

The `no_control_point` and `no_observe_point` attributes are used to mark regions within the netlist that should not be touched when inserting test logic (including test points and fixes for bidirectional, clock, and set/reset lines).

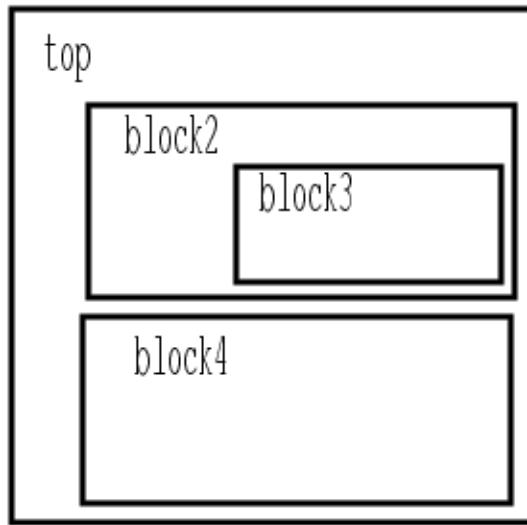

One common use model is to mark the entire netlist off-limits with the “`set_attribute_value -name no_control_point -value true`” command at the top level, and then override this by allowing test points for specific instances within the hierarchy with “`set_attribute_value /block1 -name no_control_point -value false`”.

The default attribute inheritance model works perfectly for this scenario. However, once you set the attribute for the lower level block (/block1 in this example), you will not have a way to reset to the default behavior of searching up the hierarchy. The tool will always use the specified value (true or false) for block1 and ignore the parent instances.

To get past this limitation, the inheritance model for the no_control_point and no_observe_point attributes has been extended by providing the ability to set them to true, false, or unspecified. This means you can explicitly set the value for the block (/block1 in this example) to unspecified and the tool will traverse up the hierarchy looking for an explicitly specified value.

Example 1

Figure 9-1. Hierarchical Test Logic Insertion Example

Step 1: In this example, you first set the no_control_point attribute to true for the top module. You then use the report_attributes command to get the value of the attribute at different hierarchy levels.

```
set_attribute_value [get_instances] -name no_control_point -value true  
{block1 block2 block3 ... }
```

```
SETUP> report_attributes block1
```

Attribute Definition Report

```
Attributes defined for object 'block1':
Name          Value          Inheritance
-----
...
...
...
no_control_point    true        -
no_control_reason   explicitly_specified  -
...
...
```

SETUP> report_attributes block1/block2

Attribute Definition Report

```
Attributes defined for object 'block1/block2':
Name          Value          Inheritance
-----
...
...
...
no_control_point    true        -
no_control_reason   explicitly_specified  -
...
```

Step 2: The next command allows test logic insertion inside block1 by setting the no_control_point attribute to false.

```
set_attribute_value block1-name no_control_point -value false
{block1}
```

report_attributes block1

Attribute Definition Report

```
Attributes defined for object 'block1':
Name          Value          Inheritance
-----
...
...
...
no_control_point    false       -
...
```

Example 2

Step 1: In this example, you start with the default which allows test logic insertion anywhere. You then use the report_attributes command to get the value of the no_control_point attribute at different hierarchy levels.

Step 2: The next command prevents test logic insertion inside block2 by setting the no_control_point attribute to true.

```
set_attribute_value /block1/block2 -name no_control_point -value true  
{block1/block2}
```

Step 3: Report the attribute values for block 2 and block4.

```
SETUP> report_attributes block1/block2
```

```
Attribute Definition Report
```

```
Attributes defined for object 'block1/block2':  
Name          Value          Inheritance  
-----  -----  -----  
...  
...  
...  
no_control_point      true      -  
no_control_reason    explicitly_specified  -  
...
```

```
SETUP> report_attributes block4
```

```
Attribute Definition Report
```

```
Attributes defined for object 'block4':  
Name          Value          Inheritance  
-----  -----  -----  
...  
...  
...  
no_control_point      false      -  
no_control_reason    unspecified  -  
...
```

Chapter 10

Configuration-Based Specification

This chapter documents the configuration data syntax used to encode the DftSpecification, PatternsSpecification, and DefaultsSpecification information.

The configuration data syntax is composed of nested wrappers and properties that fully describe the [DftSpecification](#), [PatternsSpecification](#), and [DefaultsSpecification/DftSpecification](#) information. These specifications can be automatically created using the [create_dft_specification](#) and [create_patterns_specification](#) commands, and they can be processed using the [process_dft_specification](#) and [process_patterns_specification](#) commands. The specifications can be edited and introspected using the commands listed in [Table 10-1](#). The specifications can also be viewed and edited in the DFTVisualizer using the [display_specification](#) command.

This chapter also includes documents how to order boundary scan cells and a description of the BISR segment order file, as described in the [MemoryBISR](#) command, that is used to order the BISR chains.

Table 10-1. Configuration Data Editing and Introspection Commands

Command	Description
add_config_element	Adds a configuration element in the configuration data.
add_config_message	Adds error, warning, or information messages to configuration elements.
add_config_tab	Adds one configuration tree tab to the DFTVisualizer Configuration Data window.
delete_config_element	Deletes one or more configuration elements. Only elements which can be added can be deleted.
delete_config_messages	Deletes error, warning or info message that were added to configuration elements using the add_config_message command.
delete_config_tabs	Deletes one or many configuration tree tabs from the Configuration Data window that was previously added using the add_config_tab or display_specification command.
get_config_elements	Returns a collection of configuration elements or a count of configuration elements when the -count option is used.
get_config_messages	Returns a list of message strings attached to a configuration element.

Table 10-1. Configuration Data Editing and Introspection Commands (cont.)

Command	Description
<code>get_config_selected_nodes</code>	Returns a collection containing the configuration elements corresponding to the tree nodes currently selected in the Configuration Data window.
<code>get_config_value</code>	Returns a value associated with a configuration element based on the specified option.
<code>move_config_element</code>	Moves a configuration element from one location to another.
<code>read_config_data</code>	Reads the content of configuration data files or a string into the Tesson Shell environment.
<code>report_config_data</code>	Reports the content of configuration wrappers in the transcript as it appears inside the file when the configuration data is written to a file using the <code>write_config_data</code> command.
<code>report_config_messages</code>	Reports messages associated to a configuration element. When the <code>-hierarchical</code> option is used, it also reports the messages associated to elements below the specified wrapper.
<code>report_config_syntax</code>	Reports the legal configuration syntax for a specified configuration object.
<code>set_config_value</code>	Sets the value of an element in the configuration data.
<code>write_config_data</code>	Writes the configuration data presently in memory into a file. When using the <code>-wrappers</code> option, the data written to the file can be limited to some specific wrappers.

This chapter uses the syntax conventions in [Table 10-2](#) when documenting wrappers and properties used in configuration data.

Table 10-2. SyntaxConventions for Configuration Files

Convention	Example	Usage
<i>Italic</i>	<code>scan_in : port_pin_name;</code>	An italic font indicates a user-supplied value.
Underline	<code>wgl_type : <u>generic</u> lsi;</code>	An underlined item indicates the default value.
	<code>logic_level : <u>both</u> high low;</code>	The vertical bar separates a list of values from which you must choose one. Do not include the bar in the configuration file.
...	<code>port_naming : port_naming, ...;</code>	Ellipses indicate a repeatable value. The comment “// repeatable” also indicates a repeatable value.
//	<code>// default: ijtag_so</code>	The double slash indicates the text immediately following is a comment and tells the tool to ignore the text.

Interface Naming Limitations

Ports named in Interface wrappers, as well as leaf_instance_name properties, are limited in the names they can be assigned. These names must begin with a letter and contain only alphanumerics (A-Z, a-z, 0-9) and underscores.

DftSpecification Configuration Syntax

The DftSpecification is an open and flexible interface into Tessent Shell. The interface is designed to make all Mentor Graphics DFT instruments available within Tessent Shell. In addition, the interface will eventually enable third-party providers (including end-user in-house instruments) to integrate their instrument types into the DftSpecification process. This enables chip designers to benefit from a unified yet flexible platform that supports the definition and insertion of test-related instruments from an unlimited number of sources into their designs.

This section describes the configuration data syntax used inside Tessent Shell to specify DFT components that are to be built and, optionally, inserted into a design. This chapter covers these wrappers that exist inside the DftSpecification wrapper:

- [EDT](#)
- [IjtagNetwork](#)
- [EmbeddedBoundaryScan](#)
- [BoundaryScan](#)
- [LogicBist](#)
- [MemoryBisr](#)
- [MemoryBist](#)
- [InSystemTest](#)
- [OCC](#)
- [LpctType3](#)

Using the configuration data syntax, you can specify a wide variety of DFT specifications in a single wrapper or in multiple DftSpecification wrappers, and generate and insert any type of instrument in one or multiple insertion passes.

DftSpecification	3179
EDT	3184
IjtagNetwork	3224
InSystemTest	3319
EmbeddedBoundaryScan	3339
BoundaryScan	3384
LogicBist	3445
LpctType3	3466
MemoryBisr	3478
MemoryBist	3510
OCC	3539
RtlCells	3563

DftSpecification

A wrapper that specifies the information used by the process_dft_specification command to build a series of instruments and, optionally, insert them into a design.

Usage

```
DftSpecification(module_name,id) {
    rtl_extension           : string; //default: v
    gate_extension          : string; //default: vg
    reuse_modules_when_possible : on | off | auto ;
    use_rtl_cells           : on | off | auto ;
    use_synchronizer_cell_with_reset : on | off ; //default: on *DefSpec
    use_rtl_synchronizer_cell   : on | off | auto ;
                                            //default: auto *DefSpec
    dft_cell_selection_name   : string ;
    persistent_clock_cell_prefix : string ;
                                            //default: tesson_persistent_cell_
    persistent_cell_prefix    : string ;
                                            //default: tesson_persistent_cell_
    force_creation_of_rtl_cells : cell_type, ... ; // legal : And2 Or2 Buf
                                            // Inv Mux2 ClkAnd2
                                            // ClkOr2 ClkBuf ClkInv
                                            // ClkMux2 ClkGateAnd
                                            // ClkGateOr PosedgeDff
                                            // PosedgeDffReset
                                            // PosedgeDffSet
                                            // NegedgeDff
                                            // NegedgeDffReset
                                            // NegedgeDffSet
                                            // PosedgeSynchronizerReset
                                            // PosedgeSynchronizer

    RtlCells {
    }
    BoundaryScan {
    }
    EDT {
    }
    EmbeddedBoundaryScan {
    }
    IjtagNetwork {
    }
    InSystemTest {
    }
    LogicBist {
    }
    LpctType3 {
    }
    MemoryBisr {
    }
    MemoryBist {
    }
    OCC (id) {
    }
    //Other instrument types to be added in future releases
}
```

Description

A wrapper that specifies the information used by the [process_dft_specification](#) command to build a series of instruments and, optionally, insert them into a design.

The DftSpecification wrapper is uniquely named using two strings. The first string is the `module_name` of the design the DFT specification is for. The second string is a general purpose `id` that differentiates multiple DFT specifications for a given design module where each DftSpecification is for a different insertion pass.

Arguments

- *module_name*

A string that identifies the design that the DFT specification is for. When running the [process_dft_specification](#) command, the name of the current design must match this string unless the `-no_insertion` option is specified with this command; if the `-no_insertion` option is used, it can also be specified using the `-design_name` `design_name` option.

- *id*

A string that identifies which insertion pass the DFT specification is to be used for. When executing the [process_dft_specification](#) command, the `id` argument of the command is used to specify this `id` used in the DftSpecification name. If only one DftSpecification wrapper for a given `module_name` is loaded in memory, the [process_dft_specification](#) command uses it even if the `id` is not specified as an option. Using either “rtl” or “gate” as the `id` string is a good strategy to identify the instruments inserted in the RTL and those inserted in the synthesized netlist.

- `rtl_extension : string ;`

A string that specifies the extension used when writing out files containing Verilog RTL descriptions of the created instruments. The string must start with a letter and may be followed by any number of letters, numbers, underscores, and periods. The value of `rtl_extension` must be different than the value of `gate_extension`. The default value when unspecified is “v”.

- `gate_extension : string ;`

A string that specifies the extension used when writing out files containing gate-level Verilog modules. This extension is used in the synthesis script of the instruments and when writing out the concatenated netlist. The `gate_extension` is only relevant in the `-no_rtl` context. The string must start with a letter and may be followed by any number of letters, numbers, underscores, and periods. The value of `gate_extension` must be different than the value of `rtl_extension`. The default value when unspecified is “vg”.

- `reuse_modules_when_possible : on | off | auto ;`

A Boolean that specifies whether instrument modules should be reused if possible, or if different modules should be created for each instance. When the value is `auto`, it is considered to be On in the `rtl` context and Off in the `no_rtl` context. When inserting

instruments into a netlist, it is customary to avoid repeated instances of any module as timing optimization requires them to be unqualified. The default value is auto.

- use_rtl_cells : on | off | auto ;

A property that specifies whether RTL or gate-level cells are to be instantiated into the generated controllers in special locations.

For example, if a controller needs a clock multiplexer, the tool does not describe the clock multiplexer in RTL but instead instantiates a cell. When the use_rtl_cells property is specified or inferred as “on”, the tool creates the clock multiplexer as a special RTL cell and instantiates this cell into your design. You can control the name of the ports for the cell such that later you can replace the RTL cell with a real cell using the [replace_instances](#) command. Modules created by tools are often marked as “hard” to prevent accidental editing inside the modules. To replace the cell instances inside those modules, you may have to set the [is_hard_module](#) attribute to false on the parent module of the cell. Ensure that you limit the editing to only cell swapping as you do not want to make the RTL views different from their associated ICL or tcd_scan views. Refer to the [RtlCells](#) wrapper to change the port names.

When the use_rtl_cells attribute is specified or inferred as “off”, the tool uses the cells in the cell library and instantiates these cells into your design. Refer to the [get_dft_cell](#) command and the dft_cell_selection_name property to understand which specific cell the tool uses.

When the default value of “auto” is used, the on value is inferred in this specific condition:

- a. The -rtl context is used.
- b. You have not loaded a tessent cell library using the [read_cell_library](#) command containing the needed cell.

The behavior of the “auto” value was changed in the Tessent v2017.2 release to favor using real cells even in rtl context when available. Using RTL cells is no longer recommended given the lack of design module boundary preservation in the modern synthesis tool.

- use_synchronizer_cell_with_reset : on | off ;

A property that when specified to “off”, allows the tool to request a basic synchronizer cell that does not have a reset. The tool will request a synchronizer cell with reset by default when this property is specified to “on”. If the requested synchronizer cell with reset is not found in the cell library, an error is issued and the user will be prompted to set use_synchronizer_cell_with_reset to “off” to allow use of a basic synchronizer cell.

This property is currently used by the OCC, MemoryBist, and LogicBist wrappers.

- use_rtl_synchronizer_cell : on | off | auto ;

A property that when set to “on”, forces the tool to create and instantiate an RTL synchronizer cell, even when use_rtl_cells is set to “off” or when operating in the -no_rtl context. When set to “auto”, the tool will follow the use_rtl_cells behavior. In the case when the property is set to “off” and the requested synchronizer cell is not found in the cell library, an error is issued and the user is prompted to set this parameter to “on”.

This property is currently used by the OCC, MemoryBist and LogicBist wrappers.

- `force_creation_of_rtl_cells : cell_type, ... ;`

A property that specifies the creation of specific RTL cells so that you can use them in a custom insertion script such as those you would use inside the `process_dft_specification.post_insertion` procedure. You can specify the following list of RTL cells: And2, Or2, Buf, Inv, Mux2, ClkAnd2, ClkOr2, ClkBuf, ClkInv, ClkMux2, ClkGateAnd, ClkGateOr, PosedgeDff, PosedgeDffReset, PosedgeDffSet, NegedgeDff, NegedgeDffReset, NegedgeDffSet, PosedgeSynchronizer and PosedgeSynchronizerReset.

Note

 If you want to use `set_config_value` to set this property with a list of cell names, use a Tcl list of cell names. The list of RTL cells will result in a comma-separated list in the configuration data. See “[Example 2](#)” on page 1995 in the `set_config_value` command description.

- `dft_cell_selection_name : string ;`

A property that specifies the name of the `dft_cell_selection` wrapper from which the cells are selected. You only need to specify this property if all of the following apply:

- RTL cells are not used
- Your cell library has more than one `dft_cell_selection` wrapper
- You have not specified a default `dft_cell_selection` wrapper using the `set_cell_library_options -default_dft_cell_selection_name` command

- `persistent_clock_cell_prefix : string ; // default: tessent_persistent_cell_`

A property that specifies the leaf instance name prefix to use when instantiating a clock cell such as a clock multiplexer or a clock gating cell. The string must start with a letter and be followed by only letters, numbers, and underscores. When unspecified, it defaults to “`tessent_persistent_cell_`”. These clock cells have a special prefix so that they are not removed during synthesis and layout. You can modify this string to match the prefix you normally use in your design flow; otherwise, use the following Design Compiler command in your synthesis and layout scripts:

```
set_size_only -all_instance \
  [get_cells tessent_persistent_cell_* -hierarchical \
  -filter "is_hierarchical==false"]
```

Refer to the SDC proc described in the “[Generating and Using SDC for Tessent Shell Embedded Test IP](#)” in the *Tessent Shell User's Manual* for more information. Specifically, look at the Synthesis Step 3 in the “[Example Design Compiler Synthesis Script](#)”.

- `persistent_cell_prefix : string ; // default: tessent_persistent_cell_`

A property that specifies a leaf instance name prefix to use when instantiating a non-clock cell such as a buffer or an inverter. The string must start with a letter and be followed by only letters, numbers, and underscores. When unspecified, it defaults to

“tesson_t_persistent_cell_”. These non-clock cells have a special prefix to ensure that they are not removed during synthesis and layout so that they can be used as anchor points for timing constraints or as start and end points in ScanDef. You can modify this string to match the prefix you normally use in your design flow; otherwise, use the following Design Compiler command in your synthesis and layout scripts:

```
set_size_only -all_instance \
[get_cells tesson_t_persistent_cell_* -hierarchical \
-filter "is_hierarchical=false"]
```

Refer to the SDC proc described in the “[Generating and Using SDC for Tessent Shell Embedded Test IP](#)” in the *Tessent Shell User’s Manual* for more information. Specifically, look at the Synthesis Step 3 in the “[Example Design Compiler Synthesis Script](#)”.

EDT

A wrapper that specifies the information used by the [process_dft_specification](#) command to build the EDT IP and, optionally, insert the IP into a design.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        ijtag_host_interface : ijtag_leaf_node_name | none;
        Connections {
        }
        Controller(id) {
        }
    }
}
```

Description

A wrapper that specifies the information used by the [process_dft_specification](#) command to build the EDT IP and, optionally, insert the IP into a design.

Arguments

- `ijtag_host_interface : ijtag_leaf_node_name | none;`

This optional property is used to specify the host scan interface that the EDT controllers will connect to. This property has an override inside the [Controller](#) wrapper.

The *node_id* value must have the format Sib(*id*), Tap(*id*)/HostIjtag(*id*), HostScanInterface(*id*), ScanMux(*id*)/Input(0|1) and must match the leafname of a wrapper in the [IjtagNetwork](#) wrapper.

To have the IjtagNetwork created with a Sib node for the service of the EDT node, use the `-sri_sib_list` switch when calling the [create_dft_specification](#) command. For example, use `-sri_sib_list {edt occ}` when inserting the logic test hardware.

When you specify `ijtag_host_interface` with a value pointing to an IJTAG host scan interface during `process_dft_specification`, a TDR is added that drives the static external controls of the EDT. If you have also specified static external controls which are tied to top level ports or pins, the TDR connections to the EDT static external controls override the specified static external controls.

When the property is unspecified, it defaults to none which may be the inherited values by all controller wrappers if the `ijtag_host_interface` property is not specified locally.

Connections

This wrapper is used to specify EDT control pin connections for each EDT controller.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        Connections {
            edt_clock      : port_pin_name | DftSignal(edt_clock) |
                               OptionalDftSignal(edt_clock);
            edt_slave_clock : port_pin_name; // default: edt_slave_clock
            edt_update      : port_pin_name | DftSignal(edt_update) |
                               OptionalDftSignal(edt_update);
            edt_reset       : port_pin_name; // default: edt_reset
            StaticExternalControls {
            }
        }
    }
}
```

Description

This wrapper is used to specify EDT control pin connections for each EDT controller.

Arguments

- `edt_clock : port_pin_name ;`

An optional property used to specify a source node to connect the `edt_clock` port to.

The node name can be a port or a pin name. The node must already exist in the design with the exception of one case. If the design level, as specified by the `set_design_level` command, is not “chip” and the name corresponds to the name of a scalar port, it is allowed to not exist in the design and it will be created as an input port during insertion.

When design level is “chip”, specified port names must already be connected to a pad cell. The connection will automatically be made to the internal side of the input pad buffer. You can specify `OptionalDftSignal(edt_clock)` or `DftSignal(edt_clock)` as the value, and it will be interpreted to request a connection to the DFT signal `edt_clock` as it was added using the `add_dft_signals` command. When using `OptionalDftSignal(edt_clock)`, you will not get an error if the DFT signal `edt_clock` was not added; a connection to the port called “`edt_clock`” will be made instead and the port will be created if not present unless design level is equal to “chip” in which case you will get an error.

When the property is unspecified, its value defaults to `OptionalDftSignal(edt_clock)`.

- `edt_slave_clock : port_pin_name ;`

An optional property that specifies the EDT slave clock. When you generate level-sensitive clocking (latch-based EDT IP), the EDT IP contains a master clock and a slave clock to connect. See “[TestKompress Compression Logic](#)” in the *Tessent TestKompress User’s Manual*. The default is `edt_slave_clock`.

- `edt_update : port_pin_name ;`

An optional property used to specify a source node to connect the `edt_update` port to.

The node name can be a port or a pin name. The node must already exist in the design with the exception of one case. If the design level, as specified by the [set_design_level](#) command, is not “chip” and the name corresponds to the name of a scalar port, it is allowed to not exist in the design and it will be created as an input port during insertion.

When design level is “chip”, specified port names must already be connected to a pad cell. The connection will automatically be made to the internal side of the input pad buffer. You can specify `OptionalDftSignal(edt_update)` or `DftSignal(edt_update)` as the value, and it will be interpreted to request a connection to the DFT signal `edt_update` as it was added using the [add_dft_signals](#) command. When using `OptionalDftSignal(edt_update)`, you will not get an error if the DFT signal `edt_update` was not added; a connection to the port called “`edt_update`” will be made instead and the port will be created if not present unless design level is equal to “chip” in which case you will get an error.

When the property is unspecified, its value defaults to `OptionalDftSignal(edt_update)`.

- `edt_reset : port_pin_name ;`

An optional property that specifies the port or pin name to be used for the EDT reset. The default is `edt_reset`. The `edt_reset` signal is an asynchronous reset for all the sequential elements in the EDT logic. For more information, see “[EDT Logic Reset](#)” in the *Tessent TestKompress User’s Manual*.

StaticExternalControls

This wrapper specifies the connections for the static EDT control signals.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        Connections {
            StaticExternalControls {
                edt_bypass : port_pin_name | 0 | 1 ; //default: 0
                edt_single_bypass_chain : port_pin_name | 0 | 1 ; //default: 0
                edt_configuration : port_pin_name | 0 | 1 ; //default: 0
                edt_low_power_shift_enable : port_pin_name | 0 | 1 ; //default: 1
            }
        }
    }
}
```

Description

This wrapper specifies the connections for the static EDT control signals.

Arguments

- **edt_bypass : *port_pin_name* ;**
An optional property that specifies the connection to the *edt_bypass* static EDT control pin. The *edt_bypass* pin connects to the specified *port_pin_name*, or is tied to high or low using the 1 or 0 symbol. The default is 0.
- **edt_single_bypass_chain : *port_pin_name* ;**
An optional property that specifies the connection to the *edt_single_bypass_chain* static EDT control pin. The *edt_single_bypass_chain* pin connects to the specified *port_pin_name*, or is tied to high or low using the 1 or 0 symbol. The default is 0.
- **edt_configuration : *port_pin_name* ;**
An optional property that specifies the connection to the *edt_configuration* static EDT control pin. The *edt_configuration* pin connects to the specified *port_pin_name*, or is tied to high or low using the 1 or 0 symbol. The default is 0.
- **edt_low_power_shift_enable : *port_pin_name* ;**
An optional property that specifies the connection to the *edt_low_power_shift_enable* static EDT control pin. The *edt_low_power_shift_enable* pin connects to the specified *port_pin_name*, or is tied to high or low using the 1 or 0 symbol. The default is 1.

Controller

This wrapper is used to add and specify properties for every EDT controller generated with `process_dft_specification`.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        Controller(id) {
            ijttag_host_interface      : ijttag_leaf_node_name | none;
            longest_chain_range       : min, max ;
            scan_chain_count          : int ;
            input_channel_count       : int ;
            output_channel_count      : int ;
            separate_control_data_channels : on | off ;
            parent_instance            : name ;
            leaf_instance_name         : name ;
            connect_bscan_segments_to_lsb_chains : on | off | auto ;
            Interface {
            }
            BypassChains {
            }
            Compactor {
            }
            Clocking {
            }
            HighCompressionConfiguration {
            }
            ShiftPowerOptions {
            }
            LogicBistOptions {
            }
            Connections {
            }
        }
    }
}
```

Description

This wrapper is used to add and specify properties for every EDT controller generated with `process_dft_specification`.

Every Controller needs to have an unique simple name. You must use a name that starts with an alphanumeric character and contains no special characters except for underscores "_" in the middle of the controller name. You can also use an integer to specify Controller names. For example, the following controller names are valid:

```
Controller(1)
Controller(c1)
Controller(controller_1)
```

Arguments

- `ijtag_host_interface : ijtag_leaf_node_name | none;`

An optional property that connects the EDT static external controls through a test data register (TDR). The `ijtag_host_interface` is inherited from the top-level. If it is specified at this level, it overrides the `ijtag_host_interface` specified at the top-level.

The `node_id` value must have the format `Sib(id)`, `Tap(id)/HostIjtag(id)`, `HostScanInterface(id)`, `ScanMux(id)/Input(0|1)` and must match the leafname of a wrapper in the [IjtagNetwork](#) wrapper.

To have the `IjtagNetwork` created with a `Sib` node for the service of the EDT node, use the `-sri_sib_list` switch when calling the [create_dft_specification](#) command. For example, use `-sri_sib_list {edt occ}` when inserting the logic test hardware.

When you specify `ijtag_host_interface` with a value pointing to an IJTAG host scan interface during `process_dft_specification`, a TDR is added that drives the static external controls of the EDT. If you have also specified static external controls which are tied to top level ports or pins, the TDR connections to the EDT static external controls override the specified static external controls.

When the property is unspecified, it inherits its value from the `ijtag_host_interface` property found in the [EDT](#) wrapper.

- `longest_chain_range : min, max ;`

A required property, for each controller, that specifies the range (min and max values) for the length of the longest scan chain. Use this switch to avoid having to regenerate the logic for minor changes.

- `scan_chain_count : int ;`

A required property, for each controller, that specifies the number of scan chains for the EDT controller. It provides the size for the scan chain bus ports. The tool will report an error if this property is missing or has no value.

- `input_channel_count : int ;`

A required property, for each controller, that specifies the number of EDT input channels in the generated EDT controller. It provides the size for the input channel bus port. The tool will report an error if this property is missing or has no value.

- `output_channel_count : int ;`

A required property, for each controller, that specifies the number of EDT output channels in the generated EDT controller. It provides the size for the output channel bus port.

- `separate_control_data_channels : on | off ;`

An optional property that specifies if control data channel separation is used in the generated EDT controller. The default is off. When set to on, the tool automatically determines the number of control channels and inserts control bits behind the control channels only. This is necessary for channel sharing between non-identical blocks.

- `parent_instance : name ;`

An optional property that specifies where in the design to insert the EDT controller. If not specified, the controller instance is created at the top level of the current design.

- `leaf_instance_name : name ;`

An optional property that specifies the EDT controller instance name. If not specified, the name is “`<design_name>_<dft_spec_id>_tessent_<edt_id>_inst`”. The `dft_spec_id` is the id specified for the DftSpecification wrapper and `edt_id` is the id specified for the EDT Controller wrapper.

- `connect_bscan_segments_to_lsb_chains : on | off | auto;`

An optional property that specifies whether to connect boundary scan chain segments to the EDT IP automatically if boundary scan is inserted in the same pass or a previous insertion pass. When this property is set to auto and a single EDT controller is present in the configuration data, then the insertion phase will connect the boundary scan chain segments to the EDT controller.

When boundary scan chain segments are created, the boundary scan instrument dictionary is populated with information about them. When you want to connect the EDT controller to boundary scan chain segments, the insertion phase collects boundary scan chain segment information from the instrument dictionary and uses the data to perform connections. For more information on the instrument dictionary see [get_instrument_dictionary](#).

The tool will not allow more than one EDT controller to connect to boundary scan chain segments. When there are more than one EDT controllers present, you need to specify which EDT controller to connect to the boundary scan chain segments. You accomplish this by setting this property to on for the EDT controller that you want to connect. When all EDT controllers have this property set to auto, or when more than one EDT controller have this property set to on, an error is reported during the validation phase.

The width of the EDT scan input and output bus on the EDT controller module is set with the `scan_chain_count` property value. If boundary scan chain segments exist and are to be connected to the EDT controller, the width of the bus is incremented by the number of boundary scan segments.

For example, if you have 100 scan chains and 5 boundary scan chain segments, the resulting bus width on the EDT controller is 105 bits. This is so there are enough bits when connecting scan chains from scan insertion.

As suggested by the name for this property, `connect_bscan_segments_to_lsb_chains`, the boundary scan chain segments are connected to the LSB bits of the EDT scan bus. Each boundary scan chain segment connection is made to the corresponding bit of the bus, so the first segment is connected to the first bit, and so on.

The default value for this property is auto.

Examples

Example 1

This example sets connect_bscan_segments_to_lsb_chains to auto, which results in the EDT controller being connected to the boundary scan chain segments.

```
DftSpecification(CoreA,rtl) {
    IjtagNetwork {
        HostScanInterface(ijtag) {
            Tap(1) {
                HostBscan {}
            }
        }
    }
    BoundaryScan {
        ijtag_host_node : Tap(1)/HostBscan;
        max_segment_length_for_logictest : 10;
    }
    EDT {
        Controller(c1) {
            longest_chain_range : 100, 110;
            scan_chain_count : 100;
            input_channel_count : 2;
            output_channel_count : 2;
            connect_bscan_segments_to_lsb_chains : auto;
        }
    }
}
```

Interface

This wrapper specifies the port names for the interface of the EDT controller.

Usage

```
DftSpecification(module_name,id) {
    EDT {
        Controller(id) {
            Interface {
                edt_clock           : port_name ; // default: edt_clock
                edt_slave_clock     : port_name ; // default: edt slave clock
                edt_update          : port_name ; // default: edt update
                edt_reset           : port_name ; // default: edt reset
                edt_channels_in_bus : bus_name   ; // default: edt channels in
                edt_channels_out_bus: bus_name   ; // default: edt channels out
                StaticExternalControls {
                }
            }
        }
    }
}
```

Description

You can use this wrapper to specify the names of the EDT controller ports. Each property has a default value, as described in the configuration data syntax. These port names are for non-static EDT signals. The [StaticExternalControls](#) wrapper specifies static EDT signal port names for the EDT controller.

Note

 Instance names inside the Interface wrapper must start with a letter and consist only of alphanumerics and underscores.

Arguments

- `edt_clock : port_name ;`

An optional property that specifies the name of the port that supplies a clock to the EDT controller. The default is `edt_clock`. See the `edt_clock` entry in [Table 3-11](#).

- `edt_slave_clock : port_pin_name ;`

An optional property that specifies the name of the EDT controller slave clock port. When you generate level-sensitive clocking (latch-based EDT IP), the EDT IP contains a master clock and a slave clock to connect. The default is `edt_slave_clock`. See “[TestKompress Compression Logic](#)” in the *Tessent TestKompress User’s Manual*.

- `edt_update : port_name ;`

An optional property that specifies name of the update enable port of the EDT controller. The default is `edt_update`. See the `edt_update` entry in [Table 3-11](#).

- `edt_reset : port_name ;`
An optional property that specifies the name of the asynchronous reset port for the EDT controller. This property applies when the controller clocking reset signal is asynchronous. The default is `edt_reset`.
- `edt_channels_in_bus : bus_name ;`
An optional property that specifies the name of the input channels bus port for the EDT controller. The default is `edt_channels_in`.
- `edt_channels_out_bus : bus_name ;`
An optional property that specifies the name of the output channels bus port for the EDT controller. The default is `edt_channels_out`.

StaticExternalControls

This wrapper specifies the port names for the static EDT signals on the interface of the EDT controller.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        Controller(id) {
            Interface {
                StaticExternalControls {
                    edt_bypass : port_name ;
                    // default: edt bypass
                    edt_single_bypass_chain : port_name ;
                    // default: edt single bypass chain
                    edt_configuration : port_name ;
                    // default: edt configuration
                    edt_low_power_shift_enable : port_name ;
                    // default: edt low power shift en
                }
            }
        }
    }
}
```

Description

This wrapper specifies the names of static EDT signals.

Arguments

- `edt_bypass : port_name ;`
An optional property that specifies the name of the bypass port for the EDT controller. The default is `edt_bypass`.
- `edt_single_bypass_chain : port_name ;`
An optional property that specifies the name of the single bypass chain port for the EDT controller. The default is `edt_single_bypass_chain`.
- `edt_configuration : port_name ;`
An optional property that specifies the EDT configuration port for the EDT controller. The default is `edt_configuration`.
- `edt_low_power_shift_enable : port_name ;`
An optional property that specifies low-power shift enable port for the EDT controller. The default is `edt_low_power_shift_enable`.

BypassChains

This wrapper is used to specify the EDT bypass chain configuration in the generated EDT controller.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        Controller(id) {
            BypassChains {
                present           : on | off ;
                bypass_chain_count : int ; // default: auto
                single_bypass_chain : on | off | auto ;
                BypassChain(id) { // legal: 1..maxposint
                    scan_chain_range_list : scan_chain_range, ... ;
                }
            }
        }
    }
}
```

Description

This wrapper is used to specify the EDT bypass chain configuration in the generated EDT controller.

Arguments

- **present : on | off ;**
An optional property that specifies whether the bypass chain is present. The default is on.
- **bypass_chain_count : *int* ;**
An optional property that specifies the bypass chain count. The default (auto) is the input or output channel count, whichever is smaller. The default is auto.
- **single_bypass_chain : on | off | auto ;**
An optional property that specifies whether a single bypass chain is present. The default is auto, with the following behavior:
 - If a LogicBist wrapper is not specified, this property switches to off.
 - If a LogicBist wrapper is specified, this property takes the value of the LogicBist/Controller/[SingleChainForDiagnosis](#)/present property.
- **BypassChain(*id*)**
A repeatable wrapper that specifies the bypass chain connections. The *id* value for this wrapper is used to specify the actual bypass chain index. You must specify the index within the bypass chain count limits. You cannot specify twice the same value for a single EDT controller. The *scan_chain_range_list* property inside this wrapper is used to specify the scan chains that create a specific bypass chain.

- `BypassChain(id)/scan_chain_range_list : scan_chain_range, ... ;`

A property that specifies a list of scan chains by their index value.

The syntax allows to use a list of comma separated range values. The format for the ranges is “*int:int*”. The order of the specified scan chains has impact on the order of scan chain connections in the generated EDT IP. The specified scan chain index values must fall within the limits specified by the `scan_chain_count` property of the EDT controller.

It is also important to remember that a single scan chain can be assigned to its connection only once and that all scan chains need to have a connection assigned. Otherwise, a validation error is reported.

Examples

Example 1

This example shows the BypassChains wrapper with the chain connections specified:

```
DftSpecification(CoreA,rtl) {
    EDT {
        Controller(c1) {
            scan_chain_count : 16;
            input_channel_count : 2;
            output_channel_count : 2;
            longest_chain_range : 100, 110;
            BypassChains {
                present: on;
                bypass_chain_count: 2;
                BypassChain(1) {
                    scan_chain_range_list: 1:2, 4:10;
                }
                BypassChain(2) {
                    scan_chain_range_list: 3, 11:16;
                }
            }
        }
    }
}
```

Compactor

This wrapper is used to add and specify properties for the EDT compactor.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        Controller(id)
        Compactor {
            type : xpress | basic ;
            pipeline_logic_levels_in_compactor : int ; // default: off
            CompactorConnection(id) { // legal: 1..maxposint
                scan_chain_range_list : scan_chain_range, ... ;
            }
        }
    }
}
```

Description

This wrapper is used to add and specify properties for the EDT compactor.

Arguments

- `type : enum ;`

An optional property that determines which compactor is used in EDT logic. This is equivalent to the “-COMpactor_type” argument in the [set_edt_options](#) command. The possible values are:

- **xpress** — The Xpress compactor, which increases compression, especially for designs that generate unknown (X) values. This is the default value.
- **basic** — The basic compactor is the first-generation compactor.

For more information, refer to “[Understanding Compactor Options](#)” in the *Tessent TestKompress User’s Manual*.

- `pipeline_logic_levels_in_compactor : int ;`

An optional property that enables pipeline stages. This is equivalent to the “-Pipeline_logic_levels_in_compactor” argument in the [set_edt_options](#) command. The possible values are:

- **off** — Disables pipeline stages in EDT logic. This is the default value.
- **<integer>** — Includes pipeline stages in the EDT logic compactor(s) and specifies the maximum number of logic levels (2-input XOR gates) allowed in the compactors before inserting a pipeline stage.

- `CompactorConnection(id)`

A repeatable wrapper that specifies compactor connections.

The *id* value of this wrapper is used to specify the actual EDT output channel index. You must specify the index within the EDT output channel count limits. You cannot specify the same value twice for a single EDT controller. The *scan_chain_range_list* property inside this wrapper is used to specify the scan chains that will be connected to the EDT output channel.

- CompactorConnection(*id*)/*scan_chain_range_list* : *scan_chain_range*, ... ;

A required property for each CompactorConnection that specifies a list of scan chains by their index values. The syntax for the property value is a list of comma-separated range values. The ranges are of the format “*int:int*”. The order of the specified scan chains impacts the order of scan chain connections in the generated EDT IP. The specified scan chain index values must be within the limits specified by the *scan_chain_count* property of the EDT controller.

Note

A single scan chain can be assigned to its connection only once, and all scan chains need to have a connection assigned. Otherwise, a validation error is reported.

Examples

Example 1

This example shows the specification wrapper with the compactor connections specified:

```
DftSpecification(CoreA,rtl) {
    EDT {
        Controller(c2) {
            scan_chain_count : 16;
            input_channel_count : 2;
            output_channel_count : 2;
            longest_chain_range : 100, 110;
            Compactor {
                type: xpress;
                CompactorConnection(1) {
                    scan_chain_range_list: 1:2, 4:10;
                }
                CompactorConnection(2) {
                    scan_chain_range_list: 3, 11:16;
                }
            }
        }
    }
}
```

Clocking

A wrapper that specifies the information used by the EDT controller clock.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        Controller(id) {
            Clocking {
                type      : edge | level ;
                lockup_cells : on | off ;
                reset_signal : asynchronous | off ;
            }
        }
    }
}
```

Description

A wrapper that specifies the information used by the EDT controller clock.

Arguments

- type : edge | level ;

An optional property that determines what type of architecture logic is used for the EDT logic. The default is edge. For more information, refer to the -CLOCKING argument of the [set_edt_options](#) command.

- lockup_cells : on | off ;

An optional property that determines whether lockup cells are inserted in the EDT logic. The default is on. For more information, refer to the -LOCKUP_cells argument of the [set_edt_options](#) command.

Caution

 It is recommended to leave this property set to on. Disabling it can lead to DRC violations during pattern generation and the inability to generate valid patterns.

- reset_signal : asynchronous | off ;

A property that specifies whether an asynchronous reset signal, `edt_reset`, is included in the EDT logic. For more information refer to the -RESET_SIGNAL argument of the [set_edt_options](#) command.

HighCompressionConfiguration

This wrapper is used to specify high-compression properties for the EDT controller.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        Controller(id) {
            HighCompressionConfiguration {
                present : on | off ;
                input_channel_count : int ;
                output_channel_count : int ;
            }
        }
    }
}
```

Description

Use this wrapper to specify the presence of the high-compression configuration for the EDT controller and the input and output channel counts for the high-compression configuration. For more information, see “[Dual Compression Configurations](#)” in the *Tessent TestKompress User’s Manual*.

Arguments

- **present : on | off ;**
A property that, when set to on, specifies that the high-compression EDT configuration is available for the EDT controller. When this property is set to on, the -parameter switch of the [add_core_instances](#) command allows a `high_compression` or `low_compression` value for the `edt_configuration` core instance parameter. The default is off.
- **input_channel_count : int ;**
A property that specifies the input channel count for the high compression configuration of the EDT controller.
- **output_channel_count : int ;**
A property that specifies the output channel count for the high compression configuration of the EDT controller.

Examples

This example shows the DftSpecification of an EDT controller. It uses a HighCompressionConfiguration wrapper, highlighted in green. The specified settings result in the generation of a second EDT configuration with one input channel and one output channel. This is in addition to the low compression configuration defined in the Controller wrapper.

```
DftSpecification(CoreA,rtl) {
    EDT {
        Controller(c1) +{
            scan_chain_count : 16;
            input_channel_count : 2;
            output_channel_count : 2;
            longest_chain_range : 100, 110;
            BypassChains {
                present: on;
                single_bypass_chain: on;
            }
            HighCompressionConfiguration {
                present : on ;
                input_channel_count : 1 ;
                output_channel_count : 1 ;
            }
            ShiftPowerOptions {
                present : on ;
            }
            Connections +{
                StaticExternalControls {
                    edt_bypass: top_edt_bypass;
                    edt_single_bypass_chain: top_edt_single_bypass_chain;
                    edt_configuration: top_edt_configuration;
                    edt_low_power_shift_enable: top_edt_low_power_shift_enable;
                }
            }
        }
    }
}
```

ShiftPowerOptions

This wrapper is used to add and specify properties for the EDT shift power options.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        Controller(id) {
            ShiftPowerOptions {
                present : on | off ;
                full_control : on | off ;
                min_switching_threshold_percentage : int ; // default: 15
            }
        }
    }
}
```

Description

This wrapper is used to add and specify properties for the EDT shift power options.

Arguments

- **present : on | off ;**
A property used to specify if the EDT low-power controller is present. The default is off.
- **full_control : on | off ;**
A property and literal value that adds one bit per scan chain to control whether that chain loads a constant value or not. This provides complete control over the scan chain input masking. When this property is on, the tool adds one bit per scan chain. Also, when on, any value specified with the -min_switching_threshold_property is ignored. The default is off.
- **min_switching_threshold_percentage : *int* ;**
A property and integer that specifies the minimum switching threshold value used to determine power controller parameters, such as input shift register size. Valid integer values are 1 to 50. If an integer greater than 50 is specified, the tool uses 50. The default value is 15, indicating 15%.

The tool uses this value to calculate the size of the power_controller. The power controller must be large enough to control the number of scan chains required to achieve the minimum switching threshold specified. For more information, see “[Low-Power Shift and Switching Thresholds](#)” in the *Tessent TestKompress User’s Manual*.

LogicBistOptions

This wrapper groups the LogicBist-related options set at the EDT controller level.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        Controller(id) {
            LogicBistOptions {
                present : on | off | auto ;
                misr_input_ratio : integer ;           // default: auto
                chain_mask_register_ratio : integer ;   // default: 1
                ShiftPowerOptions {
                }
            }
        }
    }
}
```

Description

You use this wrapper to set LogicBIST-related options for the EDT controller.

Arguments

- present : on | off | auto ;

A property that specifies the generated EDT controller will be a hybrid TK/LBIST controller. The default, auto, indicates that when the DftSpecification/LogicBist wrapper is used, this property will be set to on and hybrid controllers are generated.

- misr_input_ratio : *integer* ;

A property and integer pair that specifies the ratio of the number of scan chains to the number of MISR inputs. The default is auto. For more information, see the lbist_misr_input_ratio argument description for the [set_edt_options](#) command. A value of auto is equivalent to not specifying the lbist_misr_input_ratio argument for the [set_edt_options](#) command.

- chain_mask_register_ratio : *integer* ;

A property and integer pair that specifies the number of scan chains controlled by a single EDT chain mask register bit. By default, the ratio is 1:1; there are as many bits in the chain mask register as there are number of scan chains.

You can use this property to minimize the area impact of the chain mask register. For example, specifying 3 for *integer* means a 3:1 ratio with each chain mask register bit controlling 3 scan chains. Specify the ratio on a per EDT block basis.

The larger the ratio you specify, the more you trade off resolution for area impact. When any scan chain connected to a chain mask register bit is masked, all the other scan chains connected to the bit are also masked automatically.

Refer to “[Scan Chain Masking](#)” in the *Hybrid TK/LBIST User’s Manual* for more information.

ShiftPowerOptions

This wrapper groups properties related to Low Power Shift capabilities.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        Controller(id) {
            LogicBistOptions {
                ShiftPowerOptions {
                    present : off | on ;
                    default_operation : enabled | disabled ;
                    SwitchingThresholdPercentage{
                    }
                }
            }
        }
    }
}
```

Description

This wrapper allows you to set low power shift options for the hybrid TK/LBIST controller.

Arguments

- **present : on | off**
A property which enables the low power shift functionality for the hybrid TK/LBIST controller.
- **default_operation : enabled | disabled**
A property which specifies whether low power shift should be enabled or disabled in the default hardware mode.

SwitchingThresholdPercentage

This wrapper allows you to set the switching threshold percentage for the hybrid TK/LBIST controller.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        Controller(id) {
            LogicBistOptions {
                ShiftPowerOptions {
                    SwitchingThresholdPercentage {
                        min : integer ; //default: 15
                    }
                }
            }
        }
    }
}
```

Arguments

- *min* : *integer* ;

An optional switch and integer pair that specifies the switching threshold value for the hardware mode for the Hybrid TK/LBIST controller. Valid Values are between 1 and 50. The default is 15. For more information, see the [set_lbist_power_controller_options](#) command.

Connections

This wrapper is used to add and specify properties for the EDT controller connections.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        Controller(id) {
            Connections {
                edt_clock      : port_pin_name | DftSignal(edt_clock) | OptionalDftSignal(edt_clock);
                edt_slave_clock : port_pin_name;
                edt_update      : port_pin_name | DftSignal(edt_update) | OptionalDftSignal(edt_update);
                edt_reset       : port_pin_name;
                StaticExternalControls {
                }
                EdtChannelsIn(id) {
                }
                EdtChannelsOut(id) {
                }
            }
        }
    }
}
```

Description

This wrapper is used to add and specify properties for the EDT controller connections.

There are cases when you may need to connect multiple EDT channel connections to a single top level port. A method for doing this, along with an example, is described in the documentation for the [add_dft_modal_connections](#) command.

Arguments

- `edt_clock : port_pin_name | DftSignal(edt_clock) | OptionalDftSignal(edt_clock);`
An optional property used to specify a source node to connect the `edt_clock` port to.

The node name can be a port or a pin name. The node must already exist in the design with the exception of one case. If the design level, as specified by the [set_design_level](#) command, is not “chip” and the name corresponds to the name of a scalar port, it is allowed to not exist in the design and it will be created as an input port during insertion.

When design level is “chip”, specified port names must already be connected to a pad cell. The connection will automatically be made to the internal side of the input pad buffer. You can specify `OptionalDftSignal(edt_clock)` or `DftSignal(edt_clock)` as the value, and it will be interpreted to request a connection to the DFT signal `edt_clock` as it was added using the [add_dft_signals](#) command. When using `OptionalDftSignal(edt_clock)`, you will not get an error if the DFT signal `edt_clock` was not added; a connection to the port called “`edt_clock`” will be made instead and the port will be created if not present unless design level is equal to “chip” in which case you will get an error.

When the property is unspecified, its value is inherited from the ..[/Connections](#)/edt_clock property which itself defaults to OptionalDftSignal(edt_clock) when unspecified.

- edt_slave_clock : *port_pin_name* ;

A property that specifies the EDT slave clock. When you generate level-sensitive clocking (latch-based EDT IP), the EDT IP contains a master clock and a slave clock to connect. See “[TestKompress Compression Logic](#)” in the *Tessent TestKompress User’s Manual*. The default is edt_slave_clock.

- edt_update : *port_pin_name* | DftSignal(edt_update) | [OptionalDftSignal\(edt_update\)](#);

An optional property used to specify a source node to connect the edt_update port to.

The node name can be a port or a pin name. The node must already exist in the design with the exception of one case. If the design level, as specified by the [set_design_level](#) command, is not “chip” and the name corresponds to the name of a scalar port, it is allowed to not exist in the design and it will be created as an input port during insertion.

When design level is “chip”, specified port names must already be connected to a pad cell. The connection will automatically be made to the internal side of the input pad buffer. You can specify OptionalDftSignal(edt_update) or DftSignal(edt_update) as the value, and it will be interpreted to request a connection to the DFT signal edt_update as it was added using the [add_dft_signals](#) command. When using OptionalDftSignal(edt_update), you will not get an error if the DFT signal edt_update was not added; a connection to the port called “edt_update” will be made instead and the port will be created if not present unless design level is equal to “chip” in which case you will get an error.

When the property is unspecified, its value is inherited from the ..[/Connections](#)/edt_update property which itself defaults to OptionalDftSignal(edt_update) when unspecified.

- edt_reset : *port_pin_name* ;

A property that specifies edt_reset. The default is edt_reset.

StaticExternalControls

This wrapper is used to add and specify properties for the EDT static external controls.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        Controller(id) {
            Connections {
                StaticExternalControls {
                    edt_bypass : port_pin_name | 0 | 1 ;
                    edt_single_bypass_chain : port_pin_name | 0 | 1 ;
                    edt_configuration : port_pin_name | 0 | 1 ;
                    edt_low_power_shift_enable : port_pin_name | 0 | 1 ;
                }
            }
        }
    }
}
```

Description

This wrapper is used to add and specify properties for the EDT static external controls.

Arguments

- `edt_bypass : port_pin_name | 0 | 1 ;`

A property that specifies the connection to the `edt_bypass` EDT static control pin. The `edt_bypass` pin connects to the specified `port_pin_name`, or is tied to high or low using the 1 or 0 symbol. Setting this property overrides the `EDT/Connections/StaticExternalControls/edt_bypass` specification. The default is 0.

- `edt_single_bypass_chain : port_pin_name | 0 | 1 ;`

A property that specifies the connection to the `edt_single_bypass_chain` static EDT control pin. The `edt_single_bypass_chain` pin connects to the specified `port_pin_name`, or is tied to high or low using the 1 or 0 symbol. Setting this property overrides the `EDT/Connections/StaticExternalControls/edt_single_bypass_chain` specification. The default is 0.

- `edt_configuration : port_pin_name | 0 | 1 ;`

A property that specifies the connection to the `edt_configuration` static EDT control pin. The `edt_configuration` pin connects to the specified `port_pin_name`, or is tied to high or low using the 1 or 0 symbol. Setting this property overrides the `EDT/Connections/StaticExternalControls/edt_configuration` specification. The default is 0.

- `edt_low_power_shift_enable : port_pin_name | 0 | 1 ;`

A property that specifies the connection to the `edt_low_power_shift_enable` static EDT control pin. The `edt_low_power_shift_enable` pin connects to the specified `port_pin_name`, or is tied to high or low using the 1 or 0 symbol. Setting this property overrides the `EDT/Connections/StaticExternalControls/edt_low_power_shift_enable` specification. The default is 1.

EdtChannelsIn

This wrapper is used to add and specify properties for the EDT channel in ports.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        Controller(id) {
            Connections {
                EdtChannelsIn(id_range) {
                    port_pin_name : port_pin_name ;
                    pipeline_clock : port_pin_name ; // default : edt_clock
                    PipelineStage {
                    }
                }
            }
        }
    }
}
```

Description

The `process_dft_specification` command for EDT creates bus ports for EDT channel connections on the block level as specified in the configuration data. If the bus ports exist already, they are used for EDT channel connections. If they do not exist, they will be created on the block level by `process_dft_specification`.

You specify the bus names with the `port_pin_name` properties with this configuration data wrapper. The ports must have sufficient bits to make all of the specified EDT channel input connections. EDT `process_dft_specification` cannot enhance existing ports with additional bits.

You can specify the bus ports to be created with any bit range as long as it is a valid Verilog range. They can start with 0 or any other number. Any range is acceptable as long as the EDT channel range width matches the specified connection width. The order you specify the bus ports has an impact on the connection order made to the EDT IP.

The (*id*) component of the `EdtChannelsIn` wrapper accepts a range of positive integer values using a single value or a colon-separated pair of values. For example:

```
EdtChannelsIn(4:1) - first 4 EDT input channels
EdtChannelsIn(1:4) - first 4 EDT input channels with inverted connection
                     order
EdtChannelsIn(1)   - first EDT input channel
EdtChannelsIn(1:1) - first EDT input channel
```

When you specify at least one input connection, you must specify all values and ranges.

Note

 The EDT `process_dft_specification` does not expand existing bus ports. An error will be reported if you use more bits than are on the existing bus.

Arguments

- `port_pin_name : port_pin_name ;`

A property that specifies signals that are connected to the `edt_channels_in` port of the EDT controller. The value can be any of these:

- bus
- list of scalar ports/pins
- list of mixed bus and port/pin objects
- indexed identifier

- `pipeline_clock : port_pin_name ;`

An optional property that specifies the pipeline clock. If not specified the default is `edt_clock`. See “[Pipeline Stage Insertion](#)” and “[Lockup Cells on the Input Side of the EDT Controller](#)” in the *Tessent TestKompress User’s Manual* for more information.

Examples

Example 1

In this example, the tool connects the first four EDT input channels to the `top_bus[3:0]` port object. The first EDT channel connects to `top_bus[0]` and the fourth channel connects to `top_bus[3]`.

```
EdtChannelsIn(4:1) {
    port_pin_name : top_bus[3:0];
}
```

Example 2

This example demonstrates using a mixed list of scalar ports and buses.

```
EdtChannelsIn(8:5) {
    port_pin_name : top8, top7, in[1:0];
}
```

The tool makes connections as follows:

```
edt_ctrl_inst/edt_channels_in[7] -> top8
edt_ctrl_inst/edt_channels_in[6] -> top7
edt_ctrl_inst/edt_channels_in[5] -> in[1]
edt_ctrl_inst/edt_channels_in[4] -> in[0]
```

Example 3

This example uses an indexed bus identifier.

```
EdtChannelsIn(4:1) {
    port_pin_name : in[%d];
}
```

The tool automatically infers the bus bit values for the connection as follows:

```
edt_ctrl_inst/edt_channels_in[3] -> in[3]
edt_ctrl_inst/edt_channels_in[2] -> in[2]
edt_ctrl_inst/edt_channels_in[1] -> in[1]
edt_ctrl_inst/edt_channels_in[0] -> in[0]
```

Example 4

This example shows how to create two EDT controllers. While it shows the creation of both input and output bus ports, notice the effect of EdtChannelsIn.

```
DftSpecification(CoreB,rtl) {
    EDT {
        Controller(1) {
            scan_chain_count: 100;
            longest_chain_range: 100,110;
            input_channel_count: 4;
            output_channel_count: 4;
            leaf_instance_name: edt_ctrl_inst1;
            Connections {
                EdtChannelsIn(4:1) {
                    port_pin_name: new_input_bus[3:0];
                }
                EdtChannelsOut(4:1) {
                    port_pin_name: new_output_bus[3:0];
                }
            }
        }
        Controller(2) {
            scan_chain_count: 100;
            longest_chain_range: 100,110;
            input_channel_count: 4;
            output_channel_count: 4;
            leaf_instance_name: edt_ctrl_inst2;
            Connections {
                EdtChannelsIn(4:1) {
                    port_pin_name: new_input_bus[15:12];
                }
                EdtChannelsOut(4:1) {
                    port_pin_name: new_output_bus[15:12];
                }
            }
        }
    }
}
```

With this configuration data in place, two new EDT controllers will be created when you run the process_dft_specification command, edt_ctrl_inst1 and edt_ctrl_inst2. The input EDT channels

in each controller are connected to the created bus ports named “new_input_bus” by the EdtChannelsIn wrapper. This shows the connections made for both controllers:

```
edt_ctrl_inst1/edt_channels_in[3] -> new_input_bus[3]
edt_ctrl_inst1/edt_channels_in[2] -> new_input_bus[2]
edt_ctrl_inst1/edt_channels_in[1] -> new_input_bus[1]
edt_ctrl_inst1/edt_channels_in[0] -> new_input_bus[0]
edt_ctrl_inst2/edt_channels_in[3] -> new_input_bus[15]
edt_ctrl_inst2/edt_channels_in[2] -> new_input_bus[14]
edt_ctrl_inst2/edt_channels_in[1] -> new_input_bus[13]
edt_ctrl_inst2/edt_channels_in[0] -> new_input_bus[12]
```

The new bus ports will have a range of 16 bits (15:0) each because the MSB specified is 15 and the LSB is 0 for both of them. The tool will always create every bus port from its MSB to LSB bits as specified in the configuration data.

PipelineStage

This wrapper is used to add and specify properties for the EDT channel in pipeline stage.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        Controller(id) {
            Connections {
                EdtChannelsIn(id) {
                    PipelineStage {
                        parent_instance : instance_name ;
                        leaf_instance_name : instance_name ;
                        pipeline_clock : port_pin_name ;
                    }
                }
            }
        }
    }
}
```

Description

This wrapper is used to add and specify properties for the EDT channel in pipeline stage. See “[Pipeline Stage Insertion](#)” and “[Lockup Cells on the Input Side of the EDT Controller](#)” in the *Tessent TestKompress User’s Manual* for more information.

Arguments

- `parent_instance : instance_name ;`

An optional property that specifies the parent instance. This is the name of the instance where the pipeline IP will be generated. If it is not specified, the IP will be placed in the current design scope.

- `leaf_instance_name : instance_name ;`

An optional property that specifies the instance name of the pipeline IP. If not specified, the leaf instance name is auto generated with this format
`<top_module_name>_<dft_spec_id>_tessent_<instrument_name>_<edt_ctrl_id>_<channel_type>_<channel_bit>_pipe_inst_<pipe_index>..`

- `pipeline_clock : port_pin_name ;`

An optional property that specifies the pipeline clock port pin name. This property will override the value of the `pipeline_clock` specified in the `EdtChannelsIn` wrapper. If not specified, it will use the value specified by `EdtChannelsIn` wrapper. If that is not specified, it will default to `edt_clock`. See “[Pipeline Stage Insertion](#)” and “[Lockup Cells on the Input Side of the EDT Controller](#)” in the *Tessent TestKompress User’s Manual* for more information.

Examples

The following example uses the PipelineStage wrapper to define pipeline stages for the EDT input and output channels.

```

DftSpecification(CoreB,rtl) {
    EDT {
        Controller(1) {
            scan_chain_count: 100;
            longest_chain_range: 100,110;
            input_channel_count: 4;
            output_channel_count: 4;
            leaf_instance_name: edt_ctrl_inst1;
            Connections {
                EdtChannelsIn(4:1) {
                    port_pin_name: new_input_bus[3:0];
                    PipelineStage {
                        parent_instance : block1;
                        leaf_instance_name : pipe1 ;
                        pipeline_clock : edt_clock;
                    }
                    PipelineStage {
                        parent_instance : block1;
                        leaf_instance_name : pipe2 ;
                        pipeline_clock : edt_clock;
                    }
                }
                EdtChannelsOut(4:1) {
                    port_pin_name: new_output_bus[3:0];
                    PipelineStage {
                        parent_instance : block1;
                        leaf_instance_name : pipe3 ;
                        pipeline_clock : edt_clock;
                    }
                    PipelineStage {
                        parent_instance : block1;
                        leaf_instance_name : pipe4 ;
                        pipeline_clock : edt_clock;
                    }
                }
            }
        }
        Controller(2) {
            scan_chain_count: 100;
            longest_chain_range: 100,110;
            input_channel_count: 4;
            output_channel_count: 4;
            leaf_instance_name: edt_ctrl_inst2;
            Connections {
                EdtChannelsIn(4:1) {
                    port_pin_name: new_input_bus[15:12];
                    PipelineStage {
                        parent_instance : block1;
                        leaf_instance_name : pipe5 ;
                        pipeline_clock : edt_clock;
                    }
                }
                EdtChannelsOut(4:1) {
                    port_pin_name: new_output_bus[15:12];
                }
            }
        }
    }
}

```

}

EdtChannelsOut

This wrapper is used to add and specify properties for the EDT channel out ports.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        Controller(id) {
            Connections {
                EdtChannelsOut(id_range) {
                    port_pin_name : port_pin_name ;
                    pipeline_clock : port_pin_name ;
                    PipelineStage {
                    }
                }
            }
        }
    }
}
```

Description

The `process_dft_specification` command for EDT creates bus ports for EDT channel connections on the block level as specified in the configuration data. If the bus ports exist already, they are used for EDT channel connections. If they do not exist, they will be created on the block level by `process_dft_specification`.

You specify the bus names with the `port_pin_name` properties with this configuration data wrapper. The ports must have sufficient bits to make all of the specified EDT channel output connections. EDT `process_dft_specification` cannot enhance existing ports with additional bits.

You can specify the bus ports to be created with any bit range as long as it is a valid Verilog range. They can start with 0 or any other number. Any range is acceptable as long as the EDT channel range width matches the specified connection width. The order you specify the bus ports has an impact on the connection order made to the EDT IP.

The (*id*) component of the `EdtChannelsOut` wrapper accepts a range of positive integer values using a single value or a colon-separated pair of values. For example:

```
EdtChannelsOut(8:7) - two EDT output channels
```

When you specify at least one output connection, you must specify all values and ranges.

Note

 The EDT `process_dft_specification` does not expand existing bus ports. An error will be reported if you use more bits than are on the existing bus.

Arguments

- `port_pin_name` : *port_pin_name* ;
A property that specifies the signals connected to the `edt_channels_out` port of the EDT controller.
- `pipeline_clock` : *port_pin_name* ;
A property that specifies the pipeline clock. See “[Pipeline Stage Insertion](#)” and “[Lockup Cells on the Output Side of the EDT Controller](#)” in the *Tessent TestKompress User’s Manual* for more information.

Examples

Example 1

In this example, the tool connects the first four EDT output channels to the `out*` scalar ports.

```
EdtChannelsOut(1:4) {  
    port_pin_name : out4, out3, out2, out1;  
}
```

The EDT channel index order is reversed. Consequently, the connections are made as follows:

```
edt_ctrl_inst/edt_channels_out[3] -> out1  
edt_ctrl_inst/edt_channels_out[2] -> out2  
edt_ctrl_inst/edt_channels_out[1] -> out3  
edt_ctrl_inst/edt_channels_out[0] -> out4
```

Example 2

This example shows how to create two EDT Controllers with new bus ports.

```
DftSpecification(CoreB,rtl) {
    EDT {
        Controller(1) {
            scan_chain_count: 100;
            longest_chain_range: 100,110;
            input_channel_count: 4;
            output_channel_count: 4;
            leaf_instance_name: edt_ctrl_inst1;
            Connections {
                EdtChannelsIn(4:1) {
                    port_pin_name: new_input_bus[3:0];
                }
                EdtChannelsOut(4:1) {
                    port_pin_name: new_output_bus[3:0];
                }
            }
        }
        Controller(2) {
            scan_chain_count: 100;
            longest_chain_range: 100,110;
            input_channel_count: 4;
            output_channel_count: 4;
            leaf_instance_name: edt_ctrl_inst2;
            Connections {
                EdtChannelsIn(4:1) {
                    port_pin_name: new_input_bus[15:12];
                }
                EdtChannelsOut(4:1) {
                    port_pin_name: new_output_bus[15:12];
                }
            }
        }
    }
}
```

With this configuration data in place, two new EDT controllers will be created when you run the process_dft_specification command, edt_ctrl_inst1 and edt_ctrl_inst2. The output EDT channels in each controller are connected to the created bus ports named “new_output_bus” by the EdtChannelsOut wrapper. This shows the connections made for both controllers:

```
edt_ctrl_inst1/edt_channels_out[3] -> new_output_bus[15]
edt_ctrl_inst1/edt_channels_out[2] -> new_output_bus[14]
edt_ctrl_inst1/edt_channels_out[2] -> new_output_bus[13]
edt_ctrl_inst1/edt_channels_out[0] -> new_output_bus[12]
edt_ctrl_inst2/edt_channels_out[3] -> new_output_bus[15]
edt_ctrl_inst2/edt_channels_out[2] -> new_output_bus[14]
edt_ctrl_inst2/edt_channels_out[1] -> new_output_bus[13]
edt_ctrl_inst2/edt_channels_out[0] -> new_output_bus[12]
```

The new bus ports will have a range of 16 bits (15:0) each because the MSB specified is 15 and the LSB is 0 for both of them. The tool will always create every bus port from its MSB to LSB bits as specified in the config data.

PipelineStage

This wrapper is used to add and specify properties for the EDT channel out pipeline stage.

Usage

```
DftSpecification(module_name, id) {
    EDT {
        Controller(id) {
            Connections {
                EdtChannelsOut(id) {
                    PipelineStage {
                        parent_instance : instance_name ;
                        leaf_instance_name : instance_name ;
                        pipeline_clock : port_pin_name ;
                    }
                }
            }
        }
    }
}
```

Description

This wrapper is used to add and specify properties for the EDT channel out pipeline stage. See “[Pipeline Stage Insertion](#)” and “[Lockup Cells on the Output Side of the EDT Controller](#)” in the *Tessent TestKompress User’s Manual* for more information.

Arguments

- `parent_instance : instance_name ;`
A property that specifies the parent instance. This is the name of the instance where this IP will be generated. If it is not specified, the IP will be placed in the current design scope.
- `leaf_instance_name : instance_name ;`
An optional property that specifies the instance name of the pipeline IP. If not specified, the leaf instance name is auto generated with this format
`<top_module_name>_<dft_spec_id>_tessent_<instrument_name>_<edt_ctrl_id>_<channel_type>_<channel_bit>_pipe_inst_<pipe_index>`.
- `pipeline_clock : port_pin_name ;`
A property that specifies the pipeline clock. This property overrides the value for the `pipeline_clock` specified in the `EdtChannelsOut` wrapper. See “[Pipeline Stage Insertion](#)” and “[Lockup Cells on the Output Side of the EDT Controller](#)” in the *Tessent TestKompress User’s Manual* for more information.

Examples

The following example uses the `PipelineStage` wrapper to define pipeline stages for the EDT input and output channels.

```
DftSpecification(CoreB,rtl) {
    EDT {
        Controller(1) {
            scan_chain_count: 100;
            longest_chain_range: 100,110;
            input_channel_count: 4;
            output_channel_count: 4;
            leaf_instance_name: edt_ctrl_inst1;
            Connections {
                EdtChannelsIn(4:1) {
                    port_pin_name: new_input_bus[3:0];
                    PipelineStage {
                        parent_instance : block1;
                        leaf_instance_name : pipe1 ;
                        pipeline_clock : edt_clock;
                    }
                    PipelineStage {
                        parent_instance : block1;
                        leaf_instance_name : pipe2 ;
                        pipeline_clock : edt_clock;
                    }
                }
                EdtChannelsOut(4:1) {
                    port_pin_name: new_output_bus[3:0];
                    PipelineStage {
                        parent_instance : block1;
                        leaf_instance_name : pipe3 ;
                        pipeline_clock : edt_clock;
                    }
                    PipelineStage {
                        parent_instance : block1;
                        leaf_instance_name : pipe4 ;
                        pipeline_clock : edt_clock;
                    }
                }
            }
        }
        Controller(2) {
            scan_chain_count: 100;
            longest_chain_range: 100,110;
            input_channel_count: 4;
            output_channel_count: 4;
            leaf_instance_name: edt_ctrl_inst2;
            Connections {
                EdtChannelsIn(4:1) {
                    port_pin_name: new_input_bus[15:12];
                    PipelineStage {
                        parent_instance : block1;
                        leaf_instance_name : pipe5 ;
                        pipeline_clock : edt_clock;
                    }
                }
                EdtChannelsOut(4:1) {
                    port_pin_name: new_output_bus[15:12];
                }
            }
        }
    }
}
```

}

ItagNetwork

A wrapper that specifies the IJTAG network to be built and, optionally, inserted into the design.

Usage

```
DftSpecification(module_name,id) {
    ItagNetwork {
        ImplementationOptions {
            scan_path_retiming : latch | flop ; // default: latch
        }
        DataInPorts {
        }
        DataOutPorts {
        }
        HostScanInterface(id) {           // repeatable
            Interface { *DefSpec
            }
            DesignInstance(instance_name) { // repeatable
            }
            ScanMux(id) {               // repeatable
            }
            Sib(id) {                  // repeatable
            }
            Tdr(id) {                  // repeatable
            }
            Tap(id) {                  // repeatable
            }
        }
    }
}
```

Description

A wrapper that specifies the IJTAG network to be built and, optionally, inserted into the design.

This wrapper can be specified once for each DftSpecification wrapper. As illustrated in the syntax above, the ItagNetwork specification consists of one [ItagNetwork/DataInPorts](#) wrapper, one [ItagNetwork/DataOutPorts](#) wrapper, one [ImplementationOptions](#) wrapper, and one or more HostScanInterface wrappers.

A HostScanInterface wrapper defines a scan interface below which a network of IJTAG nodes are serially accessible. The [HostScanInterface/Interface](#) wrapper is used to specify the end points of the HostScanInterface. By default, the wrapper defines a set of ports that may or may not already exist on the current design, but you can also use this wrapper to specify how to connect to an existing host interface present inside the design. For more details and example usage, see the description of the [HostScanInterface/Interface](#) wrapper. If the [HostScanInterface/Interface](#) wrapper only consists of ports on the current design, the [add_icl_scan_interfaces](#) and the [set_icl_scan_interface_ports](#) commands are issued during insertion such that, if you perform ICL extraction once you are done with insertion, the ScanInterface in the extracted ICL module will be named using the id of the HostScanInterface you specified in the DftSpecification.

The other five wrappers, [DesignInstance](#), [ScanMux](#), [Sib](#), [Tap](#), and [Tdr](#), define nodes serially connected below the HostScanInterface. They can be specified in any order, and they are all repeatable; however, their relative order defines the scan path connectivity. The scan-out of the first element declared in the HostScanInterface wrapper sources the scan-out port of the HostScanInterface. The scan-in port of the last element declared in the HostScanInterface wrapper is sourced by the scan-in port of the HostScanInterface.

The SIB, ScanMux, and TAP nodes become host interfaces to the client interfaces of the nodes declared inside them. See the description of the [Sib](#), and [ScanMux](#), [Tap](#) wrappers for more details. The example below illustrates the hierarchical nature of the IJTAG network.

Note

 If you want to insert BoundaryScan and the TAP controller, and connect the TAP to internal pins, follow the instructions in [Example 2](#).

Scan Testability of the IJTAG Network

Elements of the IJTAG network can be used to configure the circuit in its various scan modes. The example shown in [Figure 10-1](#) illustrates the use of a TDR to generate the various scan mode signals. In this example, the portion of the network that gives access to this TDR must remain active during scan test and must remain unaffected by the scan test modes like any other test_setup hardware you may use. If the property `keep_active_during_scan_test` is set on a node, the host access path to the node is traced and every node in the access path is marked with the `keep_active_during_scan_test` attribute. The ICL modules are generated with this attribute and collected into the merged ICL file created by ICL extract. You can later use this information to declare those modules as non-scan during scan insertion, and force them to be kept in the graybox during graybox generation.

When the id of a Tdr wrapper is named “`scan_modes`”, the `keep_active_during_scan_test` property defaults to on for that TDR. This, in turn, forces all nodes needed to access it from the HostScanInterface to have `keep_active_during_scan_test` set to on.

Once you have extracted the final ICL using ICL extract, executing the command “`get_icl_instances -filter keep_active_during_scan_test`” will generate a collection of all ICL instances having `keep_active_during_scan_test` set to on. You can then use the `tessent_design_instance` attribute on the ICL instances to find the corresponding design instances and pass this list to your scan insertion and/or graybox generation step. For a complete list of attributes available on the ICL instance object type, see the [icl_instance](#) data model.

Arguments

None.

Examples

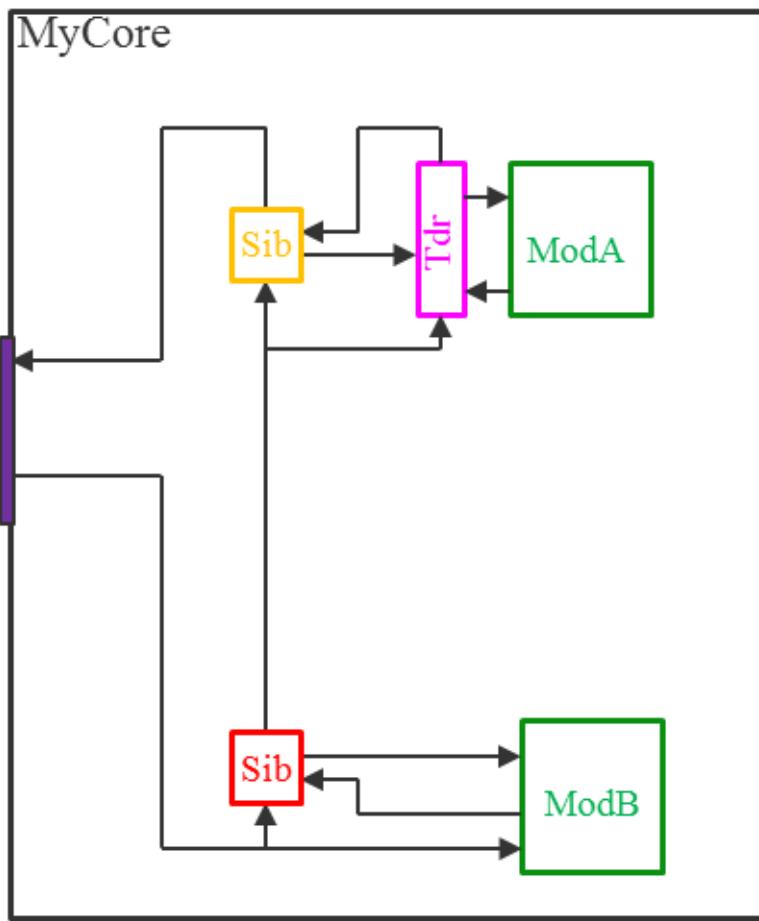

Example 1

The following example shows the DftSpecification of a simple IJTAG network having two SIBs connected in series; the first SIB hosts a design instance, and the second SIB hosts a TDR which in turn sources and observes the data signals of a second design instance. The example assumes the design already includes those two design instances and that an ICL file describing their ports exists for each of them. [Figure 10-1](#) provides the schematic for this example.

The instance “u1/bottom_green” is an instance of module ModB and has a single ScanInterface described in its ICL file; its ScanInterface will be hooked up to the host interface of the red SIB.

The instance “u2/top_green” is an instance of module ModA and has four DataInPorts and two DataOutPorts described in its ICL file. The DataOutPorts of the pink TDR is connected to the DataInPorts of ModA and vice versa. See the description of the [DesignInstance](#) wrapper for information about how the ICL files are automatically searched and matched to the design instance during the [set_current_design](#) invocation.

```
DftSpecification(MyCore,rtl) {
    IjtagNetwork {
        HostScanInterface(purple) {
            Sib(orange) {
                Tdr(pink) {
                    DataOutPorts {
                        connection(0) : u2/top_green/en;
                        connection(3:1) : u2/top_green	mode[2:0];
                    }
                    DataInPorts {
                        connection(0) : u2/top_green/go;
                        connection(1) : u2/top_green/done;
                    }
                }
            }
            Sib(red) {
                DesignInstance (u1/bottom_green) {}
            }
        }
    }
}
```

Figure 10-1. IJTAG Network Example Schematic

Example 2

The following example inserts the TAP and the Boundary Scan chain in one pass using a DftSpecification wrapper. This example shows the steps to follow when you want to connect the TAP controller to internal pins which are not directly on the pads associated to the TAP ports. You typically want to do this if you are using a compliance enable pin and the logic to enable the TAP is already present in the design. If the gating logic is not already present, you use the `-active_high_compliance_enables` and/or the `-active_low_compliance_enables` switches of the [create_dft_specification](#) command.

The following example sets the `function` attribute on the top-level ports to identify the top-level TAP port in Step 1. This example connects the TAP to internal pins which are enabled when the top-level port “myCE1” is asserted high. Step 1b shows how your compliance enable port is described such that it gets reported as such in the BSDL file. In this example, it is assumed you already have this logic in the design and that you want to connect the TAP to it. The recommended flow is to not insert this logic manually and let the tool auto create and insert it by using the `-active_high_compliance_enables` and/or the `-active_low_compliance_enables` switches of the [create_dft_specification](#) command. When you do that, the flow is fully automated. When you created your own compliance enable logic as shown in [Figure 10-2](#) on

page 3232, you need to either describe that module in ICL or assert the compliance enable ports before running ICL extraction. The explanation as to when to use which method is described at the bottom of this example

In Step2, you call “set spec [create_dft_specification]” to create the DftSpecification that includes a HostScanInterface wrapper with a TAP wrapper inside it. Step3 below augments the IjtagNetwork wrapper with a second HostScanInterface where the Interface properties are used to specify the connections to internal pins. Step 4 shows the use of the [move_config_element](#) command to move the TAP wrapper that exists in the original HostScanInterface to the new one. Finally, Step 5 reports the final DftSpecification. The HostScanInterface(tap) is used to identify the top-level TAP ports which will be reported in the BSDL file and the second HostScanInterface(tap_internal) specifies where to connect the client scan interface of the Tap controller.

```
# Step 1: set the 'function' attribute on the top level TAP ports
set_attribute_value -name function -value trst jtag_trst
set_attribute_value -name function -value tdi jtag_tdi
set_attribute_value -name function -value tms jtag_tms
set_attribute_value -name function -value tck jtag_tck
set_attribute_value -name function -value tdo jtag_tdo

# Step 1b: declare your compliance enable port so it is documented in
#           the BSDL file
set_boundary_scan_port_options myCE1 -cell_options compliance_enable1

# Step 2: create an initial DFT specification
set_system_mode analysis
set_spec [create_dft_specification]
```

```
# Step 3: add new HostScanInterface with the internal hookup points
read_config_data -in_wrapper ${spec}/IjtagNetwork -from_string {
    HostScanInterface(tap_internal) {
        Interface {
            tck : jtag_and0/o;
            trst : jtag_and3/o;
            tms : jtag_and1/o;
            tdi : jtag_and2/o;
            tdo : jtag_buf5/a;
            tdo_en : jtag_buf4/a;
            tdo_en_polarity : active_high;
        }
    }
}

# step 4: move the Tap to the new HostScanInterface
move_config_element ${spec}/IjtagNetwork/HostScanInterface(tap)/Tap(main) \
    -in_wrapper ${spec}/IjtagNetwork/HostScanInterface(tap_internal)

# step 5: report the final DftSpecification.
report_config_data $spec
The resulting DFT specification will look like:
DftSpecification(top,rtl) {
    IjtagNetwork {
        HostScanInterface(tap) {
            Interface {
                tck : jtag_tck;
                trst : jtag_trst;
                tms : jtag_tms;
                tdi : jtag_tdi;
                tdo : jtag_tdo;
            }
        }
        HostScanInterface(tap_internal) {
            Interface {
                tck : jtag_and0/o;
                trst : jtag_and3/o;
                tms : jtag_and1/o;
                tdi : jtag_and2/o;
                tdo : jtag_buf5/a;
                tdo_en : jtag_buf4/a;
                tdo_en_polarity : active_high;
            }
            Tap(main) {
                HostIjtag(1) {
                }
                HostBscan {
                }
            }
        }
    }
    BoundaryScan {
        ijtag_host_node : Tap(main)/HostBscan;
        pin_order_file : ../data/top.pinorder;
        BoundaryScanCellOptions {
            myCE1 : compliance_enable1;
        }
    }
}
```

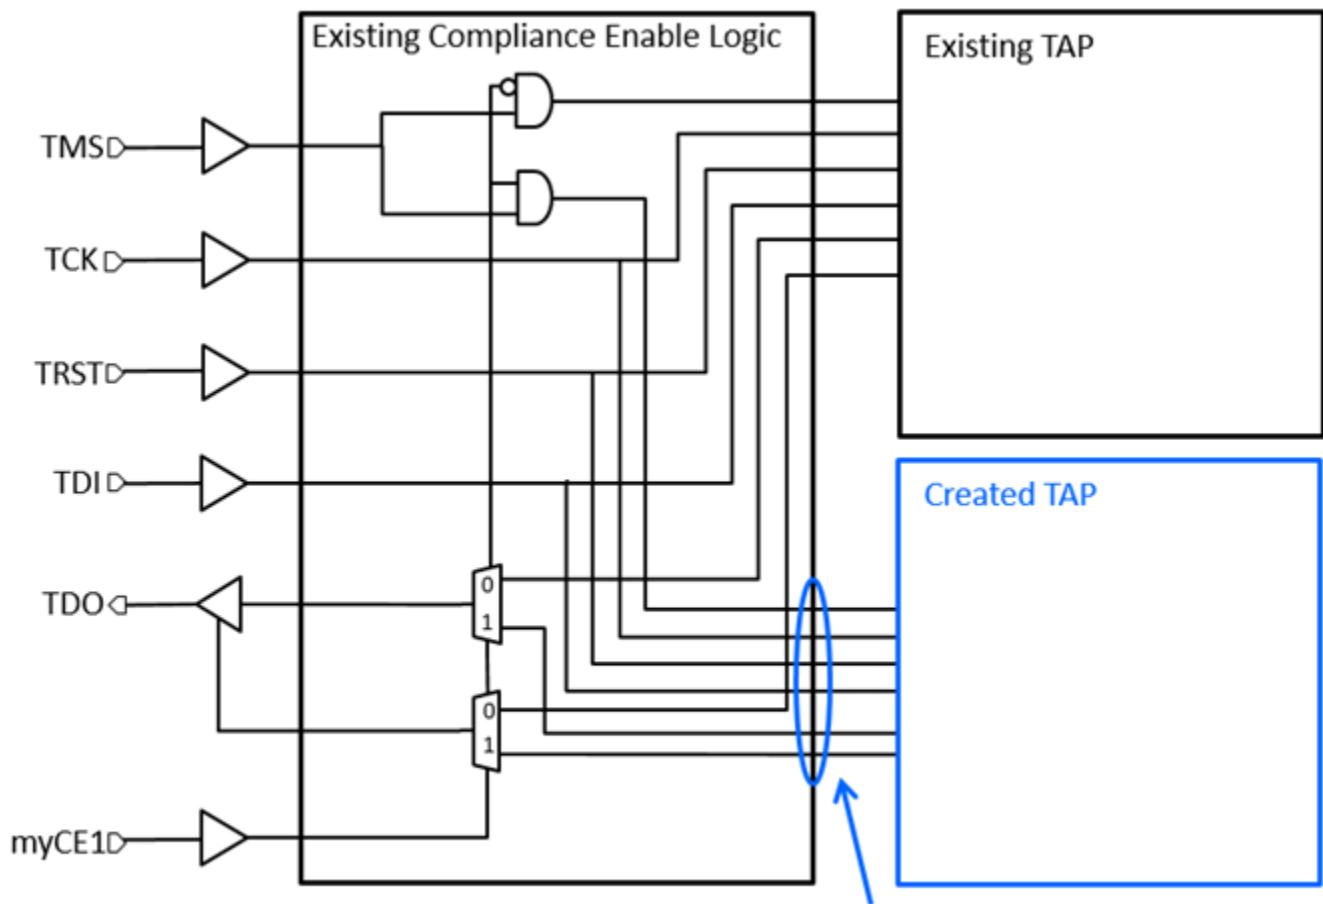

The above example explains how to connect the newly created TAP to internal pins which typically happens when you have compliance enable logic already inserted into the design. This is allowed but you have to deal with this logic before running the [extract_icl](#) command. Realize, however, that the flow is fully automated when you let the tool insert the compliance enable logic using the `-active_high_compliance_enables` and/or the `-active_low_compliance_enables` switches of the [create_dft_specification](#) command.

[Figure 10-2](#) on page 3232 shows the typical logic used to implement compliance enabling when you want to switch between an existing TAP and the Tessent Shell Tap. You may also be using this logic to switch between arbitrary functional logic and the Tessent Shell Tap. If there is no existing TAP or if the existing TAP does not have an ICL view that you want to be represented in the extract ICL file, you simply need to use the [add_input_constraints](#) command to assert the compliance enable ports to their active value before running the [extract_icl](#) command. If the enable is controlled by some internal logic, you need to use a test_setup proc file to describe the vectors needed to activate it. If on the other hand you have an ICL model for the existing TAP and you want it described in the extracted ICL file, you must model the multiplexing module with an ICL file similar the ICL module that follow:

```
Module compliance_enable {
    // from the pads
    TCKPort      tck;
    ScanInPort   tdi;
    ScanOutPort  tdo {
        Source ComplianceOutputSelect;
        Attribute forced_high_output_port_list = "tdo_en";
    }
    TMSPort      tms;
    TRSTPort     trst {
        Attribute connection_rule_option = "allowed_tied_high";
    }
    DataInPort   ce;
    ScanInterface tap_pins {
        Port tdi;
        Port tdo;
        Port tms;
        Port tck;
        Port trst;
    }
    // to the existing TAP
    ToTCKPort    tck_other;
    ToTMSPort    tms_other;
    ToTRSTPort   trst_other;
    ScanInPort   tdo_other;
    ScanOutPort  tdi_other {
        Source tdi;
    }
}
```

```
ScanInterface tap_pins_other {
    Port tdi_other;
    Port tdo_other;
    Port tms_other;
    Port tck_other;
    Port trst_other;
}
// to the Tessent Shell generated TAP
ToTCKPort tck_ts;
ToTMSPort tms_ts;
ToTRSTPort trst_ts;
ScanInPort tdo_ts;
ScanOutPort tdi_ts {
    Source tdi;
}
ScanInterface tap_pins_ts {
    Port tdi_ts;
    Port tdo_ts;
    Port tms_ts;
    Port tck_ts;
    Port trst_ts;
}
// the mux for the tdo
ScanMux ComplianceOutputSelect SelectedBy ce {
    1'b1 : tdo_ts;
    1'b0 : tdo_other;
}
}
```

IjtagNetwork/ImplementationOptions

A wrapper that specifies implementation options when building the IJTAG network.

Usage

```
IjtagNetwork {
    ImplementationOptions {
        scan_path_retiming : latch | flop ;
    }
}
```

Description

A wrapper that specifies implementation options when building the IJTAG network. The options consist of the use of latches or flip-flops for scan path retiming.

Arguments

- `scan_path_retiming : latch | flop ;`

A property that specifies if the scan path retiming element is to be implemented using a latch or a flop.

This property has significant impact on the TAP controller. When the `scan_path_retiming` property is set or left to default to “latch”, a retiming latch is used on the tdo output of the TAP controller to make sure that the `scan_out` data of any scan register is launched from the negative edge of TCK. It is likely that the IJTAG elements feeding the `scan_in` port of its HostIjtag scan interfaces already have a retiming element on their `scan_out` port. The retiming latch inserted in series before reaching TDO has no effect and simply acts as a redundant retiming latch. If you set the property to “flop”, it is no longer possible to systematically place the retiming element on all TDO paths because it would end up in series with the one that is likely already present in IJTAG elements feeding the `scan_in` port of its HostIjtag scan interfaces. Cascading two retiming latches does not affect the resulting timing but cascading two retiming flops will change the timing. When using flops for `scan_path_retiming`, you must ensure that all `scan_out` ports feeding the `scan_in` port of the HostIjtag scan interfaces already have a retiming element. This is always true when using elements created with the `process_dft_specification` command. Only when a third party IJTAG node is directly connected to the `scan_in` port of a HostIjtag scan interface of the TAP, can you fail this requirement.

Note

 Make sure third party nodes include a retiming element on their `scan_out` when you connect them directly to the `scan_in` port of the HostIjtag scan interface’s Tessent Tap, and you have specified the `scan_path_retiming` property to “flop”, otherwise your elements will not be 1149.1 compliant and will likely not be usable within a board environment.

IjtagNetwork/DataInPorts

A wrapper that specifies data-in ports that may or may not exist as input ports on the current design.

Usage

```
IjtagNetwork {
    DataInPorts {
        count           : integer ;          // default: auto
        port_naming     : port_naming, ... ; // default: ijtag_data_in[%d]
        multiplexing    : on | off | auto ;
        connection(range) : pin_name ;      // repeatable
    }
}
```

Description

A wrapper that specifies data-in ports that may or may not exist as input ports on the current design.

These data-in ports can be used to source data-in ports on child design instances, or to source the select port of a [ScanMux](#) as shown in the example for this wrapper.

Arguments

- **count : *integer* ;**

A property to request a specific number of data-in ports. If the property is set, or defaults to auto, the count is determined to be large enough to satisfy the *range* value of all connection properties. If no connection property is specified, the count is determined to be large enough to satisfy the port_naming values if they are in a non-indexed format (%d).

- **port_naming : *port_naming*, ... ;**

A property that specifies the naming of the data-in ports. The port_naming value has two distinct formats: a single string using an index symbol “%d”, or a list of port names with explicit sizes.

When using the indexed format, you specify base_name[%d] when you want to use a bus and you specify base_name%<integer>d when you want to create a set of scalar ports. In both cases, the range is <count>-1 to 0. Using <integer> in the scalar naming ensures the integer is padded with 0s to be at least <integer> bits wide. For example, Din%2d will create Din00, Din01, Din02, and so on. Din%d and Din%1d mean the same thing. The default is “ijtag_data_in[%d]”.

When using a list of port names, you control the exact naming and width of each data-in port. For example, if you specify “locked”, you will get exactly one data-in port called “locked” as illustrated in “[Example 2](#)” on page 3285 of the [Tdr/DataInPorts](#) section.

- **multiplexing : on | off | auto ;**

A property that specifies if a multiplexer is to be added when making the connection to the specified *pin_name* of the connection properties. When set to auto, a multiplexer is added

unless the pin is unconnected, connected to a constant or connected to a net with no fanin. As soon as one connection needs multiplexing, an extra data-in port is added to control the select of the multiplexers. The multiplexers are inserted in the direct parent instance of the specified *pin_name* of the connection properties. See “[DataOutPort Connection Multiplexing](#)” on page 3290 in the [Tdr/DataOutPorts](#) section for an illustration of this.

- `connection(range) : pin_name ;`

A repeatable property that specifies the connections to make between the bits of the data-in ports and the existing pins inside the design. Because data-in ports are sources, the same bit can be connected to multiple destinations by simply repeating the connection property with the same range indexes.

If the pin name refers to a bused pin and you are connecting to a full bus, you can omit the bus range if the [process_dft_specification -no_insertion](#) option is not used. If you are using the [process_dft_specification -no_insertion](#) switch, you must specify the full range of the destination pin because the range cannot be extracted from the design.

Examples

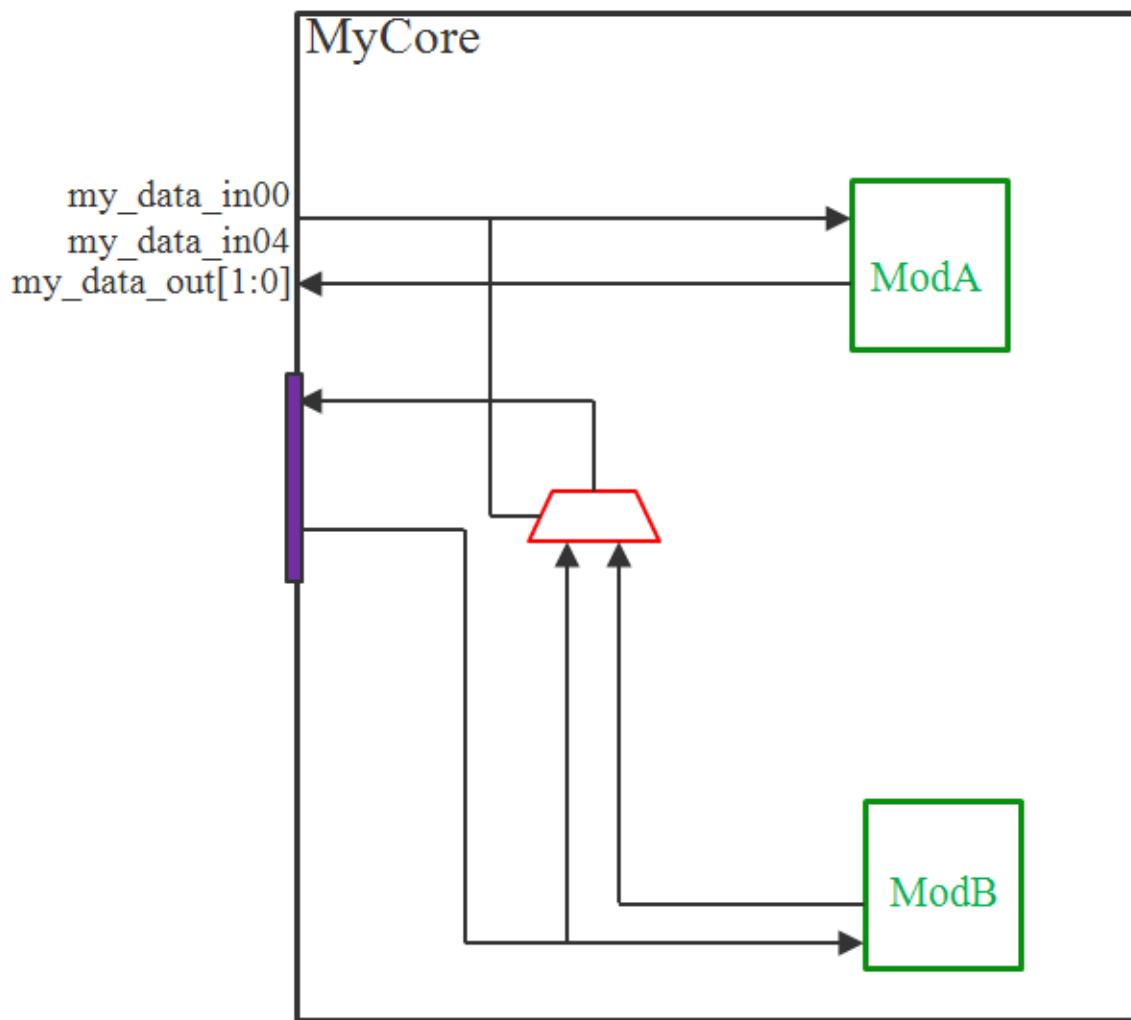

The following example illustrates defining five data-in ports. The ports are named `my_data_in04`, `my_data_in03`, `my_data_in02`, `my_data_in01`, and `my_data_in00`. The port `my_data_in00` is connected to the “en” pin of the `u2/top_green` instance. The ports `my_data_in03`, `my_data_in02`, and `my_data_in01` are connected to the `mode[2:0]` pins of the same instance. If the `count` property was not specified, it would have defaulted to four, corresponding to the largest specified connection range index value of three. In this example, a count of five is specified to request an extra data-in port to be used by the select port of the `ScanMux(red)` used in the `HostScanInterface(purple)`.

Notice that if this core was further integrated into a parent design and a Tdr was used to source the five data-in ports, the property `output_timing(4)` with a value of “`ijtag_scan_selection`” would need to be specified because bit 4 is used to reconfigure the scan network. For further explanation, see “[Update Stage Timing](#)” on page 3277.

The tool is currently unable to determine if the data-in port on a design instance is used to reconfigure the network within the specified design instance but this automation is planned for the future.

```
DftSpecification(MyCore,rtl) {
    IjtagNetwork {
        DataInPorts {
            Count           : 5 ;
            port_naming    : my_data_in%2d ;
            connection(0)  : u2/top_green/en ;
            connection(3:1) : u2/top_green/mode[2:0] ;
        }
        DataOutPorts {
            port_naming : my_data_out[%d] ;
            connection(0) : u2/top_green/go ;
            connection(1) : u2/top_green/done ;
        }
        HostScanInterface(purple) {
            ScanMux(red) {
                select : DataIn(4) ;
                Input(1) {
                    DesignInstance (u1/bottom_green) {}
                }
            }
        }
    }
}
```

[Tdr/DataInPorts](#)

[Tdr/DecodedSignal](#)

IjtagNetwork/DataOutPorts

A wrapper that specifies data-out ports that may or may not exist as output ports on the current design.

Usage

```
IjtagNetwork {
    DataOutPorts {
        count           : integer ;          // default: auto
        port_naming     : port_naming,...;   // default: ijtag_data_out[%d]
        Connection(range) : pin_name ;      // repeatable
    }
}
```

Description

A wrapper that specifies data-out ports that may or may not exist as output ports on the current design.

These data-out ports can be used to observe data-out ports on child design instances.

Arguments

- **count : *integer*;**

A property to request a specific number of data-out ports. If the property is set, or defaults to auto, the count is determined to be large enough to satisfy the *range* value of all connection properties. If no connection property is specified, the count is determined to be large enough to satisfy the *port_naming* values if they are in a non-indexed format (%d).

- **port_naming : *port_naming*, ... ;**

A property that specifies the naming of the data-out ports. The *port_naming* value as two distinct formats. It can be a single string using an index symbol or a list of port names with explicit sizes.

When using the indexed format, you specify *base_name*[%d] when you want to use a bus and you specify *base_name*%<integer>d when you want to create a set of scalar ports. In both cases, the range is <count>-1 to 0. Using <integer> in the scalar naming ensures the integer is padded with 0s to be at least <integer> bits wide. For example, Dout%2d will create Dout00, Dout01, Dout02, and so on. Dout%d and Dout%1d mean the same thing. The default is “ijtag_data_out[%d]”.

When using a list of port names, you control the exact naming and width of all data-out ports. For example, if you specify “mux_sel,mult[2:0],div[2:0]”, you will get exactly seven data-out ports where the most significant bit is called mux_sel and the least significant bit is called div[0] as illustrated in “[DataOutPort Connection Multiplexing](#)” on page 3290 of the [Tdr/DataOutPorts](#) section.

- **connection(*range*) : *pin_name*;**

A repeatable property that specifies the connections to make between the bits of the data-out port and the existing pins inside the design. Because data-out ports are sinks, the same bit

cannot be connected to multiple sources. It is, therefore, illegal to repeat the connection property with overlapping range indexes.

If the pin name refers to a bused pin and you are connecting to a full bus, you can omit the bus range if the [process_dft_specification -no_insertion](#) option is not used. If you are using the [process_dft_specification -no_insertion](#) switch, you must specify the full range of the destination pin because the range cannot be extracted from the design.

Examples

The following example illustrates the creation of two data-out ports. The count property is not specified so it defaults to two corresponding to the largest connection range index used. The port naming is specified to define a port named “my_data_out[1:0]”. Each bit is connected to a unique source.

```
DftSpecification(MyCore,rtl) {
    IjtagNetwork {
        DataOutPorts {
            port_naming : my_data_out[%d] ;
            connection(0) : u2/top_green/go ;
            connection(1) : u2/top_green/done ;
        }
    }
}
```

HostScanInterface/Interface

A wrapper used to customize the interface of the HostScanInterface.

Usage

```
IJtagNetwork {
    HostScanInterface(id) {
        Interface {
            design_instance : instance_name ; // default: null
            scan_interface : id ; // default: null
            tck : port_pin_name ; // default: ijtag_tck
            reset : port_pin_name ; // default: ijtag_reset *DefSpec
            select : port_pin_name ; // default: ijtag_sel *DefSpec
            shift_en : port_pin_name ; // default: ijtag_se *DefSpec
            capture_en : port_pin_name ; // default: ijtag_ce *DefSpec
            update_en : port_pin_name ; // default: ijtag_ue *DefSpec
            scan_in : port_pin_name ; // default: ijtag_si *DefSpec
            scan_out : port_pin_name ; // default: ijtag_so *DefSpec
            reset_polarity : active_high | active_low | auto ;
            trst : port_pin_name ; // default: trst *DefSpec
            tms : port_pin_name ; // default: tms *DefSpec
            tdi : port_pin_name ; // default: tdi *DefSpec
            tdo : port_pin_name ; // default: tdo *DefSpec
            tdo_en : port_or_pin_name ; // default: tdo_en
            tdo_en_polarity : active_high | active_low | auto ;
            active_high_compliance_enables : port_pin_name, ... ;
            active_low_compliance_enables : port_pin_name, ... ;
            daisy_chain_with_existing_client : on | off | auto ;
        }
    }
}
```

Description

A wrapper used to customize the interface of the HostScanInterface.

By default, the HostScanInterface connects directly to ports on the current design and follows the default naming shown in the syntax summary above. Those ports may or may not already exist in the current design. If they are not already present, they are created during insertion if the design level is set to "physical_block" or "sub_block". If the design level is set to "chip", ports need to already exist and be connected to pad cells. For more information, see the [set_design_level](#) and [read_cell_library](#) commands.

You can also specify internal pins to connect the HostScanInterface to an existing host interface already present in the design. The figure shows how the Interface wrapper is used to create top-level ports, and to hook up to an existing host port. [Example 2](#) shows how to hook up a SIB to a TAP inserted by ETAssemble in the LV Flow.

To insert a TAP controller on internal pins and perform boundary scan insertion, refer to [Example 2](#) of the [IJtagNetwork](#) wrapper section which shows the required specification manipulations.

When connecting to an internal pin, specifying the `reset_polarity` of the reset pin is required; otherwise, you will get an ICL extract violation later on if the assumed value is not consistent with the actual reset polarity. If specified as `auto`, `reset_polarity` is determined by counting the number of children with an active high and an active low reset polarity and taking the polarity of the larger count.

Parameters

- `design_instance : instance_name ;`

This property defines the HostScanInterface on a ScanInterface defined in an ICL module associated with an instance in the design. The specified `instance_name` must be the name of an instance that already exists in the design, and it must be the instantiation of a module having a corresponding ICL module.

ICL modules are automatically searched and matched to the design modules when the `set_current_design` command is executed. The search paths for the ICL files are specified using the `set_design_sources`-format `icl` command. The module name matching rules are specified using the `set_module_matching_options` command.

A `design_instance` cannot be specified when `process_dft_specification` is run using the `-no_insertion` option.

- `scan_interface : id ;`

This property specifies which ScanInterface to define the HostScanInterface on when the `design_instance` property points to an instance associated with an ICL module having more than one ScanInterface. If the associated ICL module only has one ScanInterface, the `scan_interface` property is not needed.

If the referenced ScanInterface is a client ScanInterface, the host ScanInterface is defined in such a way that the inserted IJTAG nodes will end up behind and in series with the referenced client ScanInterface. If the referenced ScanInterface is a host ScanInterface, the inserted IJTAG nodes will connect to it. This varying behavior based on the fact that the ScanInterface is of type host or client is illustrated in Example 1.

- `tck : port_pin_name ;`

This property defines the port or the pin name to source the IJTAG TCKPort function. The default is “`ijtag_tck`”. See `create_dft_specification` description to learn how it can be automatically set.

- `reset : port_pin_name ;`

This property defines the port or the pin name to source the IJTAG ResetPort function. The default is “`ijtag_reset`”. This property is only used when the HostScanInterface is for a non-TAP scan interface.

- `select : port_pin_name ;`

This property defines the port or the pin name that is to source the IJTAG SelectPort function. The default is “`ijtag_sel`”. This property is only used when the HostScanInterface is for a non-TAP scan interface.

- `shift_en : port_pin_name ;`

This property defines the port or the pin name that is to source the IJTAG ShiftEnPort function. The default is “ijtag_se”. This property is only used when the HostScanInterface is for a non-TAP scan interface.

- `capture_en : port_pin_name ;`

This property defines the port or the pin name that is to source the IJTAG CaptureEnPort function. The default is “ijtag_ce”. This property is only used when the HostScanInterface is for a non-TAP scan interface.

- `update_en : port_pin_name ;`

This property defines the port or the pin name that is to source the IJTAG UpdateEnPort function. The default is “ijtag_ue”. This property is only used when the HostScanInterface is for a non-TAP scan interface.

- `scan_in : port_pin_name ;`

This property defines the port or the pin name that is to source the IJTAG ScanInPort function. The default is “ijtag_si”. This property is only used when the HostScanInterface is for a non-TAP scan interface.

- `scan_out : port_pin_name ;`

This property defines the port or the pin name to receive the IJTAG ScanOutPort function. The default is “ijtag_so”. This property is only used when the HostScanInterface is for a non-TAP scan interface.

- `reset_polarity : active_high | active_low | auto ;`

This property defines the polarity of the ResetPort. When set to auto, the reset_polarity is determined by counting the number of children with an active high or an active low reset port and taking the polarity of the larger count. When the reset property points to an existing reset pin, it is required to specify the reset polarity consistent with the source being used. Failing to specify the proper polarity results in a subsequent ICL extraction DRC violation. This property is only used when the HostScanInterface is for a non-TAP scan interface.

- `trst : port_pin_name ;`

This property defines the port or the pin name that is to source the IJTAG TRSTPort function. The default is “trst”. This property is only used when the HostScanInterface is for a TAP scan interface. See [create_dft_specification](#) description to learn how it can be automatically set.

When performing boundary scan insertion, the specified port needs to be a top level port. A 5-pin TAP interface will be created for this specification. An internal pin can also be specified, which needs to be a power-on reset pin. A 4-pin TAP interface will be created for this specification.

Note

 When performing boundary scan insertion, if you need to specify an internal pin for trst that connects to a top level port, two insertion passes are needed. The TAP needs to be inserted in the first pass and the boundary scan insertion is performed in a subsequent pass.

- `tms: port_pin_name ;`

This property defines the port or the pin name to receive the IJTAG TMSPort function. The default is “tms”. This property is only used when the HostScanInterface is for a TAP scan interface. See [create_dft_specification](#) description to learn how it can be automatically set.

- `tdi : port_pin_name ;`

This property defines the port or the pin name that is to source the IJTAG ScanInPort function. The default is “tdi”. This property is only used when the HostScanInterface is for a TAP scan interface. See [create_dft_specification](#) description to learn how it can be automatically set.

- `tdo : port_pin_name ;`

This property defines the port or the pin name to receive the IJTAG ScanOutPort function. The default is “tdo”. This property is only used when the HostScanInterface is for a TAP scan interface. See [create_dft_specification](#) description to learn how it can be automatically set.

- `tdo_en : port_or_pin_name ;`

This property defines the port or the pin name to receive the tdo_en function. The default is “tdo_en”. This property is only used when the HostScanInterface is for a TAP scan interface and the tdo port is not driven by an output pad buffer in which case no tdo_en port is created as the tdo_en signal is connected to the enable pin of the output pad buffer.

- `tdo_en_polarity : active_high | active_low | auto ;`

This property defines the polarity of the port or the pin name that receive the tdo_en function. This property is only used when the HostScanInterface is for a TAP scan interface. If the tdo port is driven by an output pad buffer, the tdo_en_polarity is inferred from the polarity of the enable on the TAP. An error is generated if the tdo_en_polarity property is specified to active_high and the enable pin if the output buffer is active_low and vice versa. No error is ever generated if specified to auto. If the tdo port is not driven by an output pad buffer, a tdo_en port is created with the specified active polarity. The polarity active_low is used if the property is specified or defaults to auto.

- `active_high_compliance_enables : port_pin_name, ... ;`

This property defines active high ports or pins that need to be enabled to select the scan path of the HostScanInterface. Specifying it triggers the creation of the Tessent compliance enable module. Use this property only when the HostScanInterface is for a TAP scan interface and is not defined using the design_instance and scan_interface properties.

The Tessent compliance enable module decodes all compliance enable signals, muxes the TDO signal and gates the TMS signal going to the nodes in this HostScanInterface. You would typically use the `active_high_compliance_enables : port_pin_name, ...;` property if you currently have a TAP controller connected to the control ports and wish to use a Tessent TAP for boundary scan tests. Contrary to using a ScanMux for this purpose, the existing TAP does not need to be described in ICL. The expectation of Tessent Shell and the IEEE 1687 standard is that all other TAPs sharing the control ports have their TMS signal gated low when all compliance enable signals are active. If that is not the case, it is suggested that you use a ScanMux configuration instead.

- `active_low_compliance_enables : port_pin_name, ... ;`

This property defines active low ports or pins that need to be enabled to select the scan path of this HostScanInterface. See the `active_high_compliance_enables` property for more details. This property is only used when the HostScanInterface is for a TAP scan interface and is not defined using the `design_instance` and `scan_interface` properties.

- `daisy_chain_with_existing_client : on | off | auto ;`

A string property affecting how the connection to the HostScanInterface is done. When set to off, the source of the `scan_out` pin is first disconnected before hooking up the scan-out port of the network to it.

When set to on, it is assumed a valid scan-out source is already connected to the specified scan-out port. The source of the scan-out is used as the scan-in of the newly inserted IJTAG network.

When set or left to default to auto, the scan-out port of the HostScanInterface is checked and if it seems to already have a source (its `has_functional_source` attribute is true), the On value is assumed otherwise the Off value is assumed.

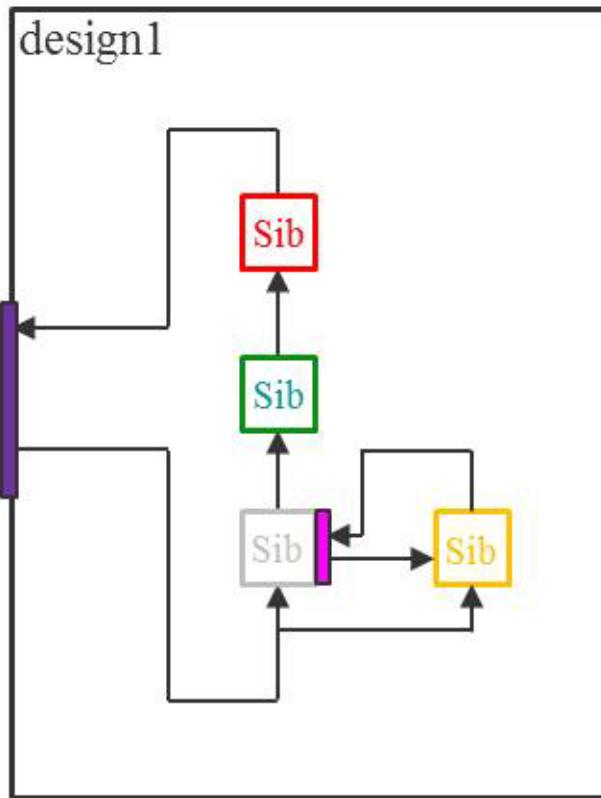

Examples

Example 1

The following example has three HostScanInterface wrappers. The first wrapper called purple is used to insert a SIB called red in series with whatever is already connected to the purple HostScanInterface (the gray SIB in [Figure 10-4](#)). The second wrapper, called pink, is used to connect a SIB called orange to the Host ScanInterface of an existing instance in the design which, in this example, is a SIB inserted in an initial insertion pass. The third wrapper, called gray, is used to connect a SIB called green in series with the Client ScanInterface of an existing instance in the design which, in this example, is a SIB inserted in an initial insertion pass.

```
DftSpecification(design1,pass2) {
    IjtagNetwork {
        HostScanInterface(purple) {
            Interface {
                scan_in      : si ;
                scan_out     : so ;
                capture_en   : ce ;
                shift_en     : se ;
                update_en    : ue ;
                reset        : rstn ;
                select       : sel ;
                daisy_chain_with_existing_client : on ;
            }
            Sib(red) {
            }
        }
        HostScanInterface(pink) {
            Interface {
                scan_in      : si ;
                scan_out     : tesson_pass1_sib_first_inst/ijtag_from_so ;
                capture_en   : ce ;
                shift_en     : se ;
                update_en    : ue ;
                reset        : rstn ;
                select       : tesson_pass1_sib_first_inst/ijtag_to_sel ;
            }
            Sib(orange) {
            }
        }
        HostScanInterface (gray){
            Interface {
                design_instance : tesson_pass1_sib_first_inst ;
                scan_interface  : client ;
            }
            Sib(green) {
            }
        }
    }
}
```

Figure 10-4. HostScanInterface/Interface Example 1 Schematic

Example 2

This example shows how to connect a SIB to the TAP controller inserted by ETAssemble as part of one of the LV flows. The first DftSpecification wrapper uses the `design_instance` syntax. The second DftSpecification wrapper uses explicit function connections but results in the same implementation as the first one. Although the second method is more verbose, it works even when the connections are not all made to a single instance having an associated ICL module, which is a requirement for the first method.

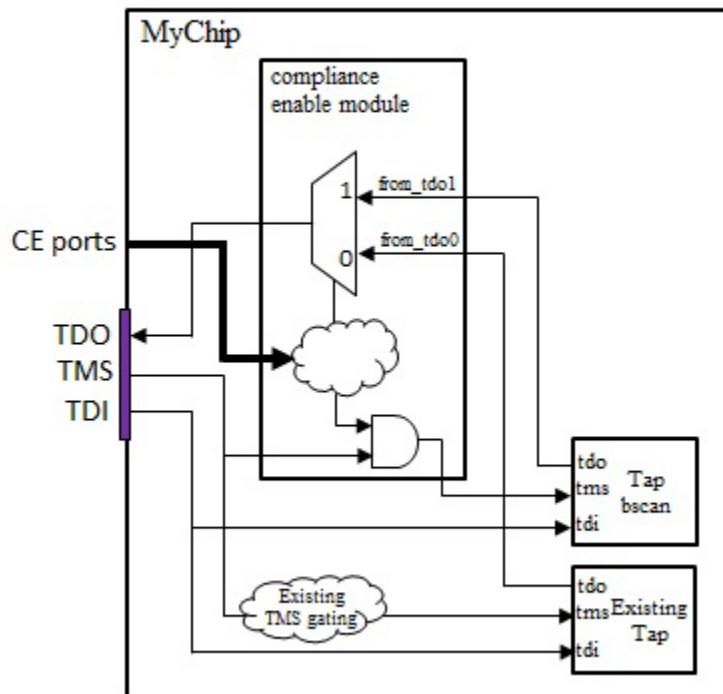

```
DftSpecification(my_design,post_etassemble) {
    IjtagNetwork {
        HostScanInterface(ijtag) {
            Interface {
                design_instance : LVISION_JTAP_INST ;
                scan_interface : Bist4 ;
            }
            Sib(1) {
            }
        }
    }
}
DftSpecification(my_design,post_etassemble) {
    IjtagNetwork {
        HostScanInterface(ijtag) {
            Interface {
                scan_in      : LVISION_JTAP_INST/tdi ;
                scan_out     : LVISION_JTAP_INST/fromBist4 ;
                select       : LVISION_JTAP_INST/bistEn4 ;
                capture_en   : LVISION_JTAP_INST/captureDR2Edge ;
                shift_en     : LVISION_JTAP_INST/shiftDR2Edge ;
                update_en    : LVISION_JTAP_INST/updateDREnable ;
                reset        : LVISION_JTAP_INST/testLogicResetInv ;
                reset_polarity : active_low ;
                tck          : LVISION_JTAP_INST/tck ;
            }
            Sib(1) {
            }
        }
    }
}
```

Example 3

This example shows how to insert a TAP with boundary scan that shares ports with an existing TAP controller through compliance enable ports. Notice that the existing TAP has TMS gating low when the compliance enable values are not selecting it. If you are inserting boundary scan, the compliance enable ports are required to be documented as shown in the BoundaryScanCellOptions.

```
DftSpecification(MyChip,bscan_tap) {
    IjtagNetwork {
        HostScanInterface(tap) {
            Interface {
                tck : TCK ;
                trst : TRST ;
                tms : TMS ;
                tdi : TDI ;
                tdo : TDO ;
                active_high_compliance_enables : CE0, CE1 ;
                active_low_compliance_enables : CE2, CE3 ;
            }
            Tap(bscan) {
                HostIjtag(1) {
                }
                HostBscan {
                }
            }
        }
    }
    BoundaryScan {
        ijtag_host_node : Tap(bscan)/HostBscan;
        BoundaryScanCellOptions {
            CE0 : compliance_enable1 ;
            CE1 : compliance_enable1 ;
            CE2 : compliance_enable0 ;
            CE3 : compliance_enable0 ;
        }
    }
}
```

[Tdr/Interface](#)

[Sib/Interface](#)

DesignInstance

A wrapper that specifies an instance in the design that has a ScanInterface to connect to.

Usage

```
IjtagNetwork {
    HostScanInterface(id) {
        DesignInstance(instance_name) {
            scan_interface : scan_interface_name ;
        }
    }
}
```

Description

A wrapper that specifies an instance in the design that has a ScanInterface to connect to.

The *instance_name* string is a design instance name relative to the current design. When the [process_dft_specification](#) command is executed without the *-no_insertion* option, the tool verifies that the specified *instance_name* exists within the design. The tool also verifies that the associated design module has a matched ICL module with at least one ScanInterface in it. If there is only one scan interface in the ICL module, you do not need to specify the *scan_interface* property, but if there is more than one ScanInterface, you must use the *scan_interface* property to identify which one to connect to.

ICL modules are automatically searched and matched to the design modules when the [set_current_design](#) command is executed. The search paths for the ICL files are specified using the [set_design_sources](#) -format *icl* command. The module name matching rules are specified using the [set_module_matching_options](#) command.

Arguments

- *instance_name*
A string that refers to a design instance relative to the current design.
- *scan_interface : scan_interface_name ;*
A property that is used only when the referenced design instance is an instance of a module having more than one ScanInterface declared in its ICL module. You must repeat the DesignInstance wrapper for each *scan_interface_name* found in the ICL module, if you want to connect all of them to the network.

If you have a design instance with multiple scan interfaces and they share a common scan-in port, you cannot connect them to a SIB because this would required independent scan-in ports. Instead, you must connect them all to inputs of a scan mux, so that you end up with one scan-in port and one scan-out port. This is illustrated in the example that follows.

Examples

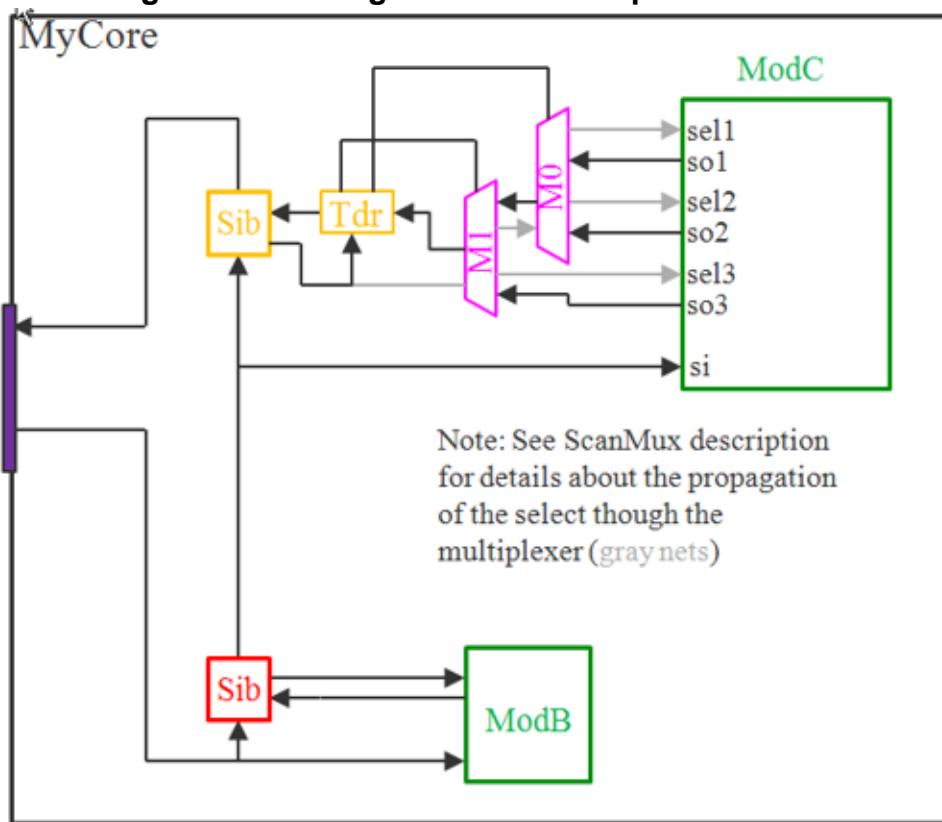

The following example illustrates connecting the ScanInterface of a DesignInstance to a SIB. It also shows how a design instance that has three scan interfaces sharing a common scan-in port is first connected to two scan multiplexers before being connected to a SIB.

The select of the multiplexers are sourced by the DataOutPorts of the orange TDR which automatically sets its output_timing setting to “ijtag_scan_selection”. For a description and impact of this setting, see the [Tdr](#) wrapper description and specifically “[Update Stage Timing](#)” on page 3277.

This example also shows the use of ScanMux in the network. It provides a hint about the backward propagation of the select signal though the selected path of the multiplexer. For a complete description of the ScanMux and the backward propagation of the select signals, refer to the [ScanMux](#) wrapper description section.

```
DftSpecification(MyCore,rtl) {
    IjtagNetwork {
        HostScanInterface(purple) {
            Sib(orange) {
                Tdr(orange) {
                    DataOutPorts {
                        Count : 2 ;
                    }
                }
            ScanMux(M1) {
                Select : tdr(orange)/DataOut(1) ;
                Input(0) {
                    ScanMux(M0) {
                        Select : tdr(orange)/DataOut(0) ;
                        Input(0) {
                            DesignInstance (u3/top_green) {
                                scan_interface : I1 ;
                            }
                        }
                        Input(1) {
                            DesignInstance (u3/top_green) {
                                scan_interface : I2 ;
                            }
                        }
                    }
                }
                Input(1) {
                    DesignInstance (u3/top_green) {
                        scan_interface : I3 ;
                    }
                }
            }
        }
        Sib(red) {
            DesignInstance (u1/bottom_green) {}
        }
    }
}

ScanMux

A wrapper that specifies the creation and, optionally, the insertion of a scan multiplexer into the design.

Usage

```
IjtagNetwork {
    HostScanInterface(id) {
        ScanMux(id) {
            Interface {
            }
            parent_instance      : instance_name ;
            leaf_instance_name  : leaf_instance_name ;
            select              : source ;
            Attributes {
                attribute_name   : attribute_value ;
            }
            Input (integer) {                                // legal: 0 1
                keep_active_during_scan_test : boolean ; // default: auto
                Sib(id) {
                }
                Tap(id) {
                }
                Tdr(id) {
                }
                ScanMux(id) {
                }
                DesignInstance(instance_name) {
                }
            }
        }
    }
}
```

Description

A wrapper that specifies the creation and, optionally, the insertion of a scan multiplexer into the design. The Input(0) and Input(1) wrappers are used to defined the nodes that feed into that input of the multiplexer. If you omit an Input wrapper, the multiplexer simply bypasses the elements connected to the other input when the unspecified input is selected. See the example that follows for an illustration of this feature.

The actual schematic of the multiplexer is shown in [Figure 10-7](#) and [Figure 10-8](#). As you can see, the scan multiplexer is actually more than a simple multiplexer. When used in a DR scan path, it also has logic to supply a select line (output_en1 and output_en0) for each set of clients connected to the two scan inputs (input1 and input0). When used in a TAP scan path, it also has logic to supply a to_tms (to_tms1 and to_tms0) for each set of tap clients connected to the two scan inputs (input1 and input0). The output port is the multiplexed scan-out data of the clients to source the scan-in of the host or of the next node in series with the ScanMux.

The select input is sourced by a data signal which is either one of the [IjtagNetwork/DataInPorts](#) of the [IjtagNetwork](#), one of the [IjtagNetwork/DataOutPorts](#) of a [Tdr](#) or a [Tap](#), or an output port

on an existing design instance. The select input is used to control the multiplexer and to create two gated versions of the enable_in or tms inputs. The gated versions are used as the select or tms source of the clients connected to each scan input. The enable_in port is sourced by the host of the ScanMux. If the host is a **Sib**, the enable_in is sourced by the to_select port. If the host is another **ScanMux**, the enable_in port is sourced by one of the “enable_out#” ports. If the host is the **HostScanInterface/Interface**, the enable_in is sourced by the select port. The tms port is sourced by the host of the ScanMux. If the host is a ScanMux, the tms port is sourced by one of the “to_tms#” ports. If the host is the HostScanInterface, the tms is sourced by the tms port.

When the reuse_modules_when_possible property is set or inferred to be on in the **DftSpecification** wrapper, the ScanMux module names are hardcoded to *design_name_design_id_tessent_scanmux_#* where # is an integer incrementing from 1. A unique module is created for each combination of port names in the interface wrapper, attributes in the Attributes wrapper, and the value of the keep_active_during_scan_test property.

When the reuse_modules_when_possible property is set or inferred to be off in the **DftSpecification** wrapper, the ScanMux module names are hardcoded to *design_name_design_id_tessent_scanmux_id*.

Figure 10-7. ScanMux Internal Schematic When Used on a DR Scan Path

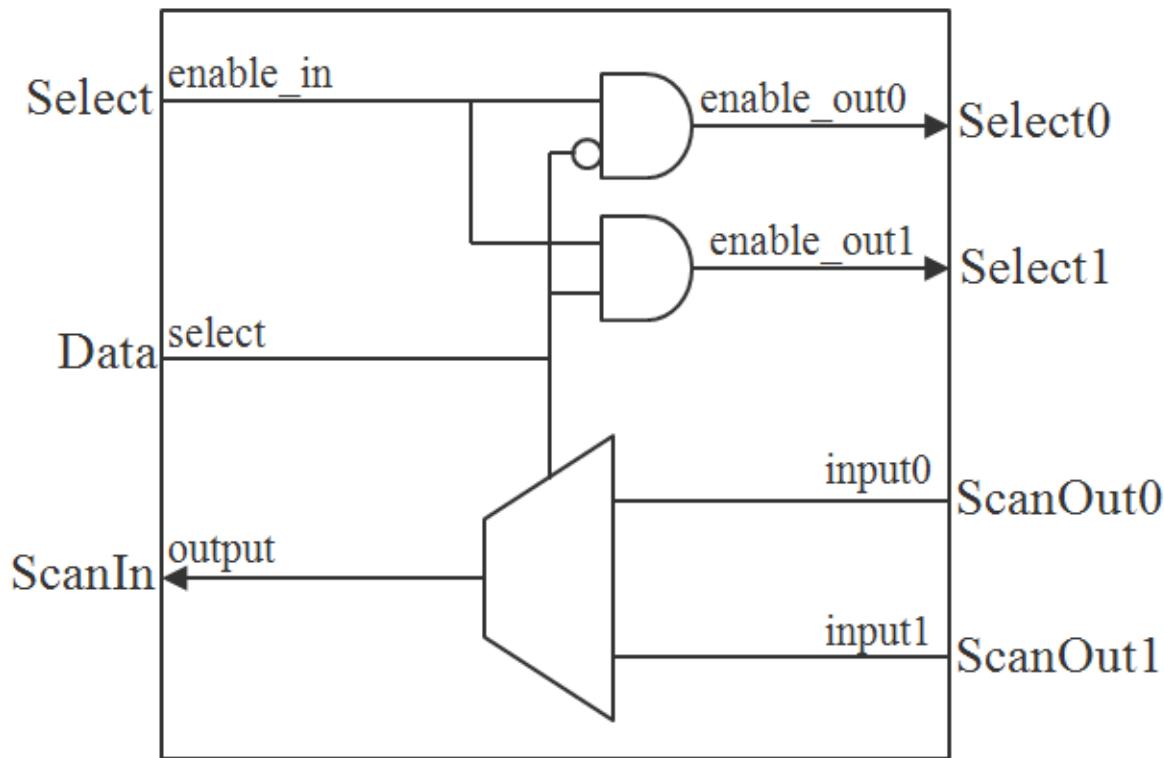

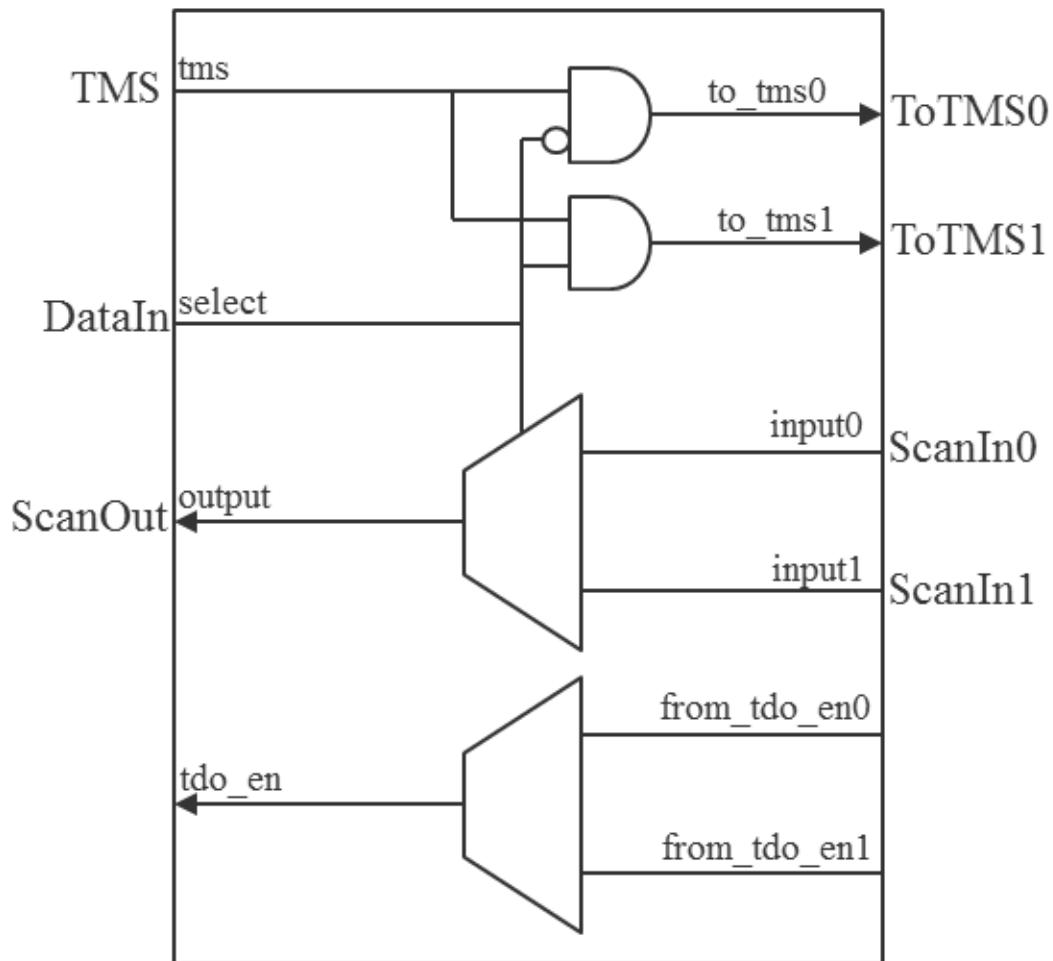

Figure 10-8. ScanMux Internal Schematic When Used on a TAP Scan Path

Arguments

- *id*
A unique id that contains only letters, numbers, and underscores. Every ScanMux wrapper must have a different id inside a common [IjtagNetwork](#) wrapper.
- *parent_instance : instance_name ;*
A string property that specifies the parent instance in which to instantiate the scan mux module. If this property is not unspecified, the scan mux is instantiated in the root module. You can use this property to push a scan multiplexer down near the client interfaces it interacts with.

If the specified *instance_name* is an instance of a repeated module, a warning is displayed during validation and a *uniquify_instances* command is automatically issued as part of the insertion process to uniquify the *instance_name*.

To perform IJTAG network insertion inside a module that is used more than once without unquifying it, you can set the current design to that module, insert the IJTAG network in it, and refer to it with a DesignInstance wrapper at the next level up. This bottom-up insertion process can be done by going back and forth between setup and insertion mode within a single Tessent Shell invocation. You simply change the current design using the `set_current_design` command in setup mode.

- `leaf_instance_name : leaf_instance_name ;`

A string property that specifies the leaf instance name of the scan multiplexer. The property defaults to `design_name_dft_spec_id_tessent_scanmux_scanmux_id_inst` when unspecified. The `dft_spec_id` string is the id specified in the [DftSpecification](#) wrapper, and the `scanmux_id` is the id of the ScanMux wrapper. Tessent Shell checks for conflicts before instantiating the scan multiplexer and, if needed, applies the unification suffix specified by the [set_insertion_options](#) command.

- `select : source ;`

A string property that specifies the source of the select. The source must match one of the formats described in this table.

Format	Description
<code>DataIn(integer)</code>	Specifies that the source of the select is one of the IjtagNetwork/DataInPorts of the IjtagNetwork wrapper. The integer value must be between count -1 and 0 where count is a property that specifies the number of DataInPorts.
<code>Tdr(id)/DataOut(integer)</code>	Specifies that the source of the select is one of the IjtagNetwork/DataOutPorts of a Tdr . The integer value must be between count -1 and 0 where count is a property that specifies the number of DataOutPorts on the <code>Tdr(id)</code> .
<code>Tdr(id)/DecodeSignal(name)</code>	Specifies that the source of the select is one of the Tdr/DecodedSignal of a Tdr . The name value must be the name of a decoded signal on the <code>Tdr(id)</code> .
<code>Tap(id)/DataOut(integer)</code>	Specifies that the source of the select is one of the IjtagNetwork/DataOutPorts of a Tap . The integer value must be between count -1 and 0 where count is a property that specifies the number of DataOutPorts on the <code>Tap(id)</code> .
<code>DesignInstance(inst_name)/port_name</code>	Specifies that the source of the select is a port on the module with the instance name <code>inst_name</code> . During ICL extraction, this pin must be or must trace to a DataOutPort or a ToSelect port of an ICL module.

- Attributes/attribute_name : *attribute_value* ;

A data wrapper that defines arbitrary attributes in the ScanMux ICL module. This mechanism is useful for finding special attributed modules in the concatenated ICL, at a later time. The attribute_name can be any identifier starting with a letter and followed by any number of letters, numbers, and underscores. The attribute_value can be any string or integer. If you want to define a personal attribute and later be able to introspect its value using [get_attribute_value_list](#), you must have registered the attribute using the “[register_attribute -object_type icl_module](#)” command. For example, assuming you have registered the attribute att1 on the [icl_module](#) object type, and you have added the attribute att1 with a value of “v1” in some of your ICL modules using the Attributes wrapper, you can later quickly find those modules using the “[get_icl_modules -filter att1==v1](#)” command.

- Input(0|1)/keep_active_during_scan_test : on | off | [auto](#) ;

A property that specifies that all clients connected to the ScanMux input are to be kept active during scan test modes. You should rarely need to use this property because when it is auto (default), it is automatically set to on if a Tdr with keep_active_during_scan_test set to on traces to it. See section “[Scan Testability of the IJTAG Network](#)” on page 3225 for information about when to use this property.

Examples

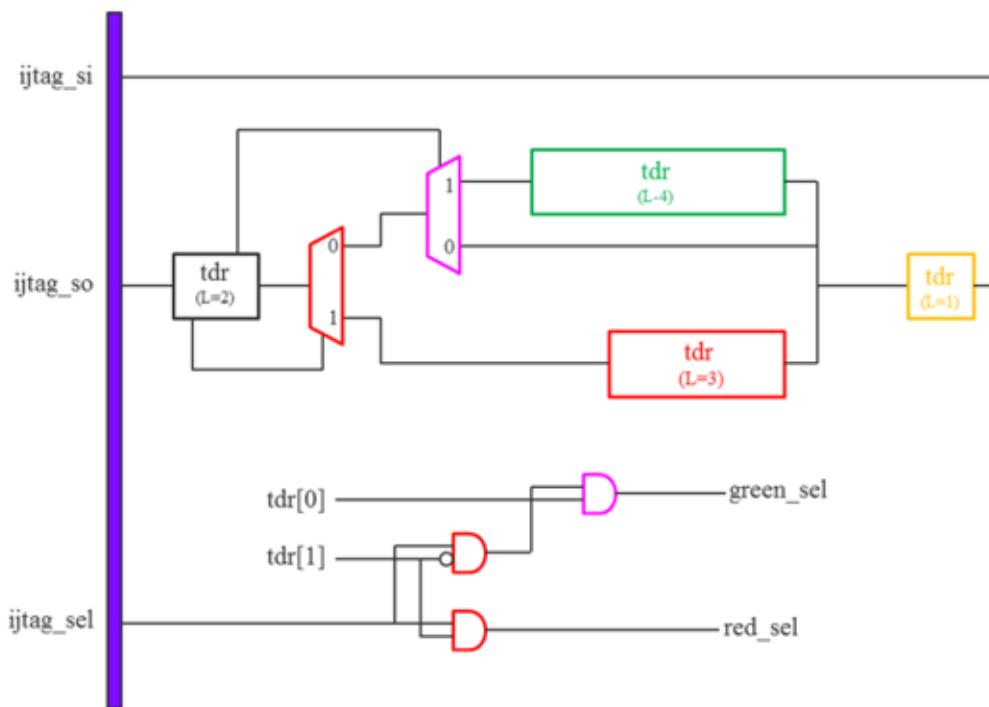

The following example illustrates the use of scan multiplexers in the DR scan paths of the IJTAG network. See [Figure 10-20](#) for an example use in the TAP scan path. The red mux has client nodes specified in both of its Input wrappers which make it a selection multiplexer. The pink mux only has client nodes in its “1” Input wrapper making it a bypass multiplexer. The clients connected to the “1” input are bypassed when the select is low. For both multiplexers, a data-out bit on the black TDR is used as the source of the select signal.

The AND gates shown at the bottom of [Figure 10-9](#) illustrate the distributed gating mechanism used to generate the select signals for the multiplexed TDRs. These AND gates correspond to the AND gates shown in [Figure 10-7](#).

```

DftSpecification(MyCore,rtl) {
    IjtagNetwork {
        HostScanInterface(purple) {
            Tdr(black) {
                DataOutPorts {
                    count : 2 ;
                }
            }
            ScanMux(red) {
                select : tdr(black)/DataOut(1) ;
                Input(1) {
                    Tdr(red) {
                        length : 3 ;
                    }
                }
                Input(0) {
                    ScanMux(pink) {
                        select : tdr(black)/DataOut(0) ;
                        Input(1) {
                            Tdr(green) {
                                length : 4 ;
                            }
                        }
                    }
                }
            }
            Tdr(orange) {
            }
        }
    }
}
    
```

ScanMux/Interface

A wrapper that specifies the name of the ports when creating the ScanMux module.

Usage

```
IjtagNetwork {
    HostScanInterface(id) {
        ScanMux(id) {
            Interface {
                select      : port_name ; // default: mux_select
                input0     : port_name ; // default: mux_in0
                input1     : port_name ; // default: mux_in1
                output      : port_name ; // default: mux_out
                enable_in   : port_name ; // default: enable_in
                enable_out0 : port_name ; // default: enable_out0
                enable_out1 : port_name ; // default: enable_out1
                tms         : port_name ; // default: tms
                to_tms0     : port_name ; // default: to_tms0
                to_tms1     : port_name ; // default: to_tms1
                tdo_en      : port_name ; // default: tdo_en
                from_tdo_en0: port_name ; // default: from_tdo_en0
                from_tdo_en1: port_name ; // default: from_tdo_en1
            }
        }
    }
}
```

Description

A wrapper that specifies the name of the ports when creating the ScanMux module.

All port names can be specified by the user; however, they can only be simple scalar port names.

Arguments

- `select : port_name ;`

This property defines the name of the port labelled “select” in [Figure 10-7](#) and [Figure 10-8](#).
The default is “mux_select”.

- `input0 : port_name ;`

This property defines the name of the port labelled “input0” in [Figure 10-7](#) and [Figure 10-8](#).
The default is “mux_in0”.

- `input1 : port_name ;`

This property defines the name of the port labelled “input1” in [Figure 10-7](#) and [Figure 10-8](#).
The default is “mux_in1”.

- `output : port_name ;`

This property defines the name of the port labelled “output” in [Figure 10-7](#) and [Figure 10-8](#).
The default is “mux_out”.

- `enable_in : port_name ;`
This property defines the name of the port labelled “enable_in” in [Figure 10-7](#). The default is “enable_in”.
- `enable_out0 : port_name ;`
This property defines the name of the port labelled “enable_out0” in [Figure 10-7](#) and [Figure 10-8](#). The default is “enable_out0”.
- `enable_out1 : port_name ;`
This property defines the name of the port labelled “enable_out1” in [Figure 10-7](#). The default is “enable_out1”.
- `tms : port_name ;`
This property defines the name of the port labelled “tms” in [Figure 10-8](#). The default is “tms”.
- `to_tms0 : port_name ;`
This property defines the name of the port labelled “to_tms0” in [Figure 10-8](#). The default is “to_tms0”.
- `to_tms1 : port_name ;`
This property defines the name of the port labelled “to_tms1” in [Figure 10-8](#). The default is “to_tms1”.
- `tdo_en : port_name ;`
This property defines the name of the port labelled “tdo_en” in [Figure 10-8](#). The default is “tdo_en”.
- `from_tdo_en0 : port_name ;`
This property defines the name of the port labelled “from_tdo_en0” in [Figure 10-8](#). The default is “from_tdo_en0”.
- `from_tdo_en1 : port_name ;`
This property defines the name of the port labelled “from_tdo_en1” in [Figure 10-8](#). The default is “from_tdo_en1”.

Examples

The following example illustrates the use of this wrapper to specify custom port names for the scan multiplexer used in a DR Scan Path.

```
IjtagNetwork {
    HostScanInterface(id) {
        ScanMux(id) {
            Interface {
                select      : sm_select ;
                input0     : sm_si0 ;
                input1     : sm_si1 ;
                output      : sm_so ;
                enable_in   : sm_en ;
                enable_out0 : sm_en0 ;
                enable_out1 : sm_en1 ;
            }
        }
    }
}
```

Sib

A wrapper that specifies the creation and, optionally, the insertion of a SIB (Segment Insertion Bit) into the IJTAG network.

Usage

```
IjtagNetwork {
    HostScanInterface(id) {
        Sib(id) {
            Interface {
            }
            parent_instance : instance_name ;
            leaf_instance_name : leaf_instance_name ;
            keep_active_during_scan_test : on | off | auto ;
            capture_value : 0 | 1 | self ;
            Attributes {
                attribute_name : attribute_value ;
            }
            Sib(id) {
            }
            Tdr(id) {
            }
            ScanMux(id) {
            }
            DesignInstance(instance_name) {
            }
        }
    }
}
```

Description

A wrapper that specifies the creation and, optionally, the insertion of a SIB (Segment Insertion Bit) into the IJTAG network.

A SIB is a special node in IJTAG that contains a single bit shift register. When the bit is zero, the SIB bypasses the client nodes connected to its host port. When the bit is one, the SIB includes the client nodes connected to its host port as part of the active scan path. [Figure 10-10](#) shows the detailed schematic of its implementation.

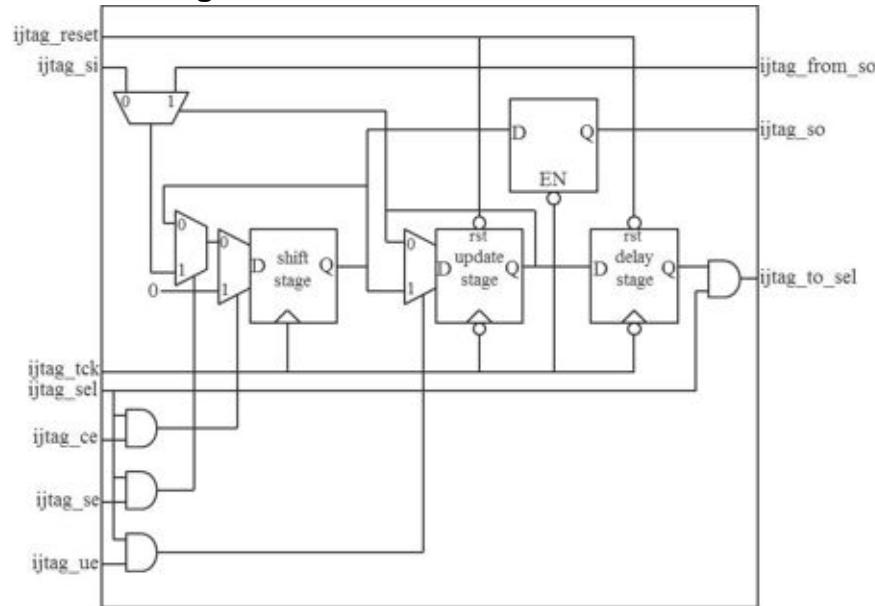

The shift register value is latched into the update stage on the falling edge of TCK when update_en is active. A delay stage is then used to delay the transition of to_select_en by one TCK cycle so as to avoid timing races that will exist if TCK is not perfectly balanced between the SIB and its clients. Refer to “[Update Stage Timing](#)” on page 3277 for more details about this feature.

When the reuse_modules_when_possible property is set or inferred to be on in the **DftSpecification** wrapper, the SIB module names are hardcoded to *design_name_design_id_tessent_sib_#* where # is an integer incrementing from 1. A unique module is created for each combination of port names in the interface wrapper, attributes in the

Attributes wrapper, and the value of the capture_value and keep_active_during_scan_test properties.

When the reuse_modules_when_possible property is set or inferred to be off in the **DftSpecification** wrapper, the SIB module names are hardcoded to *design_name_design_id_tessent_sib_id*.

Figure 10-10. SIB Internal Schematic

As described in the [create_dft_specification](#) command description, the instruments that need to remain active during scan are inserted under one SIB, and the ones which are scan tested, such as a memory BIST controller, are inserted under another SIB. This SIB is identified with a tessent_dft_function attribute set to “scan_tested_instrument_host” and is commonly referred to as the Sib(sti). When this attribute is defined as such, the SIB is equipped with the added logic shown in [Figure 10-11](#) on page 3267 such that the IJTAG network which is scan tested is fully exercised by the scan test. Notice that the Sib(sti) is also equipped with a mini-OCC used to give control to ATPG and LogicBIST as to when the scan tested TCK domain is to receive clock pulses. See [Figure 10-11](#) and [Figure 10-13](#) for a schematic view of the scan isolation logic and the mini-OCC. The ltest_to_en, ltest_to_mem_bypass_en, ltest_to_mcpBounding_en, and ltest_to_se output ports are used during Memory BIST insertion to pre-connect its logic test ports in order to meet logic test design rules (DRCs) and enable memory bypass and RAM sequential testing. The ltest_to_mcpBounding_en port is useful if you want to run logicBist on the memory BIST logic at speed.

The logic test input signals shown on the lower left side of the Sib(sti) in [Figure 10-11](#) are left tied off when the Sib(sti) is inserted. You need to drive those inputs and pick up the sub-chain during scan insertion to achieve high fault coverage of the scan testable portion of the IJTAG network. If you use the [add_dft_signals](#) command to create the scan_en, ltest_en, memory_bypass_en, ltest_to_mcpBounding_en, tck_occ_en and shift_capture_clock DFT signals, the corresponding input ports on the Sib(sti) will automatically be connected to them as

they become available. You will then benefit from all the automation provided by the [set_static_dft_signal_values](#) and [add_core_instances](#) commands to setup the Sti(sti) for logic test and to configure the mini-OCC. The ltest_capture_en port is left tied on, and the ltest_static_control_clock_mode and ltest_clock_sequence ports are left tied off unless the [LogicBist](#) wrapper is used in which case they are driven by the LogicBIST controller.

The mini-OCC enables testing of the scan tested instruments under the STI Sib (for example, MBIST hardware) given that this clock domain is different from the clock domains driving the functional logic and that the test clock driving the STI logic during logic test is usually also the trigger clock for the functional OCCs in fast capture mode (at-speed test). If you forget to add the tck_occ_en DFT signal or if you choose to not activate the TCK OCC during logic test, the TCK OCC will still inject the shift clock into the TCK domain during the load_unload sequence but it will not pulse the TCK domain during the capture sequence. The IJTAG values feeding the functional domains will have known values, but any value observed by the TCK domain will not be captured and will result in “ATPG Untestable” faults.

The [process_dft_specification](#) command creates a TCD for this mini-OCC and writes the TCD into the TSDB as it does with functional clock OCCs created by the DftSpecification/OCC wrappers. And with the functional clock OCCs, you must use the [add_core_instances](#) command in ATPG setup to define this mini-OCC.

Note

 You must add the [tck_occ_en](#) DFT signal otherwise it will not be possible to activate the mini-OCC using the [add_core_instances](#) command. If you do not activate the mini-OCC, then the mini-OCC will still inject a proper shift clock during the shift cycle but will keep the clock off during the capture cycles. The values going from the STI IJTAG network nodes will be known values during logic test, however the STI IJTAG nodes will not be able to capture and observe their inputs, which will result in numerous AU faults in the STI IJTAG network.

Figure 10-11. Sib(sti) With Scan Isolation Chain

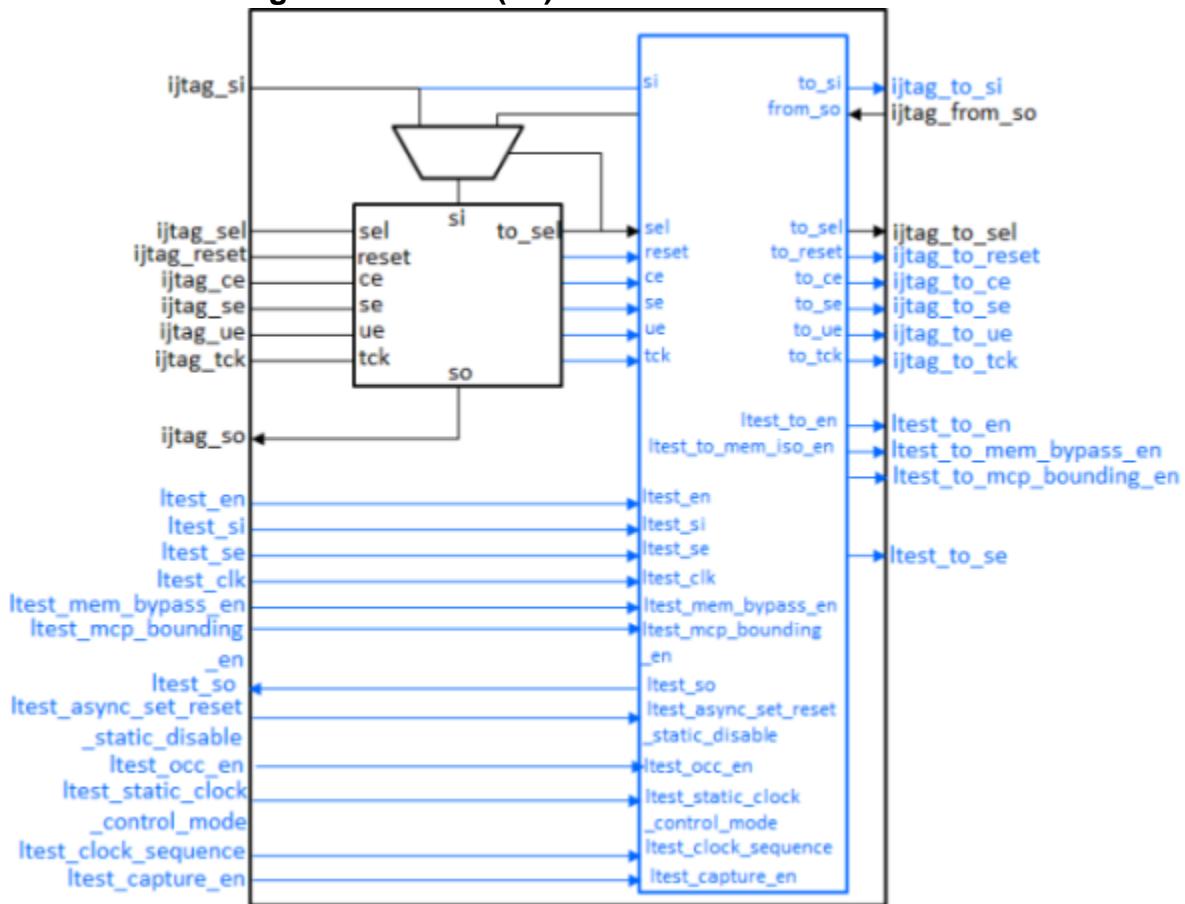

Figure 10-12. Added Scan Isolation Logic for SIB(sti)

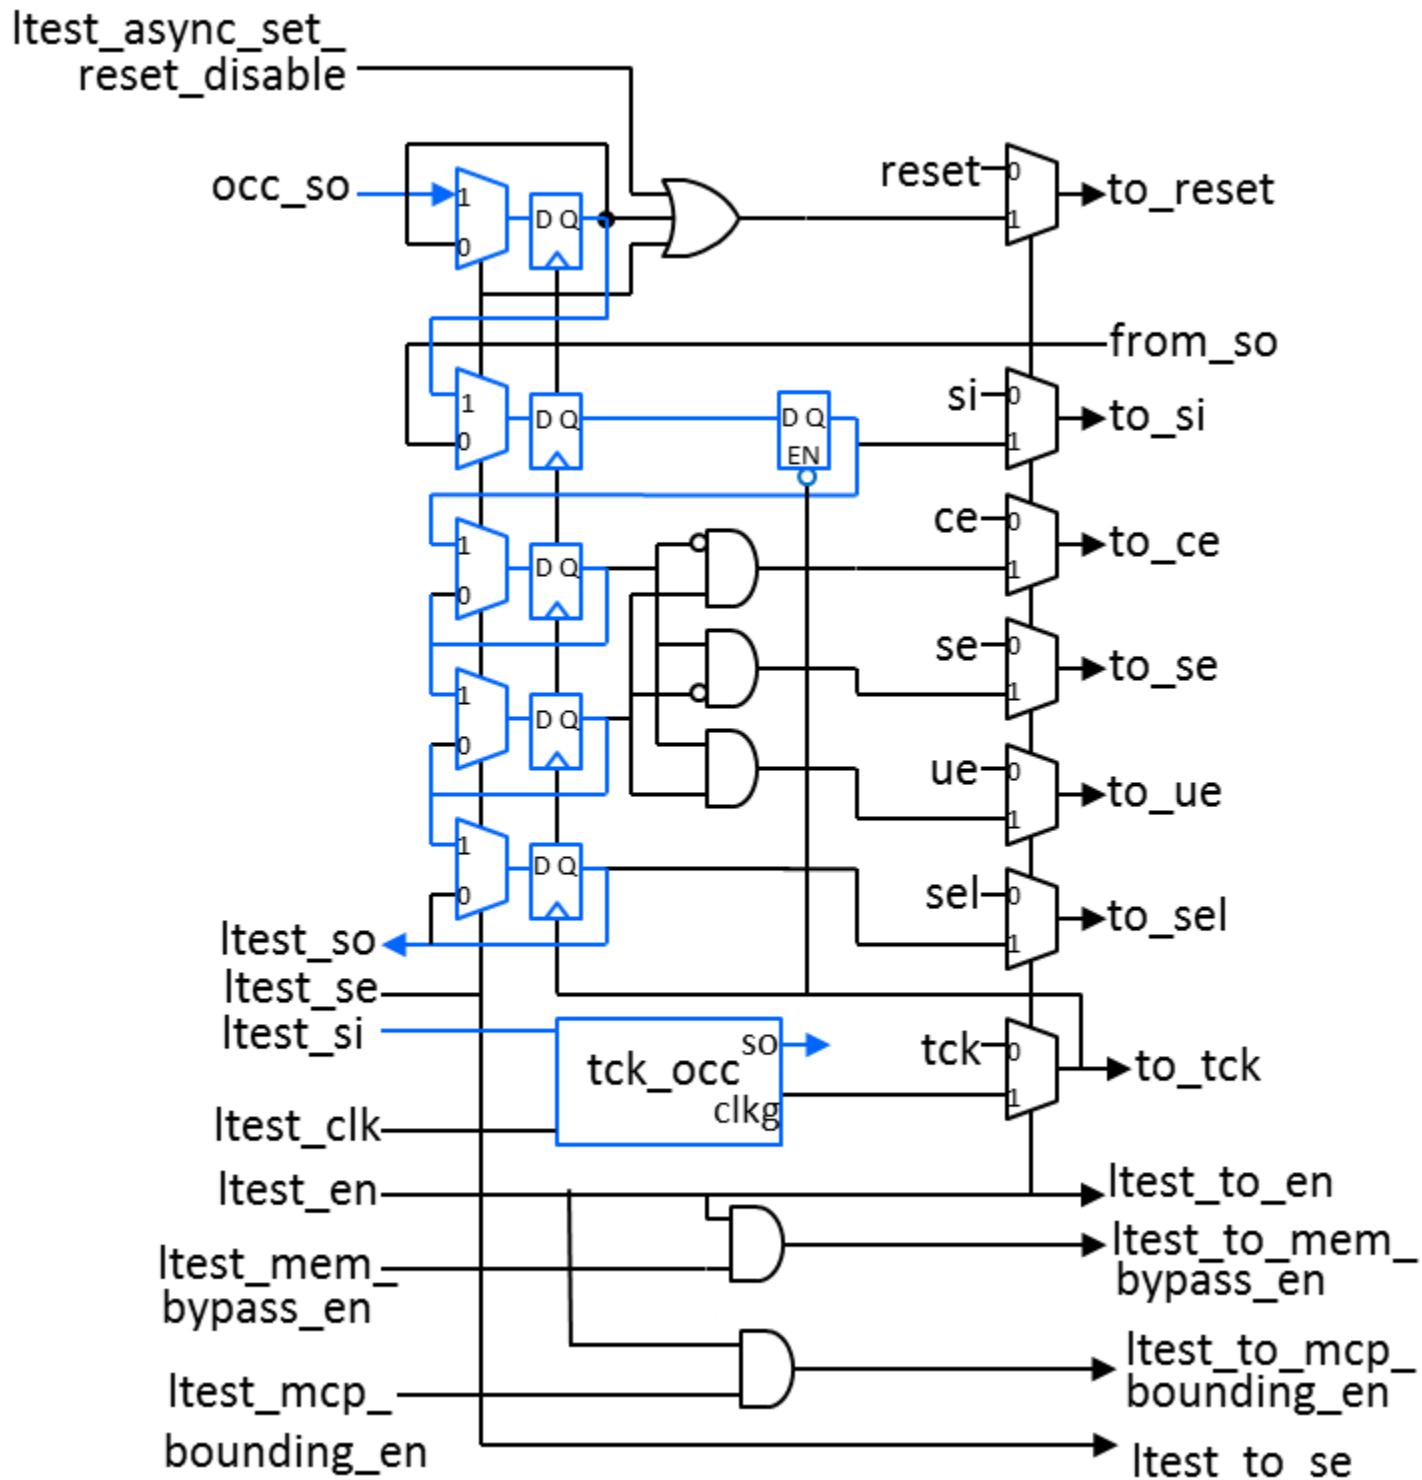

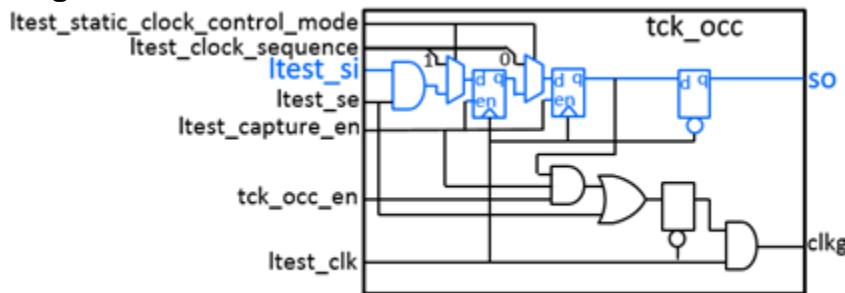

Figure 10-13. Mini-OCC for Scan Tested TCK Domain

Arguments

- *id*
A unique id that contains only letters, numbers, and underscores. Every Sib wrapper must have a different id value inside the [IitagNetwork](#) wrapper.
 - *parent_instance : instance_name ;*
A string property that specifies the parent instance in which to instantiate the SIB module. If unspecified, the SIB is instantiated in the root module. You can use this property to push a SIB down near the client interfaces it interacts with.
If the specified *instance_name* is an instance of a repeated module, a warning is displayed during validation and a *uniquify_instances* command is automatically issued as part of the insertion process to uniquify the *instance_name*.
To perform IJTAG network insertion inside a module that is used more than once without uniquifying it, you can set the current design to that module, insert the IJTAG network in it, and refer to it with a *DesignInstance* wrapper at the next level up. This bottom-up insertion process can be done by going back and forth between setup and insertion mode within a single Tessent Shell invocation. You simply change the current design using the *set_current_design* command in setup mode.
 - *leaf_instance_name : leaf_instance_name ;*
A string property that specifies the leaf instance name of the SIB. It defaults to *design_name_dft_spec_id_tessent_sib_sib_id_inst* when unspecified. The *dft_spec_id* string is the id specified in the [DftSpecification](#) wrapper, and the *sib_id* is the id of the SIB. Tessent Shell checks for conflicts before instantiating the SIB and, if needed, applies the unqualification suffix specified by the [set_insertion_options](#) command.
 - *keep_active_during_scan_test : on | off | auto ;*
A property that specifies that all nodes serially connected to the SIB are to be kept active during scan test modes. For information about when to use this property, see the section “[Scan Testability of the IJTAG Network](#)” on page 3225.
 - *capture_value : 0 | 1 | self ;*
The property controls what the shift register captures during the capture cycle. By default it captures a constant 0 which provides a predictable value that can always be compared when

it comes out on the scan-out pin. Specifying “self” makes the SIB hold during capture. The multiplexer closest to the shift stage in [Figure 10-10](#) is simply removed when using the “self” value. To diagnose a hold time issue in the scan path, it is recommended to keep the default capture value of 0.

- Attributes/*attribute_name* : *attribute_value* ;

A data wrapper that defines arbitrary attributes in the SIB ICL module. This mechanism is useful for finding special attributed modules in the concatenated ICL, at a later time. The *attribute_name* can be any identifier starting with a letter and followed by any number of letters, numbers, and underscores. The *attribute_value* can be any string or integer. If you want to define a personal attribute and later be able to introspect its value using [get_attribute_value_list](#), you must have registered the attribute using the “[register_attribute-object_type icl_module](#)” command. For example, assuming you have registered the att1 attribute on the [icl_module](#) object type, and you have added the att1 attribute with a value of “v1” in some of your ICL modules using the Attributes wrapper, you can later quickly find those modules using the “[get_icl_modules -filter att1==v1](#)” command.

Examples

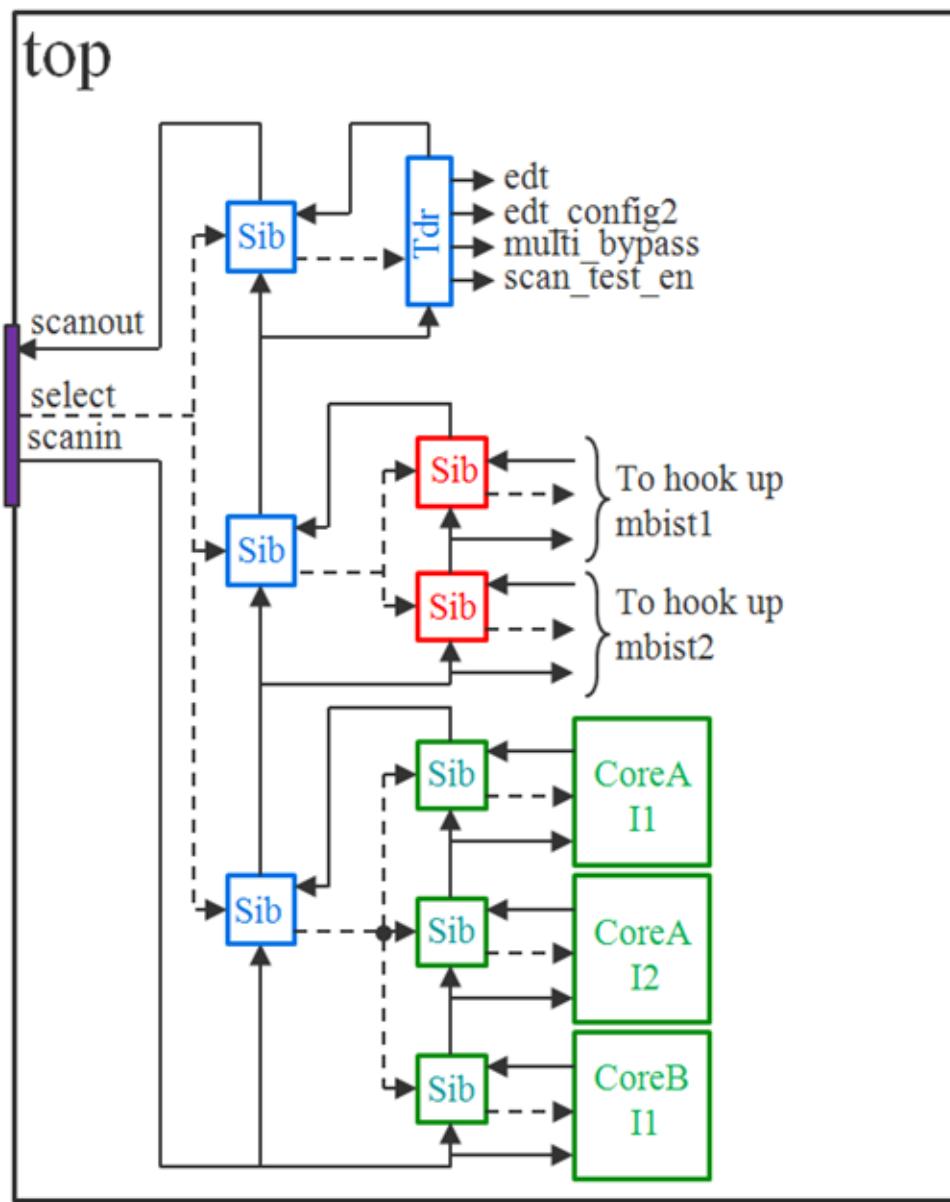

The following example illustrates the use of SIBs to provide discrete access to multiple parts of a complex network. There are three SIBs at the top of the network. The first SIB, which is closest to the scan-out and has an *id* value of “logictest_hw”, is used to provide access to a TDR that is used to create the scan mode enable signals. Because the TDR *id* has a value of “scan_modes”, the property *keep_active_during_scan_test* defaults to on, which in turns propagates to the three SIBs at the top of the network.

The second SIB, with an *id* value of “scannable_instruments”, is used to access all instruments that will not be kept active during scan test but, instead, will be scan tested like the rest of the normal functional logic. This SIB can remain closed during the scan test modes such that the rest of the network remains stable and provides valid and undisturbed *test_setup* values.

The third SIB, with an *id* value of “child_cores”, is used to access a chain of SIBs. The chained SIBs independently open the scan path to each child core. The presence of these SIBs guarantees that a defective core or a powered down core can always be bypassed when accessing other cores.

```

                    update_en : port_name ; // default: ijttag_ue
                }
                Host {
                    select : port_name ; // default: ijttag_to_sel
                    scan_in : port_name ; // default: ijttag_from_so
                }
            }
        }
    }
}
```

Description

A wrapper that contains a Client and Host wrapper that together fully specify the client and host ports.

The Client wrapper provides properties to fully specify the names of the eight client ports, and also contains a property to define the reset polarity of the reset port. The Host wrapper provides properties to fully specify the names of the two host ports.

Arguments

- Client/select : *port_name* ;
This property defines the name of the port labelled “ijtag_sel” in [Figure 10-10](#). The default is “ijtag_sel”.
- Client/tck: *port_name* ;
This property defines the name of the port labelled “ijtag_tck” in [Figure 10-10](#). The default is “ijtag_tck”.
- Client/scan_in : *port_name* ;
This property defines the name of the port labelled “ijtag_si” in [Figure 10-10](#). The default is “ijtag_si”.

- Client/scan_out : *port_name* ;
This property defines the name of the port labelled “ijtag_so” in [Figure 10-10](#). The default is “ijtag_so”.
- Client/reset : *port_name* ;
This property defines the name of the port labelled “ijtag_reset” in [Figure 10-10](#). The default is “ijtag_reset”.
- Client/reset_polarity : active_low | active_high ;
This property defines the active polarity of the port labelled “ijtag_reset” in [Figure 10-10](#). The default is “active_low”.
- Client/shift_en : *port_name* ;
This property defines the name of the port labelled “ijtag_se” in [Figure 10-10](#). The default is “ijtag_se”.
- Client/capture_en : *port_name* ;
This property defines the name of the port labelled “ijtag_ce” in [Figure 10-10](#). The default is “ijtag_ce”.
- Client/update_en : *port_name* ;
This property defines the name of the port labelled “ijtag_ue” in [Figure 10-10](#). The default is “ijtag_ue”.
- Host/select : *port_name* ;
This property defines the name of the port labelled “ijtag_to_sel” in [Figure 10-10](#). The default is “ijtag_to_sel”.
- Host/scan_in : *port_name* ;
This property defines the name of the port labelled “ijtag_from_so” in [Figure 10-10](#). The default is “ijtag_from_so”.

Examples

The following example illustrates fully specifying a unique name for each port.

```
IjtagNetwork {
    HostScanInterface (id) {
        Sib(id) {
            Interface {
                Client {
                    select      : sel ;
                    tck         : tck ;
                    scan_in     : si ;
                    scan_out    : so ;
                    reset       : reset ;
                    shift_en    : se ;
                    capture_en  : ce ;
                    update_en   : ue ;
                }
                Host {
                    select      : to_sel ;
                    scan_in     : from_so ;
                }
            }
        }
    }
}
```

Tdr

A wrapper that specifies the creation and, optionally, the insertion of a TDR inside the IJTAG network.

Usage

```
DftSpecification(module_name, id) {
    IJtagNetwork {
        HostScanInterface(id) {
            Tdr(id) {
                DataInPorts {
                }
                DataOutPorts {
                }
                Interface {
                }
                parent_instance           : instance_name ;
                leaf_instance_name       : leaf_instance_name ;
                keep_active_during_scan_test : on | off | auto ;
                length                   : integer ;           // default: auto
                extra_bits_capture_value : 0 | 1 | self ;
                reset_value               : binary ;          // default: auto
                Attributes {
                    attribute_name      : attribute_value ;
                }
                DecodedSignal(signal_name) {
                }
            }
        }
    }
}
```

Description

A wrapper that specifies the creation and, optionally, the insertion of a TDR inside the IJTAG network.

[Figure 10-16](#) on page 3281 shows the detailed schematic of a 3-bit TDR with some data-in and data-out ports as well as some decoded output signals. When requesting data-out ports or decoded signals, the default is to always use an update stage between the shift stage and the output port. In the case of decoded signals, the decoding logic is between the shift stage and the update stage. It is possible to request that the update stage be removed in situations where it does not matter that the data bits toggle during the shift cycles. See the description of the output_timing property found in the [Tdr/DataOutPorts](#) and [Tdr/DecodedSignal](#) sections. On the other hand, if the output data bit is used to enable or disable parts of the IJTAG network, its output timing must be further delayed by an extra cycle to avoid the race condition described in the [“Update Stage Timing”](#) on page 3277. The TCK clock only needs to be balanced within the TDR module but can tolerate as much as 50% of a TCK period between nodes since a negative edge retiming flip-flop is used on the scan-out port of the [Tdr](#) and [Sib](#) nodes.

The TDR module names are hardcoded to *design_name_design_id_tessent_tdr_id*.

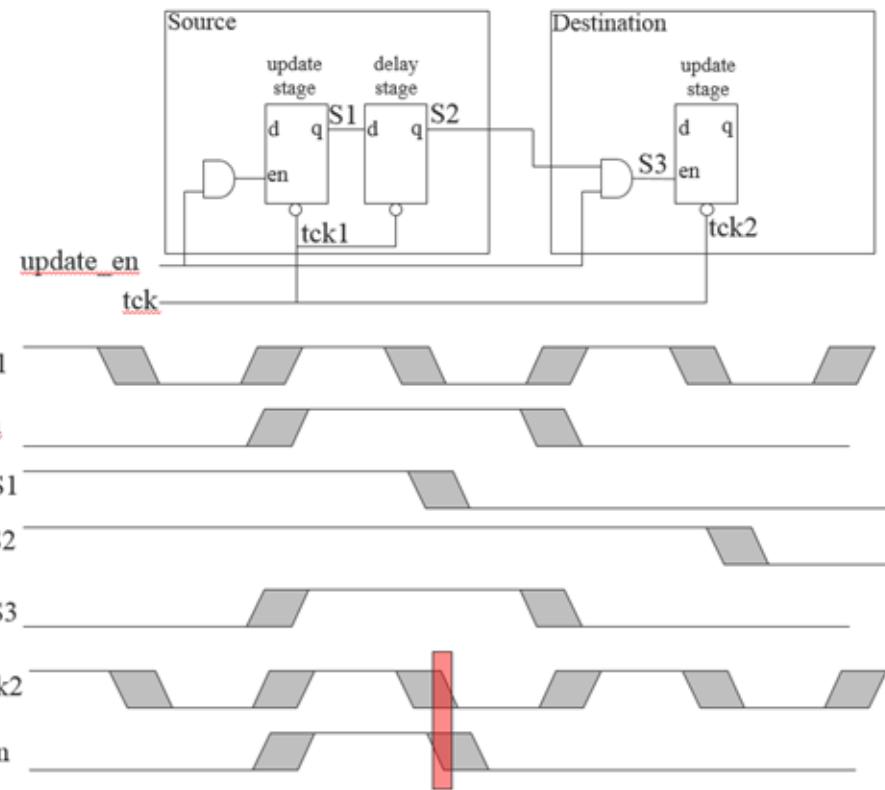

Update Stage Timing

The IJTAG network can be seen as very similar to a 1149.1 or a 1500 network. It has, however, one extra level of freedom where a TDR bit can be used to enable or disable a part of the network while that part of the network is also active. In 1149.1, you never need to worry about races on the select lines because you are in the IR states when changing the instruction and it is only used the next time you go to the DR states. In 1500, the WIR and the selected TDR are accessed in a mutually exclusive manner as controlled by the selectWIR signal.

In IJTAG, you do not have this restriction. If you look at the schematic in [Example 10-9](#) on page 3259, you can see that while you are loading the green TDR, you may also be loading into the black TDR a value that will take out the green TDR for the next scan load and, instead, select the red TDR. As the black, green and red TDRs all receive the same update_en signal, it is important that the select signal reaching the green TDR is still active by the time the falling edge of TCK reaches the green TDR. It is also important that the select signal reaching the red TDR is still inactive by the time the falling edge of TCK reaches the red TDR.

If these conditions are not met, the green TDR may not perform its last update and the red update stage may be prematurely disturbed. This racing condition is illustrated in [Figure 10-15](#). The source box can be seen as the black TDR while the destination box can be seen as the green TDR in [Figure 10-9](#) on page 3259. If you have skew in the TCK clock distribution where TCK2 is delayed with respect to TCK1, the update stage value labeled S1 could change too soon and block the overlap of S1 and update_en at the destination update flip-flop. Because the enabling can be going in all directions, you either have to precisely balance your TCK clock network all over the network or do as is done in Tessent Shell and add an extra delay stage for those select signals to remove the race condition even in the presence of large TCK clock skew.

Figure 10-15. Update Stage Timing Diagram

Arguments

- *id*
A unique id that contains only letters, numbers, and underscores. Every Tdr wrapper must have a different id inside the [IjtagNetwork](#) wrapper.
- *parent_instance* : *instance_name* ;
A string property that specifies the parent instance in which to instantiate the TDR module. When left unspecified, the TDR is instantiated in the common ancestor of the DataInPorts, DataOutPorts, and DecodedSignal connections. You can use this property to push a TDR down into a different location. You can specify “.” as the *parent_instance* to force the TDR to be placed in the root module independent of the DataInPort, DataOutPort, and DecodedSignal connections. When the TDR has no DataInPorts and DataOutPorts connections, the *parent_instance* property defaults to the root module.

If the specified or inferred *instance_name* is an instance of a repeated module, a warning is displayed during validation and a *uniquify_instances* command is automatically issued as part of the insertion process to uniquify the *instance_name*.

To perform IjtagNetwork insertion inside a module that is used more than once without uniquifying it, you can set the current design to that module, insert the IJTAG network in it, and refer to it with a DesignInstance wrapper at the next level up. This bottom-up insertion process can be done by going back and forth between setup and insertion mode within a

single Tessent Shell invocation. You simply change the current design using the `set_current_design` command in setup mode.

- `leaf_instance_name : leaf_instance_name ;`

A string property that specifies the leaf instance name of the TDR. It defaults to `design_name_design_spec_id_tessent_tdr_tdr_id_inst` when unspecified. The `dft_spec_id` string is the id specified in the [DftSpecification](#) wrapper, and the `tdr_id` string is the id of the TDR. Tessent Shell checks for conflicts before instantiating the TDR and, if needed, applies the unification suffix specified by the [set_insertion_options](#) command.

- `keep_active_during_scan_test : on | off | auto ;`

A property that specifies that all nodes serially connected to the TDR are to be kept active during scan test modes. For information about when to use this property, see section “[Scan Testability of the IJTAG Network](#)” on page 3225. This property defaults to on when the id is named “`scan_modes`”.

- `length : integer ;`

A property to request a specific shift register length. By default, the length is determined to be large enough to satisfy the specified DataInPorts/count, DataOutPorts/count or DecodedSignal/decode_values properties.

- `extra_bits_capture_value : 0 | 1 | self ;`

A property that applies to the upper bits of the TDR when the length is larger than the DataInPorts/count value. The specified values control what the extra shift register bits capture during the capture cycle. The value self means that it will hold its value.

- `reset_value : binary ;`

A property that specifies a binary number as wide as the TDR to specify the reset value of the DataOutPorts and the DecodedSignals. The shift register stage is not reset. The ICL description of the TDR automatically sets the DefaultLoadValue of the ScanRegister equal to the specified reset value such that if a TDR bit resets to 1, the DefaultLoadValue for that bit will also be set to 1.

- `Attributes/attribute_name : attribute_value ;`

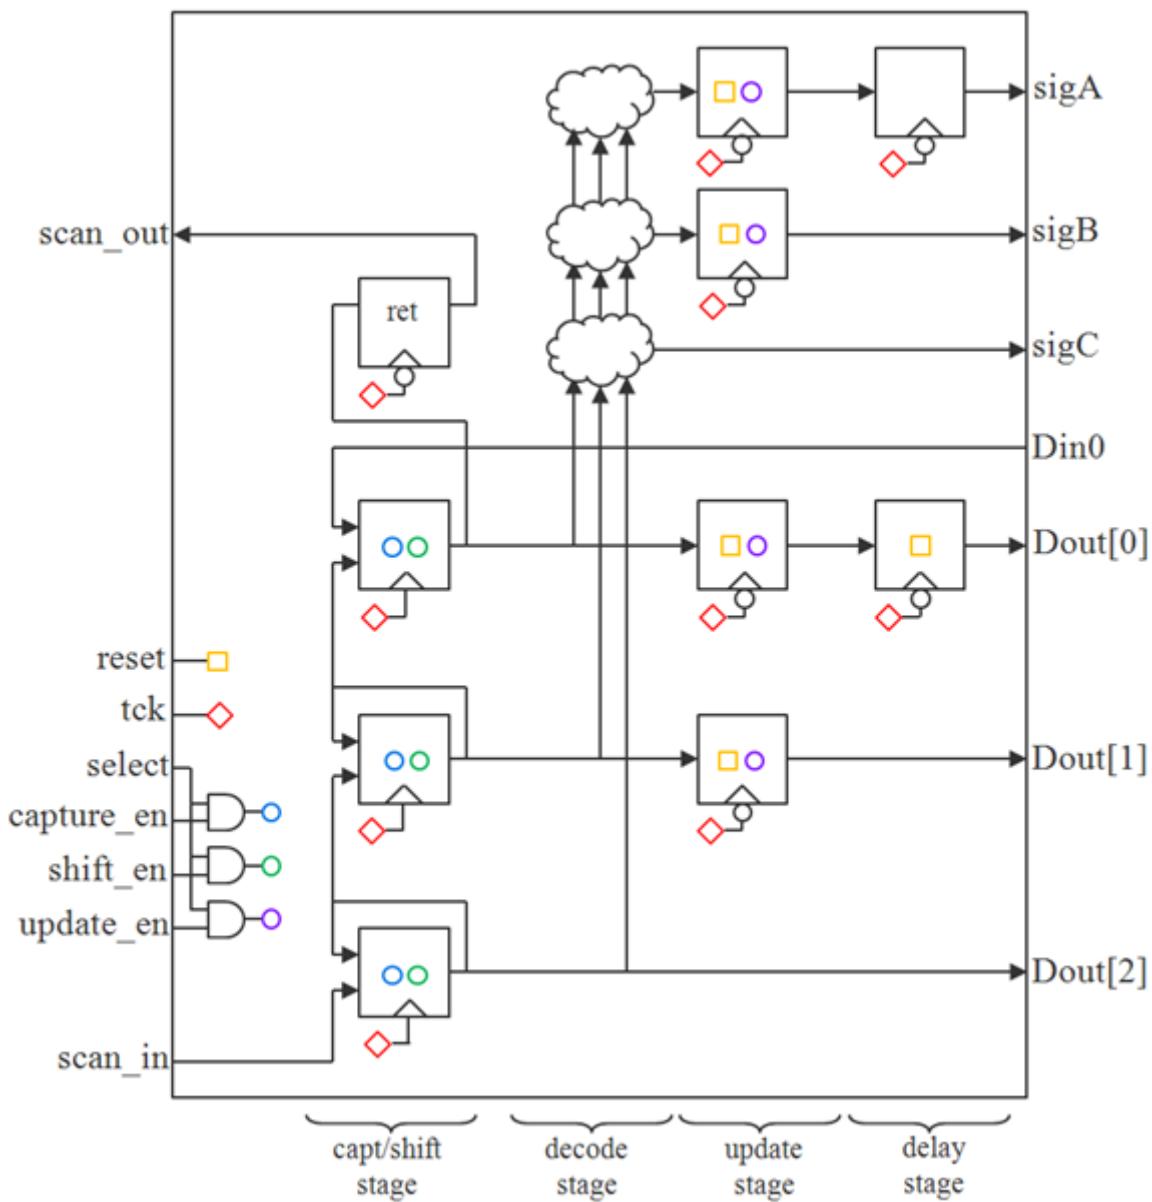

A data wrapper that defines arbitrary attributes in the TDR ICL module. This mechanism is useful for finding special attributed modules in the concatenated ICL, at a later time. The `attribute_name` can be any identifier starting with a letter and followed by any number of letters, numbers, and underscores. The `attribute_value` can be any string or integer. If you want to define a personal attribute and later be able to introspect its value using `get_attribute_value_list`, you must have registered the attribute using the “[register_attribute-object_type icl_module](#)” command. For example, assuming you have registered the `att1` attribute on the [icl_module](#) object type, and you have added the `att1` attribute with a value of “`v1`” in some of your ICL modules using the Attributes wrapper, you can later quickly find those modules using the “[get_icl_modules -filter att1==v1](#)” command.

Examples

The following example illustrates the syntax used to create a TDR exactly like the one shown in [Figure 10-16](#). Notice how the output_timing property is used to make some of the outputs unlatched and some having the extra delay stage needed for ijttag_scan_selection.

```
DftSpecification(MyCore,rtl) {
    IJtagNetwork {
        HostScanInterface(purple) {
            Tdr(blue) {
                length : 3 ;
                extra_bits_capture_value : self ;
                DataOutPorts {
                    count : 3 ;
                    port_naming : Dout[%d] ;
                    output_timing(0) : ijttag_scan_selection ;
                    output_timing(1) : normal ;
                    output_timing(2) : unlatched ;
                }
                DataInPorts {
                    count : 1 ;
                    port_naming : Din%d ;
                }
                DecodedSignal(sigA) {
                    decode_values : 3'bx00 ;
                    output_timing : ijttag_scan_selection ;
                }
                DecodedSignal(sigB) {
                    decode_values : 3'bx01 ;
                    output_timing : normal ;
                }
                DecodedSignal(sigC) {
                    decode_values : 3'bx1x ;
                    output_timing : unlatched ;
                }
            }
        }
    }
}
```

Tdr/Interface

A wrapper that provides properties to fully specify the names of the eight client ports of the TDR.

Usage

```
IJtagNetwork {
    HostScanInterface(id) {
        Tdr(id) {
            Interface {
                select      : port_name ;      // default: ijttag_sel
                tck         : port_name ;      // default: ijttag_tck
                scan_in     : port_name ;      // default: ijttag_si
                scan_out    : port_name ;      // default: ijttag_so
                reset       : port_name ;      // default: ijttag_reset
                reset_polarity : active_high | active_low;
                shift_en    : port_name ;      // default: ijttag_se
                capture_en  : port_name ;      // default: ijttag_ce
                update_en   : port_name ;      // default: ijttag_ue
            }
        }
    }
}
```

Description

A wrapper that provides properties to fully specify the names of the eight client ports of the TDR.

The wrapper also allows defining the active polarity of the reset port.

Arguments

- **select : *port_name* ;**
This property defines the name of the select port. The default is “ijtag_sel”.
- **tck : *port_name* ;**
This property defines the name of the tck port. The default is “ijtag_tck”.
- **scan_in : *port_name* ;**
This property defines the name of the scan_in port. The default is “ijtag_si”.
- **scan_out : *port_name* ;**
This property defines the name of the scan_out port. The default is “ijtag_so”.
- **reset : *port_name* ;**
This property defines the name of the reset port. The default is “ijtag_reset”.
- **reset_polarity : active_high | active_low ;**
This property defines the active polarity of the reset port. The default is “active_low”.

- `shift_en : port_name ;`
This property defines the name of the shift_en port. The default is “ijtag_se”.
- `capture_en : port_name ;`
This property defines the name of the capture_en port. The default is “ijtag_ce”.
- `update_en : port_name ;`
This property defines the name of the update_en port. The default is “ijtag_ue”.

Examples

The following example illustrates fully specifying a unique name for each port of the TDR.

```
Tdr(id) {
    Interface {
        select      : sel ;
        tck         : tck ;
        scan_in     : si ;
        scan_out    : so ;
        reset       : reset ;
        shift_en    : se ;
        capture_en  : ce ;
        update_en   : ue ;
    }
}
```

[ScanMux/Interface](#)

[Sib/Interface](#)

Tdr/DataInPorts

A wrapper that specifies the number (count) of data-in ports to create on the TDR, the naming of the ports, and the connections to make to them.

Usage

```
IJtagNetwork {
    HostScanInterface(id) {
        Tdr(id) {
            DataInPorts {
                count           : integer ;          //default: auto
                port_naming    : port_naming,...; //default: ijtag_data_in[%d]
                connection(range) : pin_name;
            }
        }
    }
}
```

Description

A wrapper that specifies the number (count) of data-in ports to create on the TDR, the naming of the ports, and the connections to make to them.

Arguments

- `count : integer ;`

A property that specifies the number of data-in bits needed on the TDR. If the property is set, or defaults to auto, the count is determined to be large enough to satisfy the *range* value of all connection properties. If no connection property is specified, the count is determined to be large enough to satisfy the `port_naming` values if they are in a non-indexed format (%d). If the `port_naming` property is set, or defaults to an indexed format, the count is determined to be large enough to satisfy the length of the TDR.

- `port_naming : port_naming, ... ;`

A property that specifies the naming of the data-in ports. The `port_naming` value has two distinct formats. It can be a single string using an index symbol or a list of port names with explicit sizes.

When using the indexed format, you specify `base_name[%d]` when you want to use a bus and you specify `base_name%<integer>d` when you want to create a set of scalar ports. In both cases, the range is <count>-1 to 0. Using <integer> in the scalar naming ensures the integer is padded with 0s to be at least <integer> bits wide. For example, `Din%2d` will create `Din00`, `Din01`, `Din02`, and so on. `Din%d` and `Din%1d` mean the same thing. The default is “`ijtag_data_in[%d]`”.

When using a list of port names, you control the exact naming and width of each data-in port. For example, if you specify “locked”, you will get exactly one data-in port called “locked” as illustrated in [Example 2](#).

- `connection(range) : pin_name ;`

A repeatable property that specifies the connections to make between the bits of the data-in ports and the existing pins inside the design. Because data-in ports are sinks, the same bit cannot be connected to multiple sources. It is, therefore, illegal to repeat the connection property with overlapping range indexes.

If the pin name refers to a bused pin and you are connecting to a full bus, you can omit the bus range if the [process_dft_specification -no_insertion](#) option is not used. If you are using the [process_dft_specification -no_insertion](#) switch, you must specify the full range of the destination pin because the range cannot be extracted from the design.

Examples

Example 1

The following example illustrates the specification of two data-in ports with connections to pins on a design instance.

```
DftSpecification(MyCore,rtl) {
    IjtagNetwork {
        HostScanInterface(purple) {
            Sib(orange) {
                Tdr(orange) {
                    DataInPorts {
                        connection(0) : u2/top_green/go ;
                        connection(1) : u2/top_green/done ;
                    }
                }
            }
        }
    }
}
```

Example 2

The following example illustrates the explicit naming of the data-in and data-out ports. The data-in port is a single bit wide and called “locked”. There are 7 data-out ports. The port associated with connection(0) is div[0] and the one associated with connection(5) is mult[2].

```
DftSpecification(clk_gen,bottom_up) {
    IjtagNetwork {
        HostScanInterface(ijtag) {
            Tdr(1) {
                DataOutPorts {
                    connection(5:3) : pll/mult[2:0] ;
                    connection(2:0) : pll/div[2:0] ;
                    port_naming     : mux_sel, mult[2:0], div[2:0] ;
                }
                DataInPorts {
                    connection(0) : pll/locked ;
                    port_naming   : locked ;
                }
            }
        }
    }
}
```

Related Topics

[Tdr/DataOutPorts](#)

[Tdr/DecodedSignal](#)

Tdr/DataOutPorts

A wrapper that specifies the number (count) of data-out ports to create on the TDR, the naming of the ports, the output_timing of the ports, and the connections to make to them.

Usage

```
IJtagNetwork {
    HostScanInterface(id) {
        Tdr(id) {
            DataOutPorts {
                count           : integer;          // default: auto
                port_naming     : port_naming,...; //default: ijtag_data_out[%d]
                multiplexing    : on | off | auto ;
                output_timing(range) : timing_spec ; // legal : auto unlatched
                                            // normal
                                            // ijtag_scan_selection
                connection(range)   : pin_name ;   // repeatable
            }
        }
    }
}
```

Description

A wrapper that specifies the number (count) of data-out ports to create on the TDR, the naming of the ports, the output_timing of the ports, and the connections to make to them.

Arguments

- count : *integer* ;

A property that specifies the number of data-out bits needed on the TDR. If the property is set, or defaults to auto, the count is determined to be large enough to satisfy the *range* value of all connection properties. If no connection property is specified, the count is determined to be large enough to satisfy the port_naming values if they are in a non-indexed format (%d). If the port_naming property is set, or defaults to an indexed format, the count is determined to be large enough to satisfy the length of the TDR.

- port_naming : *port_naming*, ... ;

A property that specifies the naming of the data-out ports. The port_naming value has two distinct formats. It can be a single string using an index symbol or a list of port names with explicit sizes.

When using the indexed format, you specify base_name[%d] when you want to use a bus and you specify base_name%<integer>d when you want to create a set of scalar ports. In both cases, the range is <count>-1 to 0. Using <integer> in the scalar naming ensures the integer is padded with 0s to be at least <integer> bits wide. For example, Dout%2d will create Dout00, Dout01, Dout02, and so on. Dout%d and Dout%1d mean the same thing. The default is “ijtag_data_out[%d]”.

When using a list of port names, you control the exact naming and width of each data-out port. For example, if you specify “mux_sel,mult[2:0],div[2:0]”, you will get exactly seven

data-out ports where the most significant bit is called mux_sel and the least significant bit is called div[0] as illustrated in [DataOutPort Connection Multiplexing](#).

- multiplexing : on | off | auto ;

A property that specifies whether to add a multiplexer when making the connection to the specified pin_name of the connection properties. When set to auto, a multiplexer is added unless the pin is unconnected, connected to a constant, or connected to a net with no fanin. As soon as one connection needs multiplexing, an extra data-out port is added to control the select of the multiplexers. The multiplexers are inserted in the direct parent instance of the specified pin_name of the connection properties. See [DataOutPort Connection Multiplexing](#) for illustration.

- output_timing(*range*) : auto | unlatched | normal | ijttag_scan_selection ;

A repeatable property that specifies the output timing of the data-out ports. The default value is auto. The auto will become ijttag_scan_selection if the DataOutPort is used as a ScanMux select source; otherwise, it will become normal.

As you can see in [Figure 10-16](#):

- unlatched — A data-out port can be directly connected to the shift register when output timing is specified as unlatched. This corresponds to Dout[2] in [Figure 10-16](#).
 - normal — A data-out port can be connected to the shift register through an update stage when output timing is specified as normal. This corresponds to Dout[1] in [Figure 10-16](#).
 - ijttag_scan_selection — A data-out port can be connected to the shift register through an update stage and another delay stage when output timing is specified as ijttag_scan_selection. This corresponds to Dout[0] in [Figure 10-16](#). For a description of when the delay stage is needed, refer to “[Update Stage Timing](#)” on page 3277.
- connection(*range*) : pin_name ;
- A repeatable property that specifies connections to make between bits of the data-out ports and existing pins inside the design. Because data-out ports are sources, the same bit can be connected to multiple destinations by simply repeating the connection property with the same range indexes.
- If the pin name refers to a bused pin and you are connecting to a full bus, you can omit the bus range if the [process_dft_specification -no_insertion](#) option is not used. If you are using the [process_dft_specification -no_insertion](#) switch, you must specify the full range of the destination pin because the range cannot be extracted from the design.

Examples

Example 1

The following example illustrates the specification of four data-out ports with connections to pins on a design instance. The example associated with [Figure 10-16](#) shows the use of the output_timing property.

```
DftSpecification(MyCore,rtl) {
    IjtagNetwork {
        HostScanInterface(purple) {
            Sib(orange) {
                Tdr(orange) {
                    DataOutPorts {
                        connection(0) : u2/top_green/en ;
                        connection(3:1) : u2/top_green/mode[2:0] ;
                    }
                }
            }
        }
    }
}
```

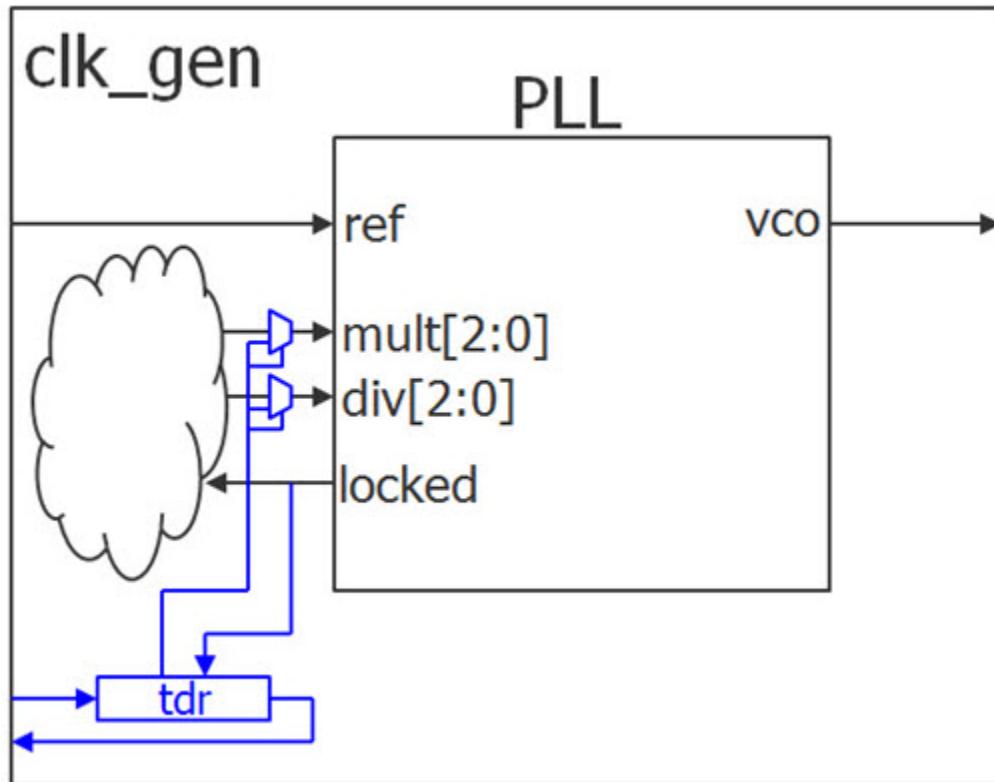

Example 2

The following example illustrates the explicit naming of the data-in and data-out ports. The data-in port is a single bit wide and called “locked”. There are 7 data-out ports. The port associated with connection(0) is div[0] and the one associated with connection(5) is mult[2].

Multiplexing is left unspecified so it defaults to auto. Because the pll/mult[2:0] and pll/div[2:0] pins have a functional source, a multiplexer is inserted and a 7th data-out bit named mux_sel is used to control the multiplexers.

```
DftSpecification(clk_gen,bottom_up) {
    IjtagNetwork {
        HostScanInterface(ijttag) {
            Tdr(1) {
                DataOutPorts {
                    connection(5:3) : pll/mult[2:0] ;
                    connection(2:0) : pll/div[2:0] ;
                    port_naming : mux_sel, mult[2:0], div[2:0] ;
                }
                DataInPorts {
                    connection(0) : pll/locked ;
                    port_naming : locked ;
                }
            }
        }
    }
}
```

[Tdr/DecodedSignal](#)

Tdr/DecodedSignal

A wrapper that specifies the creation of a decoded signal.

Usage

```
IjtagNetwork {
    HostScanInterface(id) {
        Tdr(id) {
            DecodedSignal(signal_name) {
                decode_values      : binary_code, ... ;
                multiplexing       : on | off | auto ;
                output_timing     : timing_spec ;
                    // legal : auto unlatched normal
                    //          ijtag_scan_selection
                connection        : port_pin_name ; // repeatable
                Attributes {
                    attribute_name : attribute_value ;
                }
            }
        }
    }
}
```

Description

A wrapper that specifies the creation of a decoded signal.

The decode_values property is used to specify which values of the TDR make the decoded signal active. The connection property specifies connections from the decoded signals.

Arguments

- decode_values : *binary_code*, ... ;

A property that specifies a list of binary codes that define when the decoded signal is active. The binary codes must be as wide as the TDR. The binary numbers may contain Xs as long as there is at least one 0 or one 1 in each value.

- multiplexing : on | off | auto ;

A property that specifies whether to add a multiplexer when making the connection to the specified pin_name of the connection properties. When set to auto, a multiplexer is added unless the pin is unconnected, connected to a constant, or connected to a net with no fanin. As soon as one connection needs multiplexing, an extra data-out port is added on the TDR to control the select of the multiplexers. The multiplexers are inserted in the direct parent instance of the specified pin_name of the connection properties. See [DataOutPort Connection Multiplexing](#) of the [Tdr/DataOutPorts](#) section for an illustration of this.

- output_timing : auto | unlatched | normal | *ijtag_scan_selection* ;

A property that specifies the output timing of the decoded signal port. The default value is auto. The auto will become *ijtag_scan_selection* if the DecodedSignal is used as a ScanMux select source; otherwise, it will become normal.

As you can see in [Figure 10-16](#):

- unlatched — A decoded signal is directly connected to the decoding logic when output timing is specified as unlatched; this corresponds to SigC in [Figure 10-16](#).
- normal — A data-out port is connected to the decoding logic through an update stage when output timing is specified as normal; this corresponds to SigB in [Figure 10-16](#).
- *ijtag_scan_selection* — A data-out port is connected to the decoding logic through an update stage and another delay stage when output timing is specified as *ijtag_scan_selection*; this corresponds to SigA in [Figure 10-16](#).

Refer to the “[Update Stage Timing](#)” on page 3277 for a description of when the delay stage is needed.

- **connection : *port_pin_name* ;**

A repeatable property that specifies connections to make between the decoded signal and existing pins inside the design. Because decoded signals are sources, they can be connected to multiple destinations by simply repeating the connection property.

- **Attributes/*attribute_name* : *attribute_value* ;**

A data wrapper that defines arbitrary attributes on the ICL port associated with the decoded signal. This mechanism is useful for finding special attributed ports in the concatenated ICL. The *attribute_name* can be any identifier starting with a letter and followed by any number of letters, numbers and underscores. The *attribute_value* can be any string or integer. If you want to define a personal attribute and later be able to introspect its value using [get_attribute_value_list](#), you must have registered the attribute using the “[register_attribute-object_type icl_module](#)” command. For example, assuming you have registered the att1 attribute on the [icl_port](#) object type, and you have added the att1 attribute with a value of “v1” to some DecodedSignal ports of your TDR modules using the above Attributes wrapper, you can later quickly find those ports using the “[get_icl_ports -of module_name -filter att1==v1](#)” command. The [icl_port](#) attributes are also inherited by the [icl_pin](#) objects so you can also find the pins using “[get_icl_pins -filter att1==v1](#)”.

Examples

The following example illustrates the creation of three decoded signals with each having a different output timing. The example corresponds to the schematic shown in [Figure 10-16](#).

```
DftSpecification(MyCore,rtl) {
    IJtagNetwork {
        HostScanInterface(purple) {
            Tdr(blue) {
                DecodedSignal(sigA) {
                    decode_values      : 3'bx00 ;
                    output_timing     : ijtag_scan_selection ;
                }
                DecodedSignal(sigB) {
                    decode_values      : 3'bx01 ;
                    output_timing     : normal ;
                }
                DecodedSignal(sigC) {
                    decode_values      : 3'bx1x ;
                    output_timing     : unlatched ;
                }
            }
        }
    }
}
```

Tap

A wrapper that specifies the creation and, optionally, the insertion of a TAP controller into the IJtagNetwork.

Usage

```
DftSpecification(module_name, id) {
    IJtagNetwork {
        HostScanInterface(id) {
            Tap(id) {
                Interface {
                }
                parent_instance           : instance_name ;
                leaf_instance_name       : leaf_instance_name ;
                keep_active_during_scan_test : on | off | auto ;
                bypass_instruction_codes   : auto | binary , ... ;
                add_buffers_on_jtag_signal_sources : on | off | auto ;
                Attributes {
                    attribute_name : attribute_value;
                }
                DataOutPorts {
                }
                HostBscan {
                }
                DeviceIDRegister {
                }
                HostIjtag(id) {
                }
            }
        }
    }
}
```

Description

A wrapper that specifies the creation and, optionally, the insertion of a TAP controller into the IJtagNetwork.

A TAP is a special node in IJTAG. It contains an IEEE1149.1 state machine controlled by a TMS port. The TMS port is used to steer the state machine into various states and control when the capture, shift, and update cycles happen. Unlike a SIB and a TDR, which are only active in the DR States, the TAP has an instruction register that is activated in the IR States. The value in the instruction register determines which data register is selected when in the DR States. The TAP state machine is illustrated in [Figure 10-18](#). A block diagram of a TAP controller is shown in [Figure 10-19](#).

A TAP wrapper is only allowed to exist in a HostScanInterface or inside the Input wrapper of a ScanMux. A TAP is only allowed to be in series with other TAP controllers and can never be in series with [Tdr](#) and [Sib](#) nodes even through [ScanMux](#) nodes. The name of all ports on the TAP controller are user-specifiable using the Interface wrappers. BoundaryScan host ports are present when the [Tap/HostBScan](#) wrapper is specified. The device id register is present when the [Tap/DeviceIDRegister](#) wrapper is specified. Finally, the IJTAG host ports are present when

one or more HostIjtag wrappers are specified. The bypass register is required and always present.

If you are familiar with the LogicVision TAP, you will remember that it had an internal DR register used to observe status bits and control user bits and decoded signals. If you need such a register, you can and should use a [Tdr](#) wrapper inside a HostIjtag wrapper of the Tap; this will give you access to the [Tdr/DataInPorts](#), [Tdr/DataOutPorts](#), and [Tdr/DecodedSignal](#) wrapper syntax.

All registers operate on the rising edge of TCK except for the update stage, labelled “inst_latch” in [Figure 10-19](#), which operates on the falling edge of TCK.

The retiming latch shown in [Figure 10-19](#) is replaced by a retiming flip-flop when the scan_path_retimining property within the IjtagNetwork/ImplementationOptions section is set to “flop”. For the reason explained in the description of that property, the retiming flop is moved as compared to where the latch is shown so as not to be in the path between the from_hostX_so ports and the tdo port in order to avoid the cascaded retiming flip-flops situation described there. As stated in that section, make sure third party nodes include a retiming element on their scan_out when you connect them directly to the scan_in port of the HostIjtag scan interfaces Tesson Tap and you specify the scan_path_retimining property to “flop”, otherwise your elements will not be 1149.1 compliant and will likely not be usable within a board environment.

The tap module names are hardcoded to *design_name_design_id_tesson_tap_id*.

Figure 10-18. TAP FMS Diagram

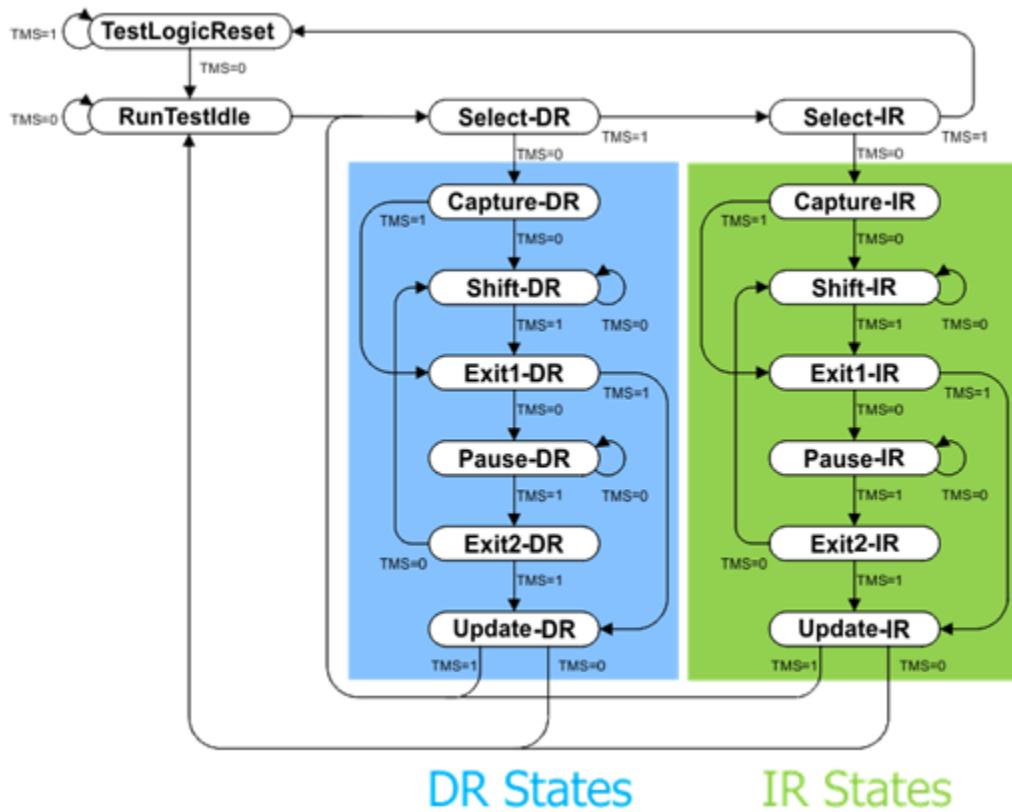

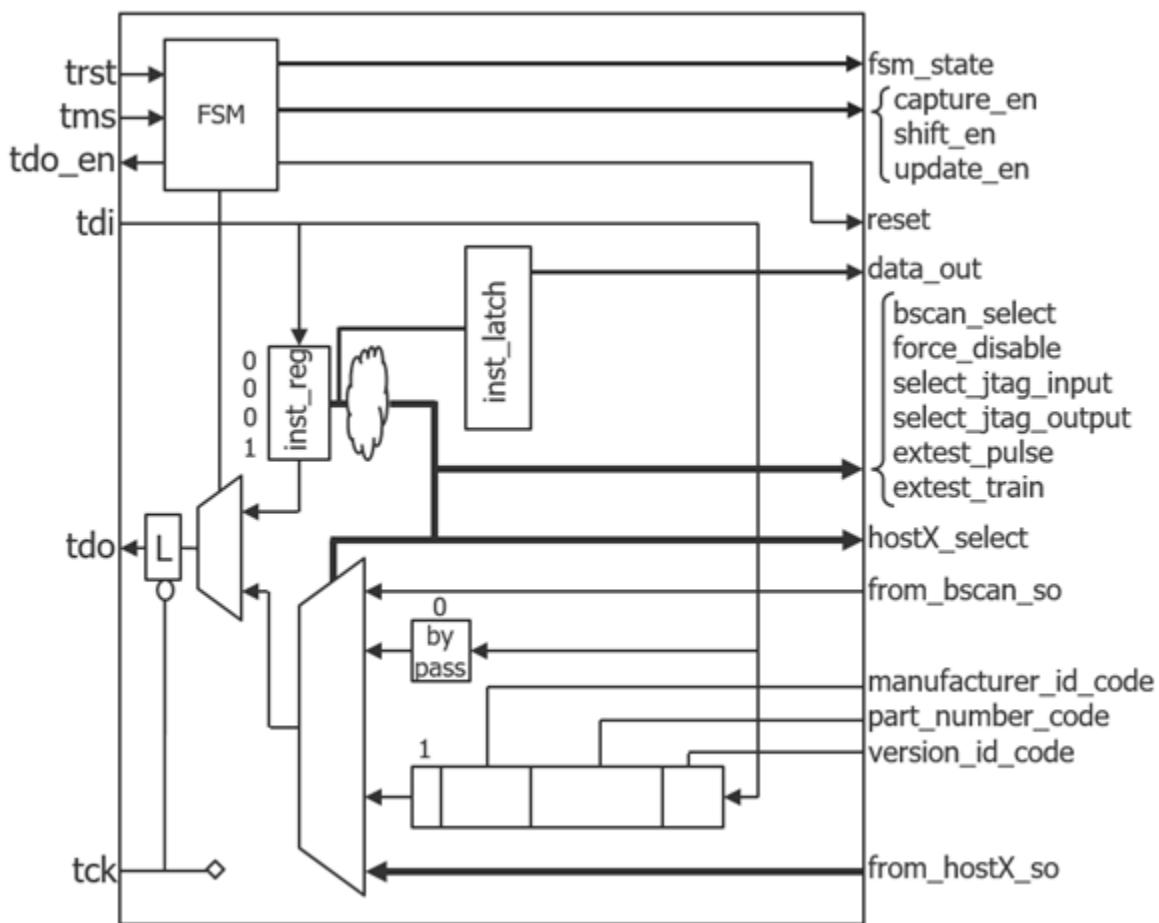

Figure 10-19. TAP Block Diagram

Arguments

- *id*
A unique id that contains only letters, numbers, and underscores. Every Tap wrapper must have a different id value inside the [IJtagNetwork](#) wrapper.
- *parent_instance* : *instance_name* ;
A string property that specifies the parent instance in which to instantiate the TAP module. If unspecified, the TAP is instantiated in the root module. You can use this property to push a TAP down near the client interfaces it interacts with.
If the specified *instance_name* is an instance of a repeated module, the tool issues a warning during validation and automatically issues a [uniquify_instances](#) command as part of the insertion process to uniquify the *instance_name*.
To perform IJTAG network insertion inside a module that is used more than once without uniquifying it, you can set the current design to that module, insert the IJTAG network in it, and refer to it with a DesignInstance wrapper at the next level up. This bottom-up insertion process can be done by going back and forth between setup and insertion mode within a

single Tesson Shell invocation. You simply change the current design using the `set_current_design` command in setup mode.

- `leaf_instance_name : leaf_instance_name ;`

A string property that specifies the leaf instance name of the TAP. It defaults to `design_name_dft_spec_id_tesson_tap_tap_id_inst` when unspecified. The `dft_spec_id` string is the id specified in the [DftSpecification](#) wrapper, and the `tap_id` is the `id` of the Tap wrapper. Tesson Shell checks for conflicts before instantiating the TAP controller and, if needed, applies the unification suffix specified by the [set_insertion_options](#) command.

- `keep_active_during_scan_test : on | off | auto ;`

A property that specifies that all nodes serially connected to the TAP are to be kept active during scan test modes. For information about when to use this property, see the section “[Scan Testability of the IJTAG Network](#)” on page 3225.

- `bypass_instruction_codes : auto | binary, ... ;`

A property used to define one or many opcodes for the BYPASS instruction. The all 0 code is automatically assigned to the BYPASS instruction whether specified or not. All codes must differ from the other codes by at least one non-X bit. When left to auto, the tool automatically selects a unique code and describes it in the ICL file.

- `add_buffers_on_jtag_signal_sources : on | off | auto ;`

A property that adds persistent buffers to the TAP controller's input control signals: TDI, TMS, TCK and TRST. The buffers are added to create an interception point for the TAP and the nodes in the networks it hosts. When set to “auto”, the buffers will be added if there is at least one InSystemTest controller wrapper in the current DftSpecification. Use this property if you intend to insert InSystemTest controllers to intercept a specific TAP controller.

- `Attributes/attribute_name : attribute_value ;`

A data wrapper that defines arbitrary attributes in the TAP ICL module. This mechanism is useful for finding special attributed modules in the concatenated ICL at a later time. The `attribute_name` can be any identifier starting with a letter and followed by any number of letters, numbers, and underscores. The `attribute_value` can be any string or integer. If you want to define a personal attribute and later be able to introspect its value using `get_attribute_value_list`, you must have registered the attribute using the “[register_attribute-object_type icl_module](#)” command. For example, assuming you have registered the `att1` attribute on the [icl_module](#) object type, and you have added the `att1` attribute with a value of “`v1`” in some of your ICL modules using the Attributes wrapper, you can later quickly find those modules using the “[get_icl_modules -filter att1==v1](#)” command.

Examples

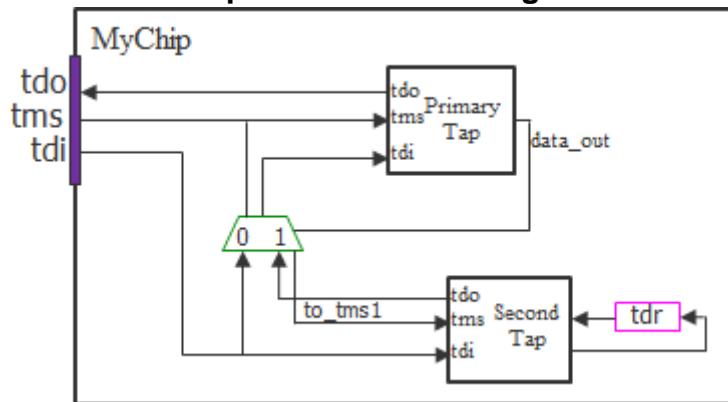

Example 1

This example defines two TAP controllers where a DataOutPort on the primary TAP is used to control if the secondary TAP is active or not. When the DataOutPort on the primary TAP is high, the secondary TAP is in series with it. When the DataOutPort on the primary TAP is low, the secondary TAP is bypassed and it is held in run_test_idle by gating its tms port low.

```

DftSpecification(module_name,id) {
    IJtagNetwork {
        HostScanInterface(purple) {
            Tap(main) {
                DataOutPorts {
                    count : 1 ;
                }
            }
            ScanMux(green) {
                select : Tap(main)/DataOut(0) ;
                Input(1) {
                    Tap(secondary) {
                        HostIJtag(0) {
                            Tdr(pink) {
                            }
                        }
                    }
                }
            }
        }
    }
}

```

Figure 10-20. Example Multi-TAP Configuration Schematic**Example 2**

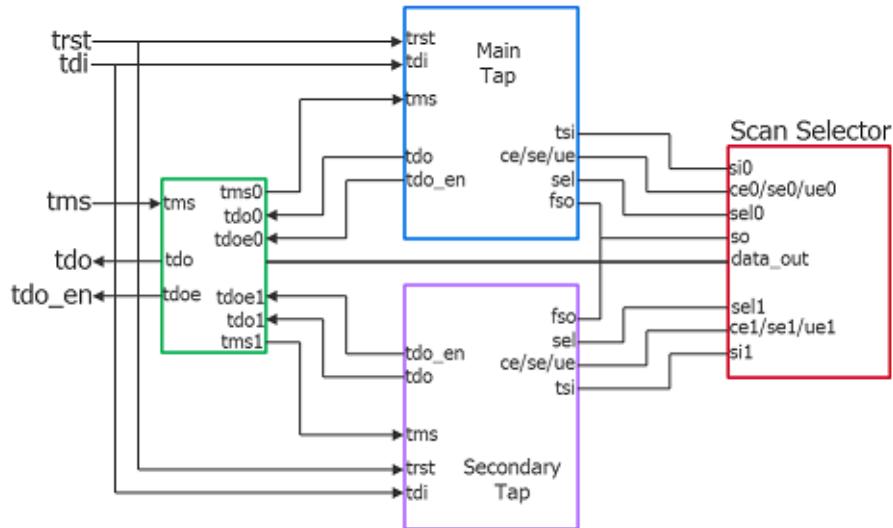

The following example uses a special one bit TDR to select between two TAPs. The special aspect of this circuit is that the one bit TDR (called Scan Selector in Figure 10-21) used to select which TAP is active remains active below the selected TAP. Both TAPs have a HostIJtag connected to one ScanInterface of the Scan Selector and the state of the Scan Selector itself decides which ScanInterface controls it. The advantage of this circuit is that the currently selected TAP remains alone between TDI and TDO. Using the instruction on the Main TAP that accesses the TDR enables changing the value in the TDR to give control to the Secondary TAP. The same method in the newly selected Secondary TAP can be used to return control to the Main TAP. The IJTAG solver can automatically switch between TAPs based on the elements it is being asked to access.

Figure 10-21 shows the block diagram of the circuit. Below it is the DftSpecification used to insert two TAP controllers and a ScanMux and connect the HostIJtag of each TAP to the two

ScanInterfaces of the Scan Selector. The Verilog description and ICL of the Scan Selector are shown next.

The TDR in the Scan Selector module resets to 0 when the trst port is pulled low or the 5 tms sequence is applied for the active TAP. The process_dft_specification.post_insertion callback shown below is used to insert the AND gate during the [process_dft_specification](#) execution. This AND gate is not described in the ICL but it does not matter as it is the implied behavior.

Figure 10-21. Example of TDR Scan Selector

DftSpecification:

```
DftSpecification(chip,rtl) {
    IjtagNetwork {
        HostScanInterface(tap) {
            Interface {
                tck : tck ;
                tdi : tdi ;
                tdo : tdo ;
                trst : trst ;
                tms : tms ;
            }
            ScanMux(tap_mux) {
                select : DesignInstance(scan_selector)/data_out ;
                Input(0) {
                    Tap(main) {
                        HostIjtag(0) {
                            DesignInstance(scan_selector) {
                                scan_interface : Int0 ;
                            }
                        }
                        HostIjtag(1) {
                            tdr(1) {
                                DataOutPorts {
                                    count : 8 ;
                                }
                            }
                        }
                    }
                }
                Input(1) {
                    Tap(secondary) {
                        HostIjtag(0) {
                            DesignInstance(scan_selector) {
                                scan_interface : Int1 ;
                            }
                        }
                        HostIjtag(1) {
                            tdr(2) {
                                DataOutPorts {
                                    count : 8 ;
                                }
                            }
                        }
                    }
                }
            }
        }
    }
}
```

The process `_dft_specification.post_insertion` callback to AND the two rstn pins of the TAP:

```
proc process_dft_specification.post_insertion {root_wrapper args} { \
    create_connections chip_rtl_tessent_tap_main_inst/test_logic_reset/ \
    scan_selector/rstn \
    intercept_connection scan_selector/rstn -cell_function_name and \
    -input2 chip_rtl_tessent_tap_secondary_inst/test_logic_reset
}
```

Verilog view of the special TDR called `scan_selector`:

```
module scan_selector (tck, rstn1, sel1, sil, sel1, ue1, so1,
                      rstn0, sel0, si0, se0, ue0, so0, data_out);
  input tck, rstn1, sel1, sil, sel1, ue1, rstn0, sel0, si0, se0, ue0;
  output so1, so0, data_out;
  reg shift_stage, update_stage;
  assign se = (data_out) ? sel1 : se0;
  assign ue = (data_out) ? ue1 : ue0;
  assign sel = (data_out) ? sel1 : sel0;
  assign si = (data_out) ? sil : si0;
  assign rstn = (data_out) ? rstn1 : rstn0;
  assign data_out = update_stage;
  assign so1 = shift_stage;
  assign so0 = shift_stage;
  assign se_gated = sel & se;
  assign ue_gated = sel & ue;
  always @ (posedge tck or negedge rstn) begin
    if (~rstn) begin
      update_stage <= 1'b0;
    end else begin
      if (ue_gated) begin
        update_stage <= shift_stage;
      end
    end
  end
  endalways @ (posedge tck) begin
    if (se_gated) begin
      shift_stage <= si;
    end
  end
end
endmodule
```

ICL view of the special TDR called scan_selector:

```
Module scan_selector {
    TCKPort      tck;
    SelectPort   sel1;

        ScanInSource M1;
        ResetValue 1'b0;
    }
}
```

Tap/Interface

A wrapper that contains a Client and Host wrapper that together fully specify the names and polarity of the client and host ports.

Usage

```
DftSpecification(module_name, id) {
    IJtagNetwork {
        HostScanInterface(id) {
            Tap(id) {
                Interface {
                    fsm_state : port_name ; // def: fsm_state[%d]
                    Client {
                        tdi : port_name ; // default: tdi
                        tdo : port_name ; // default: tdo
                        tck : port_name ; // default: tck
                        tms : port_name ; // default: tms
                        trst : port_name ; // default: trst
                        tdo_en : port_name ; // default: tdo_en
                        tdo_en_polarity : active_high | active_low | auto ;
                    }
                    Host {
                        reset : port_name ; // default: test_logic_reset
                        capture_en : port_name ; // default: capture_dr_en
                        shift_en : port_name ; // default: shift_dr_en
                        update_en : port_name ; // default: update_dr_en
                        reset_polarity : active_high | active low ;
                    }
                }
            }
        }
    }
}
```

Description

A wrapper that contains a Client and Host wrapper that together fully specify the names and polarity of the client and host ports.

The Client wrapper provides properties to fully specify the names of the six client ports, and also contains a property to define the polarity of the tdo_en port. The Host wrapper provides properties to fully specify the names of the four global host ports as well as a property to define the polarity of the reset port. The rest of the host ports related to the IJTAG and boundary scan ports are specified in the [Tap/HostIjtag](#) and [Tap/HostBScan](#) wrappers respectively.

Arguments

- fsm_state : *port_name* ;

This property defines the name of the port labeled “fsm_state” in [Figure 10-19](#). The specified value must end with “[%d]”. The default is “fsm_state[%d]”.

- Client/td : *port_name*;
This property defines the name of the port labeled “td” in [Figure 10-19](#). The default name when unspecified is “td”.
- Client/tdo : *port_name*;
This property defines the name of the port labeled “tdo” in [Figure 10-19](#). The default name when unspecified is “tdo”.
- Client/tck : *port_name*;
This property defines the name of the port labeled “tck” in [Figure 10-19](#). The default name when unspecified is “tck”.
- Client/tms : *port_name*;
This property defines the name of the port labeled “tms” in [Figure 10-19](#). The default name when unspecified is “tms”.
- Client/trst : *port_name*;
This property defines the name of the port labeled “trst” in [Figure 10-19](#). The default name when unspecified is “trst”. This port is always active low.
- Client/tdo_en : *port_name*;
This property defines the name of the port labeled “tdo_en” in [Figure 10-19](#). The default name when unspecified is “tdo_en”. Its active polarity is controlled by the tdo_en_polarity property. The port is active in the Shift-DR and Shift-IR states. See [Figure 10-18](#) for a diagram of the state machines.
- Client/tdo_en_polarity : active_high | active_low | auto ;
This property controls the polarity of the tdo_en port. The default is active_low. When the **DftSpecification** is created by the [create_dft_specification](#) command, the property is automatically specified to match the polarity of the enable pin for the output pad buffer associated with the tdo port.
- Host/reset : *port_name* ;
This property defines the name of the port labelled “reset” in [Figure 10-19](#). The default name when unspecified is “test_logic_reset”. Its active polarity is defined using the reset_polarity property. This port is active when the TAP fsm is in the TestLogicReset state which can be synchronously entered by keeping the tms port high for a minimum of 5 TCK cycles or asynchronously entered by setting the trst port to zero.
- Host/capture_en : *port_name* ;
This property defines the name of the port labeled “capture_en” in [Figure 10-19](#). The default name when unspecified is “capture_dr_en”.
- Host/shift_en : *port_name* ;
This property defines the name of the port labelled “shift_en” in [Figure 10-19](#). The default name when unspecified is “shift_dr_en”.

- Host/update_en : *port_name* ;

This property defines the name of the port labelled “update_en” in Figure 10-19. The default name when unspecified is “update_dr_en”.

- Host/reset_polarity : active_high | active_low ;

This property defines the active polarity of the reset port.

Examples

This example defines all client ports with a “client_” prefix and all host ports with a “host_” prefix. The polarity of tdo_en and reset are both specified as active high.

```
DftSpecification(module_name,id) {  IjtagNetwork {
    HostScanInterface(id) {
        Tap(id) {
            Interface {
                Client {
                    tdi           : client_si ;
                    tdo           : client_so ;
                    tck           : client_tck ;
                    tms           : client_tms ;
                    trst          : client_reset ;
                    tdo_en        : client_so_en ;
                    tdo_en_polarity : active_high ;
                }
                Host {
                    reset          : host_reset ;
                    capture_en     : host_capture_en ;
                    shift_en       : host_shift_en ;
                    update_en      : host_update_en ;
                    reset_polarity : active_high ;
                }
            }
        }
    }
}
```

Tap/HostBScan

The presence of this wrapper specifies that the TAP is to be equipped with a port capable of hosting a boundary scan chain.

Usage

```
DftSpecification(module_name, id) {
    IJtagNetwork {
        HostScanInterface(id) {
            Tap(id) {
                HostBscan {
                    Interface {
                        select : port_name ; // def: host_bscan_to_sel
                        force_disable : port_name ; // def: force_disable
                        select_jtag_input : port_name ; // def: select_jtag_input
                        select_jtag_output : port_name ; // def: select_jtag_output
                        extest_pulse : port_name ; // def: extest_pulse
                        extest_train : port_name ; // def: extest_train
                        scan_in : port_name ; // def: host_bscan_from_so
                    }
                    InstructionCodes {
                        CLAMP : auto | unused | binary, ... ;
                        EXTEST : auto | binary, ... ;
                        EXTEST_PULSE : auto | unused | binary, ... ;
                        EXTEST_TRAIN : auto | unused | binary, ... ;
                        INTEST : auto | unused | binary, ... ;
                        SAMPLE_PRELOAD : auto | binary, ... ;
                        HIGHZ : auto | unused | binary, ... ;
                    }
                }
            }
        }
    }
}
```

Description

The presence of this wrapper specifies that the TAP is to be equipped with a port capable of hosting a boundary scan chain.

The interface wrapper is used to change the default port naming of the various functions. When the HostBscan wrapper is present, the ICL description of the Tap includes all the elements described in the section “[Requirements on a TAP to be usable for BoundaryScan](#)” on page 3385 on page 92.

The tool automatically assigns the instruction codes when you specify auto for all instructions. If you want to specify specific binary values, you must specify them for all instructions.

Arguments

- Interface/select : *port_name* ;

This property defines the name of the port labelled “bscan_select” in [Figure 10-19](#). The default is “host_bscan_to_sel”.

- Interface/force_disable : *port_name* ;

This property defines the name of the port labelled “force_disable” in [Figure 10-19](#). The default is “force_disable”.

- Interface/select_jtag_input : *port_name* ;

This property defines the name of the port labelled “select_jtag_input” in [Figure 10-19](#). The default is “select_jtag_input”.

- Interface/select_jtag_output : *port_name* ;

This property defines the name of the port labelled “select_jtag_output” in [Figure 10-19](#). The default is “select_jtag_output”.

- Interface/extest_pulse : *port_name* ;

This property defines the name of the port labelled “extest_pulse” in [Figure 10-19](#). The default is “extest_pulse”. This port is not created when the EXTEST_PULSE property inside the [Tap/HostIjtag](#) wrapper is specified as “unused”.

- Interface/extest_train : *port_name* ;

This property defines the name of the port labelled “extest_train” in [Figure 10-19](#). The default is “extest_train”. This port is not created when the EXTEST_TRAIN property inside the [Tap/HostIjtag](#) wrapper is specified as “unused”.

- Interface/scan_in : *port_name* ;

This property defines the name of the port labelled “from_bscan_so” in [Figure 10-19](#). The default is “host_bscan_from_so”.

- InstructionCodes/CLAMP : auto | unused | binary, ... ;

A property used to define one or many opcodes for the CLAMP instruction. All codes must differ from the other codes by at least one non-X bit. When left as auto, the tool automatically selects a unique code and describes it in the ICL file when the [Tap/HostBScan](#) wrapper is specified. When specified as unused, the instruction is not included in the TAP controller.

- InstructionCodes/EXTEST : auto | binary, ... ;

A property used to define one or many opcodes for the EXTEST instruction. All codes must differ from the other codes by at least one non-X bit. When left to auto, the tool automatically selects a unique code and describes it in the ICL file when the [Tap/HostBScan](#) wrapper is specified.

- InstructionCodes/EXTEST_PULSE : auto | unused | binary, ... ;

A property used to define one or many opcodes for the EXTEST_PULSE instruction. All codes must differ from the other codes by at least one non-X bit. When left to auto, the tool automatically selects a unique code and describes it in the ICL file when the [Tap/HostBScan](#) wrapper is specified. When specified as unused, the instruction is not included in the TAP controller.

- InstructionCodes/EXTEST_TRAIN : auto | unused | binary, ... ;

A property used to define one or many opcodes for the EXTEST_TRAIN instruction. All codes must differ from the other codes by at least one non-X bit. When left to auto, the tool automatically selects a unique code and describes it in the ICL file when the [Tap/HostBScan](#) wrapper is specified. When specified as unused, the instruction is not included in the TAP controller.

- InstructionCodes/INTEST : auto | unused | binary, ... ;

A property used to define one or many opcodes for the INTEST instruction. All codes must differ from the other codes by at least one non-X bit. When left to auto, the tool automatically selects a unique code and describes it in the ICL file when the [Tap/HostBScan](#) wrapper is specified. When specified as unused, the instruction is not included in the TAP controller.

- InstructionCodes/SAMPLE_PRELOAD : auto | binary, ... ;

A property used to define one or many opcodes for the SAMPLE_PRELOAD instruction. All codes must differ from the other codes by at least one non-X bit. When left to auto, the tool automatically selects a unique code and describes it in the ICL file when the [Tap/HostBScan](#) wrapper is specified.

- InstructionCodes/HIGHZ : auto | unused | binary, ... ;

A property used to define one or many opcodes for the HIGHZ instruction. All codes must differ from the other codes by at least one non-X bit. When left to auto, the tool automatically selects a unique code and describes it in the ICL file when the [Tap/HostBScan](#) wrapper is specified. When specified as unused, the instruction is not included in the TAP controller.

Examples

This example specifies that the TAP is to be equipped with a boundary scan host port. The port naming is left unspecified so the default naming is used. It specifies explicit opcodes for the required instructions related to boundary scan and makes a few of the optional ones unused. Notice that the all 0 opcode is not used as it is reserved for the bypass register. This example assumes no Tap/HostIjtag and no [Tap/DataOutPorts](#) wrappers are specified as there would be no room for those opcodes.

```
DftSpecification(mychip,rtl) {
    IjtagNetwork {
        HostScanInterface(tap) {
            Tap(main) {
                bypass_instruction_codes : 2'b00 ;
            HostBscan {
                InstructionCodes {
                    CLAMP          : unused ;
                    EXTEST         : 2'b01 ;
                    EXTEST_PULSE   : unused ;
                    EXTEST_TRAIN   : unused ;
                    INTEST         : unused ;
                    SAMPLE_PRELOAD : 2'b11 ;
                    HIGHZ          : unused ;
                }
            }
        }
    }
}
```

Tap/DataOutPorts

A wrapper that specifies the number (count) of data-out ports to create on the TAP module, the naming of the ports, the connections to make from them, and whether multiplexing is to be inserted when making the connections.

Usage

```
DftSpecification(module_name, id) {
    IJtagNetwork {
        HostScanInterface(id) {
            Tap(id) {
                DataOutPorts {
                    count           : integer ;          //default: auto
                    port_naming     : port_naming, ;      //default: user_ir_bits[%d]
                    multiplexing    : on | off | auto ;
                    connection(range) : pin_name ;       // repeatable
                }
            }
        }
    }
}
```

Description

A wrapper that specifies the number (count) of data-out ports to create on the TAP module, the naming of the ports, the connections to make from them, and whether multiplexing is to be inserted when making the connections.

Mentor Graphics does not recommend using the TAP as a source of DataOut ports. Instead, you should use the [Tdr/DataOutPorts](#) wrapper as a source. It is good practice to include a data-out port on a TAP to control the select of a [ScanMux](#) that inserts one or many secondary TAP controllers in series with the main one as illustrated in [Figure 10-20](#). Notice that the property `output_timing` which exists in the [Tdr/DataOutPorts](#) wrapper is not present. There is no risk of races here because the TAP data-out ports change in the Update-IR state while all client registers are only reacting to the Update-DR state. When using the data-out port to control the insertion or exclusion of a TAP controller, the TMS signal is clocked on the rising edge of TCK, and the data-out signal changes on the falling edge of TCK thereby removing any risk of races.

Important Note: The bits in the instruction register and, consequently, the value on the ports is overwritten by the following:

- A TAP reset tested in the `test_logic_reset` test in the [PatternsSpecification/Patterns/TestStep/BoundaryScan/RunTest](#) wrapper. The value of the IR register is the determined by the implemented reset value in the hardware.

You can use a separate [TestStep](#) wrapper for the `test_logic_reset` test in which the user IR bits will be overwritten.
- By using the all-1 opcode that is mandated by the IEEE 1149.1 standard.

Arguments

- `count : integer ;`

A property to request a specific number of data-out ports. If the property is set, or defaults to auto, the count is determined to be large enough to satisfy the *range* value of all connection properties. If no connection property is specified, the count is determined to be large enough to satisfy the port_naming values if they are in a non-indexed format (%d).

- `port_naming : port_naming ;`

A property that specifies the naming of the data-out ports. The *port_naming* value has two distinct formats: a single string using an index symbol, or a list of port names with explicit sizes.

When using the indexed format, you specify “base_name[%d]” when you want to use a bus and you specify “base_name%<integer>d” when you want to create a set of scalar ports. In both cases, the range is <count>-1 to 0. Using <integer> in the scalar naming ensures the integer is padded with 0s to be at least <integer> bits wide. For example, “Dout%2d” will create Dout00, Dout01, Dout02, and so on. “Dout%d” and “Dout%1d” mean the same thing. The default is “user_ir_bits[%d]”.

When using a list of port names, you control the exact naming and width of each data-out port. For example, if you specify “mux_sel,mult[2:0],div[2:0]”, you will get exactly 7 data-out ports where the most significant bit is called mux_sel and the least significant bit is called div[0] as illustrated in [DataOutPort Connection Multiplexing](#) of the Tdr/[DataOutPorts](#).

- `multiplexing : on | off | auto ;`

A property that specifies whether to add a multiplexer when making the connection to the specified pin_name of the connection properties. When set to auto, a multiplexer is added unless the pin is unconnected, connected to a constant, or connected to a net with no fanin. As soon as one connection needs multiplexing, an extra data-out port is added to control the select of the multiplexers. The multiplexers are inserted in the direct parent instance of the specified pin_name of the connection properties. See this illustrated in [DataOutPort Connection Multiplexing](#) of the Tdr/DataOutPorts wrapper.

- `connection(range) : pin_name ;`

A repeatable property that specifies connections to make between bits of the data-out ports and existing pins inside the design. Because data-out ports are sources, the same bit can be connected to multiple destinations by simply repeating the connection property with the same range indexes.

If the pin name refers to a bused pin and you are connecting to a full bus, you can omit the bus range if the “[process_dft_specification -no_insertion](#)” option is not used. If you are using the process_dft_specification -no_insertion switch, you must specify the full range of the destination pin because the range cannot be extracted from the design.

Examples

Example 1

The following example illustrates the specification of four data-out ports with connections to pins on a design instance.

```
DftSpecification(MyCore,rtl) {
    IjtagNetwork {
        HostScanInterface(purple) {
            Tap(orange) {
                DataOutPorts {
                    connection(0) : u2/top_green/en ;
                    connection(3:1) : u2/top_green	mode[2:0] ;
                }
            }
        }
    }
}
```

Tap/DeviceIDRegister

A wrapper that specifies that the TAP controller is to be equipped with a device id register.

Usage

```
DftSpecification(module_name, id) {
    IJtagNetwork {
        HostScanInterface(id) {
            Tap(id) {
                DeviceIDRegister {
                    Interface {
                        version_code      : port_name ; // def: version_code[%d]
                        part_number_code : port_name ; // def: part_number_code[%d]
                        manufacturer_id_code: port_name ;
                                         // def: manufacturer_id_code[%d]
                    }
                    capture_source      : internal | external ;
                    instruction_codes : auto | binary, ... ;
                    version_code       : binary ;      // default: 4'h0
                    manufacturer_id_code: binary ;    // default: 11'h0
                    part_number_code   : binary ;    // default: 16'h0
                }
            }
        }
    }
}
```

Description

A wrapper that specifies that the TAP controller is to be equipped with a device id register.

Properties are used to specify the version id, manufacturer id, and the part number codes. When the property `capture_source` is set to external, the version and part_number codes are captured from ports on the TAP controller. The port names are user-specifiable using the `Interface` wrapper. The specified version and part_number codes are used as tie values on the version and part_number code ports when instantiating the TAP controller inside the design.

The tool automatically assigns the instruction codes when you specify `auto` for all instructions. If you want to specify specific binary values, you must specify them for all instructions.

Arguments

- `Interface/version_code : port_name ;`

This property defines the name of the port labelled “version_code” in [Figure 10-19](#). The specified value must include the “[%d]” or “%<integer>d” symbol. The default is “`version_code[%d]`”.

- `Interface/part_number_code : port_name ;`

This property defines the name of the port labelled “part_number_code” in [Figure 10-19](#). The specified value must include the “[%d]” or “%<integer>d” symbol. The default is “`part_number_code[%d]`”.

- Interface/manufacturer_id_code : *port_name* ;

This property defines the name of the port labelled “manufacturer_id_code” in [Figure 10-19](#). The specified value must include the “[%d]” or “%<integer>d” symbol. The default is “manufacturer_id_code[%d]”.

- capture_source : internal | external ;

A property that defines where the capture value of the part number, version and manufacturer_id codes comes from. When the property is set to external, the manufacturer_id_code, version_code and part_number_code properties are captured from ports on the TAP controller. The manufacturer_id_code, version_code and part_number_code properties are used as tie values on the manufacturer_id, version and part_number ports when instantiating the TAP controller inside the design. When the property is set to internal, no ports are created and the capture value is described in the RTL description of the TAP. If you set this property to internal, you will not be able to have version and part_number codes specified in the BondingConfigurations wrapper of the BoundaryScan wrapper. The default value is external.

- instruction_codes : auto | *binary*, ... ;

A property used to define one or many opcodes for the DEVICE_ID instruction. All codes must differ from the other codes by at least one non-X bit. When left to auto, the tool automatically selects a unique code and describes it in the ICL file.

- version_code : *binary* ;

A property that specifies a version id code using a 4-bit binary or hexadecimal number. The default value is “4'h0”.

- manufacturer_id_code : *binary* ;

A property that specifies a manufacturer id code using an 11-bit binary or hexadecimal number. The default value is “11'h0”.

- part_number_code : *binary* ;

A property that specifies a part number code using a 16-bit binary or hexadecimal number. The default value is “16'h0”.

Examples

This example specifies that the TAP controller is to have a device id register. The version and part number codes are encoded as tie values on ports of the TAP controller. This will make it possible to have version and *part_number* codes specified in the BondingConfigurations wrapper of the BoundaryScan wrapper.

```
DftSpecification (module_name, id) {
    IJtagNetwork {
        HostScanInterface(id) {
            Tap(id) {
                DeviceIDRegister {
                    version_code      : 4'h0 ;
                    manufacturer_id_code : 11'hA3 ;
                    part_number_code   : 16'h0105 ;
                }
            }
        }
    }
}
```

Tap/HostIjtag

A repeatable wrapper that specifies the presence of one or many IJTAG host ports on the TAP controller.

Usage

```
DftSpecification(module_name, id) {
    IjtagNetwork {
        HostScanInterface(id) {
            Tap(id) {
                HostIjtag(id) {
                    instruction_codes : auto | binary, ... ;
                    Interface {
                        select          : port_name ; // default: host_%s_to_sel
                        scan_in         : port_name ; // default: host_%s_from_so
                    }
                    Sib(id) {
                    }
                    Tdr(id) {
                    }
                    ScanMux(id) {
                    }
                    DesignInstance(instance_name) {
                    }
                }
            }
        }
    }
}
```

Description

A repeatable wrapper that specifies the presence of one or many IJTAG host ports on the TAP controller.

The optional properties allow you to specify a specific opcode to access each IJTAG host port, and to name the ports. You can then specify any other IJTAG node types inside it.

The tool automatically assigns the instruction codes when you specify auto for all instructions. If you want to specify specific binary values, you must specify them for all instructions.

Arguments

- *id*
A string that uniquely identifies the HostIjtag wrapper. The string contains only letters, numbers, and underscores.
- **instruction_codes** : auto | binary, ... ;
A property that defines one or many opcodes for the instruction that selects the IJTAG host port. All codes must differ from the other codes specified in the other wrappers such as inside the [Tap/HostBScan](#) wrapper by at least one non-X bit and the width must be the

same. When left to auto, the tool automatically selects a unique code and describes it in the ICL file.

- Interface/select : *port_name* ;

This property defines the name of the port labelled “hostX_select” in [Figure 10-19](#). The specified value may include the %s symbol which is replaced by the id of the HostIjtag wrapper. The default is “host_%s_to_sel”.

- Interface/scan_in : *port_name* ;

This property defines the name of the port labelled “hostX_from_so” in [Figure 10-19](#). The specified value may include the %s symbol which is replaced by the id of the HostIjtag wrapper. The default is “host_%s_from_so”.

Examples

This example defines two IJTAG host scan interfaces. The default opcodes and port naming are used.

```
DftSpecification(my_chip,rtl) {
    IjtagNetwork {
        HostScanInterface(tap) {
            Tap(main) {
                HostIjtag(mission) {
                }
                HostIjtag(debug) {
                }
            }
        }
    }
}
```

InSystemTest

Specifies the generation and optional insertion of an IST controller in the design using the DftSpecification wrapper.

Usage

```
DftSpecification (module_name, id) {
    InSystemTest {
        Controller(id) {
            host_interface      : name;           // mutually exclusive
                                                // with DesignInstance
            DesignInstance (instance_name) { // mutually exclusive
                client_interface: name;           // with host_interface
            }
            protocol          : direct_memory_access | cpu_interface;
            data_width        : int;             // required
            parent_instance   : name;           // default: ""
            leaf_instance_name : name;
            async_reset_all_registers : on | off;
            DirectMemoryAccessOptions {
            }
            Interface {
            }
            Connections {
            }
        }
    }
}
```

Description

InSystemTest is an optional wrapper within the DFTSpecification that you use to generate and optionally insert an IST controller in the design. You can run in-system tests during power up of the device (Power-On Self Test or POST) or run on demand during system operation.

The IST controller is a unique, simple alphanumeric *id*. The *id* should start with an alphanumeric character and can contain no special characters except for underscores (_) after the first character. For example, the following controller ids are valid:

```
Controller(1)
Controller(c1)
Controller(controller_1)
```

The Controller wrapper is a repeatable wrapper. You can specify more than one IST controller.

Specify the IST controller using the host_interface property or the DesignInstance wrapper. Use the host_interface property to specify the scan interface that connects the IST controller when the IJTAG network is inserted at the same time as the IST controller. The *name* is the HostScanInterface() wrapper name inside the IjtagNetwork specification.

Use the DesignInstance wrapper to specify the scan interface connected to the controller when the IJTAG network was inserted prior to the IST controller. The *instance_name* is an instance

name of a module with a matching ICL description. Specifying an IST controller without either a pre-existing or co-generated intercept is not allowed.

For details about Tessent MissionMode, refer to the [Tessent MissionMode User's Manual](#).

Arguments

- host_interface : *name* ;

A required property that specifies the scan interface that will be connected to the controller when the IJTAG network is inserted at the same time as the controller. This property points to the HostScanInterface() wrapper inside the IjtagNetwork Specification. This is the interface at which the controller is connected and the in-system test applied. This property cannot be specified with the DesignInstance() wrapper.

- DesignInstance(*instance_name*) {
 client_interface : *name* ;
}

A required wrapper that specifies a design instance with a scan interface that is to be connected to the controller when the IJTAG network is inserted prior to the controller generation. The id of the wrapper is an *instance_name* of a module with matching ICL description or “.” for the current design.

If there are multiple client scan interfaces in the specified instance, point to a single client using the client_interface property.

This wrapper cannot be specified with the host_interface property.

- protocol : direct_memory_access | cpu_interface ;

An optional property that specifies whether a direct memory access or CPU-based access controller is generated. A direct memory access controller is generated if this property is not specified.

- data_width : *int* ;

An required property that specifies the word size of the memory for the direct memory access controller or system data bus width for a CPU-based access controller.

- parent_instance : *name* ;

An optional property that specifies the parent instance *name* of the IST controller. The default is an empty string, “”. The controller is inserted at the top level of the design when this property is not specified.

- leaf_instance_name : *name* ;

An optional property that specifies the instance *name* of the IST controller. The default for *name* is “*designname_passID_tessent_in_system_test_ctrlID*” and cannot be changed.

- async_reset_all_registers : on | off ;

An optional property that specifies whether all registers will be reset using an asynchronous reset input port. By default (off), only a subset of registers that are functionally required to

be reset (such as the FSM state register) will have asynchronous reset. Set this property to on to ensure all registers in the IST controller have an asynchronous reset; this may be required to conform to certain RTL coding guidelines that require all registers to have asynchronous control.

Examples

In the following example, the controller attached to a TAP controller is generated in the same session as the IST controller:

```
DftSpecification(piccpu,rtl) {
    IJtagNetwork {
        HostScanInterface(dft) {
            Tap(t1) {
                HostIjttag(i1) {
                    Sib(sri) {
                        ...
                    }
                    Sib(sti) {
                        ...
                    }
                }
            }
        }
    }
    MemoryBist {
        ijtag_host_node : Sib(mbist);
        ...
    }
    OCC {
        ijtag_host_interface : Sib(occ);
        ...
    }
    InSystemTest {
        Controller(c0) {
            protocol : cpu_interface;
            host_interface : HostScanInterface(dft);
            Connections {
                reset : istb/reset;
                CpuInterface {
                    clock : istb/clock;
                    enable : istb/enable;
                    write_en : istb/write_en;
                    data_in : istb/data_out;
                    data_out : istb/data_in;
                }
            }
        }
    }
}
```

The following dofile snippet shows that you are inserting three IST controllers. These controllers drive the IJTAG scan interface of the design instances m8051_A, m8051_B and piccpu. These are either sub-blocks or physical blocks on which the IJTAG network was previously inserted.

```
...
}

InSystemTest {
    Controller(m8051_A) {
        protocol: cpu_interface;
        DesignInstance(m8051_A) {
            }
        data_width: 8;
        Connections {
            reset: istb/reset;
            CpuInterface {
                clock: istb/clock;
                enable: istb/en1;
                write_en: istb/write_en;
                data_in: istb/data_out[7:0];
                data_out: istb/data_in1;
            }
        }
    }

    Controller(m8051_B) {
        protocol: cpu_interface;
        DesignInstance(m8051_B) {
            client_interface: C0;
        }
        data_width: 10;
        Connections {
            reset: istb/reset;
            CpuInterface {
                clock: istb/clock;
                enable: istb/en2;
                write_en: istb/write_en;
                data_in: istb/data_out[9:0];
                data_out: istb/data_in2;
            }
        }
    }

    Controller(piccpu) {
        protocol: cpu_interface;
        DesignInstance(piccpu) {
            }
        data_width: 12;
        Connections {
            reset: istb/reset;
            CpuInterface {
                clock: istb/clock;
                enable: istb/en3;
                write_en: istb/write_en;
                data_in: istb/data_out;
                data_out: istb/data_in3;
            }
        }
    }
}
```

DirectMemoryAccessOptions

An optional wrapper that specifies properties related to the direct memory access IST controller.

Usage

```
DftSpecification (module_name, id) {
    InSystemTest {
        Controller(id) {
            DirectMemoryAccessOptions {
                begin_address      : int; // default: 0
                end_address        : int; // default:
                                         // max addressable memory
                address_width     : int; // required
                max_wait_cycles   : int; // default: 1 million (20 bits)
                max_test_program_count : int; // default: 1
            }
        }
    }
}
```

Description

An optional wrapper that groups properties related to the direct memory access controller.

The begin_address and end_address arguments specify the memory space that is utilized for in-system test when sharing with a functional memory. The controller address counter is set to begin_address when the controller is reset. The tool generates an error message during pattern generation if the entire program does not fit in memory between the begin_address and end_address.

Arguments

- begin_address : *int* ;
An optional property used to specify the begin address for the memory block. The default is 0.
- end_address: *int* ;
An optional property used to specify the end address for the memory block. The default is the max addressable memory size.
- address_width: *int* ;
A required property used to specify the design memory width.
- max_wait_cycles: *int* ;
An optional property used to specify the max wait cycles. The default is 1 million cycles, which corresponds to a 20 bit wait register.
- max_test_program_count: *int* ;
An optional property used to specify the max test program count. The default is 1.

Interface

An optional wrapper that specifies the interface port names for the IST controller.

Usage

```
DftSpecification (module_name, id) {
    InSystemTest {
        Controller(id) {
            Interface {
                reset : port_name;      // default: reset
                reset_polarity: active_high | active_low;
                test_active : port_name; // default: test_active
                CpuInterface {
                }
                DirectMemoryAccess {
                }
                TapScanInterface {
                }
                IjtagScanInterface {
                }
            }
        }
    }
}
```

Description

An optional wrapper that specifies the interface port names for the IST controller.

The TapScanInterface tck, trst, tms, tdi, tdo, and tdo_en ports specify the client side of the controller connected to the design source pins (that is, the pads). Ports to_tck, to_trst, to_tms, to_tdi, from_tdo, and from_tdo_en specify the host side of the controller connected to the instrument interface, such as TAP controller pins.

Arguments

- **reset : *port_name* ;**
An optional property that defines the asynchronous reset input port of the IST controller.
- **reset_polarity : active_high | active_low ;**
An optional property that defines the polarity of the reset input port. A reset polarity of active_high applies the reset. A reset polarity of active_low does not apply the reset. The default is active_low.
- **test_active : *port_name* ;**
An optional property that defines the test active output port name. The default *port_name* is test_active. This property is typically used to make connections when test mode is running. For example, use the test_active property to configure the memory to be accessible by the IST controller during test.

CpuInterface

An optional wrapper defined within the Interface wrapper that specifies interface port names for the CPU-based access IST controller.

Usage

```
DftSpecification (module_name, id) {
    InSystemTest {
        Controller(id) {
            Interface {
                CpuInterface {
                    clock      : port_name; // default: cpu_interface_clock
                    data_in    : port_name; // default: data_from_cpu[%d]
                    data_out   : port_name; // default: data_to_cpu[%d]
                    write_en   : port_name; // default: write_en_from_cpu
                    enable     : port_name; // default: cpu_interface_en
                }
            }
        }
    }
}
```

Description

The CpuInterface wrapper is an optional wrapper that defines interface port names for the CPU-based access controller. The tool generates the CPU-based access controller based on a DftSpecification. During IJTAG pattern generation, the tool generates a Verilog testbench that uses Verilog tasks to mimic CPU operation. This testbench directly forces and observes the internal design pins and cannot be used as a tester program. All control signals are asserted at the internal pins on the controller boundary.

Arguments

- **clock : *port_name* ;**
An optional property that specifies the name of the clock input for the controller. The default *port_name* is `cpu_interface_clock`. The CPU's native clock is not required to be synchronous with this clock. This clock will drive the connected IJTAG network in test mode.
- **data_in : *port_name* ;**
An optional property that specifies the name of the parallel input bus port. The default *port_name* is “`data_from_cpu[%d]`”, where `%d` is a literal string that is expanded to the range of the vector. This bus contains IST controller instruction opcode and data to write to the IJTAG network through the TAP controller. The two most significant bits represent an opcode for the controller and the remaining bits are the write data that will be shifted into the network.
- **data_out : *port_name* ;**
An optional property that specifies the name of the parallel output bus port. The default *port_name* is “`data_to_cpu[%d]`”, where `%d` is a literal string that is expanded to the range

of the vector. This bus contains the status of the controller read operation and the data read from the IJTAG network. The two most significant bits represent a status code and the remaining bits are the read data shifted out from the network.

- `write_en : port_name ;`

An optional property that specifies the name of the IST controller write enable input port. The default *port_name* is `write_en_from_cpu`. This input signal indicates valid data is present in the DataIn bus and is to be asserted by the CPU after writing to DataIn.

- `enable : port_name ;`

An optional property that specifies the name of the IST controller enable port. The default *port_name* is `cpu_interface_en`. This port is the input signal used to enable InSystemTest mode. This signal should be asserted and stay asserted during the entire test. This signal is also used outside the controller to provide multiplexed access to the IJTAG network inputs from the controller.

DirectMemoryAccess

An optional wrapper defined within the Interface wrapper that groups properties related to the direct memory access IST controller.

Usage

```
DftSpecification (module_name, id) {
    InSystemTest {
        Controller(id) {
            Interface {
                DirectMemoryAccess {
                    clock : port_name; // default: dma_clock
                    test_program_index: port_name; // default:
                                                // dma_test_program[%d]
                    test_program_done : port_name; // default:
                                                // dma_test_program_done
                    fail_flag : port_name; // default: dma_fail_flag
                    mem_address : port_name; // default: dma_address[%d]
                    mem_data : port_name; // default: dma_data[%d]
                    enable : port_name; // default: dma_en
                }
            }
        }
    }
}
```

Description

The DirectMemoryAccess wrapper is an optional wrapper defined within the Interface wrapper that groups properties related to the direct memory access controller. This wrapper is applied when using the direct memory access protocol.

Arguments

- **clock : *port_name* ;**
An optional property that specifies the name of the controller or direct memory access controller clock input port. The default *port_name* is *dma_clock*.
- **test_program_index : *port_name* ;**
An optional property that specifies the name of the test program index input port. The default *port_name* is *dma_test_program[%d]*, where %d is a literal string that is expanded to the range of the vector during execution. Use this property only when multiple test programs exist.
- **test_program_done : *port_name* ;**
An optional property that specifies the name of the test program done output port. The default *port_name* is *dma_test_program_done*.

- `fail_flag : port_name ;`

An optional property that specifies the name of the fail flag output port. The default *port_name* is `dma_fail_flag`. Use this port to determine test status. The signal indicates when mismatches between read and expect data has occurred. This signal is cleared when the FSM goes to the Idle state.

- `mem_address : port_name ;`

An optional property that specifies the name of the memory address output port. The default *port_name* is “`dma_address[%d]`”, where `%d` is a literal string that is expanded to the range of the vector. This bus provides the address for the next memory read. When memory is shared with functional logic, ensure the controller has exclusive access to the memory address bus.

- `mem_data : port_name ;`

An optional property that specifies the name of the memory data input port. The default *port_name* is “`dma_data[%d]`”, where `%d` is a literal string that is expanded to the range of the vector during processing. Use this input bus to provide the data corresponding to the current address.

- `enable : port_name;`

An optional property that specifies the name of the enable input port. The default *port_name* is `dma_en`. Use this port to start the in-system test. The enable must stay active for the entire duration of the test. This signal can be de-asserted at anytime to stop a running test.

TapScanInterface

An optional wrapper defined within the Interface wrapper that specifies the interface port names when the IST controller uses a TAP controller to execute tests.

Usage

```
DftSpecification (module_name, id) {
    InSystemTest {
        Controller(id) {
            Interface {
                TapScanInterface {
                    tck      : port_name; // default: ijttag_tck
                    trst     : port_name; // default: trst
                    tms      : port_name; // default: tms
                    tdi      : port_name; // default: tdi
                    tdo      : port_name; // default: tdo
                    tdo_en   : port_name; // default: tdo_en
                    to_tck   : port_name; // default: to_ijtag_tck
                    to_trst  : port_name; // default: to_trst
                    to_tms   : port_name; // default: to_tma
                    to_tdi   : port_name; // default: to_tdi
                    from_tdo : port_name; // default: from_tdo
                    from_tdo_en: port_name; // default: from_tdo_en
                }
            }
        }
    }
}
```

Description

The TapScanInterface wrapper defined within the Interface wrapper is an optional wrapper that specifies the interface port names when the IST controller uses a TAP controller to execute tests.

The top-level TAP signals are tck, trst, tms, tdi, and tdo. These signals are brought into the controller for multiplexing with the controller generated signals. The output signals from the controller are to_tck, to_trst, to_tms, to_tdi, and from_tdo.

Arguments

- `tck : port_name ;`
An optional property that specifies the name of the test clock input port. The default *port_name* is ijttag_tck.
- `trst : port_name ;`
An optional property that specifies the name of the test reset input port. The default *port_name* is trst.
- `tms : port_name ;`
An optional property that specifies the name of the tms input port. The default *port_name* is tms.

- `tdi : port_name ;`
An optional property that specifies the name of the tdi input port. The default *port_name* is `tdi`.
- `tdo : port_name ;`
An optional property that specifies the name of the tdo output port. The default *port_name* is `tdo`.
- `tdo_en : port_name ;`
An optional property that specifies the name of the tdo enable input port. The default *port_name* is `tdo_en`.
- `to_tck : port_name ;`
An optional property that specifies the name of the output clock port. The default *port_name* is `to_ijtag_tck`. This property handles the output signal from the IST controller. When the controller is active the clock input of the controller drives this port, otherwise the tck input drives this port.
- `to_trst : port_name ;`
An optional property that specifies the name of the output test reset port. The default *port_name* is `to_trst`. This property handles the output signal from the IST controller that is held inactive when the controller is running, otherwise it is driven by the top-level trst port.
- `to_tms : port_name ;`
An optional property that specifies the name of the output tms port. The default *port_name* is `to_tms`. This property handles the output signal from the IST controller that is multiplexed with the top-level tms port at the input of the TAP controller.
- `to_tdi : port_name ;`
An optional property that specifies the name of the output tdi port. The default *port_name* is `to_tdi`. This property handles the output signal from the IST controller that is multiplexed with the top-level tdi port at the source of the TAP controller `tdi` input.
- `from_tdo : port_name ;`
An optional property that specifies the name of the from tdo output port. The default *port_name* is `from_tdo`. This property handles the input signal to the IST controller that comes from the internal tdo signal (before the tristate buffer) of the TAP controller.
- `from_tdo_en : port_name ;`
An optional property that specifies the name of the output tdo enable port. The default *port_name* is `from_tdo_en`.

IjtagScanInterface

An optional wrapper defined within the Interface wrapper that specifies the interface port names when the IST controller uses an IJTAG scan interface to execute tests.

Usage

```
DftSpecification (module_name, id) {
    InSystemTest {
        Controller(id) {
            Interface {
                IjtagScanInterface {
                    tck      : port_name; // default: ijtag_tck
                    reset   : port_name; // default: ijtag_reset
                    select   : port_name; // default: ijtag_sel
                    capture_en : port_name; // default: ijtag_ce
                    shift_en  : port_name; // default: ijtag_se
                    update_en : port_name; // default: ijtag_ue
                    scan_in   : port_name; // default: ijtag_si
                    scan_out   : port_name; // default: ijtag_so

                    to_tck      : port_name; // default: to_ijtag_tck
                    to_reset   : port_name; // default: to_ijtag_reset
                    to_select   : port_name; // default: to_ijtag_sel
                    to_capture_en: port_name; // default: to_ijtag_ce
                    to_shift_en : port_name; // default: to_ijtag_se
                    to_update_en : port_name; // default: to_ijtag_ue
                    to_scan_in   : port_name; // default: to_ijtag_si
                    from_scan_out: port_name; // default: from_ijtag_so
                }
            }
        }
    }
}
```

Description

The IjtagScanInterface wrapper is an optional wrapper defined within the Interface wrapper that specifies the interface port names when the IST controller uses an IJTAG scan interface.

Arguments

- **tck : *port_name*;**
An optional property that specifies the name of the test clock port. The default *port_name* is ijtag_tck.
- **reset : *port_name*;**
An optional property that specifies the name of the reset port. The default *port_name* is ijtag_reset.
- **select : *port_name*;**
An optional property that specifies the name of the select port. The default *port_name* is ijtag_sel.

- `capture_en : port_name;`
An optional property that specifies the name of the enable capture port. The default *port_name* is `ijtag_ce`.
- `shift_en : port_name;`
An optional property that specifies the name of the enable shift port. The default *port_name* is `ijtag_se`.
- `update_en : port_name;`
An optional property that specifies the name of the enable update port. The default *port_name* is `ijtag_ue`.
- `scan_in : port_name;`
An optional property that specifies the name of the scan in port. The default *port_name* is `ijtag_si`.
- `scan_out : port_name;`
An optional property that specifies the name of the scan out port. The default *port_name* is `ijtag_so`.
- `to_tck : port_name;`
An optional property that specifies the name of the output clock port. The default *port_name* is `to_ijtag_tck`.
- `to_reset : port_name;`
An optional property that specifies the name of the output reset port. The default *port_name* is `to_ijtag_reset`.
- `to_select : port_name;`
An optional property that specifies the name of the select output port. The default *port_name* is `to_ijtag_sel`.
- `to_capture_en : port_name;`
An optional property that specifies the name of the output capture enable port. The default *port_name* is `to_ijtag_ce`.
- `to_shift_en : port_name;`
An optional property that specifies the name of the output shift enable port. The default *port_name* is `to_ijtag_se`.
- `to_update_en : port_name;`
An optional property that specifies the name of the output enable update port. The default *port_name* is `to_ijtag_ue`.
- `to_scan_in : port_name;`
An optional property that specifies the name of the output scan in port. The default *port_name* is `to_ijtag_si`.

- `from_scan_out : port_name;`

An optional property that specifies the name of the from scan output port. The default *port_name* is `from_ijtag_so`.

Connections

An optional wrapper used to define the design node used to connect the corresponding IST controller pin.

Usage

```
DftSpecification (module_name, id) {
    InSystemTest {
        Controller(id) {
            Connections {
                reset           : port_pin_name; // required
                test_active     : port_pin_name; // default: "" (no connection)
                CpuInterface {
                    // required
                }
                DirectMemoryAccess {
                    // required
                }
            }
        }
    }
}
```

Description

The Connections wrapper is an optional wrapper used to define the design node used to connect the corresponding IST controller pin. Connections do not exist for the TapScanInterface intercept pins. The intercept pins are connected to the location defined by host_interface or DesignInstance() arguments.

When design nodes for the Connections wrapper do not exist, or you do not want to make connections, specify “0” for the input *port_pin_name* and empty string, “”, for the output *port_pin_name*. This includes the reset and test_active properties, as well as the properties defined within the CpuInterface and DirectMemoryAccess wrappers.

Pin names should be existing pin names from the design. Port names can be any name, but must be the correct direction.

Arguments

- *reset* : *port_pin_name*;
A required property that specifies the reset input port or pin name. This property specifies the asynchronous input, for example a design’s reset or poweron_reset.
- *test_active* : *port_pin_name*;
An optional property that specifies the test active output port or pin name. The default is an empty string, “”, if there is no connection.

CpuInterface

A required wrapper defined within the Connections wrapper that specifies the required input and output port or pin names used by the CPU interface.

Usage

```
DftSpecification (module_name, id) {
    InSystemTest {
        Controller(id) {
            Connections {
                CpuInterface {
                    clock : port_pin_name; // required input
                    data_in : port_pin_name; // required input
                    data_out: port_pin_name; // required output
                    write_en: port_pin_name; // required input
                    enable : port_pin_name; // required input
                }
            }
        }
    }
}
```

Description

The CpuInterface wrapper is a required wrapper defined within the Connections wrapper that specifies the required input and output port or pin names used by the CPU interface.

When design nodes for the Connections wrapper do not exist or you do not want to make connections, specify “0” for the input *port_pin_name* and empty string, “”, for the output *port_pin_name*.

Arguments

- *clock* : *port_pin_name* ;
A required property that specifies the clock input port or pin name. The CPU’s native clock is not required to be synchronous with this clock. This clock will drive the connected IJTAG network in test mode.
- *data_in* : *port_pin_name* ;
A required property that specifies the name of the parallel input bus port or pin name. This bus contains IST controller instruction opcode and data to write to the IJTAG network through the TAP controller. The two most significant bits represent an opcode for the controller and the remaining bits are the write data that will be shifted into the network.
- *data_out* : *port_pin_name* ;
A required property that specifies the name of the parallel output bus port or pin name. This bus contains the status of the controller read operation and the data read from the IJTAG network. The two most significant bits represent a status code and the remaining bits are the read data shifted out from the network.

- `write_en : port_pin_name ;`

A required property that specifies the write enable input port or pin name. This input signal indicates valid data is present in the DataIn bus and is to be asserted by the CPU after writing to DataIn.

- `enable : port_pin_name ;`

A required property that specifies the name of the IST controller enable input port or pin name. This port is the input signal used to enable In-System Test mode. This signal should be asserted and stay asserted during the entire test. This signal is also used outside the IST controller to provide multiplexed access to the IJTAG network inputs from the controller.

DirectMemoryAccess

A required wrapper defined within the Connections wrapper that groups properties related to the direct memory access IST controller.

Usage

```
DftSpecification (module_name, id) {
    InSystemTest {
        Controller(id) {
            Connections {
                DirectMemoryAccess {
                    clock : port_pin_name; // required
                    test_program_index: port_pin_name; // required
                    test_program_done : port_pin_name; // required
                    fail_flag : port_pin_name; // required
                    mem_address : port_pin_name; // required
                    mem_data : port_pin_name; // required
                    enable : port_pin_name; // required
                }
            }
        }
    }
}
```

Description

The DirectMemoryAccess wrapper is a required wrapper defined within the Connections wrapper that groups properties related to the direct memory access controller.

When design nodes for the Connections wrapper do not exist or you do not want to make connections, specify “0” for the input *port_pin_name* and empty string, “”, for the output *port_pin_name*.

Arguments

- *clock* : *port_pin_name* ;

A required property that specifies the input clock port or pin name for the IST controller. The CPU’s native clock is not required to be synchronous with this clock. This clock will drive the connected IJTAG network in test mode.

- *test_program_index* : *port_pin_name* ;

A required property that specifies the name of the test program index input port. Use this property only when multiple test programs exist.

- *test_program_done* : *port_pin_name* ;

A required property that specifies the test program done output port or pin name.

- *fail_flag* : *port_pin_name* ;

A required property that specifies the fail flag output port or pin name. Use this port to determine test status. The signal indicates when mismatches between read and expect data have occurred. This signal is cleared when the FSM goes to the Idle state.

- mem_address : *port_pin_name* ;
A required property that specifies the memory address output port or pin name. This bus provides the address for the next memory read. When memory is shared with functional logic, ensure the controller has exclusive access to the memory address bus.
- mem_data : *port_pin_name* ;
A required property that specifies the memory data input port or pin name. This bus provides the data corresponding to the current address.
- enable : *port_pin_name* ;
A required property that specifies the input enable port or pin name. This input enables InSystemTest mode and should be asserted and stay asserted during the entire test. You can also use this signal outside the IST controller to provide multiplexed access to the IJTAG network inputs from the controller.

EmbeddedBoundaryScan

Specifies the creation of a boundary scan segment inside a module.

Usage

```
DftSpecification(module_name,id) {
    EmbeddedBoundaryScan {
        pad_io_ports           : port_name, ... ;
        interface_parent_instance : parent_instance ;
        outputs_per_enable_cell : int ; // default: 16 *DefSpec
        Interface {
            // *DefSpec
        }
        ImplementationOptions { // *DefSpec
        }
        BoundaryScanCellOptions {
        }
        LogicalGroups {
        }
        AuxiliaryInputOutputPorts {
        }
        ACModeOptions {
        }
        EnableGroups {
        }
        InternalBScanCells {
        }
        InternalBscanSegments {
        }
    }
}
```

Description

A wrapper that specifies the creation of a boundary scan segment inside a module. This module can then be reused as a building block when constructing the boundary scan chain at the next level up. This feature is useful in two situations. The first usage is when you have a physical region containing pads and you want to insert the boundary-scan cells into it before laying it out. The second usage is when you want to insert the boundary-scan cells into non-unique sub-modules without having to uniquify them. You can make the sub-module the current design, insert a boundary scan segment into it, and then reuse the module more than once at the next level.

A *.bcd* file containing a BoundaryScan wrapper (see “[Tessent Core Description](#)” on page 3755) is created for the current design. Once loaded in memory, the tool automatically recognizes the existing boundary scan segments in the design and includes them in the boundary scan chain at the current level. The legacy *.lvbscan* file format is also natively supported and translated into the current BoundaryScan wrapper syntax when loaded into Tessent Shell. Refer to the [set_module_matching_options](#) and the “[set_design_sources -format](#)” commands to learn how to have them automatically searched and loaded. Refer to the [read_core_descriptions](#) command to learn how to explicit load them in.

Arguments

- `pad_io_ports : port_name, ... ;`

A property that lists all ports that are to be equipped with a boundary-scan cell. Those ports must all be directly connected to an input and/or output pad cell. The order of the list is used to order the boundary scan segment where the cell associated with the first port is closer to scanin and the cell associated with the last port is closer to scanout. You have to list each port one by one; no wildcards are allowed. However you can use the `%#d[left_bit:right_bit]` syntax to specify a group of numbered ports. A bused port can be specified with the order of the index following the required order of the boundary scan segment, and it does not necessarily have to be the order in which it is declared in the design. For example, the bus `GPIO[7:0]` can be specified as `GPIO[4:7], GPIO[0:3]` to specify that bit 4 is closest to scanin and is followed by bit 5 even if the bus is declared with the larger index on the left.

This property is automatically populated by the [create_dft_specification](#) command with the port list you have specified with the [set_boundary_scan_port_options](#) -pad_io_ports option. The port list is physically ordered if you read in a DEF file using the [read_def](#) command.

- `interface_parent_instance : parent_instance ;`

An optional property that identifies the design module in which the tool will place the boundary scan interface. The default placement will be at the top level if this property is not specified.

- `outputs_per_enable_cell : int ;`

An optional property that instructs the tool to limit the number of output pins controlled by a given output enable cell. If the enable pin of the output pad cell is tied on or off, the tool is free to assign any output pad cell to any given enable cell in order to meet the outputs_per_enable_cell constraints. If, on the other hand, a group of output pad cells have their enable pin controlled by a single functional net, the tool will insert N enable boundary-scan cells and automatically separate the fanout of the enable signal such that the fanout of each enable cell is smaller than the specified outputs_per_enable_cell value. The splitting of the functional enable fanout is illustrated in the example of the [LogicalGroups](#) wrapper in [Figure 10-25](#) and [Figure 10-26](#).

Examples

The following example defines a boundary scan chain associated with the `GPIO[7:0]` ports inside a module. This module will then be used as a building block for the boundary scan chain at the next level up, either to construct a larger segment in a parent module or as part of the chain for a chip.

```
DftSpecification(my_block,rtl) {
    EmbeddedBoundaryScan {
        pad_io_ports : GPIO[4:7], GPIO[0:3] ;
    }
}
```

Interface

Specifies the naming of all ports created on the current design to provide access to the boundary scan segment.

Usage

```
DftSpecification(module_name, id) {
    EmbeddedBoundaryScan {
        Interface { *DefSpec
            select : port_naming ; // bscan_select
            reset : port_naming ; // bscan_reset
            force_disable : port_naming ; // bscan_force_disable
            select_jtag_input : port_naming ; // bscan_select_jtag_input
            select_jtag_output : port_naming ; // bscan_select_jtag_output
            bscan_clock : port_naming ; // bscan_clock
            capture_en : port_naming ; // bscan_capture_en
            shift_en : port_naming ; // bscan_shift_en
            update_en : port_naming ; // bscan_update_en
            scan_in : port_naming ; // bscan_scan_in
            scan_out : port_naming ; // bscan_scan_out
            auxiliary_output : port_naming ; // bscan_%s_aux_out
            auxiliary_output_enable : port_naming ; // bscan_%s_aux_out_en
            auxiliary_input : port_naming ; // bscan_%s_aux_in
            auxiliary_input_enable : port_naming ; // bscan_%s_aux_in_en
            ac_init_clock0 : port_naming ; // bscan_ac_init_clk0
            ac_init_clock1 : port_naming ; // bscan_ac_init_clk1
            ac_signal : port_naming ; // bscan_ac_signal
            ac_mode_en : port_naming ; // bscan_ac_mode_en
        }
    }
}
```

Description

A wrapper that specifies the naming of all ports created on the current design to provide access to the boundary scan segment.

Arguments

- `select : port_naming ;`

An optional property that defines the name of the select signal. The select signal is used to enable or disable the embedded boundary scan interface of the core. When not specified, the port is named “bscan_select”. Setting this value in the [DefaultsSpecification](#) implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.

- `reset : port_naming ;`

An attribute used to provide the name for the port carrying the reset function. When not specified, the port is named “bscan_reset”. The reset function is active low.

- **force_disable : *port_naming* ;**
An attribute used to provide the name for the port carrying the force_disable function. When not specified, the port is named “bscan_force_disable”.
- **select_jtag_input : *port_naming* ;**
An attribute used to provide the name for the port carrying the select_jtag_input function. When not specified, the port is named “bscan_select_jtag_input”.
- **select_jtag_output : *port_naming* ;**
An attribute used to provide the name for the port carrying the select_jtag_output function. When not specified, the port is named “bscan_select_jtag_output”.
- **bscan_clock : *port_naming* ;**
An attribute used to provide the name for the port carrying the bscan_clock function. When not specified, the port is named “bscan_clock”.
- **capture_en : *port_naming* ;**
An attribute used to provide the name for the port carrying the capture_en function. When not specified, the port is named “bscan_capture_en”.
- **shift_en : *port_naming* ;**
An attribute used to provide the name for the port carrying the shift_en function. When not specified, the port is named “bscan_shift_en”.
- **update_en : *port_naming* ;**
An attribute used to provide the name for the port carrying the update_en function. When not specified, the port is named “bscan_update_en”.
- **scan_in : *port_naming* ;**
An attribute used to provide the name for the port carrying the scan_in function. When not specified, the port is named “bscan_scan_in”.
- **scan_out : *port_naming* ;**
An attribute used to provide the name for the port carrying the scan_out function. When not specified, the port is named “bscan_scan_out”.
- **auxiliary_output : *port_naming* ;**
An attribute used to provide the name for the port carrying the auxiliary_output function. When not specified, the port is named “bscan_%s_aux_out”. The presence of the %s symbol somewhere in the string is required. The symbol %s is replaced by the port_name the auxiliary output is associated with. If the port is an element of a bus, the opening bracket is replaced by an underscore. For example, the default name for the auxiliary output port associated with port GPIO[4] is “bscan_GPIO_4_aux_out”.
- **auxiliary_output_enable : *port_naming* ;**
An attribute used to provide the name for the port carrying the auxiliary_output_enable function. When not specified, the port is named “bscan_%s_aux_out_en”. The presence of

the %s symbol somewhere in the string is required. The symbol %s is replaced by the port_name the auxiliary output enable is associated with. If the port is an element of a bus, the opening bracket is replaced by an underscore. For example, the default name for the auxiliary output enable port associated with port GPIO[4] is “bscan_GPIO_4_aux_out_en”.

- auxiliary_input : *port_naming*, ... ;

An attribute used to provide the name for the port carrying the auxiliary_input function. When not specified, the port is named “bscan_%s_aux_in”. The presence of the %s symbol somewhere in the string is required. The symbol %s is replaced by the port_name the auxiliary input is associated with. If the port is an element of a bus, the opening bracket is replaced by an underscore. For example, the default name for the auxiliary input port associated with port GPIO[4] is “bscan_GPIO_4_aux_in”.

- auxiliary_input_enable : *port_naming*, ... ;

An attribute used to provide the name for the port carrying the auxiliary_input_enable function. When not specified, the port is named “bscan_%s_aux_in_en”. The presence of the %s symbol somewhere in the string is required. The symbol %s is replaced by the port_name the auxiliary output enable is associated with. If the port is an element of a bus, the opening bracket is replaced by an underscore. For example, the default name for the auxiliary input enable port associated with port GPIO[4] is “bscan_GPIO_4_aux_in_en”. This function is rarely used. It is only used when the input pad cell has a built-in JTAG mux or when the input pad buffer has a bscan_select port function.

- ac_init_clock0 : *port_naming* ;

An attribute used to provide the name for the port carrying the ac_init_clock0 function, which has a low “off” state. When not specified, the port is named “bscan_ac_init_clk0”. This port is only created when AC pads are present.

- ac_init_clock1 : *port_naming* ;

An attribute used to provide the name for the port carrying the ac_init_clock1 function, which has a high “off” state. When not specified, the port is named “bscan_ac_init_clk1”. This port is only created when AC pads are present.

- ac_signal : *port_naming* ;

An attribute used to provide the name for the port carrying the ac_signal function. When not specified, the port is named “bscan_ac_signal”. This port is only created when AC pads are present.

- ac_mode_en : *port_naming* ;

An attribute used to provide the name for the port carrying the ac_mode_en function. When not specified, the port is named “bscan_ac_mode_en”. This port is only created when AC pads are present.

Examples

The following example changes the interface port naming by adding the prefix “ts_bscan_” to all created ports. Not all port names will be affected because it will depend on the values

specified in the [ImplementationOptions](#) wrappers and the use of those functions in reused BScanSegment elements.

```
DftSpecification(my_block,rtl) {
    EmbeddedBoundaryScan {
        Interface {
            force_disable : ts_bscan_force_disable ;
            select_jtag_input : ts_bscan_select_jtag_input ;
            select_jtag_output : ts_bscan_select_jtag_output ;
            capture_shift_clock : ts_bscan_cs_clock ;
            capture_shift_clock_inv : ts_bscan_cs_clock_inv ;
            update_clock : ts_bscan_update_clock ;
            capture_en : ts_bscan_capture_en ;
            shift_en : ts_bscan_shift_en ;
            update_en : ts_bscan_update_en ;
            scan_in : ts_bscan_scan_in ;
            scan_out : ts_bscan_scan_out ;
            auxiliary_output : ts_bscan_%s_aux_out ;
            auxiliary_output_enable : ts_bscan_%s_aux_out_en ;
            auxiliary_input : ts_bscan_%s_aux_in ;
            auxiliary_input_enable : ts_bscan_%s_aux_in_en ;
            ac_init_clock0 : ts_bscan_ac_init_clk0 ;
            ac_init_clock1 : ts_bscan_ac_init_clk1 ;
            ac_signal : ts_bscan_ac_signal ;
            ac_mode_en : ts_bscan_ac_mode_en ;
        }
    }
}
```

ImplementationOptions

Specifies implementation options when building the boundary-scan cells.

Usage

```
DftSpecification(module_name, id) {
    BoundaryScan | EmbeddedBoundaryScan {
        ImplementationOptions {
            clocking           : tck | gated_tck | gated_tck_inv ; // *DefSpec
            update_stage       : flop | latch ;
            scan_path_retiming : flop | latch ;
        }
    }
}
```

Description

A wrapper that specifies implementation options when building the boundary-scan cells. The options consist of the clocking, and the use of latches or flip-flops as an update stage and for scan path retiming.

Arguments

- **clocking: tck | gated_tck | gated_tck_inv ;**

A property that specifies how the clocking of the boundary-scan cell should be constructed. When specifying tck, the boundary-scan cells are clocked with the free-running TCK clock and the capture and shift is enabled using the capture_en and shift_en functions. This option requires one extra multiplexer per boundary-scan cell as compared to the gated_tck or gated_tck_inv implementations. When specifying gated_tck, a gated low version of TCK is used and the gating lets the TCK go through during the capture and shift enable pulse. When specifying gated_tck_inv, a gated high version of TCK is used and the gating lets the inverted TCK go through during the capture and shift enable pulse. All three clocking specifications behaves identically in IEEE 1149.1 mode. Using TCK versus the other two gated TCK options is a trade-off between area and the number and sizes of clock trees. Note that in all three cases, the boundary-scan cells are always built such that the scanin of each cell is strobed on the rising edge of TCK and the scanout is launched off the negedge of TCK to make sure boundary-scan cells will always work without having to balance TCK to all boundary scan cells which makes the ground bounce issue worst.

The gated_tck_inv option is a legacy clocking mode and is the one that is compatible with the existing LogicVision burst mode architecture. For more information, see the “[BurstMode Logic BIST Architecture](#)” section in the *LV Flow User’s Manual*.

[Table 10-3](#) illustrates the boundary scan cell implementations based on the clocking, update_stage and scan_path_retiming values.

- **update_stage: flop | latch ;**

A property that specifies if the update stage is to be implemented using a latch or a flop.

[Table 10-3](#) illustrates the boundary scan cell implementations based on the clocking, update_stage, and scan_path_retiming values.

- scan_path_retiming : flop | latch ;

A property that specifies if the scan path retiming element is to be implemented using a latch or a flop.

Table 10-3 illustrates the boundary scan cell implementations based on the clocking, update_stage, and scan_path_retiming values. Refer to **Table 10-5** to see the implementation of an input and sample_only boundary scan cell using the default implementation options. The following function abbreviations are used in the table figures:

- se — shift enable
- ce — capture enable
- ue — update enable
- si — scan input
- so — scan output
- sji — select jtag input
- sjo — select jtag output
- tck — test clock

Table 10-3. Illustration of Different Boundary Scan Implementations

- 1) This example shows how the boundary-scan cells are constructed when clocking is set to gated_tck, and update_stage and scan_path_retiming are both set to latch.

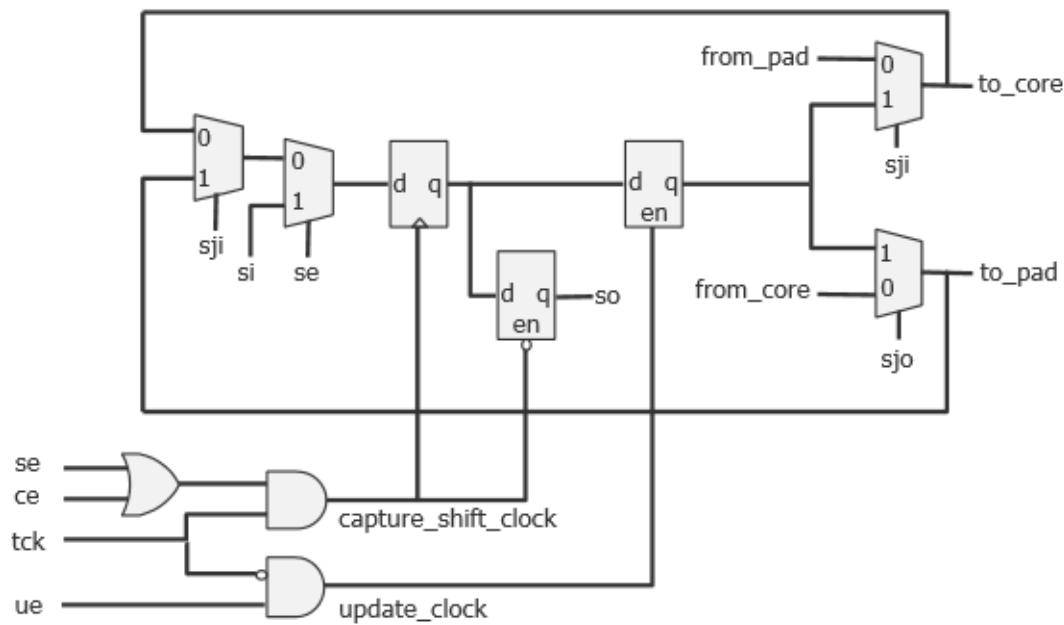

Table 10-3. Illustration of Different Boundary Scan Implementations (cont.)

2) This example shows how the boundary-scan cells are constructed when the clocking is set to gated_tck and update_stage and scan_path_retimng are both set to flop. Compared to the prior example, this shows how changing update_stage and scan_path_retimng from latch to flop simply converts the latch into a flop.

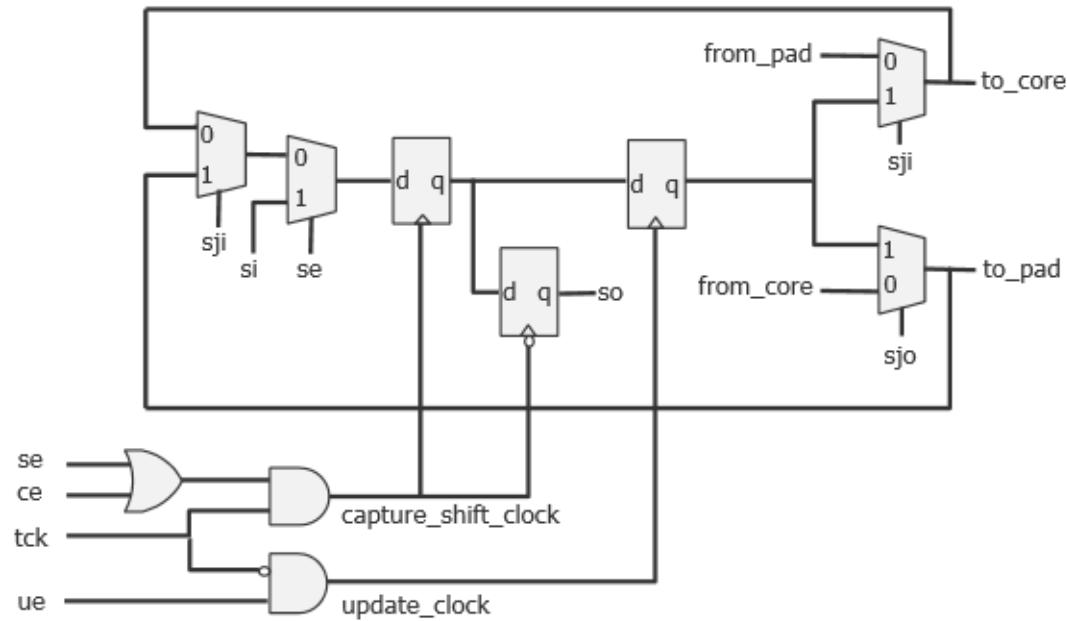

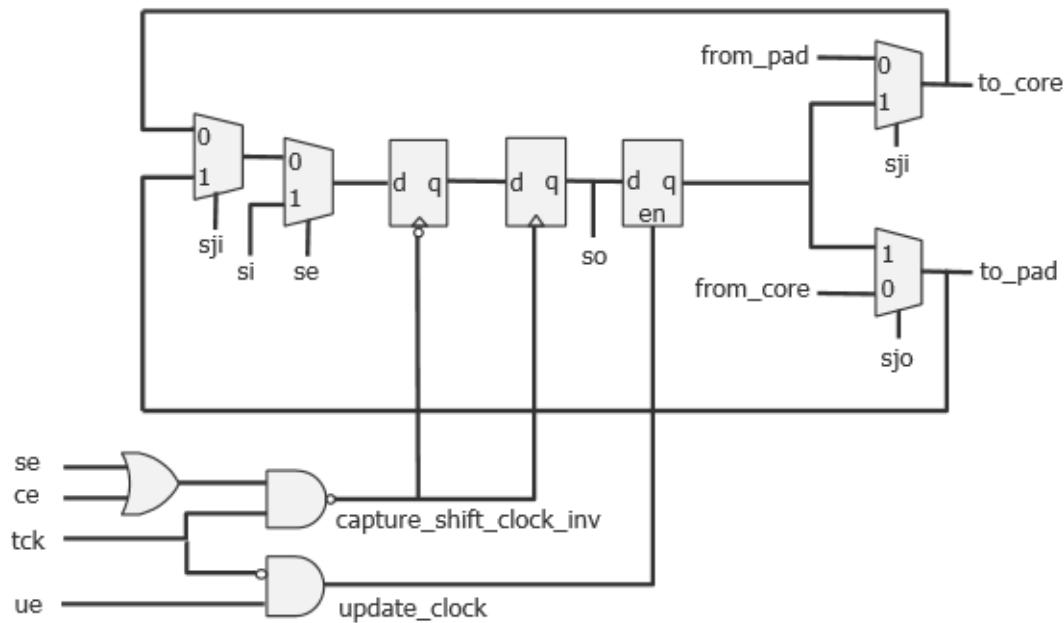

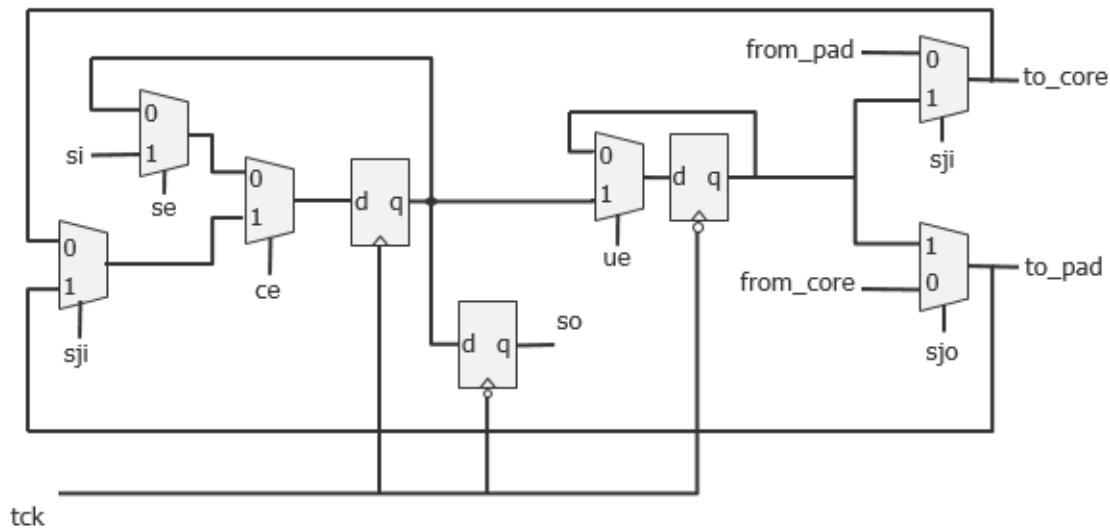

Table 10-3. Illustration of Different Boundary Scan Implementations (cont.)

3) This example shows how the boundary-scan cells are constructed when clocking is set to gated_tck_inv, and update_stage and scan_path_retimining are both set to latch. This is a legacy mode that makes the boundary-scan cell compatible with the LogicVision burst mode architecture. Notice how the implementation for gated_tck and gated_tck_inv are almost the same; only the active-low retiming flop is placed before the data flop.

4) This example shows how the boundary-scan cells are constructed when clocking is set to tck, and both update_stage and scan_path_retimining are set to flop. Notice the two extra multiplexers that are needed in each cell.

Examples

The following example sets the clocking property to gated_tck_inv and the update_stage to latch. The scan_path_retiming is unspecified so it defaults to latch.

```
DftSpecification(mychip,rtl) {
    BoundaryScan {
        ImplementationOptions {
            clocking      : gate_tck_inv ;
            update_stage : latch ;
        }
    }
}
```

BoundaryScanCellOptions

Assigns options to boundary scan ports.

Usage

```
DftSpecification(module_name, id) {
    BoundaryScan | EmbeddedBoundaryScan {
        BoundaryScanCellOptions {
            port_name_pattern : option, ... ; // repeatable
        }
    }
}
```

Description

This wrapper is used to assign options to boundary scan ports. This wrapper replaces the Overrides wrapper in the .etassemble file.

Arguments

- *port_pattern_name* : option, ...;

A syntax used to assign one or more option to a set of ports matched by the specified *port_pattern_name*. The *port_pattern_name* can include an asterisk “*” as a wildcard and %#d[lb:rb] as a counter. The # entry is optional and, when specified, is an integer specifying the minimum number of digits the number must have. For example, ABC%2d[0:2] will match “ABC00”, “ABC01”, and “ABC02”.

[Table 10-4](#) lists the option names and their meanings. The option can be specified in the BoundaryScanCellOptions wrapper or in the third column of the pin_order_file, as explained in the section.

Table 10-4. BoundaryScanCellOptions list

Option name	Meaning
add_dot6_from_pad_cell	Used to identify AC input and inout ports where the from_pad data signal will be intercepted with an additional boundary scan cell. The boundary scan cells sampling the AC pad Test Receivers will be added as normally done.
analog	Used to identify input, output, and inout ports that are analog. These pins do not have a boundary scan cell and are reported as linkage pins in the BSDL file.

Table 10-4. BoundaryScanCellOptions list (cont.)

Option name	Meaning
compliance_enable0	<p>Used to identify input and inout ports that are active low compliance enable pins. These ports are reflected as such in the BSDL file to reflect the fact that these pins must be driven low for the chip to behave in accordance with the BSDL description. The compliance enable zero pins are automatically asserted low in any pattern that makes use of the TAP controller.</p> <p>This option is automatically set when you use the <code>-enable_low_compliance_enables</code> switch of the create_dft_specification command. If the compliance enable logic is already present in your design, you cannot use the <code>-enable_low_compliance_enables</code> switch of the create_dft_specification command. Instead, you follow the steps illustrated in Example 2 of the IjtagNetwork wrapper section.</p>
compliance_enable1	<p>Used to identify input and inout ports that are active high compliance enable pins. Those ports are reflected as such in the BSDL file to reflect the fact that these pins must be driven high for the chip to behave in accordance with the BSDL description. The compliance enable one ports are automatically asserted high in any pattern that makes use of the TAP controller.</p> <p>This option is automatically set when you use the <code>-enable_high_compliance_enables</code> switch of the create_dft_specification command. If the compliance enable logic is already present in your design, you cannot use the <code>-enable_high_compliance_enables</code> switch of the create_dft_specification command. Instead, you follow the steps illustrated in Example 2 of the IjtagNetwork wrapper section.</p>
clock	<p>Used to identify input, output, and inout ports that are clocks. Specifying this value alters the RTL and the BSDL definition of the generated boundary-scan cells associated with the port.</p> <ul style="list-style-type: none"> • If the port is of type input or inout, the boundary-scan cell will have a BSDL function of “clock” and no JTAG multiplexer is inserted along the functional input path just as if the <code>sample_only</code> option was specified. • If the port is of type output or inout, the boundary-scan cell is modified to capture itself instead of the <code>from_core</code> signal in the output direction just as if the <code>no_capture_core_signal</code> option was specified.

Table 10-4. BoundaryScanCellOptions list (cont.)

Option name	Meaning
dont_touch	Used to identify input, output, and inout ports that are to be fully excluded from boundary scan. It is similar to using the no_bscan_cell option except that for output and inout ports, the output enable pin of the output pad buffer is not intercepted with the force_disable signal such that the port will not go tri-state during the HIGHZ instruction. These ports are reported as linkage pins in the BSDL file.
ground	Used to identify input and inout ports that are ground pins in the package part. These ports are reported as linkage in the BSDL file. The ports associated with the ground option may or may not exist in the design. If they do not exist in the design file, the port name pattern is not allowed to include the asterisk wildcard symbol "*" but you can use the %d[range] syntax to define a group of numbered ports as ground ports. The ports on which you have set the function attribute to ground prior to running the check_design_rules command are automatically identified as ground pins in the created DftSpecification wrapper when you run the create_dft_specification command.
input_only	Used to identify inout ports that are to be treated as input-only ports during boundary-scan insertion even if the actual port direction is inout in the netlist and the port is connected to a bidirectional pad cell. The generated BSDL file will document the port as input, and the port will only be equipped with an input-type boundary-scan cell.
no_bscan_cell	Used to identify input, output, and inout ports that are not to be equipped with a boundary-scan cell. It is similar to using the dont_touch option except that for output and inout ports, the output enable pin of the output pad buffer is still intercepted with the force_disable signal such that the port will still go tri-state during the HIGHZ instruction. These ports are reported as linkage pins in the BSDL file.
no_connect	Used to identify input, output, and inout ports that are not connected to package pins. Those ports are treated as dont_touch pins and they are not reported at all in the BSDL file.

Table 10-4. BoundaryScanCellOptions list (cont.)

Option name	Meaning
no_capture_core_signal	Used to identify output and inout ports that are to be equipped with boundary-scan cells that do not capture the functional core signal but instead hold their values during the capture cycle of the INTEST instruction. This option is useful when you are reusing the boundary scan chain as isolation during logictest and you want to avoid the boundary-scan cells from capturing unknowns when the from_core signal is not controllable during logictest. Avoiding unknowns is a requirement if you are using LogicBIST.
output_only	Used to identify inout ports that are to be treated as output-only ports during boundary-scan insertion even if the actual port direction is inout in the netlist and the port is connected to a bidirectional pad cell. The generated BSDL file will document the port as output, and the port will only be equipped with an output-type boundary-scan cell.
power	Used to identify input and inout ports that are power pins in the package part. These ports are reported as linkage in the BSDL file. The ports associated with the power option may or may not exist in the design. If they do not exist in the design file, the port name pattern is not allowed to include the asterisk wildcard symbol “*” but you can use the %d[range] syntax to define a group of numbered ports as ground ports. The ports on which you have set the function attribute to power prior to running the check_design_rules command are automatically identified as power pins in the created DftSpecification wrapper when you run the create_dft_specification command.
sample_only	Used to identify input and inout ports that are not to have a JTAG multiplexer inserted along the functional input path. The fanout of these ports cannot be intercepted by the boundary-scan cell value during the INTEST instruction. Also, if you reuse the boundary scan as isolation during logictest, these ports will not be isolated. This option is inferred for input or inout ports having the clock option. You typically also want to use it for Async reset input ports.

The differences between a normal input boundary scan cell and one assigned the sample_only option are illustrated in [Table 10-5](#) below. Refer to [Table 10-3](#) for information

on how an inout cell is constructed. The following function abbreviations are used in the table figures:

- se — shift enable
- ce — capture enable
- ue — update enable
- si — scan input
- so — scan output
- sji — select jtag input
- sjo — select jtag output
- tck — test clock

Table 10-5. Illustration of the “sample_only” Boundary Scan Cell Option

1) This example shows a normal input boundary scan cell. The multiplexer shown on the right intercepts the from_pad connection of the pad cell. The boundary scan cell can drive a value to the core in INTEST mode.

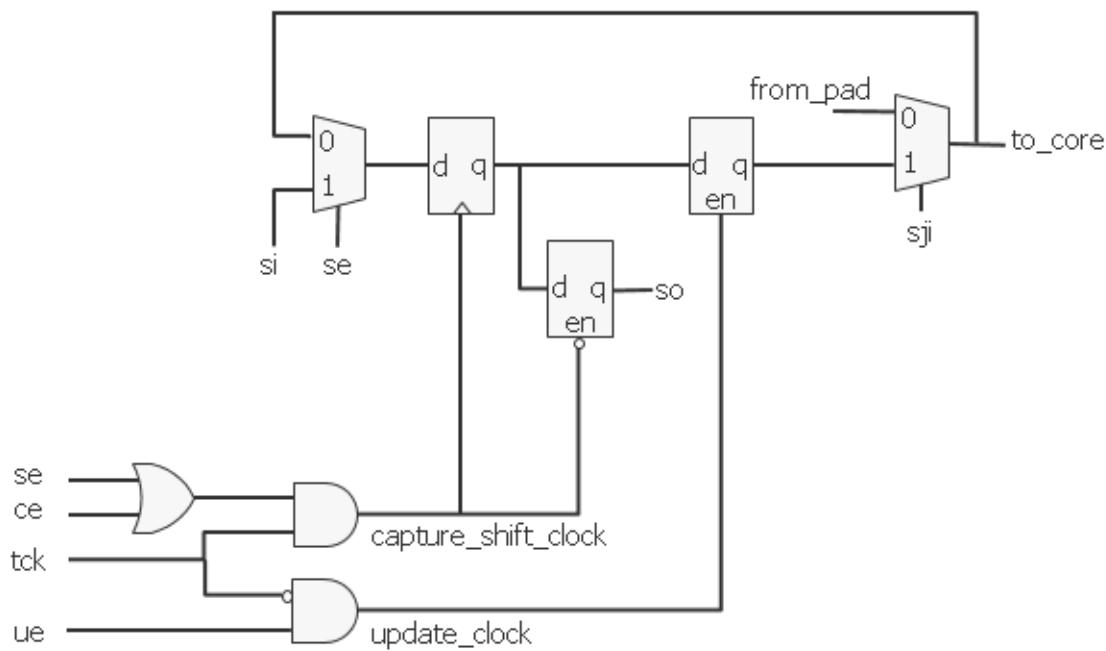

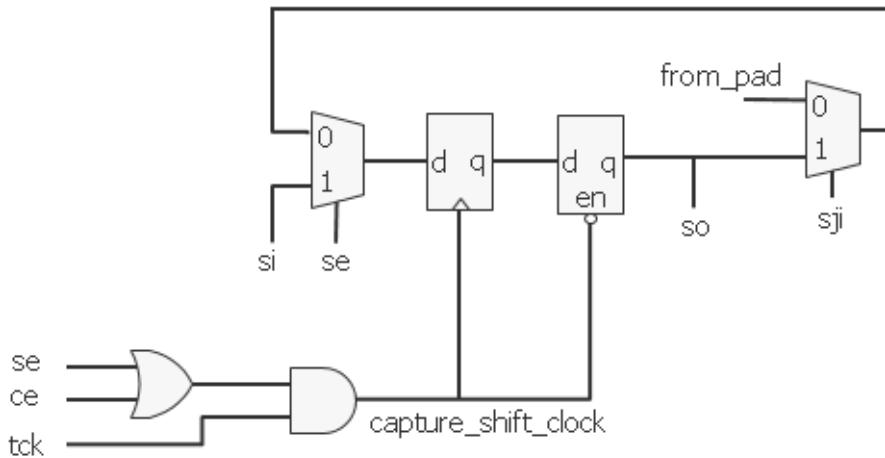

Table 10-5. Illustration of the “sample_only” Boundary Scan Cell Option (cont.)

2) The example below shows a sample_only input boundary scan cell. The multiplexer shown on the right will no longer intercept the from_pad connection of the pad cell, but will simply connect to it, preserving the direct connection between the pad and core. Note that compared to the normal input boundary scan cell, the update latch has been removed and the retiming latch is now connected to the multiplexer on the right.

Examples

The following example uses the `BoundaryScanCellOptions` wrapper to identify VDD and VSS ports in the BSDL file. These port do not exist in the design. The pattern `clk*` is used to match any ports in the design starting with the string “clk” as clock ports. They will not have a JTAG mux inserted along their functional input path, and they will be identified as Clock ports in the BSDL file.

```
DftSpecification(mychip,rtl) {
    BoundaryScan {
        BoundaryScanCellOptions {
            VDD%d[0:32] : power ;
            VSS%d[0:56] : ground ;
            clk* : clock;
        }
    }
}
```

LogicalGroups

Specifies how to group the boundary-scan cells into logical grouping modules.

Usage

```
DftSpecification(module_name, id) {
    BoundaryScan | EmbeddedBoundaryScan {
        LogicalGroups {
            LogicalGroup(group_name) {
                first_port : port_name ;
                parent_instance : parent_instance ;
                leaf_instance_name : leaf_instance_name ;
            }
        }
    }
}
```

Description

A wrapper that specifies how to group the boundary-scan cells into logical grouping modules. You can specify more than one LogicalGroup wrapper only when you have specified the `pin_order_file` property in the [BoundaryScan](#) wrapper.

You use the `first_port` property to identify the first port in the pin order file that belongs to the logical grouping. The association between ports and the LogicalGroup can also be specified in the forth column of the pin order file. If you do not specify any `LogicalGroup(group_name)` wrapper, all boundary scan cells are grouped into a single module, the module is instantiated into the top module, and the leaf instance name is as follows:

`design_name_design_id_tessent_bscan_logical_group_DEF_inst`

as if you had specified an empty `LogicalGroup(DEF)` wrapper.

You use the `parent_instance` property to specify where you want the logical grouping module to be instantiated. By default, it will be instantiated in the top module. You use the `leaf_instance_name` property to specify the leaf instance name used when instantiating the module if you are not satisfied with the default value. The default `leaf_instance_name` used is `design_name_design_id_tessent_bscan_logical_group_group_name_inst`.

The example below shows how to specify the `parent_instance` property in order to insert each logical grouping module in the same instance where the pins or nets to be intercepted by the boundary-scan cells are located.

Arguments

- `group_name`

A string that uniquely identifies each logical group. The string starts with a letter and it is allowed to be followed by any number of letters, numbers, and underscores. The `group_name` is used in constructing the grouping module name as follows:

`design_name_design_id_tessent_bscan_logical_group_group_name`

- `first_port : port_name ;`

A property that specifies a port name that exists in the specified pin_order_file. This property is optional when there is only one LogicalGroup wrapper but it is required when there are more than one. Specifying a port_name for the first_port property is equivalent to specifying the group_name in the forth column of that port in the pin_order_file. See the pin_order_file property description in the BoundaryScan wrapper for a description of that file format and usage.

- `parent_instance : parent_instance ;`

A property that controls where the logical grouping module will be instantiated. By default, it is instantiated in the root module but you can push it down into instances. See the following example to understand the requirement that must be met when choosing the parent_instance of the logical grouping module.

If the specified parent_instance is not unique, it will be uniquified before the logical grouping module is inserted in it. You can do bottom up insertion using the [EmbeddedBoundaryScan](#) wrapper on sub modules to insert segments of boundary scan chains into repeated modules, and then reuse them as building blocks at the next level up if you want to avoid uniquifying the parent_instance. Specify the “[set_design_level sub_block](#)” command and option when inserting boundary scan into those sub modules.

- `leaf_instance_name : leaf_instance_name ;`

A property that specifies a different leaf name when instantiating the logical grouping module into its parent instance. The default value when unspecified is `design_name_design_id_tessent_bscan_logical_group_group_name_inst`.

If you choose to change it, you do not have to worry about picking a unique leaf name in the given parent_instance. The tool will automatically append the `instance_uniquification_suffix` to your specified leaf instance name in case of conflicts. See the [set_insertion_options](#) command description for a complete description of the `-instance_unification_suffix` option.

Examples

The following example illustrates the use of the parent_instance property of the LogicalGroup wrapper to meet the rule that the logical grouping module must be instantiated where all the intercepted nets are visible. [Figure 10-22](#) shows the circuit before the insertion of the boundary-scan cells. You can see that the functional connections to and from the pad cells associated with ports P3 and P4 do not exist outside the B1_I instance. In this example, a single logical grouping module is specified so it can only be instantiated inside B1_I as illustrated in [Figure 10-23](#).

```
BoundaryScan {
    LogicalGroups {
        LogicalGroup(g1) {
            parent_instance : B1_I ;
        }
    }
}
```

The same example is modified to use a pin_order file thus enabling the splitting of the boundary-scan cells into more than one logical grouping module. The pin order file defines the order from P1 to P4. Two logical grouping modules are specified in which the first one, g1, starts with P1 and goes until P2 and the second one, g2, starts with P3 and goes until P4. The g2 group is still restricted to having its parent_instance property as B1_I because this is the only place where all of the connections to be intercepted are visible. The g1 group is, on the other hand, allowed to be instantiated in four locations because all of the connections to be intercepted are visible in those four locations. The parent_instance is shown for the four options and the corresponding locations of the logical grouping modules are shown in [Figure 10-24](#).

```
BoundaryScan {
    pin_order_file      : mychip.pin_order
    LogicalGroups {
        LogicalGroup(g1) {
            first_port      : P1 ;
            parent_instance : B1_I ;           // Option1
            parent_instance : . ;             // Option2
            parent_instance : B2_I ;           // Option3
            parent_instance : B2_I/B3_I ;     // Option4
        }
        LogicalGroup(g2) {
            first_port      : P3 ;
            parent_instance : B1_I ;
        }
    }
}
```

The example also illustrates that you can specify the outputs_per_enable_cell property with a value smaller than the actual fanout count of the functional enable signal. In this case, the functional enable signal fans outs to two output pads. One enable boundary-scan cell is inserted per output port, requiring the tool to split the output enable connectivity to each pad.

[Figure 10-25](#) shows this example with option1 for the parent_instance property. No new ports need to be created. The functional enable signal is observable by two enable bscan cells, and one connection per output pad is made between the logical grouping module and the enable pin of the output pad cells.

[Figure 10-26](#) shows this example with option3 for the parent_instance property. In this case, the connections between the logical grouping module and the output pads require the creation of new pins as illustrated with the orange net crossing the hierarchy. If you are familiar with Tessent Boundary Scan within ETAssemble, the flexibility to precisely control the fanout of the enable signals was not present in that tool. All of those existing limitations are removed within Tessent Shell, and a net driven by RTL can now be intercepted and split for boundary scan usage. In ETAssemble, you needed the functional enable signal to be identified on a pin which often meant you had to insert buffers in the RTL to enable the Boundary Scan to be placed in the same module as the pads.

```
BoundaryScan {
    pin_order_file      : mychip.pin_order
    OutputPerEnableCell : 1 ;
    LogicalGroups {
        LogicalGroup(g1) {
            first_port      : P1 ;
            parent_instance : B1_I ;           // Option1
            parent_instance : B2_I ;           // Option3
        }
        LogicalGroup(g2) {
            first_port      : P3 ;
            parent_instance : B1_I ;
        }
    }
}
```

ACModeOptions

Specifies options relevant to the IEEE 1149.6 AC mode of the boundary scan chain.

Usage

```
DftSpecification(module_name, id) {
    BoundaryScan {
        ACModeOptions {
            test_receiver_init_clock_value : initialization_event ;
                // Legal: logic_low logic_high
                // falling_edge rising_edge auto
            pulse_min_duration : time | auto ;
            train_minimum_count : count | unused ;
            train_max_duration : time | unlimited ;
            ACGroup(group_name) {
                insert_before_port : port_name ;
                insert_after_port : port_name ;
                port_list : port_name, ... ;
            }
        }
    }
    EmbeddedBoundaryScan {
        ACModeOptions {
            test_receiver_init_clock_value : initialization_event ;
                // Legal: logic_low logic_high
                // falling_edge rising_edge auto
            ACGroup(group_name) {
                insert_before_port : port_name ;
                insert_after_port : port_name ;
                port_list : port_name, ... ;
            }
        }
    }
}
```

Description

A wrapper that specifies options relevant to the IEEE 1149.6 AC mode of the boundary scan chain. You use this wrapper to define AC enable cells and associate them with a group of ports. You also use this wrapper to specify the event type that initializes the test receiver when the value is not described in the cell library. Finally, you can use this wrapper to specify three properties that are simply forwarded into the BSDL file.

Arguments

- test_receiver_init_clock_value : initialization_event ;

A property that is useful when the cell library description of the dot6 pad cell uses the legacy pad_init_clock_dot6 attribute instead of one of the new attributes that precisely describe the initialization event: pad_init_posedge_clock_dot6, pad_init_negedge_clock_dot6, pad_init_enable_high_dot6, and pad_init_enable_low_dot6. If the value is “auto” and the dot6 pad cell uses the legacy pad_init_clock_dot6 attribute instead of one of the four new attributes, the tool issues an error; you are required to specify the initialization event when it cannot be inferred from the cell library.

- `pulse_min_duration : time | auto ;`

An optional property that defines the minimum time to use between the rising and a falling edge during the AC tests. This property is forwarded into the BSDL file using the AIO_EXTEST_Pulse_Execution attribute. When unspecified or specified to “auto”, the minimum pulse duration is chosen so as not to be smaller than three times the larger of the HP_time and LP_Time BSDL values of each pad cell.

```
attribute AIO_EXTEST_Pulse_Execution of <current_design>: entity is
    "Wait_Duration <pulse_min_duration_in_seconds>" ;
```

- `train_minimum_count : count | unused ;`

An optional property that defines the minimum number of pulses the train test must have. This property is forwarded in the BSDL file using the AIO_EXTEST_Train_Execution attribute. The property defaults to “unused” when unspecified. Specifying a value of one effectively makes the train test equivalent to the pulse test.

```
attribute AIO_EXTEST_Train_Execution of <current_design>: entity is
    "train <train_minimum_count>, maximum_time <train_max_duration>" ;
```

- `train_max_duration : time | unlimited ;`

An optional property that defines a maximum time the train test must take. This property is forwarded in the BSDL file using the AIO_EXTEST_Train_Execution attribute. It defaults to “unlimited” when unspecified.

- `group_name`

A string that uniquely identifies the ACGroup. This name is not reflected in the BSDL file but is used to name the leaf instance name of the AC group enable cell in the logical grouping module.

If no AcGroup wrappers are specified, then all AC ports are active during the AC tests. If you specified at least one ACGroup wrapper but you have some AC ports not associated with an ACGroup, they will always be active during the AC tests. In this situation, a warning is generated to let you know that not all AC pins were equipped with an AC enable cell. You can define an extra ACGroup wrapper without a port_list property to indicate that you want all AC ports not associated with another ACGroup wrapper to be associated with that one.

- `insert_before_port : port_name ;`

A property that specifies the position of the AC enable boundary-scan cell. This property can only be used when the pin_order_file property inside the [BoundaryScan](#) wrapper is specified. The specification of the insert_before_port property is mutually exclusive with the specification of the insert_after_port property. If neither the insert_before_port nor insert_after_port properties are specified, the AC enable boundary-scan cell is inserted in front of the boundary-scan cell of the first port that is part of the group. The location of the AC group enable boundary-scan cell is reflected in the BSDL file using the AIO_Pin_Behavior attribute.

- `insert_after_port : port_name ;`

A property that specifies the position of the AC enable boundary-scan cell. This property can only be used when the `pin_order_file` property inside the [BoundaryScan](#) wrapper is specified. The specification of the `insert_before_port` property is mutually exclusive with the specification of the `insert_after_port` property. If neither the `insert_before_port` nor `insert_after_port` properties are specified, the AC enable boundary-scan cell is inserted in front of the boundary-scan cell of the first port that is part of the group. The location of the AC group enable boundary-scan cell is reflected in the BSDL file using the `AIO_Pin_Behavior` attribute.

- `port_list : port_name_pattern, ... ;`

A property used to list the port names that belong to the AC group. The `port_name_pattern` can include the asterisk “*” as a wildcard and `%#d[lb:rb]` as a counter. The `#` entry is optional and, when specified, is an integer specifying the minimum number of digits the number must have. For example, `ABC%2d[0:2]` will match ABC00, ABC01, and ABC02.

You are allowed to have one `ACGroup` wrapper with an unspecified `port_list`. This `ACGroup` will collect all AC ports that are not already associated with another `ACGroup` wrapper.

Examples

The following example defines an `ACGroup` wrapper with the name “`pci`” to specify that all ports starting with `PCI_` belong to the group. All other AC ports are associated with the “`other`” group. The “`other`” `ACGroup` collects all other AC ports because it does not specify the `port_list` property.

```
DftSpecification(my_chip,rtl) {
    BoundaryScan {
        AcGroups {
            ACGroup(pci) {
                port_list : PCI_* ;
            }
            ACGroup(other) {
            }
        }
    }
}
```

AuxiliaryInputOutputPorts

Specifies two lists of port name patterns to be used as Auxiliary input and/or output ports during some test modes.

Usage

```
DftSpecification(module_name, id) {
    BoundaryScan {
        AuxiliaryInputOutputPorts {
            auxiliary_input_ports : port_name_pattern, ... ;
            auxiliary_output_ports : port_name_pattern, ... ;
        }
    }
    EmbeddedBoundaryScan{
        AuxiliaryInputOutputPorts {
            internal_auxiliary_input_ports : port_name_pattern, ... ;
            internal_auxiliary_output_ports : port_name_pattern, ... ;
            external_auxiliary_input_ports : port_name_pattern, ... ;
            external_auxiliary_output_ports : port_name_pattern, ... ;
        }
    }
}
```

Description

A wrapper that specifies two lists of port name patterns to be used as Auxiliary input and/or output ports during some test modes. An inout port is allowed to be specified in both lists at the same time. In the output directions, a 2-to-1 multiplexer (shown in green in [Figure 10-29](#)) is added on the test side of the JTAG multiplexer (shown in red in [Figure 10-29](#)). The auxiliary output multiplexing is added in the boundary-scan cell to avoid cascading two multiplexers along the functional output path. For auxiliary input logic, an AND gate is used to prevent the aux_in_data signal from toggling in functional mode. The aux_in_en signal is also used to force the output pad driver off when adding AuxIn logic on an inout pad.

The aux_out_enable and aux_in_enable signals are kept separate for each port to provide full flexibility as to which output and input ports are enabled to carry input or output auxiliary data in any given test mode. The ports equipped with auxiliary data input and output logic are useful for supplying channel input and output data to EDT controllers. They are also useful to provide the source of the scan_en, test_clock, and edt_update DFT signals. See the description of the [add_dft_signals](#) command for more info. Notice that the aux_out_en and aux_in_en signals have higher priority than the select_jtag_input and select_jtag_output signals. The reason for this is explained below but has the implication that the aux_out_en and aux_in_en sources must reset off and remain off when using the IEEE 1149.1 test mode of the chip. This requirement is met if you use the DFT signals created by the [add_dft_signals](#) to control those pins.

[Figure 10-27](#) shows the typical boundary scan cell inserted on a inout pad. The red multiplexers are those referred to as JTAG multiplexers in the first paragraph. They are controlled by the select_jtag_output to allow the output data and the output enable values to be controlled by the Boundary Scan cells in IEEE 1149.1 test modes.

Figure 10-27. Typical Boundary Scan Cell Inserted for an Inout Pad

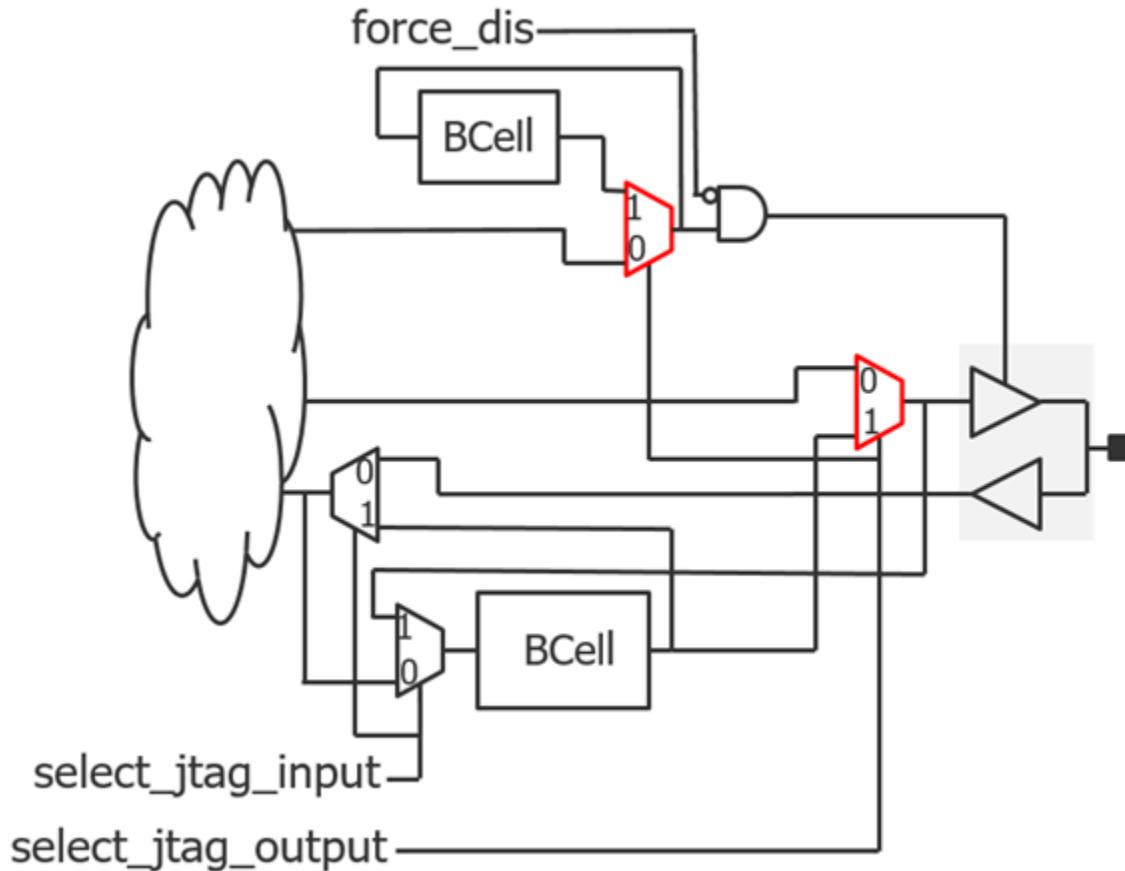

Figure 10-28 shows the boundary scan cell when it is used during ATPG. If you set the `max_segment_length_for_logictest` property found in the Boundary Scan wrapper to an integer or to unlimited, ATPG scan chains are created with the Boundary Scan chain. The blue path shows how the boundary scan cell is used to isolate the core values from the input ports by forcing `select_jtag_input` to 1 which is done by forcing the `int_ltest_en` pin on the boundary scan interface module. For more information about the boundary scan interface module and the logic inserted in it when the boundary scan chain is reused in logic test, see [Figure 10-35](#) on page 3391.

Note

If you are using the DFT signal flow, simply add the `int_ltest_en` DFT signal using the `add_dft_signals` command when you reach the top level and it will be connected to the boundary scan interface module. You can then activate the input isolation using the “`set_static_dft_signal_values int_ltest_en 1`” command and switch when it is time to create your ATPG patterns.

The `select_jtag_output` signal is under ATPG control allowing both the input of the output of the JTAG multiplexers (shown in red) to be tested. If you do not force the `int_ltest_en` pin to 1, then the `select_jtag_input` will also be under ATPG control and the input path can also be tested.

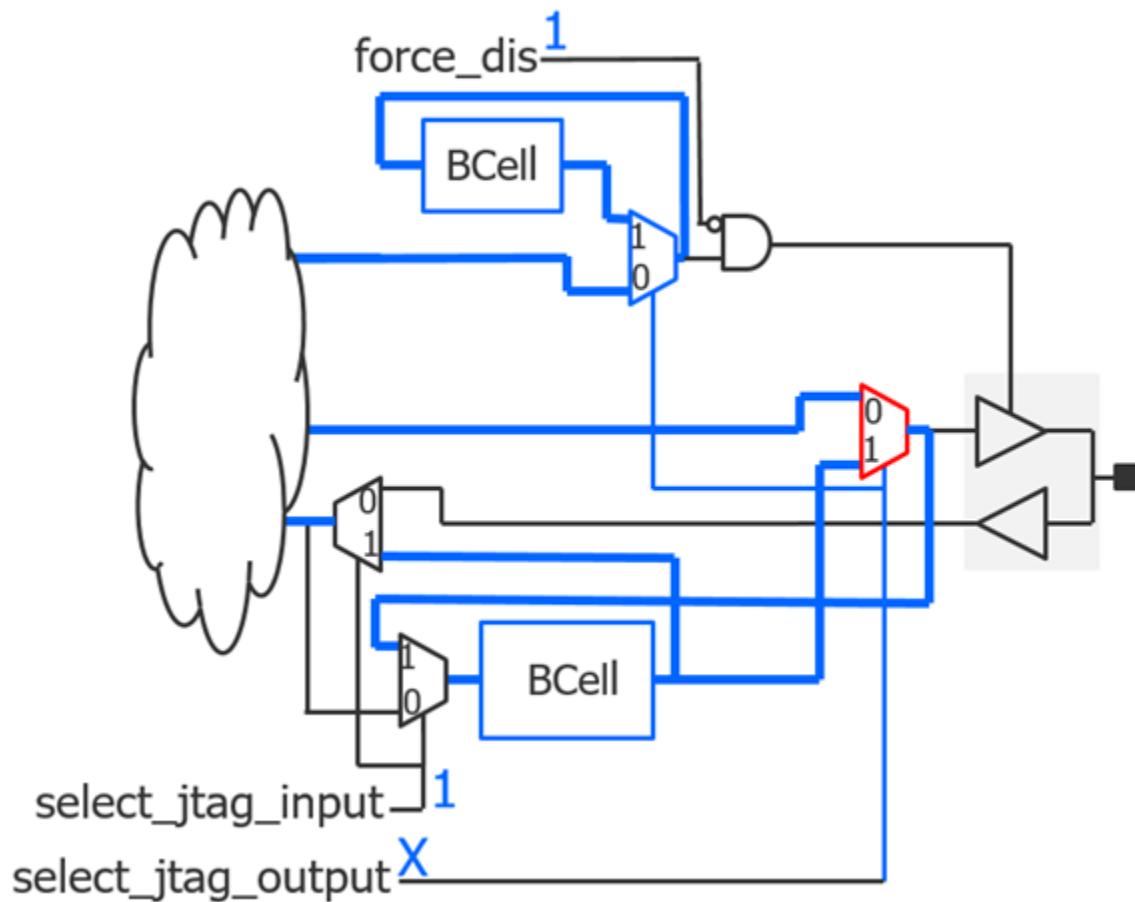

Figure 10-28. Boundary Scan Cell as Observation and Control in Logic Test Modes

Figure 10-29 shows the same boundary scan cell shown in Figure 10-27 but with auxiliary logic (colored green) added for both the input and output directions. Notice how the green multiplexer is not inserted along the functional path but on the test side of the JTAG multiplexer shown in red. The `aux_in_en` and `aux_out_en` signals are mutually exclusive, and the boundary scan cell is in functional mode when they are both low.

Figure 10-29. Adding Auxiliary Input and Output Logic in Bscan Cell

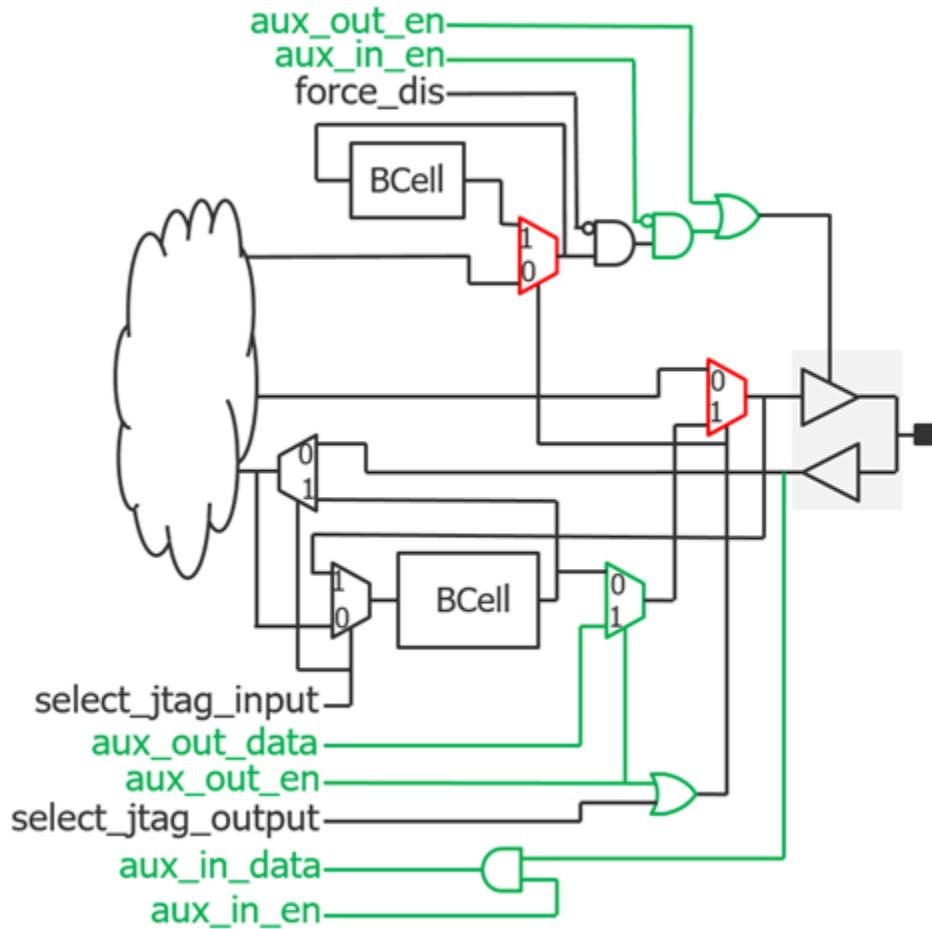

Figure 10-30 shows aux_out_en asserted to 1 to enable the auxiliary output data path. The two multiplexers are switched to select the aux_out_data value, and the enable of the output pad is forced on. When aux_out_en is high, the boundary scan cell is not able to observe the value coming from the core. This is why the [add_dft_modal_connections](#) command gates the aux_out_en signals with “scan_en” such that it is active only in shift mode. In capture mode, the aux_out_data is not needed, and instead the boundary scan cell is used to observe the functional core output. The capture mode is shown in Figure 10-31.

Figure 10-30. Path Used When AuxOut Logic Activated

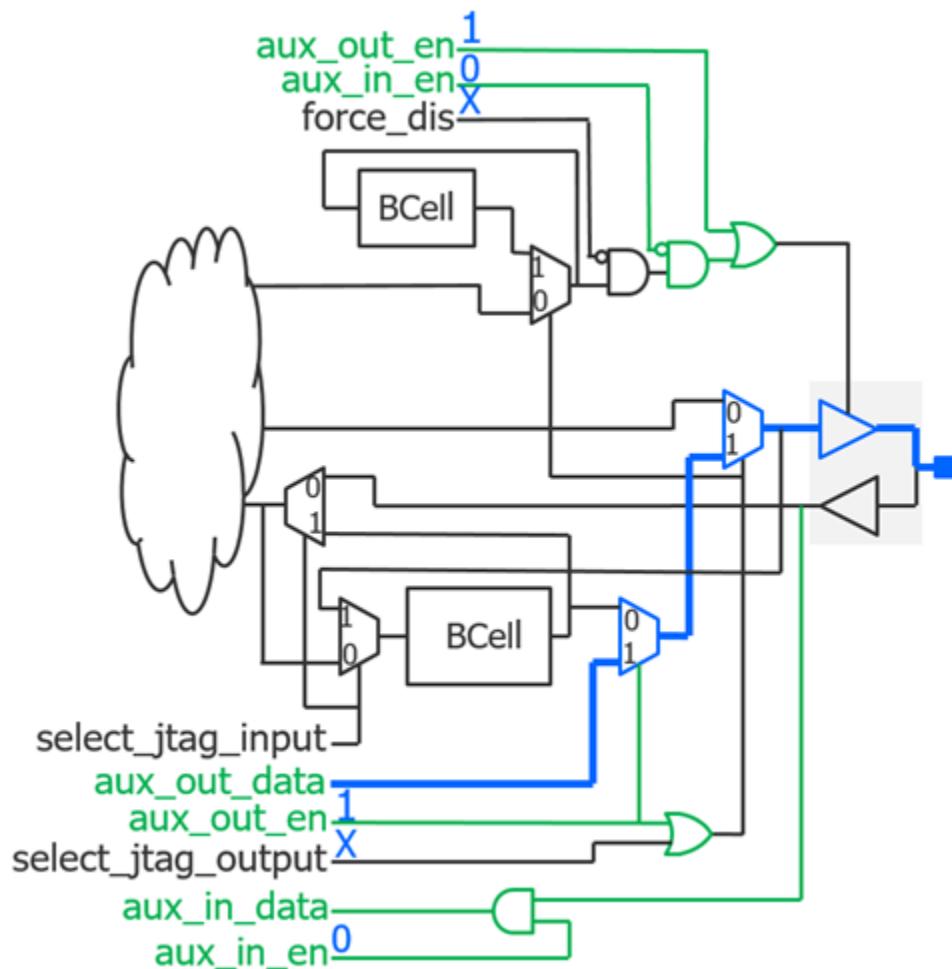

Figure 10-31. Forcing aux_out_en Low in Capture Mode to Observe Core Output

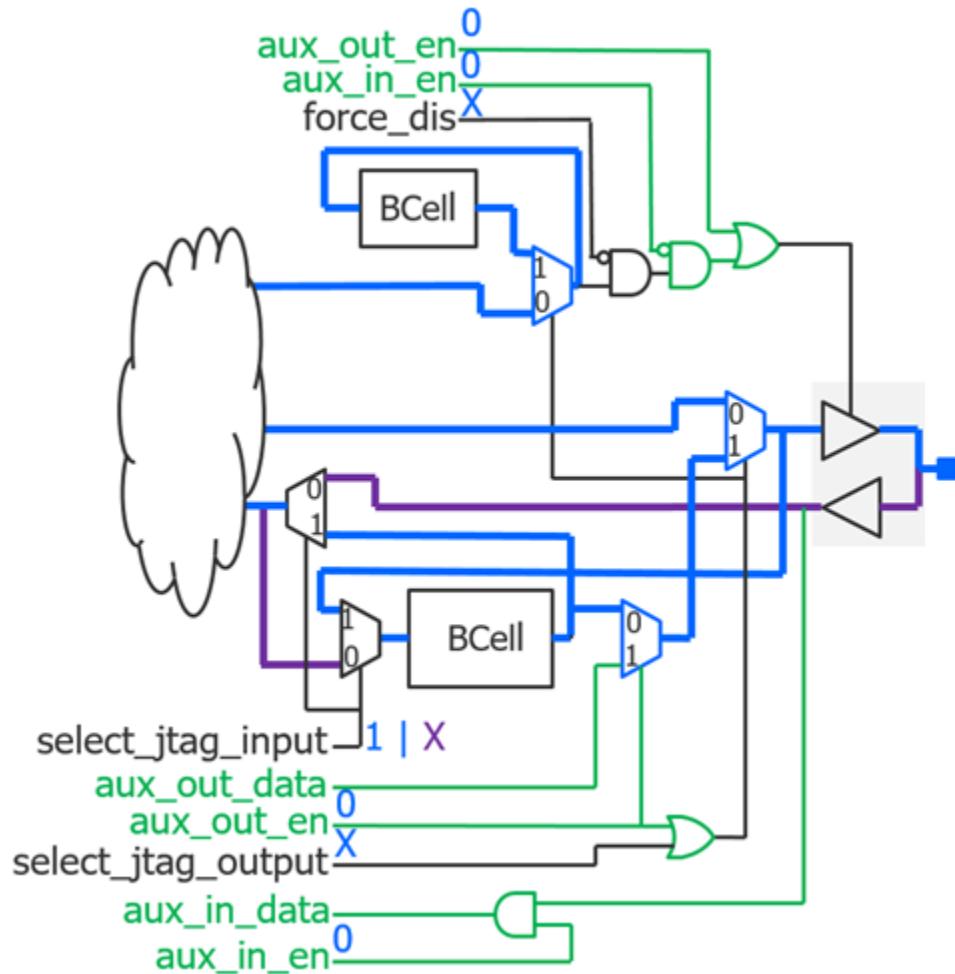

Figure 10-32 shows the IO pad used as an auxiliary input during ATPG. The boundary scan cell is used to control the signal going to the core while the input buffer provides the value to the auxiliary in data. This scheme is useful to allow reusing functional pins for the DFT signals scan_en, test_clock, and edt_update without losing ATPG fault coverage of those inputs.

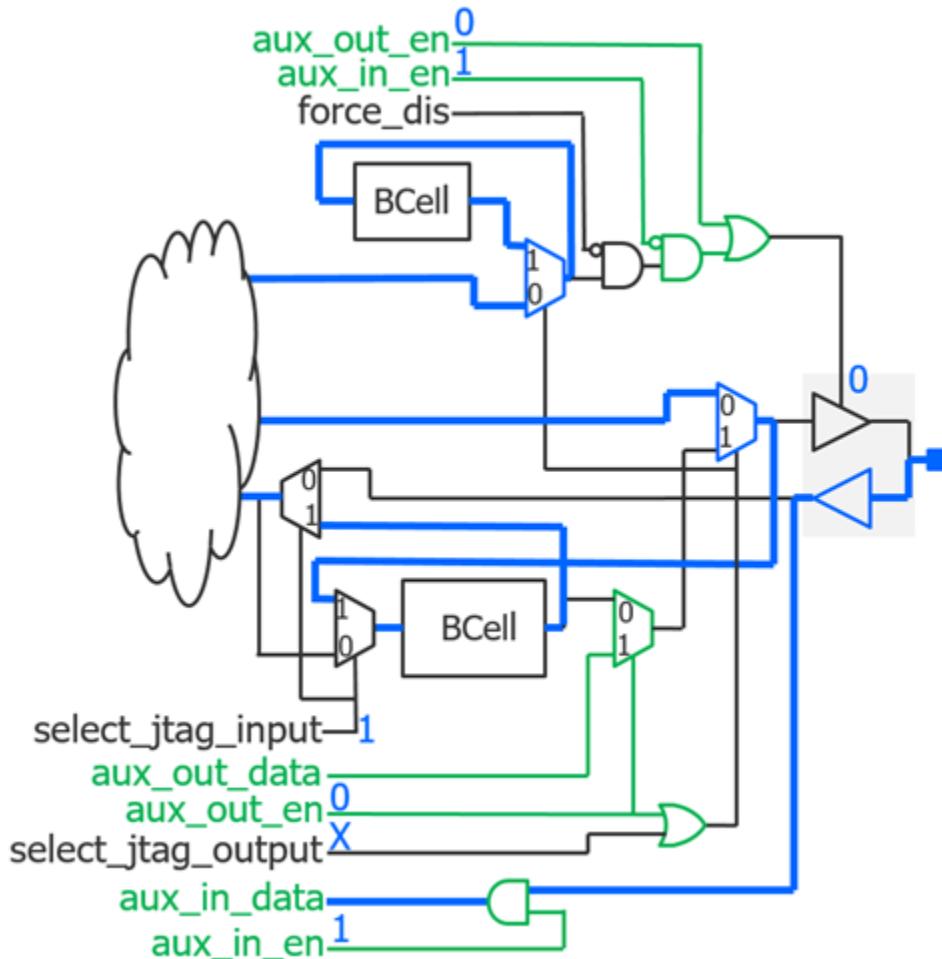

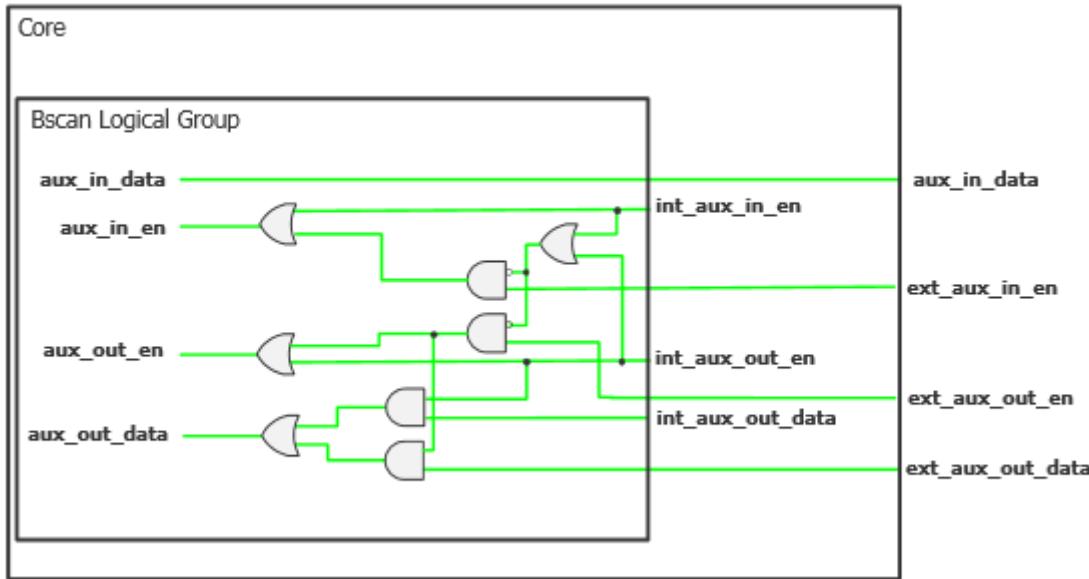

Figure 10-32. Using AuxIn and Controlling to Core Signal in ATPG

Figure 10-33 shows the extra logic that is added when the same port is used as both an internal and an external auxiliary data in the EmbeddedBoundaryScan/AuxiliaryInputOutputPorts wrapper. In the output direction, two data_out input pins are created on the logical grouping module. One of those inputs is used to make auxiliary output connections for elements found within the block and the other input is connected to an input of the block to make auxiliary output connections for elements found outside the block. In the input direction, the same data output port on the logical grouping module is used for providing auxiliary data inputs to elements located inside and outside the block. Both directions have an internal and external enable pin. The internal pins are used by the elements inside the blocks and the external pins are used by the elements outside the blocks. For example, if you call `add_dft_modal_connections` inside the block, it will make connections to the internal pins; and if you call `add_dft_modal_connections` outside the block, it will make connections to the external pins.

Figure 10-33. Extra Logic Added When a Port is Used Both Internally and Externally

Arguments

- auxiliary_input_ports : *port_name_pattern*, ... ;

A property that specifies a list of port name patterns to define a group of input or inout ports as auxiliary input ports. The same inout port can be both an input and an output auxiliary port. The auxiliary inputs are left tied on the logic group module to be used by test logic found inside the chip.

The *port_name_pattern* values can include an asterisk "*" as a wildcard and %#d[lb:rb] as a counter. The # entry is optional, and when specified is an integer specifying the minimum number of digits the number must have. For example, ABC%2d[0:2] will match ABC00, ABC01, and ABC02.

- auxiliary_output_ports : *port_name_pattern*, ... ;

A property that specifies a list of port name patterns that defines a group of output or inout ports as auxiliary output ports. The same inout port can be both an input and an output auxiliary port. The auxiliary output ports are left dangling on the logic group module to be used by test logic found inside the chip.

The *port_name_pattern* can include an asterisk "*" as a wildcard and %#d[lb:rb] as a counter. The # entry is optional and when specified is an integer specifying the minimum number of digits the number must have. For example, ABC%2d[0:2] will match ABC00, ABC01, and ABC02.

- internal_auxiliary_input_ports : *port_name_pattern*, ... ;

A property that specifies a list of port name patterns to define a group of input or inout ports as internal auxiliary input ports. The same inout port can be both an input and an output auxiliary port. An internal auxiliary input port differs from an external one in how the

auxiliary ports on the boundary scan logical group module are connected. When internal, they are left dangling on the logic group module to be used by test logic found inside the block. When external, the ports are connected to primary input and output ports of the block to be used by test circuit outside the block.

The *port_name_pattern* values can include an asterisk “*” as a wildcard and %#d[lb:rb] as a counter. The # entry is optional and when specified is an integer specifying the minimum number of digits the number must have. For example, ABC%2d[0:2] will match ABC00, ABC01, and ABC02.

- `internal_auxiliary_output_ports : port_name_pattern, ... ;`

A property that specifies a list of port name patterns that defines a group of output or inout ports as internal auxiliary output ports. The same inout port can be both an input and an output auxiliary port. An internal auxiliary output port differs from an external one in how the auxiliary ports on the boundary scan logical group module are connected. When internal, they are left tied on the instance of the logic group module to be used by test logic found inside the block. When external, the ports are connected to primary input ports of the block to be used by test circuit outside the block.

The *port_name_pattern* can include an asterisk “*” as a wildcard and %#d[lb:rb] as a counter. The # entry is optional and when specified is an integer specifying the minimum number of digits the number must have. For example, ABC%2d[0:2] will match ABC00, ABC01, and ABC02.

- `external_auxiliary_input_ports : port_name_pattern, ... ;`

A property that specifies a list of port name patterns to define a group of input or inout ports as external auxiliary input ports. The same inout port can be both an input and an output auxiliary port. An internal auxiliary input port differs from an external one in how the auxiliary ports on the boundary scan logical group module are connected. When internal, they are left dangling on the instance of the logic group module to be used by test logic found inside the block. When external, the ports are connected to primary output ports of the block to be used by test circuit outside the block. The ports on the block follow the naming specified by the [Interface](#)/`auxiliary_*` properties.

The *port_name_pattern* can include an asterisk “*” as a wildcard and %#d[lb:rb] as a counter. The # entry is optional and when specified is an integer specifying the minimum number of digits the number must have. For example, ABC%2d[0:2] will match ABC00, ABC01, and ABC02.

- `external_auxiliary_output_ports : port_name_pattern, ... ;`

A property that specifies a list of port name patterns that defines a group of output or inout ports as external auxiliary output ports. The same inout port can be both an input and an output auxiliary port. An internal auxiliary output port differs from an external one in how the auxiliary ports on the boundary scan logical group module are connected. When internal, they are left tied on the instance of the logic group module to be used by test logic found inside the block. When external, the ports are connected to primary input ports of the block to be used by test circuit outside the block. The ports on the block follow the naming specified by the [Interface](#)/`auxiliary_*` properties.

The *port_name_pattern* can include an asterisk “*” as a wildcard and %#d[lb:rb] as a counter. The # entry is optional and when specified is an integer specifying the minimum number of digits the number must have. For example, ABC%2d[0:2] will match ABC00, ABC01, and ABC02.

Examples

The following example defines the GPIO00 to GPIO31 ports as both auxiliary input and output ports. The first 16 are usable by test logic that is both internal and external to the block. The last 16 are only used by test logic that is external to the block. The full flexibility is preserved such that each test mode will be able to use N of them as auxiliary output ports and the rest as auxiliary inputs where N can be different for each test mode.

```
DftSpecification(my_chip,rtl) {
    EmbeddedBoundaryScan {
        AuxiliaryInputOutputPorts {
            internal_auxiliary_input_ports : GPIO%2d[0:15] ;
            internal_auxiliary_output_ports : GPIO%2d[0:15] ;
            external_auxiliary_input_ports : GPIO%2d[0:31] ;
            external_auxiliary_output_ports : GPIO%2d[0:31] ;
        }
    }
}
```

EnableGroups

Specifies the creation of enable groups using either the ports in the fanout of a functional enable signal or a specified port list.

Usage

```
DftSpecification(module_name, id) {
    BoundaryScan | EmbeddedBoundaryScan {
        EnableGroups {
            EnableGroup(name) {
                capture_core_signal : on | off ;
                internal_enable_signal : pin_or_net_name ;
                port_list : port_name_pattern, ... ;
                insert_before_port : port_name ;
                insert_after_port : port_name ;
            }
        }
    }
}
```

Description

A wrapper that specifies the creation of enable groups using either the ports in the fanout of a functional enable signal or a specified port list. The properties `insert_before_port` and `insert_after_port` are used to specify the location of the enable cells associated with the group. The property `capture_core_signal` is used to prevent the cell from capturing the core signal during INTEST or during logictest when the boundary scan is used as isolation.

Arguments

- `capture_core_signal : on | off ;`

A property that specifies if the enable boundary-scan cells associated with the group are allowed to capture the core signal during INTEST or during the capture pulse when you reuse it for logictest isolation. See the `max_segment_length_for_logictest` property in the [BoundaryScan](#) wrapper for information about the logictest usage. When specified to off, the enable boundary-scan cell captures itself instead of capturing the core signal. This may be useful if you are using LogicBIST and the functional enable is X during the logictest mode.

- `internal_enable_signal : pin_or_net_name ;`

A property that references an internal signal inside the chip that directly controls the enable pin of a group of output pad cells. Specifying this enable signal is equivalent to listing all the ports controlled by that enable signal in the `port_list` property. The specification of the `internal_enable_pin` and `port_list` properties are mutually exclusive. If the number of output pad cells controlled by the enable signal is larger than the specified `outputs_per_enable_cell` property, the fanout of the enable cell will be split into smaller groups to meet the specified `outputs_per_enable_cell` value. One enable boundary-scan cell will be added per group.

- `port_list : port_name_pattern, ... ;`

A property that associates a group of output or inout ports with a given enable group. The `port_name_pattern` values can include an asterisk "*" as a wildcard and %#d[lb:rb] as a

counter. The # entry is optional and, when specified, is an integer specifying the minimum number of digits the number must have. For example, ABC%2d[0:2] will match ABC00, ABC01, and ABC02.

The specification of the internal_enable_pin and port_list properties are mutually exclusive. If the number of output pad cells specified in the list is larger than the specified outputs_per_enable_cell value, the list will be split into smaller groups to meet the specified outputs_per_enable_cell value. One enable boundary-scan cell will be added per group.

You do not need to specify an enable group for all output and inout ports. For the tri-state inout and output ports not explicitly associated to an enable group, one or more additional enable groups will be inferred. The inferring is done to match the common functional enable signal sourcing a group of pads. A given group can further be split to satisfy the specified outputs_per_enable_cell value described in the following sections:

- BoundaryScan — [outputs_per_enable_cell](#) property
- EmbeddedBoundaryScan — [outputs_per_enable_cell](#) property
- insert_before_port : *port_name* ;
A property that specifies the position of the enable boundary-scan cell. This property can only be used when the pin_order_file property inside the BoundaryScan wrapper is specified. The specification of the insert_before_port property is mutually exclusive with the specification of the insert_after_port property. If neither the insert_before_port nor insert_after_port properties are specified, the enable boundary-scan cell is inserted before the first boundary cell that is associated with a port controlled by the enable cell.
- insert_after_port : *port_name* ;
A property that specifies the position of the enable boundary-scan cell. This property can only be used when the pin_order_file property inside the BoundaryScan wrapper is specified. The specification of the insert_before_port property is mutually exclusive with the specification of the insert_after_port property. If neither the property insert_before_port nor insert_after_port properties are specified, the enable boundary-scan cell is inserted before the first boundary cell that is associated with a port controlled by the enable cell.

Examples

The following example defines three enable groups. The first one is associated with the ports in the fanout of the functional enable signal “core_i/en”. The second one is associated with all ports matching the pattern “OUT*”. The third group is associated with all other remaining ports as it does not specify either the internal_enable_signal nor the port_list property.

```
DftSpecification(my_chip,rtl) {
    BoundaryScan {
        EnableGroups {
            EnableGroup(g1) {
                internal_enable_signal : core1/en ;
            }
            EnableGroup(g2) {
                port_list : OUT* ;
            }
            EnableGroup(g3) {
            }
        }
    }
}
```

InternalBScanCells

Specifies the insertion of internal boundary-scan cells that are not associated with ports but instead are used to control and/or observe internal nodes inside the design.

Usage

```
DftSpecification(module_name, id) {
    BoundaryScan | EmbeddedBoundaryScan {
        InternalBScanCells {
            InternalBScanCell(name) {
                insert_before_port : port_name ;
                insert_after_port : port_name ;
                safe_value : 0 | 1 | X ;
                type : control | observation | both ;
                connection : pin_or_net_name ;
                multiplexing : on | off | auto ;
            }
        }
    }
}
```

Description

A wrapper that specifies the insertion of internal boundary-scan cells that are not associated with ports but instead are used to control and/or observe internal nodes inside the design.

Arguments

- *name*

A string that uniquely identifies the internal boundary-scan cell in the BSDL file. The string starts with a letter and may be followed by any numbers of letters, numbers, or underscores. The string must be unique across all InternalBScanCell wrappers. The name of internal boundary-scan cells are mapped to the cell position inside the boundary scan chain using an attribute called TESSENT_INTERNAL_CELL_LABELS as shown in this example. The two InternalBScanCell wrappers have the names “my_name1” and “my_name2”.

```
-- BSDL local extensions
attribute TESSENT_INTERNAL_CELL_LABELS: BSDL_EXTENSION;
attribute TESSENT_INTERNAL_CELL_LABELS of TOP: entity is
    -- Label Cell
    "((my_name1 , 36 ) , " &
    " (my_name2 , 30 ))";
```

- *insert_before_port : port_name ;*

A property that specifies the position of the internal boundary-scan cell. This property can only be used when the pin_order_file property inside the BoundaryScan wrapper is specified. The specification of the *insert_before_port* property is mutually exclusive with the specification of the *insert_after_port* property. If neither the *insert_before_port* nor *insert_after_port* properties are specified, the internal boundary-scan cell is inserted at the end of the boundary scan chain near *scan_out* in the order they were specified. The location

of the internal boundary-scan cell is reflected in the BSDL file using the TESSENT_INTERNAL_CELL_LABELS attribute.

- `insert_after_port : port_name ;`

A property that specifies the position of the internal boundary-scan cell. This property can only be used when the `pin_order_file` property inside the [BoundaryScan](#) wrapper is specified. The specification of the `insert_after_port` property is mutually exclusive with the specification of the `insert_before_port` property. If neither the property `insert_before_port` nor `insert_after_port` properties are specified, the internal boundary-scan cell is inserted at the end of the boundary scan chain near `scan_out` in the order they were specified. The location of the internal boundary-scan cell is reflected in the BSDL file using the TESSENT_INTERNAL_CELL_LABELS attribute.

- `safe_value : 0 | 1 | X ;`

A property that specifies a safe value for the internal boundary-scan cell. This value is reflected into the BSDL file. If a non-X safe value is specified, the [BoundaryScan](#) signoff and manufacturing pattern set will never load a different value into that register during any of its [RunTest](#) specifications.

- `type : control | observation | both ;`

A property that specifies if the internal boundary-scan cell is to be used to control and/or observe an internal node. [Table 10-6](#) shows the hardware inserted into the design based on the value of the type and multiplexing property.

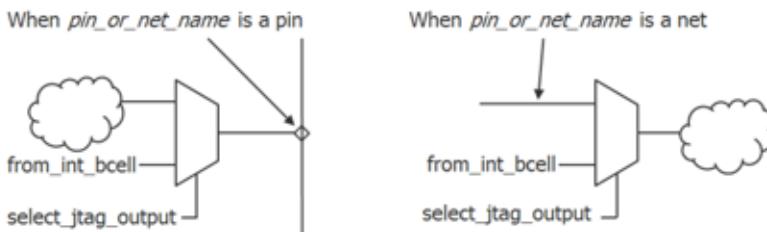

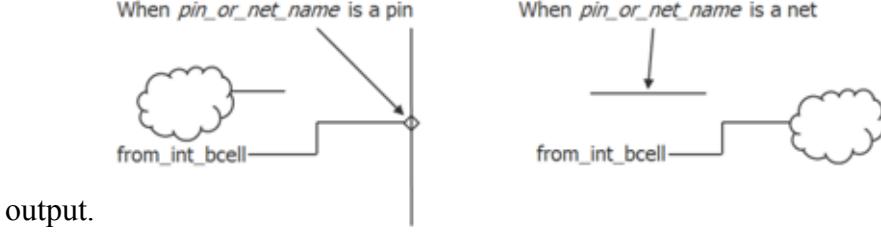

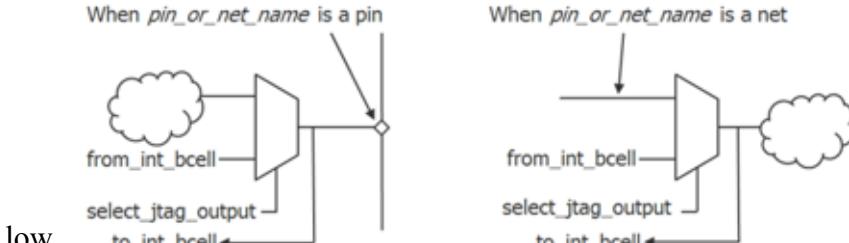

- `connection : pin_or_net_name ;`

A property that specifies the name of a pin or a net to control and/or observe. The `parent_instance` of `pin_or_net_name` will be auto-uniquified if not unique.

- `multiplexing : on | off | auto ;`

A property that is only relevant when the property `type` is set to “control” or “both”. A multiplexer is inserted as shown in [Table 10-6](#). When the value is “auto”, the multiplexer is inserted only when the `has_functional_source` attribute of the specified `pin_or_net_name` is set to “true”. See [Pin](#) and [Net](#) for more information about this attribute.

Table 10-6. Connections to and from Internal Boundary Scan Cells

type	description
control	<p>If multiplexing is specified as “on” or “auto” and the has_functional_source attribute for <i>pin_or_net_name</i> is set to “true”, the driver is intercepted with a multiplexer located in the <i>parent_instance</i> of the <i>pin_or_net_name</i>. A net is intercepted at its source while a pin is intercepted at its destination. The internal boundary-scan cell captures its own output.</p>  <p>If multiplexing is specified as “off” or “auto” and the has_functional_source attribute for <i>pin_or_net_name</i> is set to “false”, the original driver is disconnected and replaced by the signal from the internal boundary-scan cell. The internal boundary-scan cell captures its own output.</p> 
observation	<p>The specified <i>pin_or_net_name</i> is connected to the input of the internal boundary-scan cell.</p>
both	<p>If multiplexing is specified as “on” or “auto” and the has_functional_source attribute for <i>pin_or_net_name</i> is set to “true”, the driver is intercepted with a multiplexer located in the <i>parent_instance</i> of the <i>pin_or_net_name</i>. A net is intercepted at its source while a pin is intercepted at its destination. The observation net is taken after the multiplexer. The functional source of the <i>pin_or_net_name</i> is observable when <i>select_jtag_output</i> is low.</p>  <p>If multiplexing is specified as “off” or “auto” and the has_functional_source attribute for <i>pin_or_net_name</i> is set to “false”, the original driver is disconnected and replaced by the signal from the internal boundary-scan cell. The internal boundary-scan cell captures its own output.</p>

Examples

The following example creates an internal boundary-scan cell that is used to control the u1/pll_reset signal using the boundary scan chain. The specified safe value of 0 ensures this cell will never be loaded with a 1 during any of the [RunTest](#) in the [PatternsSpecification](#) or with any board test patterns created from the BSDL file.

```
DftSpecification(module_name,id) {
    BoundaryScan | EmbeddedBoundaryScan {
        InternalBScanCells {
            InternalBScanCell(mycell) {
                insert_before_port : PortA ;
                safe_value         : 0 ;
                type              : control ;
                connection        : u1/pll_reset ;
                multiplexing      : auto ;
            }
        }
    }
}
```

InternalBscanSegments

Specifies the position of an existing internal boundary scan segment in the boundary scan chain.

Usage

```
DftSpecification(module_name, id) {
    BoundaryScan | EmbeddedBoundaryScan {
        InternalBscanSegments {
            InternalBScanSegment(instance_name) {
                insert_before_port : port_name ;
                insert_after_port : port_name ;
                logical_group_name : logical_group_name ;
            }
        }
    }
}
```

Description

A wrapper that is used to specify the position of an existing internal boundary scan segment in the boundary scan chain. When the BScanSegment contains cells associated with a port of the design, the position of the BScanSegment and its *logical_group_name* is taken from the position and the logical group of the first port associated with the BScanSegment in the *pin_order_file*. In the case of pure internal boundary scan segments, their position and logical grouping name cannot be extracted from associated ports because they are not associated with ports. The logical group name is not used to create logical grouping modules for existing boundary scan segments because they are already grouped into modules. Instead, they are used to refer to the segments that use the *bypass_logical_group* inside the [BondingConfigurations](#) wrapper.

This wrapper is automatically created when the [create_dft_specification](#) command is invoked if a BScanSegment description is found for a module. You simply need to delete this wrapper prior to invoking [process_dft_specification](#) if you do not want it to be part of the boundary scan chain. Refer to the “[set_design_sources -format bscan_lib](#)” command description for information about automatically finding the BScanSegment files without having to explicitly read them in using the [read_core_descriptions](#) command. You specify the module matching options using the [set_module_matching_options](#) command.

Arguments

- *insert_before_port* : *port_name* ;

A property that specifies the position of the internal boundary segment relative to the position of the boundary-scan cell associated with a port. The specification of the *insert_before_port* is mutually exclusive with the specification of the *insert_after_port* property. When neither the *insert_before_port* nor *insert_after_port* properties are specified, the boundary scan segment is placed at the end of the boundary scan chain near the scanout. You can only specify this property if the *pin_order_file* property is used inside the [BoundaryScan](#) wrapper.

- `insert_after_port : port_name ;`

A property that specifies the position of the internal boundary segment relative to the position of the boundary-scan cell associated with a port. The specification of the `insert_before_port` is mutually exclusive with the specification of the `insert_after_port` property. When neither the `insert_before_port` nor `insert_after_port` properties are specified, the boundary scan segment is placed at the end of the boundary scan chain near the scanout. You can only specify this property if the `pin_order_file` property is used inside the `BoundaryScan` wrapper.

- `logical_group_name : logical_group_name ;`

A property used to associate a `logical_group_name` to the existing internal boundary scan segment. This name is not used to create a logical grouping module as the existing boundary scan segment is already grouped into a module. It is used instead to refer to the segment using the `bypass_logical_group` property inside the [BondingConfigurations](#) wrapper.

Examples

The following example defines a design instance as an internal boundary scan segment. It is given a logical group name so that it can be bypassed in some bounding options. A `BscanSegment` definition must exist for the module associated with instance u1/u2.

```
DftSpecification(module_name,id) {
    BoundaryScan {
        InternalBScanSegments {
            InternalBScanSegment(u1/u2) {
                logical_group_name      : seg1 ;
            }
        }
    }
}
```

BoundaryScan

Specifies the boundary scan chain to build and optionally insert into the design.

Usage

```
DftSpecification(module_name,id) {
    BoundaryScan {
        ijtag_host_node           : id ;
        pin_order_file            : file_name ;
        interface_parent_instance : parent_instance ;
        outputs_per_enable_cell   : int ;          // default: 16
        max_segment_length_for_logictest : int | unlimited | off ;
        tristate_enable_non_contacted_test_support : on | off ;
        tck_period                 : period ;     // default 100ns
        ImplementationOptions {
        }
        BoundaryScanCellOptions {
        }
        LogicalGroups {
        }
        ACModeOptions {
        }
        AuxiliaryInputOutputPorts {
        }
        EnableGroups {
        }
        InternalBScanCells {
        }
        InternalBScanSegments {
        }
        BondingConfigurations {
        }
        UserInstructions {
        }
    }
}
```

Description

A wrapper that specifies the boundary scan chain to build and optionally insert into the design.

This wrapper can only be specified once in a given DftSpecification wrapper. As illustrated in the syntax above, the BoundaryScan wrapper uses the `ijtag_host_node` property to specify the host scan interface that drives the boundary scan register; this can be a TAP controller specified in the [IjtagNetwork](#) wrapper of the same DftSpecification, or a tap instance already existing in the design. The TAP controller may have been inserted using a prior execution of the [process_dft_specification](#) command, or it may be a third-party TAP controller manually inserted into your design. If you want to use a third-party TAP controller, you must have a valid ICL description for it and it must have the port functions described in section “[Requirements on a TAP to be usable for BoundaryScan](#)” on page 3385.

If you have existing boundary scan segments that are described with BoundaryScan wrappers (see “[Tessent Core Description](#)” on page 3755), the tool automatically recognizes the existing

boundary scan segments in the design and includes them in the boundary scan chain. The legacy *.lvbscan* file format is also natively supported and translated into the current BoundaryScan wrapper syntax when it is loaded into Tesson shell. You can refer to the [set_module_matching_options](#) and “[set_design_sources](#)-format bscan” commands to learn how to have them automatically searched and loaded. You can also use the [read_core_descriptions](#) command to load them explicitly.

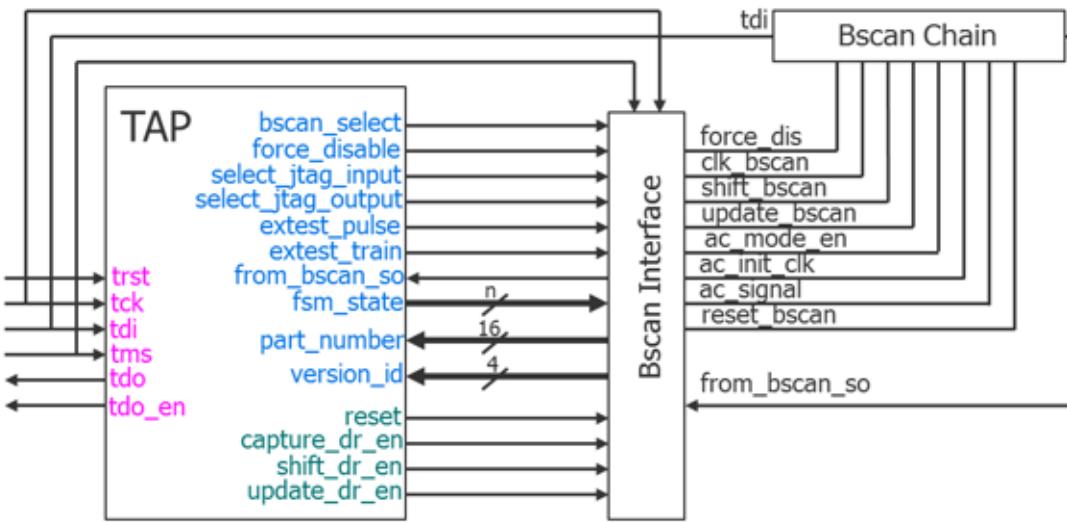

Note

 If you want to insert BoundaryScan and the TAP controller, and connect the TAP to internal pins, follow the instructions in [Example 2](#) of the [IjtagNetwork](#) wrapper description.

Requirements on a TAP to be usable for BoundaryScan

You can use any TAP controller as the access point to the boundary scan as long as it is described in ICL and contains a minimum set of port functions. As with any ICL module that is handed off, the port names used in the ICL file must exactly match the port names of the corresponding Verilog or VHDL module. [Figure 10-34](#) illustrates the connections made to and from a TAP controller to implement boundary scan. The blue ports are ports that are dedicated to Boundary scan. Most of the ports are required. You only need the `extest_pulse` and `extest_train` ports if your chip contains pads that require the IEEE 1149.6 ac modes. You only need the `fsm_state` port if your chip contains pads that require IEEE 1149.6 ac modes or if the chip has `tristate_enable_non_contacted_test_support` testing enabled. You only need the `part_number_code` and `version_code` ports if you want to use the `part_number_code` and `version_code` properties of the [BondingConfigurations](#) wrapper.

Figure 10-34. Needed Resources From Third-Party TAP Controller

The remainder of this section lists the ports that must exist on the third-party TAP controller in order for it to be usable by Tesson BoundaryScan, the conditions that make them required, and

the required ICL descriptions in the ICL files. You can use the following dofile to create a TAP controller and look at its ICL as an example:

```
set_context dft -rtl
read_config_data -from_string {
    DftSpecification(ex,rtl) {
        IjtagNetwork {
            HostScanInterface(tap) {
                Tap(main) {
                    HostBscan {
                    }
                    HostIjtag(1) {
                    }
                    DeviceIDRegister {
                    }
                }
            }
        }
    }
}
process_dft_specification -no_insertion
```

The ICL of the TAP must include the following three attributes: tessent_instruction_reg, tessent_bypass_reg, and tessent_device_id_reg. The value of the attribute is the name of the ScanRegister in ICL that is associated with the instruction, bypass, and dev_id registers. The tessent_device_id_reg attribute is optional and only needed if your TAP supports the device id feature. The ScanRegister referenced by the tessent_instruction_reg attribute must have a RefEnum pointing to an Enum table that defines the listed Opcodes. The IDCODE opcode is optional and only needed if the TAP has a device id register. The EXTEST_PULSE and EXTEST_TRAIN opcodes are only needed if IEEE 1149.6 is used. The tessent_use_in_dft_specification attribute is used to tell the [create_dft_specification](#) command to ignore this module and not infer TDRs to control and observes the unconnected DataIn and DataOut ports of your TAP.

```

Attribute tessent_instruction_reg = "instruction" ;
Attribute tessent_bypass_reg = "bypass" ;
Attribute tessent_device_id_reg = "devid" ;
Attribute tessent_use_in_dft_specification = "false";
ScanRegister instruction[4:0] {
    CaptureSource 5'bXXX01 ;
    ResetValue     5'b00000 ;
    ScanInSource   tdi ;
    RefEnum        IROpcodes ;
}
RefEnum instruction_opcodes {
    BYPASS          = 5'bx0000 ;
    CLAMP           = 5'bx0001 ;
    EXTEST          = 5'bx0010 ;
    EXTEST_PULSE    = 5'bx0011 ;
    EXTEST_TRAIN    = 5'bx0100 ;
    IDCODE          = 5'bx0101 ;
    INTEST          = 5'bx0110 ;
    SAMPLE          = 5'bx0111 ;
    PRELOAD         = 5'bx0111 ;
    HIGHZ           = 5'bx1000 ;
}

```

If your TAP has the part_number_code and/or version_code ports, they must be part of the CaptureSource of the ScanRegister that is referenced by the tessent_device_id_reg attribute as shown here. In this example, man_id is a parameter that defines the 11-bit manufacturing id constant.

```

DataInPort version_code[3:0] {
    Attribute connection_rule_option = "allowed_no_source";
}
DataInPort part_number_code[15:0] {
    Attribute connection_rule_option = "allowed_no_source";
}
ScanRegister devid[31:0] {
    ScanInSource tdi ;
    CaptureSource version_code[3:0], part_number_code[15:0], $man_id, 1'b1 ;
}

```

The BoundaryScan host port must be described in a ScanInterface wrapper as shown here. The actual port name in your TAP may differ from these names, but the name of the ScanInterface must be host_bscan if you want it to be automatically recognized by the [create_dft_specification](#) command without having to use the -existing_bscan_host_scan_in option.

```

ScanInterface host_bscan {
    Port from_bscan_so ;
    Port bscan_select ;
    Port capture_dr_en ;
    Port shift_dr_en ;
    Port update_dr_en ;
}

```

The following list presents the port functions that may exist on the third-party TAP, describes when they are needed, and shows how to describe them in the ICL file. The examples illustrate

the use of the connection_rule_option attribute to indicate to the ICL extraction process that it must allow the bscan host port to *not* be connected to a boundary scan chain. The ICL description of the boundary scan interface module must be connected to a TAP; ICL extraction will report errors if the boundary scan interface module is present but incorrectly connected to a TAP. However, having a TAP controller with no boundary scan chain connected to it is allowed.

- `bscan_en`

This function is required. It is a signal that is high during the EXTEST, SAMPLE, PRELOAD, INTEST, HIGHZ, EXTEST_TRAIN, and EXTEST_PULSE opcodes. The source is a LogicSignal that properly describes the decoding of this signal from the instruction register bits. It must be described in the ICL file as shown here.

```
ToSelectPort bscan_en  {
    Source bscan_en_int;
    Attribute connection_rule_option = "allowed_no_destination";
}
LogicSignal bscan_en_int {
    IR == EXTEST      ||
    IR == SAMPLE     ||
    IR == PRELOAD    ||
    IR == INTEST     ||
    IR == HIGHZ       ||
    IR == EXTEST_TRAIN ||
    IR == EXTEST_PULSE;
}
```

- `force_disable`

This function is required. It is a signal that is active during the HIGHZ opcode. The source is a LogicSignal that properly describes the decoding of this signal from the instruction register bits. It must be described in the ICL file as shown here.

```
DataOutPort force_disable  {
    Source force_disable_int;
    Attribute connection_rule_option = "allowed_no_destination";
    Attribute tessent_bscan_function = "force_disable";
}
```

The value of the attribute tessent_bscan_function is “force_disable_inv” if your port is active low.

- `select_jtag_input`

This function is required. It is a signal that is active during the INTEST opcode. The source is a LogicSignal that properly describes the decoding of this signal from the instruction register bits. It must be described in the ICL file as shown here.

```
    DataOutPort select_jtag_input {
        Source select_jtag_input_int;
        Attribute connection_rule_option = "allowed_no_destination";
        Attribute tesson_bscan_function = "select_jtag_input";
    }
```

The attribute tesson_bscan_function is “select_jtag_input_inv” if your port is active low.

- `select_jtag_output`

This function is required. It is a signal that is active during the EXTEST, HIGHZ, CLAMP, EXTEST_TRAIN and the EXTEST_PULSE opcodes. The source is a LogicSignal that properly describes the decoding of this signal from the instruction register bits. It must be described in the ICL file as shown here.

```
    DataOutPort      select_jtag_input {
        Source select_jtag_input_int;
        Attribute connection_rule_option = "allowed_no_destination";
        Attribute tesson_bscan_function = "select_jtag_output";
    }
```

The attribute tesson_bscan_function is “select_jtag_output_inv” if your port is active low.

- `extest_pulse`

This function is optional and only needed if the chip includes pads requiring the IEEE 1149.6 ac tests. It is a signal that is active during the EXTEST_PULSE opcode. The source is a LogicSignal that properly describes the decoding of this signal from the instruction register bits. It must be described in the ICL file as shown here.

```
    DataOutPort      extest_pulse {
        Source extest_pulse_int;
        Attribute connection_rule_option = "allowed_no_destination";
        Attribute tesson_bscan_function = "extest_pulse";
    }
```

The attribute tesson_bscan_function is “extest_pulse_inv” if your port is active low.

- `extest_train`

This function is optional and only needed if the chip includes pads requiring the IEEE 1149.6 tests. It is a signal that is active during the EXTEST_TRAIN opcode. The source is a LogicSignal that properly describes the decoding of this signal from the instruction register bits. It is must be described in the ICL file as shown here.

```
    DataOutPort      extest_train {
        Source extest_pulse_int;
        Attribute connection_rule_option = "allowed_no_destination";
        Attribute tesson_bscan_function = "extest_train";
    }
```

The attribute tesson_bscan_function is “extest_train_inv” if your port is active low.

- fsm_state

This function is optional and only needed if the chip includes pads requiring the IEEE 1149.6 tests or if [tristate_enable_non_contacted_test_support](#):on is specified. It is a bus that represents the TAP fsm state encoding. The fsm_state signals must change on the rising of TCK, and they must be described in the ICL file as shown here. The name of the Enum can be any arbitrary name as long as it includes the symbols for all 16 fsm state values.

```
    DataOutPort      fsm_state[3:0] {
        Attribute connection_rule_option = "allowed_no_destination" ;
        Attribute function_modifier = "tap_fsm_state" ;
        RefEnum      state_encoding ;
    }
    Enum state_encoding {
        test_logic_reset      = 4'b0000 ;
        run_test_idle         = 4'b0001 ;
        select_dr             = 4'b0010 ;
        capture_dr            = 4'b0011 ;
        shift_dr              = 4'b0100 ;
        exit1_dr              = 4'b0101 ;
        pause_dr               = 4'b0110 ;
        exit2_dr              = 4'b0111 ;
        update_dr              = 4'b1000 ;
        select_ir              = 4'b1001 ;
        capture_ir             = 4'b1010 ;
        shift_ir               = 4'b1011 ;
        exit1_ir              = 4'b1100 ;
        pause_ir               = 4'b1101 ;
        exit2_ir              = 4'b1110 ;
        update_ir              = 4'b1111 ;
    }
```

If you want to insert BoundaryScan and the TAP controller, and connect the TAP to internal pins, follow the instructions in “[Example 2](#)” on page 3227 in the [IjtagNetwork](#) wrapper description.

Boundary Scan Interface Module

As shown in [Figure 10-34](#), the boundary scan interface module resides between the TAP controller and the boundary scan chain. The normal logic included in the interface module is shown in black in [Figure 10-35](#) and includes the clock gaters to create the bscan_update_clock and bscan_shift_capture_clock used by some boundary scan cells. See the [ImplementationOptions](#) wrapper’s description section for a description of boundary scan cells using gated clocks. If you are using IEEE 1149.6 boundary scan cells, the interface will have more logic that is used to create the IEEE 1149.6 signals but this logic is not shown in [Figure 10-35](#). The blue logic shown in [Figure 10-35](#) is the logic added in the interface module when the boundary scan chain is re-used during the logic test modes. This feature is requested by setting the “[max_segment_length_for_logictest](#)” property described below to an integer or to “unlimited”. The inserted multiplexer segments the boundary scan chains into one or more logic test scan chains as shown in [Figure 10-36](#). The name of the scan_in and scan_out pins created by this feature are documented in the [Instrument Dictionary](#) described below. The blue module

shown in bold contains a scan chains of 6 flip-flops between `ltest_si` and `ltest_so` used to provide ATPG control to the 6 output ports of the module. This allow achieving high ATPG fault coverage of the boundary scan logic. The same module also include a mini-OCC as shown in [Figure 10-13](#) on page 3269 of the [Sib](#) wrapper description section. Notice how the “`int_ltest_en`” input is ORed with the ATPG controlled “`select_jtag_input`” signal before being sent to the boundary scan cells. This enables using the boundary scan cells to isolate the input of the chip from the core input values in order to support low count pin test for multi-site testing. See [Figure 10-31](#) on page 3370 and [Figure 10-32](#) on page 3371 in the [AuxiliaryInputOutputPorts](#) section for more explanation of this feature. You use the “`set_static_dft_signal_values int_ltest_en 1`” to set `int_ltest_en` in your `test_setup`.

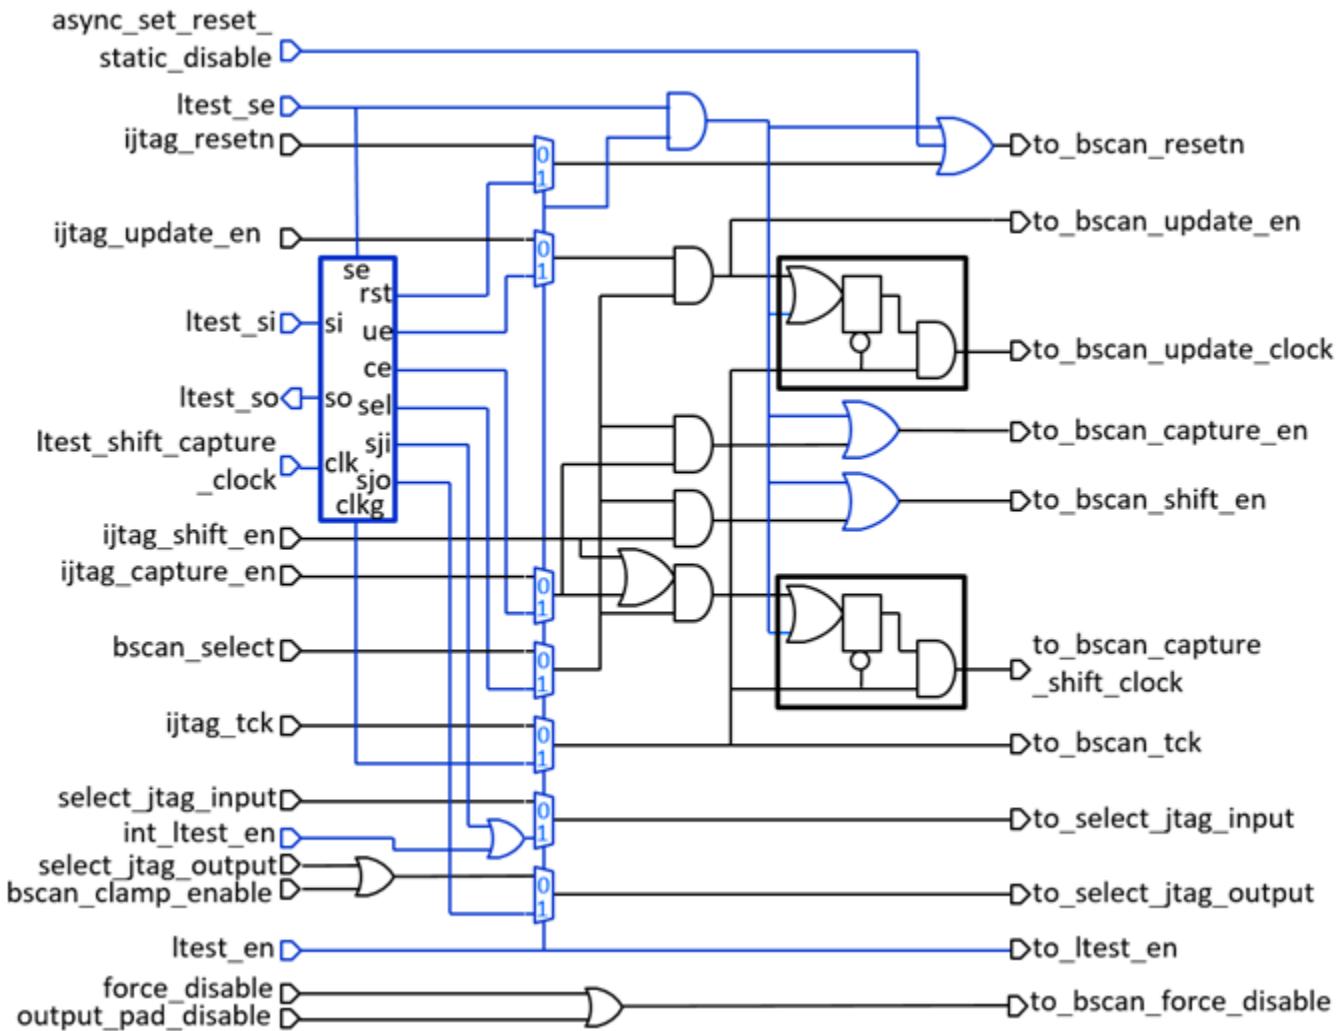

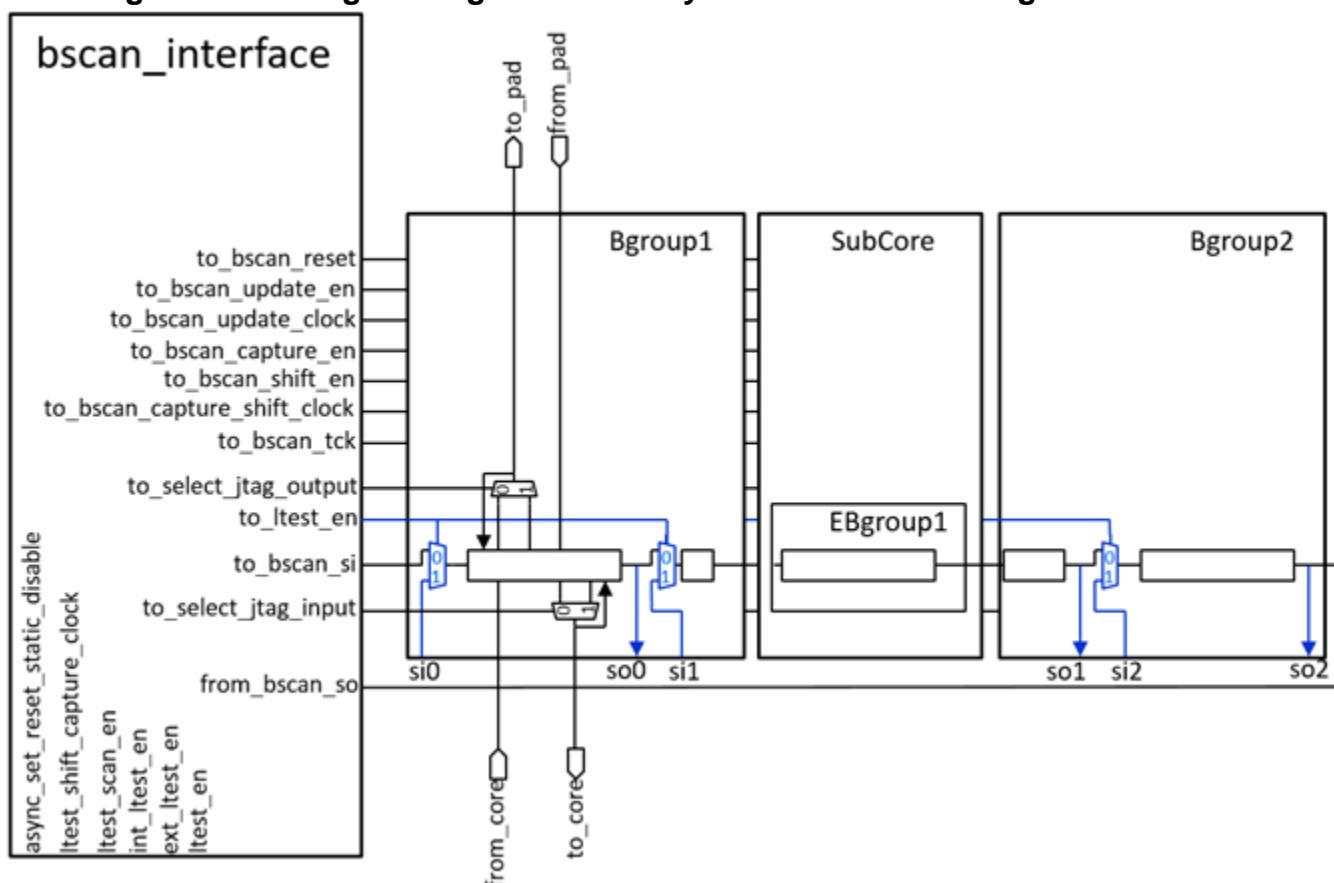

Figure 10-36. Segmenting the Boundary Scan Chains into Logic Test Chains

Instrument Dictionary

When you have run the `process_dft_spec` commands and the `BoundaryScan` wrapper or the `EmbeddedBoundaryScan` wrapper was present in the `DftSpecification`, an instrument dictionary is created to describe what was done on each ports. You can access this dictionary using this command:

```
format_dictionary [get_instrument_dictionary mentor::jtag_bscan::DftSpecification]
```

The format of the dictionary is the following:

```
ports {
    <port_name> {
        bscan_cell_presence added | existing | none
        bcell_pad_connection_functions {
            from_pad          pin_name
            to_core           pin_name
            from_core         pin_name
            to_core           pin_name
            init_data_dot6   pin_name
            init_data_inv_dot6 pin_name
            test_data_dot6   pin_name
            test_data_inv_dot6 pin_name
            from_sji_mux     pin_name
            to_sji_mux       pin_name
            from_sjo_mux     pin_name
            to_sjo_mux       pin_name
        }
        // class is one of input, output, or inout
        // sub-classes are no_capture_core_signal, sample_only
        // no_sji_mux, no_sjo_mux, clock, dot6
        added_bscan_cell_options {list of class and sub-classes}
        output_during_force_disable 0 | 1 | X | Z
        auxiliary_output_pin pin_name
        auxiliary_output_enable_pin pin_name
        auxiliary_input_pin pin_name
        auxiliary_input_enable_pin pin_name
        ac_cell on | off
        bsdl_pin_name pin_name
        bonding_configurations {list of bonding options}

```

The ports section gives you the information about the boundary scan cell associated to each port and where it gets connected on the pad cell. If a port was equipped with Auxiliary muxing logic as requested in the [AuxiliaryInputOutputPorts](#) wrapper, you can find the associated pin on the Logical grouping modules in the dictionary. The “boundary_scan_interface” section gives you the pins on the right hand side of the boundary scan interface module, illustrated in [Figure 10-34](#), for all pin functions needed by the boundary scan segments. Finally, the logic_test_scan_chains section is created if you used the max_segment_length_for_logictest property documented below. It describes all logictest chains created with their length, scan_in and scan out port and the edge timing for scan_in and scan_out with respect to the shift clock.

See the example below on how to retrieve the dictionary and manipulate the chain data.

Note

 The mini OCC is added to the BoundaryScan interface when max_segment_length_for_logictest is an integer or unlimited. For more information about the mini OCC, refer to the [Sib](#) command description.

Arguments

- `ijtag_host_node : id ;`

A required property that specifies the ScanInterface that is hosting the boundary scan register. The format of the *id* is either “Tap(*id*)” or “HostScanInterface(*id*)”. You use Tap(*id*) when the boundary scan host is a Tap controller specified in the IJtagNetwork wrapper of the current DftSpecification wrapper. You use HostScanInterface(*id*) when the host of the boundary scan is a TAP that already exists in the design. The IJtagNetwork must have a HostScanInterface(*id*) wrapper with `design_instance` and `scan_interface` properties that identify the TAP and the bscan host interface as shown in “[Example 2](#)” on page 3246 in the [HostScanInterface/Interface](#) section.

- `pin_order_file : file_name ;`

An optional property that specifies the name of a file that provides an ordered list of ports that the tool will use to order the boundary-scan cells. The *file_name* can be an absolute or relative path. If the path is relative, it is taken with respect to the current working directory.

The pin order file format is shown in [Figure 10-37](#) on page 3396. It consists of a four-column table in which the boundary scan ordering is taken from top to bottom. If you do not have a pin order file, you will not be able to specify more than one LogicalGroup wrapper in the [LogicalGroups](#) wrapper. If you have read in a DEF file using the `read_def` command, the order will be extracted from the placement of the pad cell in order to minimize the routing of the boundary scan chain.

The first column lists the name of the port as it exists in the chip netlist.

The second column lists the pin name the port maps to in its package. This information is only forwarded to the BSDL file and only needs to be accurate by the time the BSDL is used in the board environment. If you specify a “-” or nothing in this column, an integer will be automatically assigned to this port in the BSDL file which is often good enough given that chips today have multiple bounding configurations and packages. The pin name typically needs to be adjusted long after the design has been completed. You can specify nothing in the second column if you do not have anything to specify in the third or forth column. You must use “-” if you want to let the tool pick an integer for the pin name but you have entries to specify in the third or forth columns.

The third column is used to attach options to specific ports. It is equivalent to using the `port_name_pattern` property inside the [BoundaryScanCellOptions](#) wrapper. When specifying more than one option for a given port, you separate the options with a comma. If you have no option, you can specify “-”. You can also specify nothing at all in the third column as long as you do not have an entry in the LogicalGroups column.

The fourth column is used to group the boundary-scan cells into logical modules. It is equivalent to using the [LogicalGroups](#) wrapper inside the BoundaryScan wrapper. A “-” or no value at all in the forth column means that the given port belongs to the logical grouping of the port above it.

You can simply supply a `pin_order_file` which lists the ordered port list and nothing else in the second, third, and forth column. The pin names will be automatically assigned to

integers which you can adjust later on when the true pin names on the package are known. The options and the logical grouping can be specified more easily in the BoundaryScan wrapper because wildcards are supported.

Figure 10-37. Example pin_order_file

// PortName	PinName	OptionList	LogicalGroups
// -----	-----	-----	-----
IN1	1	-	left_0
IN2	2	-	-
GND1 [2]	3	GND	-
GND1 [1]	3A	GND	left_1
GND1 [0]	X1	GND	-
IN3	4	-	-
IN4	5	-	top
OUT1	6	-	-
OUT2	7	-	right_0
VDD1	Y1	PWR	-
TN	9	CE1	bottom
SCANIN	10	NJTAG	-
NC1	-	NC	right_0
TCKP	11	TCK	right_0
TMSP	12	TMS	right_0
TRSTP	13	TRST	right_0
TDIP	15	TDI	right_0
TDOP	16	TDO	right_0

- `interface_parent_instance : parent_instance ;`

An optional property that identifies the design module in which the tool will place the boundary scan interface. The default placement will be at the top level if this property is not specified.

- `outputs_per_enable_cell : int ;`

An optional property that instructs the tool to limit the number of output pins controlled by a given output enable cell. If the enable pin of the output pad cell is tied on or off, the tool is free to associate any output pad cell to any given enable cell in order to meet the outputs_per_enable_cell constraints. If, on the other hand, a group of output pad cells have their enable pin controlled by a single functional net, the tool inserts N enable boundary-scan cells and automatically separates the fanout of the enable signal such that the fanout of each enable cell is smaller than or equal to the specified outputs_per_enable_cell value. The splitting of the functional enable fanout is illustrated in the example of the [LogicalGroups](#) wrapper in [Figure 10-25](#) and [Figure 10-26](#).

- `max_segment_length_for_logictest : int | unlimited | off ;`

An optional property that when set to “unlimited” or an integer value, instructs the tool to segment the boundary scan chains into smaller segments to be reused by scan chain testing, EDT, or LogicBIST. If “unlimited” is specified the boundary scan chain will be accessible as one long scan chain.

Note

 To use the boundary scan cells to isolate the core from the primary input ports, add the int_ltest_en DFT signal using the [add_dft_signals](#) command. The signal will be connected to the boundary scan interface module and force the to_select_jtag_input port to 1 when asserted.

If you have inout ports or if you want to save power during the LogicBIST modes, add the output_pad_disable DFT signal to allow turning off the tri-state output buffers. The signal will be connected to the boundary scan interface module and force the to_force_disable port to one when asserted. The output pads used for channel outputs will be turned on during shift and tri-stated in capture mode. This will avoid bus conflict during ATPG and save burning power in the output pad buffers. The pad buffers will be tested by the boundary scan test patterns.

If an integer is specified, the boundary scan chain will be partitioned into segments of the specified size. Note that segments can end up having a different length because Tessent Shell is not able split the boundary scan chain at some positions, such as within a given [EmbeddedBoundaryScan](#) segment. You should choose a number that does not exceed the length of the other scan chains in the design because the boundary scan segments will otherwise increase your test time.

The default value of “off” indicates that the boundary scan chain is not reused during logic test.

- tristate_enable_non_contacted_test_support : on | off ;

An optional property that when set to “on” generates the hardware needed to test if the pad driver of a bidirectional non-contacted pad can be disabled by the global force_disable signal and the local output enable signal. Pattern generation is controlled through specifying the tristate_enable_non_contacted test for [RunTest](#).

The generated hardware is controlled by the two global DFT control signals tristate_enable_nc_test and tristate_enable_nc_test_type, which can be shown with the [report_dft_signal_names](#) command. It is recommended to specify these control signals with [add_dft_control_points](#) before creating the DFT specification so the IJTAG network will have TDRs to control the generated hardware.

This feature is not available in the embedded boundary scan implementation.

- tck_period : *period* ;

An optional property that instructs the tool to use a different default period of the test clock. The default value of the Tessent BoundaryScan period is 100ns.

Examples

The following example defines a BoundaryScan wrapper. The ijttag_host_node property is used to specify that the boundary scan chain is to be connected to a Tap controller defined in the IjttagNetwork wrapper. The file *./mychip.pin_order* is referenced using the pin_order_file property to order the boundary-scan cell so as to minimize routing. See the [set_boundary_scan_port_options -pin_order_file](#) option to have the [create_dft_specification](#)

command create a DftSpecification that points to an existing pin order file. See the [read_def](#) command to learn how to load a def file and have the pin order file automatically created following the placement of the ports in your design.

In this example, the pin order file only contains the column that lists the port names. The PinName column is omitted and the tool will auto assign integers to the pin names in the BSDL file. The Option column is also not used and, instead, the Options are specified using the [BoundaryScanCellOptions](#) wrapper. The outputs_per_enable_cell property is specified with a value of 8 which means that one enable boundary-scan cell will be inserted for every eight ports. A group of 22 pads in this design share a common functional enable signal. The tool will insert 3 enable cells for this group, each controlling the enable pin of 7 or 8 output pad buffers. The max_segment_length_for_logictest property is used to specify that the tool is to provide access to the boundary scan chain for logictest in chain segments no longer than 200 flip-flops long.

```
DftSpecification(mychip,rtl) {
    BoundaryScan {
        ijtag_host_node : Tap(main) ;
        pin_order_file : ./mychip.pin_order ;
        outputs_per_enable_cell : 8 ;
        max_segment_length_for_logictest : 200 ;
    }
}
```

Because the above example used the “max_segment_length_for_logictest” property, the instrument dictionary “mentor::jtag_bscan::DftSpecification” contains the “logic_test_scan_chains” section which can be accessed this way:

```
set logic_test_enable [get_instr_dict \
    mentor::jtag_bscan::DftSpecification logic_test_scan_chains]
foreach chain [dict keys $logic_test_enable chain*] {
    dict with logic_test_enable $chain {
        puts "length = $length"
        puts "scan_in = $scan_in"
        puts "scan_out = $scan_out"
        puts "scan_in_capture_edge = $scan_in_capture_edge"
        puts "scan_out_launch_edge = $scan_out_launch_edge"
    }
}
```

The dictionary can also be exported to file and re-used in a separate tool invocation when using the -variable_name switch and the redirection option “>”. The generated file can then later be sourced into a dofile to recover a variable called “bscan_ltest_chains” which holds the value of the dictionary.

```
format_dictionary [
    get_instrument_dictionary mentor::jtag_bscan::DftSpecification \
        logic_test_scan_chains \
] -variable_name bscan_ltest_chains > bscan_ltest_chains.dict
```

ImplementationOptions

Specifies implementation options when building the boundary-scan cells.

Usage

```
DftSpecification(module_name, id) {
    BoundaryScan | EmbeddedBoundaryScan {
        ImplementationOptions {
            clocking           : tck | gated_tck | gated_tck_inv ; // *DefSpec
            update_stage       : flop | latch ;
            scan_path_retiming : flop | latch ;
        }
    }
}
```

Description

A wrapper that specifies implementation options when building the boundary-scan cells. The options consist of the clocking, and the use of latches or flip-flops as an update stage and for scan path retiming.

Arguments

- **clocking: tck | gated_tck | gated_tck_inv ;**

A property that specifies how the clocking of the boundary-scan cell should be constructed. When specifying tck, the boundary-scan cells are clocked with the free-running TCK clock and the capture and shift is enabled using the capture_en and shift_en functions. This option requires one extra multiplexer per boundary-scan cell as compared to the gated_tck or gated_tck_inv implementations. When specifying gated_tck, a gated low version of TCK is used and the gating lets the TCK go through during the capture and shift enable pulse. When specifying gated_tck_inv, a gated high version of TCK is used and the gating lets the inverted TCK go through during the capture and shift enable pulse. All three clocking specifications behaves identically in IEEE 1149.1 mode. Using TCK versus the other two gated TCK options is a trade-off between area and the number and sizes of clock trees. Note that in all three cases, the boundary-scan cells are always built such that the scanin of each cell is strobed on the rising edge of TCK and the scanout is launched off the negedge of TCK to make sure boundary-scan cells will always work without having to balance TCK to all boundary scan cells which makes the ground bounce issue worst.

The gated_tck_inv option is a legacy clocking mode and is the one that is compatible with the existing LogicVision burst mode architecture. For more information, see the “[BurstMode Logic BIST Architecture](#)” section in the *LV Flow User’s Manual*.

[Table 10-3](#) illustrates the boundary scan cell implementations based on the clocking, update_stage and scan_path_retiming values.

- **update_stage: flop | latch ;**

A property that specifies if the update stage is to be implemented using a latch or a flop.

[Table 10-3](#) illustrates the boundary scan cell implementations based on the clocking, update_stage, and scan_path_retiming values.

- scan_path_retiming : flop | latch ;

A property that specifies if the scan path retiming element is to be implemented using a latch or a flop.

Table 10-3 illustrates the boundary scan cell implementations based on the clocking, update_stage, and scan_path_retiming values. Refer to **Table 10-5** to see the implementation of an input and sample_only boundary scan cell using the default implementation options. The following function abbreviations are used in the table figures:

- se — shift enable
- ce — capture enable
- ue — update enable
- si — scan input
- so — scan output
- sji — select jtag input
- sjo — select jtag output
- tck — test clock

Table 10-7. Illustration of Different Boundary Scan Implementations

- 1) This example shows how the boundary-scan cells are constructed when clocking is set to gated_tck, and update_stage and scan_path_retiming are both set to latch.

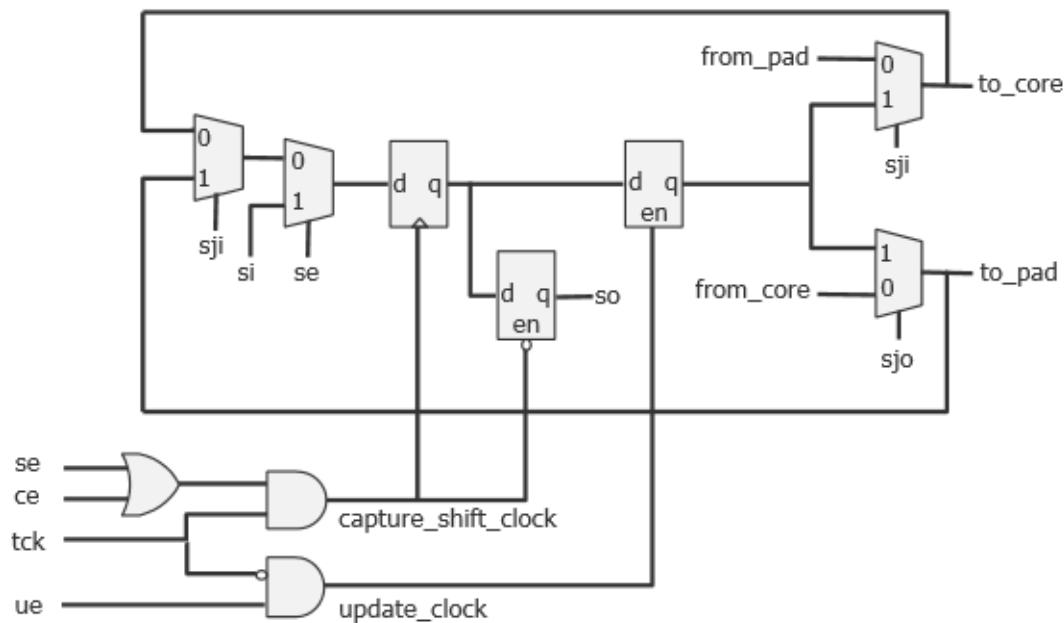

Table 10-7. Illustration of Different Boundary Scan Implementations (cont.)

2) This example shows how the boundary-scan cells are constructed when the clocking is set to gated_tck and update_stage and scan_path_retimng are both set to flop. Compared to the prior example, this shows how changing update_stage and scan_path_retimng from latch to flop simply converts the latch into a flop.

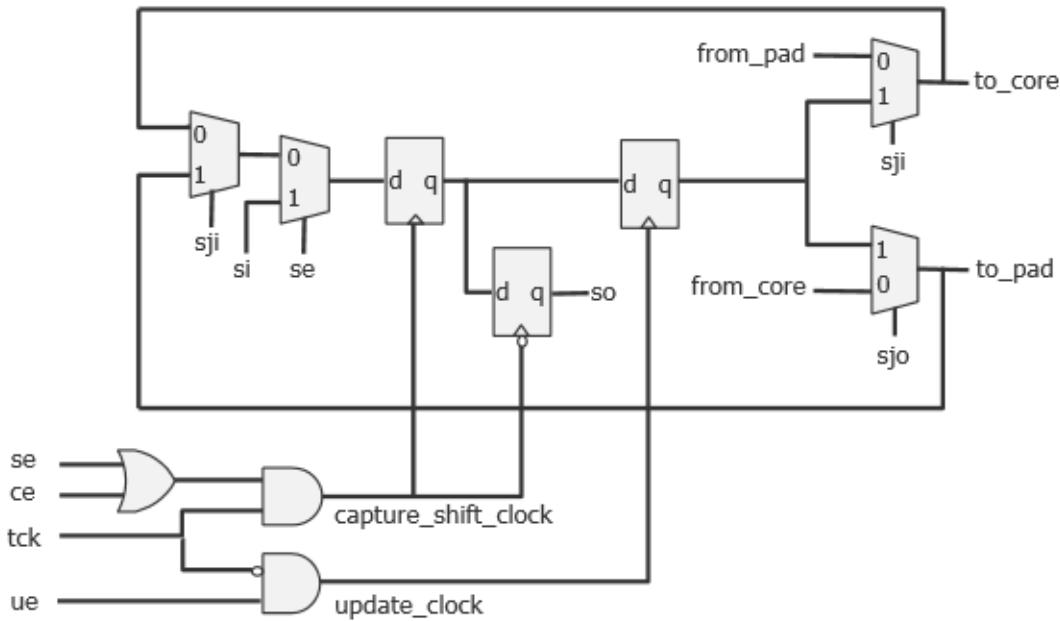

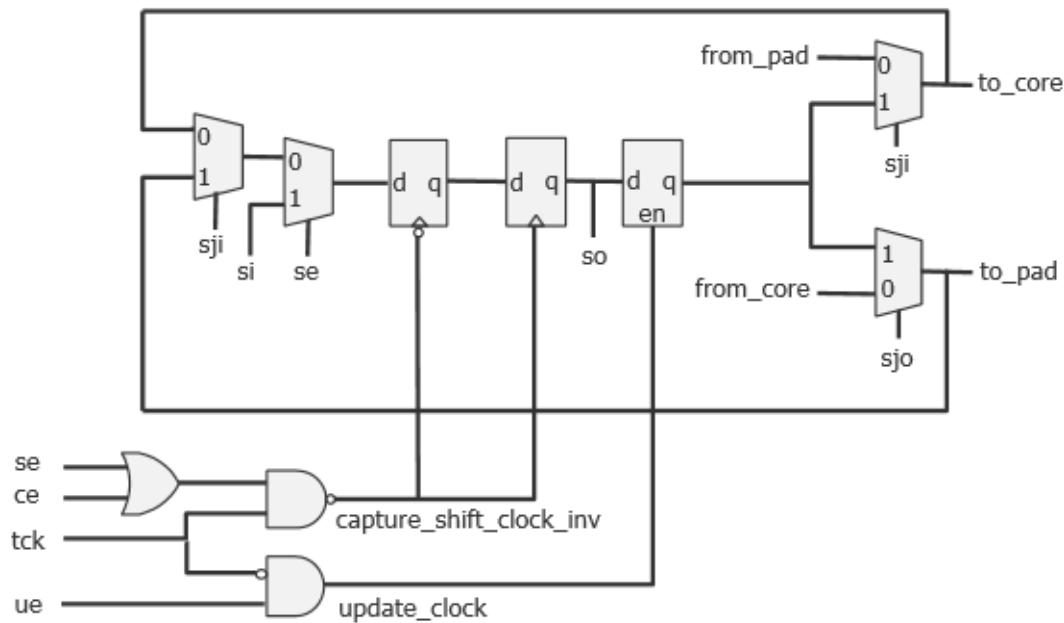

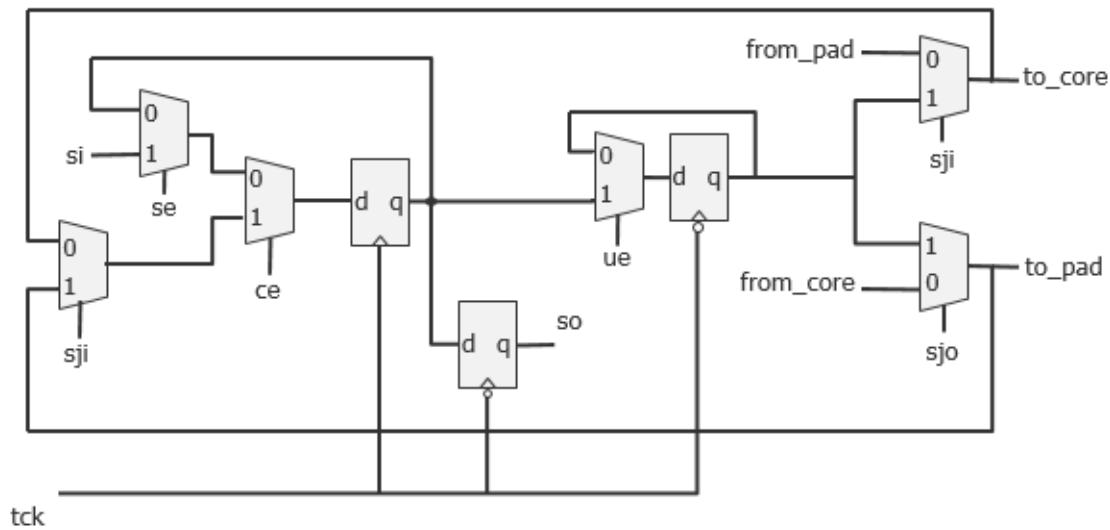

Table 10-7. Illustration of Different Boundary Scan Implementations (cont.)

3) This example shows how the boundary-scan cells are constructed when clocking is set to gated_tck_inv, and update_stage and scan_path_retimining are both set to latch. This is a legacy mode that makes the boundary-scan cell compatible with the LogicVision burst mode architecture. Notice how the implementation for gated_tck and gated_tck_inv are almost the same; only the active-low retiming flop is placed before the data flop.

4) This example shows how the boundary-scan cells are constructed when clocking is set to tck, and both update_stage and scan_path_retimining are set to flop. Notice the two extra multiplexers that are needed in each cell.

Examples

The following example sets the clocking property to gated_tck_inv and the update_stage to latch. The scan_path_retiming is unspecified so it defaults to latch.

```
DftSpecification(mychip,rtl) {
    BoundaryScan {
        ImplementationOptions {
            clocking      : gate_tck_inv ;
            update_stage : latch ;
        }
    }
}
```

BoundaryScanCellOptions

Assigns options to boundary scan ports.

Usage

```
DftSpecification(module_name, id) {
    BoundaryScan | EmbeddedBoundaryScan {
        BoundaryScanCellOptions {
            port_name_pattern : option, ... ; // repeatable
        }
    }
}
```

Description

This wrapper is used to assign options to boundary scan ports. This wrapper replaces the Overrides wrapper in the .etassemble file.

Arguments

- *port_pattern_name* : option, ...;

A syntax used to assign one or more option to a set of ports matched by the specified *port_pattern_name*. The *port_pattern_name* can include an asterisk “*” as a wildcard and %#d[lb:rb] as a counter. The # entry is optional and, when specified, is an integer specifying the minimum number of digits the number must have. For example, ABC%2d[0:2] will match “ABC00”, “ABC01”, and “ABC02”.

[Table 10-4](#) lists the option names and their meanings. The option can be specified in the BoundaryScanCellOptions wrapper or in the third column of the pin_order_file, as explained in the section.

Table 10-8. BoundaryScanCellOptions list

Option name	Meaning
add_dot6_from_pad_cell	Used to identify AC input and inout ports where the from_pad data signal will be intercepted with an additional boundary scan cell. The boundary scan cells sampling the AC pad Test Receivers will be added as normally done.
analog	Used to identify input, output, and inout ports that are analog. These pins do not have a boundary scan cell and are reported as linkage pins in the BSDL file.

Table 10-8. BoundaryScanCellOptions list (cont.)

Option name	Meaning
compliance_enable0	<p>Used to identify input and inout ports that are active low compliance enable pins. These ports are reflected as such in the BSDL file to reflect the fact that these pins must be driven low for the chip to behave in accordance with the BSDL description. The compliance enable zero pins are automatically asserted low in any pattern that makes use of the TAP controller.</p> <p>This option is automatically set when you use the <code>-enable_low_compliance_enables</code> switch of the create_dft_specification command. If the compliance enable logic is already present in your design, you cannot use the <code>-enable_low_compliance_enables</code> switch of the create_dft_specification command. Instead, you follow the steps illustrated in Example 2 of the IjtagNetwork wrapper section.</p>
compliance_enable1	<p>Used to identify input and inout ports that are active high compliance enable pins. Those ports are reflected as such in the BSDL file to reflect the fact that these pins must be driven high for the chip to behave in accordance with the BSDL description. The compliance enable one ports are automatically asserted high in any pattern that makes use of the TAP controller.</p> <p>This option is automatically set when you use the <code>-enable_high_compliance_enables</code> switch of the create_dft_specification command. If the compliance enable logic is already present in your design, you cannot use the <code>-enable_high_compliance_enables</code> switch of the create_dft_specification command. Instead, you follow the steps illustrated in Example 2 of the IjtagNetwork wrapper section.</p>
clock	<p>Used to identify input, output, and inout ports that are clocks. Specifying this value alters the RTL and the BSDL definition of the generated boundary-scan cells associated with the port.</p> <ul style="list-style-type: none"> • If the port is of type input or inout, the boundary-scan cell will have a BSDL function of “clock” and no JTAG multiplexer is inserted along the functional input path just as if the <code>sample_only</code> option was specified. • If the port is of type output or inout, the boundary-scan cell is modified to capture itself instead of the <code>from_core</code> signal in the output direction just as if the <code>no_capture_core_signal</code> option was specified.

Table 10-8. BoundaryScanCellOptions list (cont.)

Option name	Meaning
dont_touch	Used to identify input, output, and inout ports that are to be fully excluded from boundary scan. It is similar to using the no_bscan_cell option except that for output and inout ports, the output enable pin of the output pad buffer is not intercepted with the force_disable signal such that the port will not go tri-state during the HIGHZ instruction. These ports are reported as linkage pins in the BSDL file.
ground	Used to identify input and inout ports that are ground pins in the package part. These ports are reported as linkage in the BSDL file. The ports associated with the ground option may or may not exist in the design. If they do not exist in the design file, the port name pattern is not allowed to include the asterisk wildcard symbol "*" but you can use the %d[range] syntax to define a group of numbered ports as ground ports. The ports on which you have set the function attribute to ground prior to running the check_design_rules command are automatically identified as ground pins in the created DftSpecification wrapper when you run the create_dft_specification command.
input_only	Used to identify inout ports that are to be treated as input-only ports during boundary-scan insertion even if the actual port direction is inout in the netlist and the port is connected to a bidirectional pad cell. The generated BSDL file will document the port as input, and the port will only be equipped with an input-type boundary-scan cell.
no_bscan_cell	Used to identify input, output, and inout ports that are not to be equipped with a boundary-scan cell. It is similar to using the dont_touch option except that for output and inout ports, the output enable pin of the output pad buffer is still intercepted with the force_disable signal such that the port will still go tri-state during the HIGHZ instruction. These ports are reported as linkage pins in the BSDL file.
no_connect	Used to identify input, output, and inout ports that are not connected to package pins. Those ports are treated as dont_touch pins and they are not reported at all in the BSDL file.

Table 10-8. BoundaryScanCellOptions list (cont.)

Option name	Meaning
no_capture_core_signal	Used to identify output and inout ports that are to be equipped with boundary-scan cells that do not capture the functional core signal but instead hold their values during the capture cycle of the INTEST instruction. This option is useful when you are reusing the boundary scan chain as isolation during logictest and you want to avoid the boundary-scan cells from capturing unknowns when the from_core signal is not controllable during logictest. Avoiding unknowns is a requirement if you are using LogicBIST.
output_only	Used to identify inout ports that are to be treated as output-only ports during boundary-scan insertion even if the actual port direction is inout in the netlist and the port is connected to a bidirectional pad cell. The generated BSDL file will document the port as output, and the port will only be equipped with an output-type boundary-scan cell.
power	Used to identify input and inout ports that are power pins in the package part. These ports are reported as linkage in the BSDL file. The ports associated with the power option may or may not exist in the design. If they do not exist in the design file, the port name pattern is not allowed to include the asterisk wildcard symbol “*” but you can use the %d[range] syntax to define a group of numbered ports as ground ports. The ports on which you have set the function attribute to power prior to running the check_design_rules command are automatically identified as power pins in the created DftSpecification wrapper when you run the create_dft_specification command.
sample_only	Used to identify input and inout ports that are not to have a JTAG multiplexer inserted along the functional input path. The fanout of these ports cannot be intercepted by the boundary-scan cell value during the INTEST instruction. Also, if you reuse the boundary scan as isolation during logictest, these ports will not be isolated. This option is inferred for input or inout ports having the clock option. You typically also want to use it for Async reset input ports.

The differences between a normal input boundary scan cell and one assigned the sample_only option are illustrated in [Table 10-5](#) below. Refer to [Table 10-3](#) for information

on how an inout cell is constructed. The following function abbreviations are used in the table figures:

- se — shift enable
- ce — capture enable
- ue — update enable
- si — scan input
- so — scan output
- sji — select jtag input
- sjo — select jtag output
- tck — test clock

Table 10-9. Illustration of the “sample_only” Boundary Scan Cell Option

1) This example shows a normal input boundary scan cell. The multiplexer shown on the right intercepts the from_pad connection of the pad cell. The boundary scan cell can drive a value to the core in INTEST mode.

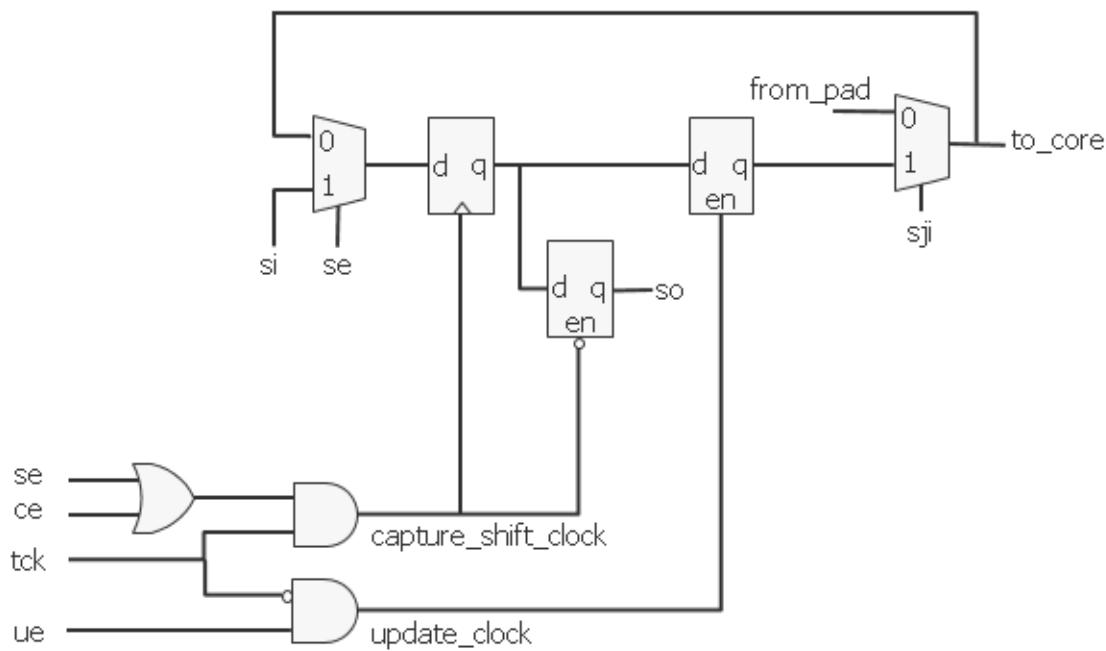

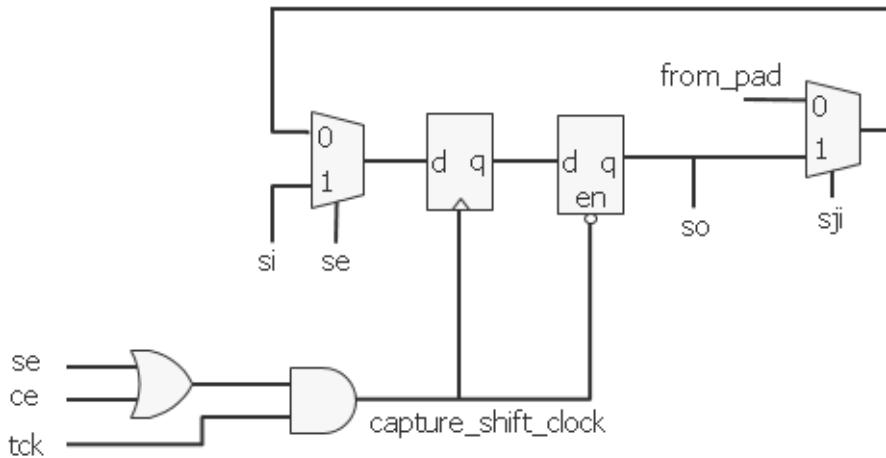

Table 10-9. Illustration of the “sample_only” Boundary Scan Cell Option (cont.)

2) The example below shows a sample_only input boundary scan cell. The multiplexer shown on the right will no longer intercept the from_pad connection of the pad cell, but will simply connect to it, preserving the direct connection between the pad and core. Note that compared to the normal input boundary scan cell, the update latch has been removed and the retiming latch is now connected to the multiplexer on the right.

Examples

The following example uses the `BoundaryScanCellOptions` wrapper to identify VDD and VSS ports in the BSDL file. These port do not exist in the design. The pattern `clk*` is used to match any ports in the design starting with the string “clk” as clock ports. They will not have a JTAG mux inserted along their functional input path, and they will be identified as Clock ports in the BSDL file.

```
DftSpecification(mychip,rtl) {
    BoundaryScan {
        BoundaryScanCellOptions {
            VDD%d[0:32] : power ;
            VSS%d[0:56] : ground ;
            clk* : clock;
        }
    }
}
```

LogicalGroups

Specifies how to group the boundary-scan cells into logical grouping modules.

Usage

```
DftSpecification(module_name, id) {
    BoundaryScan | EmbeddedBoundaryScan {
        LogicalGroups {
            LogicalGroup(group_name) {
                first_port : port_name ;
                parent_instance : parent_instance ;
                leaf_instance_name : leaf_instance_name ;
            }
        }
    }
}
```

Description

A wrapper that specifies how to group the boundary-scan cells into logical grouping modules. You can specify more than one LogicalGroup wrapper only when you have specified the pin_order_file property in the [BoundaryScan](#) wrapper.

You use the first_port property to identify the first port in the pin order file that belongs to the logical grouping. The association between ports and the LogicalGroup can also be specified in the forth column of the pin order file. If you do not specify any LogicalGroup(*group_name*) wrapper, all boundary scan cells are grouped into a single module, the module is instantiated into the top module, and the leaf instance name is as follows:

design_name_design_id_tessent_bscan_logical_group_DEF_inst

as if you had specified an empty LogicalGroup(DEF) wrapper.

You use the parent_instance property to specify where you want the logical grouping module to be instantiated. By default, it will be instantiated in the top module. You use the leaf_instance_name property to specify the leaf instance name used when instantiating the module if you are not satisfied with the default value. The default leaf_instance_name used is *design_name_design_id_tessent_bscan_logical_group_group_name_inst*.

The example below shows how to specify the parent_instance property in order to insert each logical grouping module in the same instance where the pins or nets to be intercepted by the boundary-scan cells are located.

Arguments

- *group_name*

A string that uniquely identifies each logical group. The string starts with a letter and it is allowed to be followed by any number of letters, numbers, and underscores. The group_name is used in constructing the grouping module name as follows:

design_name_design_id_tessent_bscan_logical_group_group_name

- `first_port : port_name ;`

A property that specifies a port name that exists in the specified pin_order_file. This property is optional when there is only one LogicalGroup wrapper but it is required when there are more than one. Specifying a port_name for the first_port property is equivalent to specifying the group_name in the forth column of that port in the pin_order_file. See the pin_order_file property description in the BoundaryScan wrapper for a description of that file format and usage.

- `parent_instance : parent_instance ;`

A property that controls where the logical grouping module will be instantiated. By default, it is instantiated in the root module but you can push it down into instances. See the following example to understand the requirement that must be met when choosing the parent_instance of the logical grouping module.

If the specified parent_instance is not unique, it will be uniquified before the logical grouping module is inserted in it. You can do bottom up insertion using the [EmbeddedBoundaryScan](#) wrapper on sub modules to insert segments of boundary scan chains into repeated modules, and then reuse them as building blocks at the next level up if you want to avoid uniquifying the parent_instance. Specify the “[set_design_level sub_block](#)” command and option when inserting boundary scan into those sub modules.

- `leaf_instance_name : leaf_instance_name ;`

A property that specifies a different leaf name when instantiating the logical grouping module into its parent instance. The default value when unspecified is `design_name_design_id_tessent_bscan_logical_group_group_name_inst`.

If you choose to change it, you do not have to worry about picking a unique leaf name in the given parent_instance. The tool will automatically append the `instance_uniquification_suffix` to your specified leaf instance name in case of conflicts. See the [set_insertion_options](#) command description for a complete description of the `-instance_unification_suffix` option.

Examples

The following example illustrates the use of the parent_instance property of the LogicalGroup wrapper to meet the rule that the logical grouping module must be instantiated where all the intercepted nets are visible. [Figure 10-22](#) shows the circuit before the insertion of the boundary-scan cells. You can see that the functional connections to and from the pad cells associated with ports P3 and P4 do not exist outside the B1_I instance. In this example, a single logical grouping module is specified so it can only be instantiated inside B1_I as illustrated in [Figure 10-23](#).

```
BoundaryScan {
    LogicalGroups {
        LogicalGroup(g1) {
            parent_instance : B1_I ;
        }
    }
}
```

The same example is modified to use a pin_order file thus enabling the splitting of the boundary-scan cells into more than one logical grouping module. The pin order file defines the order from P1 to P4. Two logical grouping modules are specified in which the first one, g1, starts with P1 and goes until P2 and the second one, g2, starts with P3 and goes until P4. The g2 group is still restricted to having its parent_instance property as B1_I because this is the only place where all of the connections to be intercepted are visible. The g1 group is, on the other hand, allowed to be instantiated in four locations because all of the connections to be intercepted are visible in those four locations. The parent_instance is shown for the four options and the corresponding locations of the logical grouping modules are shown in [Figure 10-24](#).

```
BoundaryScan {
    pin_order_file      : mychip.pin_order
    LogicalGroups {
        LogicalGroup(g1) {
            first_port      : P1 ;
            parent_instance : B1_I ;           // Option1
            parent_instance : . ;           // Option2
            parent_instance : B2_I ;           // Option3
            parent_instance : B2_I/B3_I ;     // Option4
        }
        LogicalGroup(g2) {
            first_port      : P3 ;
            parent_instance : B1_I ;
        }
    }
}
```

The example also illustrates that you can specify the outputs_per_enable_cell property with a value smaller than the actual fanout count of the functional enable signal. In this case, the functional enable signal fans outs to two output pads. One enable boundary-scan cell is inserted per output port, requiring the tool to split the output enable connectivity to each pad.

[Figure 10-25](#) shows this example with option1 for the parent_instance property. No new ports need to be created. The functional enable signal is observable by two enable bscan cells, and one connection per output pad is made between the logical grouping module and the enable pin of the output pad cells.

[Figure 10-26](#) shows this example with option3 for the parent_instance property. In this case, the connections between the logical grouping module and the output pads require the creation of new pins as illustrated with the orange net crossing the hierarchy. If you are familiar with Tessent Boundary Scan within ETAssemble, the flexibility to precisely control the fanout of the enable signals was not present in that tool. All of those existing limitations are removed within Tessent Shell, and a net driven by RTL can now be intercepted and split for boundary scan usage. In ETAssemble, you needed the functional enable signal to be identified on a pin which often meant you had to insert buffers in the RTL to enable the Boundary Scan to be placed in the same module as the pads.

```
BoundaryScan {
    pin_order_file      : mychip.pin_order
    OutputPerEnableCell : 1 ;
    LogicalGroups {
        LogicalGroup(g1) {
            first_port      : P1 ;
            parent_instance : B1_I ;           // Option1
            parent_instance : B2_I ;           // Option3
        }
        LogicalGroup(g2) {
            first_port      : P3 ;
            parent_instance : B1_I ;
        }
    }
}
```

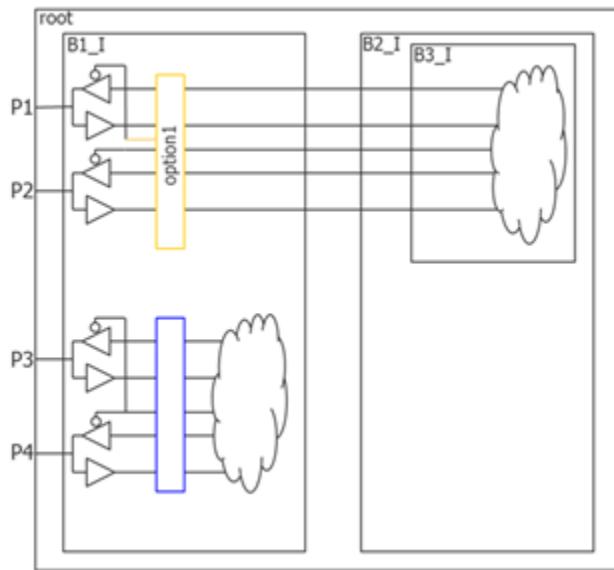

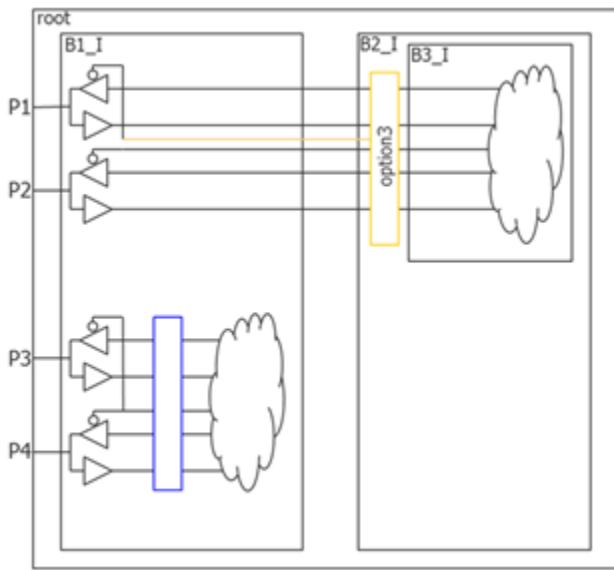

Figure 10-42. Two Logical Groups Example2 with One Output per Enable Cells

ACModeOptions

Specifies options relevant to the IEEE 1149.6 AC mode of the boundary scan chain.

Usage

```
DftSpecification(module_name, id) {
    BoundaryScan {
        ACModeOptions {
            test_receiver_init_clock_value : initialization_event ;
                // Legal: logic_low logic_high
                // falling_edge rising_edge auto
            pulse_min_duration : time | auto ;
            train_minimum_count : count | unused ;
            train_max_duration : time | unlimited ;
            ACGroup(group_name) {
                insert_before_port : port_name ;
                insert_after_port : port_name ;
                port_list : port_name, ... ;
            }
        }
    }
    EmbeddedBoundaryScan {
        ACModeOptions {
            test_receiver_init_clock_value : initialization_event ;
                // Legal: logic_low logic_high
                // falling_edge rising_edge auto
            ACGroup(group_name) {
                insert_before_port : port_name ;
                insert_after_port : port_name ;
                port_list : port_name, ... ;
            }
        }
    }
}
```

Description

A wrapper that specifies options relevant to the IEEE 1149.6 AC mode of the boundary scan chain. You use this wrapper to define AC enable cells and associate them with a group of ports. You also use this wrapper to specify the event type that initializes the test receiver when the value is not described in the cell library. Finally, you can use this wrapper to specify three properties that are simply forwarded into the BSDL file.

Arguments

- `test_receiver_init_clock_value : initialization_event ;`

A property that is useful when the cell library description of the dot6 pad cell uses the legacy `pad_init_clock_dot6` attribute instead of one of the new attributes that precisely describe the initialization event: `pad_init_posedge_clock_dot6`, `pad_init_negedge_clock_dot6`, `pad_init_enable_high_dot6`, and `pad_init_enable_low_dot6`. If the value is “auto” and the dot6 pad cell uses the legacy `pad_init_clock_dot6` attribute instead of one of the four new attributes, the tool issues an error; you are required to specify the initialization event when it cannot be inferred from the cell library.

- `pulse_min_duration : time | auto ;`

An optional property that defines the minimum time to use between the rising and a falling edge during the AC tests. This property is forwarded into the BSDL file using the AIO_EXTEST_Pulse_Execution attribute. When unspecified or specified to “auto”, the minimum pulse duration is chosen so as not to be smaller than three times the larger of the HP_time and LP_Time BSDL values of each pad cell.

```
attribute AIO_EXTEST_Pulse_Execution of <current_design>: entity is
    "Wait_Duration <pulse_min_duration_in_seconds>" ;
```

- `train_minimum_count : count | unused ;`

An optional property that defines the minimum number of pulses the train test must have. This property is forwarded in the BSDL file using the AIO_EXTEST_Train_Execution attribute. The property defaults to “unused” when unspecified. Specifying a value of one effectively makes the train test equivalent to the pulse test.

```
attribute AIO_EXTEST_Train_Execution of <current_design>: entity is
    "train <train_minimum_count>, maximum_time <train_max_duration>" ;
```

- `train_max_duration : time | unlimited ;`

An optional property that defines a maximum time the train test must take. This property is forwarded in the BSDL file using the AIO_EXTEST_Train_Execution attribute. It defaults to “unlimited” when unspecified.

- `group_name`

A string that uniquely identifies the ACGroup. This name is not reflected in the BSDL file but is used to name the leaf instance name of the AC group enable cell in the logical grouping module.

If no AcGroup wrappers are specified, then all AC ports are active during the AC tests. If you specified at least one ACGroup wrapper but you have some AC ports not associated with an ACGroup, they will always be active during the AC tests. In this situation, a warning is generated to let you know that not all AC pins were equipped with an AC enable cell. You can define an extra ACGroup wrapper without a port_list property to indicate that you want all AC ports not associated with another ACGroup wrapper to be associated with that one.

- `insert_before_port : port_name ;`

A property that specifies the position of the AC enable boundary-scan cell. This property can only be used when the pin_order_file property inside the [BoundaryScan](#) wrapper is specified. The specification of the insert_before_port property is mutually exclusive with the specification of the insert_after_port property. If neither the insert_before_port nor insert_after_port properties are specified, the AC enable boundary-scan cell is inserted in front of the boundary-scan cell of the first port that is part of the group. The location of the AC group enable boundary-scan cell is reflected in the BSDL file using the AIO_Pin_Behavior attribute.

- `insert_after_port : port_name ;`

A property that specifies the position of the AC enable boundary-scan cell. This property can only be used when the `pin_order_file` property inside the [BoundaryScan](#) wrapper is specified. The specification of the `insert_before_port` property is mutually exclusive with the specification of the `insert_after_port` property. If neither the `insert_before_port` nor `insert_after_port` properties are specified, the AC enable boundary-scan cell is inserted in front of the boundary-scan cell of the first port that is part of the group. The location of the AC group enable boundary-scan cell is reflected in the BSDL file using the `AIO_Pin_Behavior` attribute.

- `port_list : port_name_pattern, ... ;`

A property used to list the port names that belong to the AC group. The `port_name_pattern` can include the asterisk “*” as a wildcard and `%#d[lb:rb]` as a counter. The `#` entry is optional and, when specified, is an integer specifying the minimum number of digits the number must have. For example, `ABC%2d[0:2]` will match ABC00, ABC01, and ABC02.

You are allowed to have one `ACGroup` wrapper with an unspecified `port_list`. This `ACGroup` will collect all AC ports that are not already associated with another `ACGroup` wrapper.

Examples

The following example defines an `ACGroup` wrapper with the name “`pci`” to specify that all ports starting with `PCI_` belong to the group. All other AC ports are associated with the “`other`” group. The “`other`” `ACGroup` collects all other AC ports because it does not specify the `port_list` property.

```
DftSpecification(my_chip,rtl) {
    BoundaryScan {
        AcGroups {
            ACGroup(pci) {
                port_list : PCI_* ;
            }
            ACGroup(other) {
            }
        }
    }
}
```

AuxiliaryInputOutputPorts

Specifies two lists of port name patterns to be used as Auxiliary input and/or output ports during some test modes.

Usage

```
DftSpecification(module_name, id) {
    BoundaryScan {
        AuxiliaryInputOutputPorts {
            auxiliary_input_ports : port_name_pattern, ... ;
            auxiliary_output_ports : port_name_pattern, ... ;
        }
    }
    EmbeddedBoundaryScan{
        AuxiliaryInputOutputPorts {
            internal_auxiliary_input_ports : port_name_pattern, ... ;
            internal_auxiliary_output_ports : port_name_pattern, ... ;
            external_auxiliary_input_ports : port_name_pattern, ... ;
            external_auxiliary_output_ports : port_name_pattern, ... ;
        }
    }
}
```

Description

A wrapper that specifies two lists of port name patterns to be used as Auxiliary input and/or output ports during some test modes. An inout port is allowed to be specified in both lists at the same time. In the output directions, a 2-to-1 multiplexer (shown in green in [Figure 10-29](#)) is added on the test side of the JTAG multiplexer (shown in red in [Figure 10-29](#)). The auxiliary output multiplexing is added in the boundary-scan cell to avoid cascading two multiplexers along the functional output path. For auxiliary input logic, an AND gate is used to prevent the aux_in_data signal from toggling in functional mode. The aux_in_en signal is also used to force the output pad driver off when adding AuxIn logic on an inout pad.

The aux_out_enable and aux_in_enable signals are kept separate for each port to provide full flexibility as to which output and input ports are enabled to carry input or output auxiliary data in any given test mode. The ports equipped with auxiliary data input and output logic are useful for supplying channel input and output data to EDT controllers. They are also useful to provide the source of the scan_en, test_clock, and edt_update DFT signals. See the description of the [add_dft_signals](#) command for more info. Notice that the aux_out_en and aux_in_en signals have higher priority than the select_jtag_input and select_jtag_output signals. The reason for this is explained below but has the implication that the aux_out_en and aux_in_en sources must reset off and remain off when using the IEEE 1149.1 test mode of the chip. This requirement is met if you use the DFT signals created by the [add_dft_signals](#) to control those pins.

[Figure 10-27](#) shows the typical boundary scan cell inserted on a inout pad. The red multiplexers are those referred to as JTAG multiplexers in the first paragraph. They are controlled by the select_jtag_output to allow the output data and the output enable values to be controlled by the Boundary Scan cells in IEEE 1149.1 test modes.

Figure 10-43. Typical Boundary Scan Cell Inserted for an Inout Pad

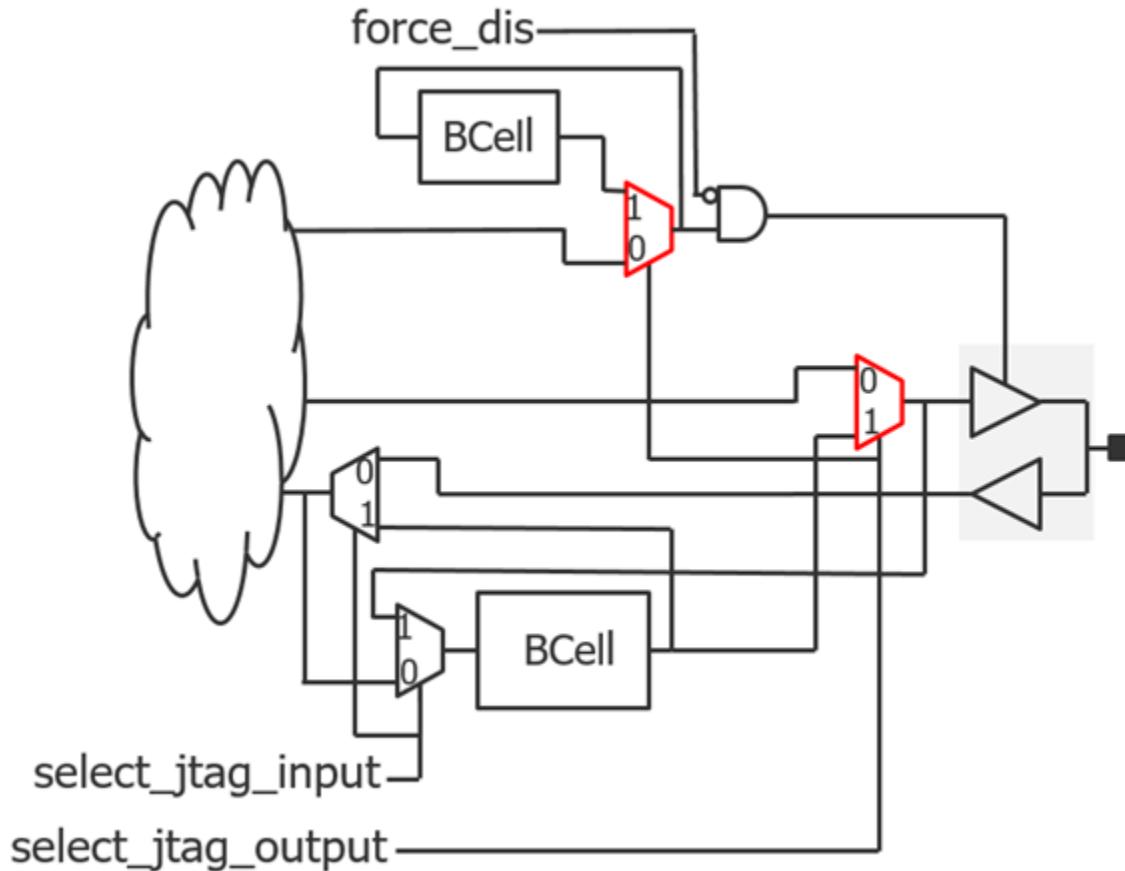

Figure 10-28 shows the boundary scan cell when it is used during ATPG. If you set the `max_segment_length_for_logictest` property found in the Boundary Scan wrapper to an integer or to unlimited, ATPG scan chains are created with the Boundary Scan chain. The blue path shows how the boundary scan cell is used to isolate the core values from the input ports by forcing `select_jtag_input` to 1 which is done by forcing the `int_ltest_en` pin on the boundary scan interface module. For more information about the boundary scan interface module and the logic inserted in it when the boundary scan chain is reused in logic test, see [Figure 10-35](#) on page 3391.

Note

If you are using the DFT signal flow, simply add the `int_ltest_en` DFT signal using the `add_dft_signals` command when you reach the top level and it will be connected to the boundary scan interface module. You can then activate the input isolation using the “`set_static_dft_signal_values int_ltest_en 1`” command and switch when it is time to create your ATPG patterns.

The `select_jtag_output` signal is under ATPG control allowing both the input of the output of the JTAG multiplexers (shown in red) to be tested. If you do not force the `int_ltest_en` pin to 1, then the `select_jtag_input` will also be under ATPG control and the input path can also be tested.

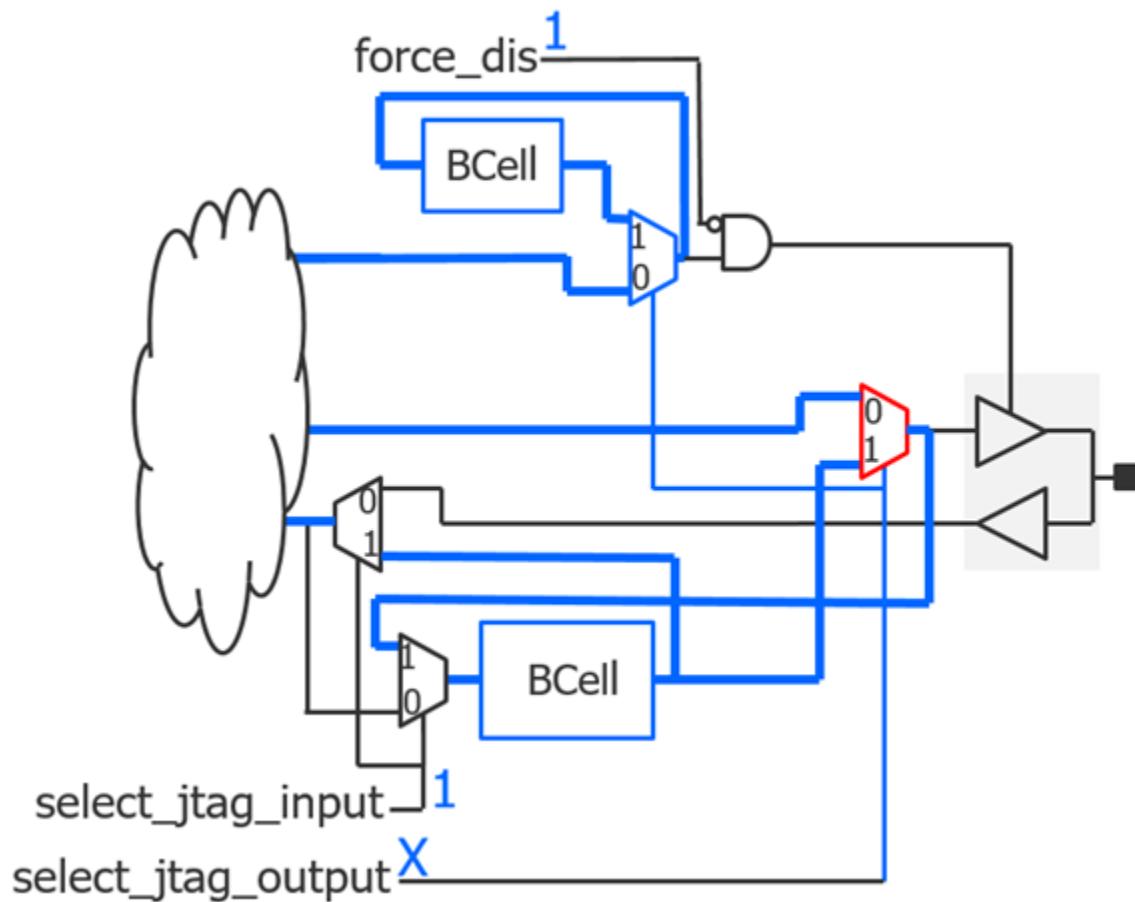

Figure 10-44. Boundary Scan Cell as Observation and Control in Logic Test Modes

Figure 10-29 shows the same boundary scan cell shown in Figure 10-27 but with auxiliary logic (colored green) added for both the input and output directions. Notice how the green multiplexer is not inserted along the functional path but on the test side of the JTAG multiplexer shown in red. The aux_in_en and aux_out_en signals are mutually exclusive, and the boundary scan cell is in functional mode when they are both low.

Figure 10-45. Adding Auxiliary Input and Output Logic in Bscan Cell

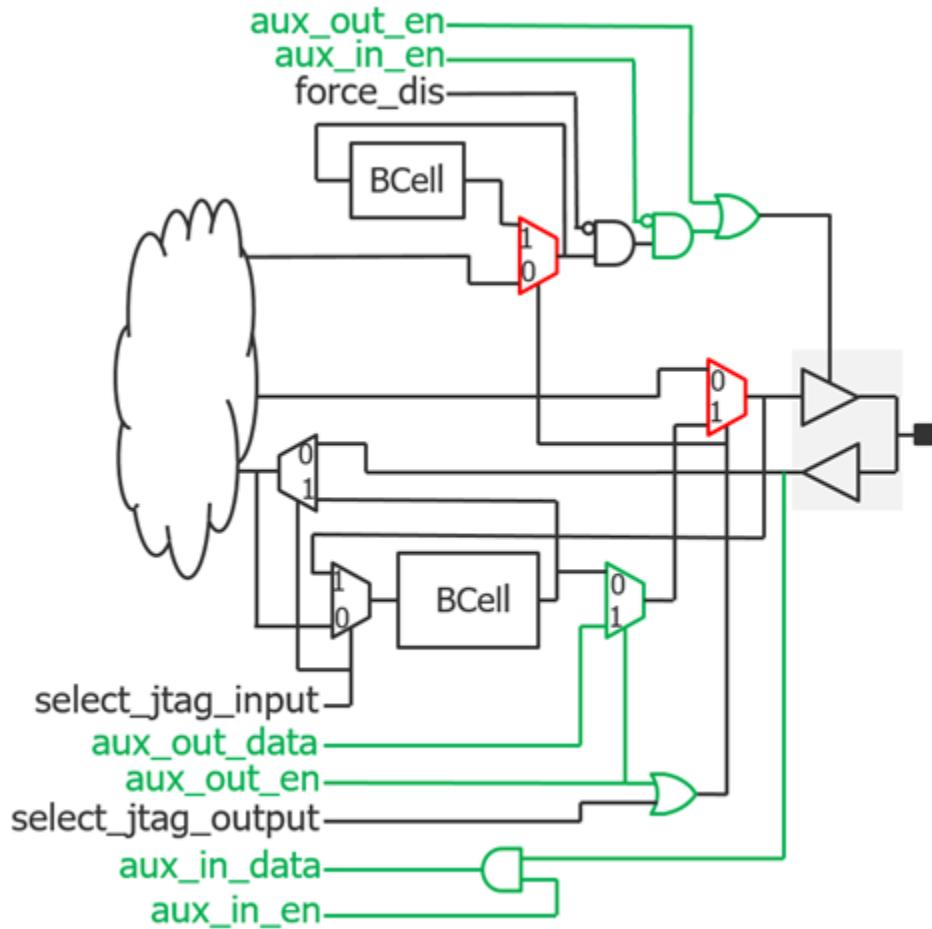

Figure 10-30 shows aux_out_en asserted to 1 to enable the auxiliary output data path. The two multiplexers are switched to select the aux_out_data value, and the enable of the output pad is forced on. When aux_out_en is high, the boundary scan cell is not able to observe the value coming from the core. This is why the [add_dft_modal_connections](#) command gates the aux_out_en signals with “scan_en” such that it is active only in shift mode. In capture mode, the aux_out_data is not needed, and instead the boundary scan cell is used to observe the functional core output. The capture mode is shown in Figure 10-31.

Figure 10-46. Path Used When AuxOut Logic Activated

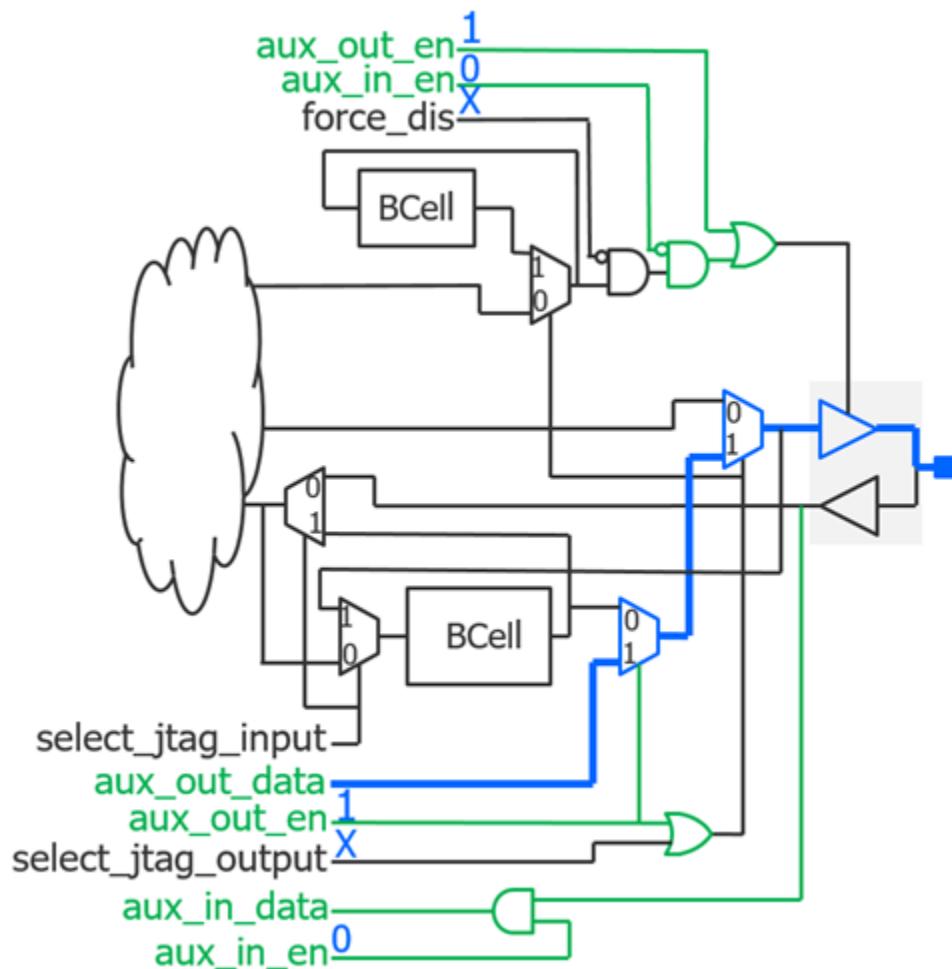

Figure 10-47. Forcing aux_out_en Low in Capture Mode to Observe Core Output

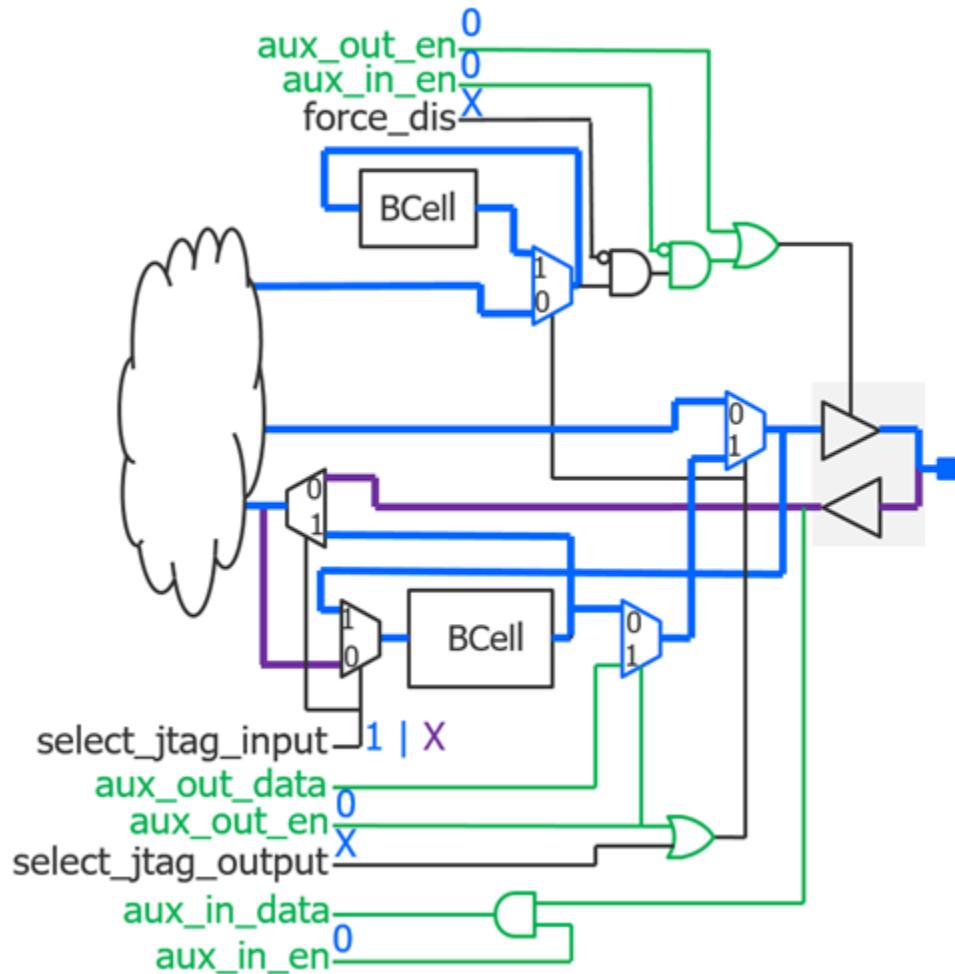

Figure 10-32 shows the IO pad used as an auxiliary input during ATPG. The boundary scan cell is used to control the signal going to the core while the input buffer provides the value to the auxiliary in data. This scheme is useful to allow reusing functional pins for the DFT signals `scan_en`, `test_clock`, and `edt_update` without losing ATPG fault coverage of those inputs.

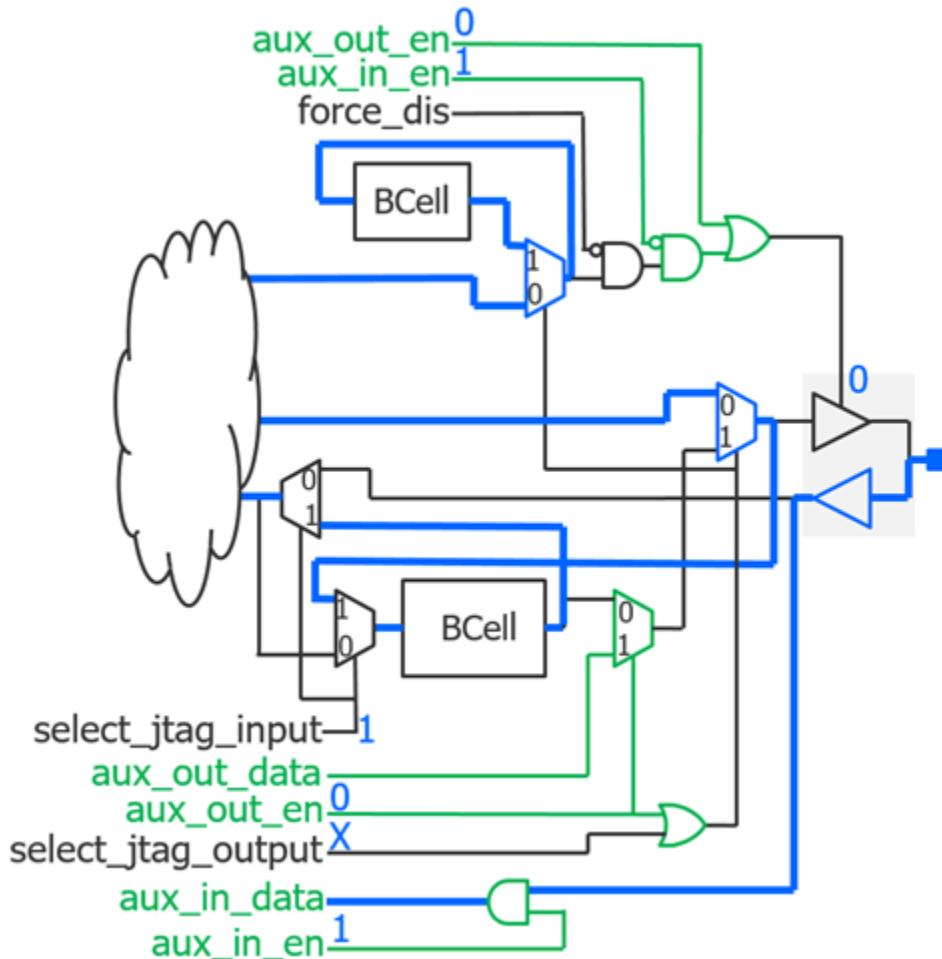

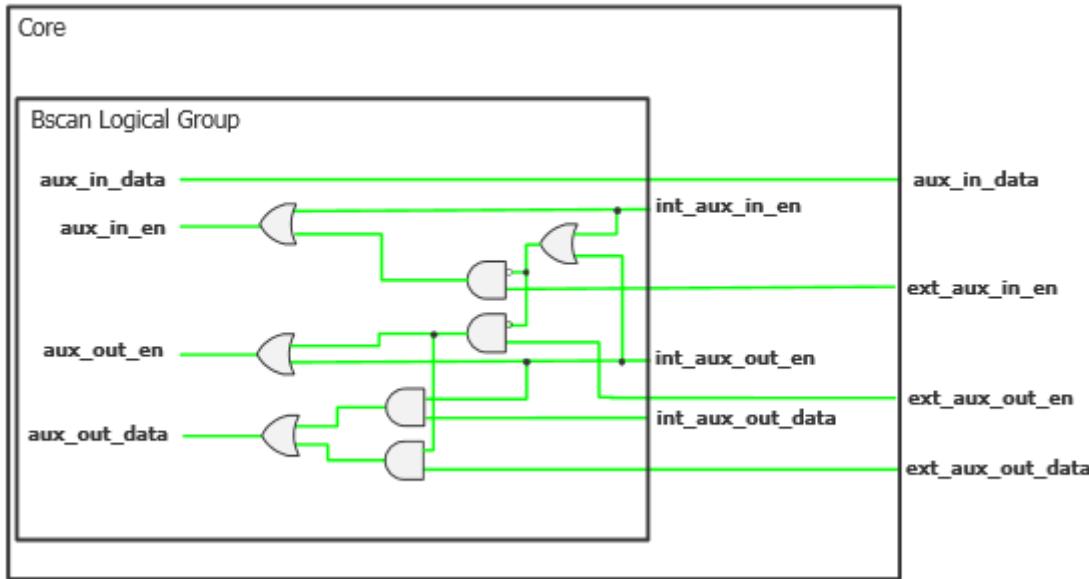

Figure 10-48. Using AuxIn and Controlling to Core Signal in ATPG

Figure 10-33 shows the extra logic that is added when the same port is used as both an internal and an external auxiliary data in the EmbeddedBoundaryScan/AuxiliaryInputOutputPorts wrapper. In the output direction, two data_out input pins are created on the logical grouping module. One of those inputs is used to make auxiliary output connections for elements found within the block and the other input is connected to an input of the block to make auxiliary output connections for elements found outside the block. In the input direction, the same data output port on the logical grouping module is used for providing auxiliary data inputs to elements located inside and outside the block. Both directions have an internal and external enable pin. The internal pins are used by the elements inside the blocks and the external pins are used by the elements outside the blocks. For example, if you call [add_dft_modal_connections](#) inside the block, it will make connections to the internal pins; and if you call [add_dft_modal_connections](#) outside the block, it will make connections to the external pins.

Figure 10-49. Extra Logic Added When a Port is Used Both Internally and Externally

Arguments

- auxiliary_input_ports : *port_name_pattern*, ... ;

A property that specifies a list of port name patterns to define a group of input or inout ports as auxiliary input ports. The same inout port can be both an input and an output auxiliary port. The auxiliary inputs are left tied on the logic group module to be used by test logic found inside the chip.

The *port_name_pattern* values can include an asterisk "*" as a wildcard and %#d[lb:rb] as a counter. The # entry is optional, and when specified is an integer specifying the minimum number of digits the number must have. For example, ABC%2d[0:2] will match ABC00, ABC01, and ABC02.

- auxiliary_output_ports : *port_name_pattern*, ... ;

A property that specifies a list of port name patterns that defines a group of output or inout ports as auxiliary output ports. The same inout port can be both an input and an output auxiliary port. The auxiliary output ports are left dangling on the logic group module to be used by test logic found inside the chip.

The *port_name_pattern* can include an asterisk "*" as a wildcard and %#d[lb:rb] as a counter. The # entry is optional and when specified is an integer specifying the minimum number of digits the number must have. For example, ABC%2d[0:2] will match ABC00, ABC01, and ABC02.

- internal_auxiliary_input_ports : *port_name_pattern*, ... ;

A property that specifies a list of port name patterns to define a group of input or inout ports as internal auxiliary input ports. The same inout port can be both an input and an output auxiliary port. An internal auxiliary input port differs from an external one in how the

auxiliary ports on the boundary scan logical group module are connected. When internal, they are left dangling on the logic group module to be used by test logic found inside the block. When external, the ports are connected to primary input and output ports of the block to be used by test circuit outside the block.

The *port_name_pattern* values can include an asterisk “*” as a wildcard and %#d[lb:rb] as a counter. The # entry is optional and when specified is an integer specifying the minimum number of digits the number must have. For example, ABC%2d[0:2] will match ABC00, ABC01, and ABC02.

- `internal_auxiliary_output_ports : port_name_pattern, ... ;`

A property that specifies a list of port name patterns that defines a group of output or inout ports as internal auxiliary output ports. The same inout port can be both an input and an output auxiliary port. An internal auxiliary output port differs from an external one in how the auxiliary ports on the boundary scan logical group module are connected. When internal, they are left tied on the instance of the logic group module to be used by test logic found inside the block. When external, the ports are connected to primary input ports of the block to be used by test circuit outside the block.

The *port_name_pattern* can include an asterisk “*” as a wildcard and %#d[lb:rb] as a counter. The # entry is optional and when specified is an integer specifying the minimum number of digits the number must have. For example, ABC%2d[0:2] will match ABC00, ABC01, and ABC02.

- `external_auxiliary_input_ports : port_name_pattern, ... ;`

A property that specifies a list of port name patterns to define a group of input or inout ports as external auxiliary input ports. The same inout port can be both an input and an output auxiliary port. An internal auxiliary input port differs from an external one in how the auxiliary ports on the boundary scan logical group module are connected. When internal, they are left dangling on the instance of the logic group module to be used by test logic found inside the block. When external, the ports are connected to primary output ports of the block to be used by test circuit outside the block. The ports on the block follow the naming specified by the [Interface](#)/`auxiliary_*` properties.

The *port_name_pattern* can include an asterisk “*” as a wildcard and %#d[lb:rb] as a counter. The # entry is optional and when specified is an integer specifying the minimum number of digits the number must have. For example, ABC%2d[0:2] will match ABC00, ABC01, and ABC02.

- `external_auxiliary_output_ports : port_name_pattern, ... ;`

A property that specifies a list of port name patterns that defines a group of output or inout ports as external auxiliary output ports. The same inout port can be both an input and an output auxiliary port. An internal auxiliary output port differs from an external one in how the auxiliary ports on the boundary scan logical group module are connected. When internal, they are left tied on the instance of the logic group module to be used by test logic found inside the block. When external, the ports are connected to primary input ports of the block to be used by test circuit outside the block. The ports on the block follow the naming specified by the [Interface](#)/`auxiliary_*` properties.

The *port_name_pattern* can include an asterisk “*” as a wildcard and %#d[lb:rb] as a counter. The # entry is optional and when specified is an integer specifying the minimum number of digits the number must have. For example, ABC%2d[0:2] will match ABC00, ABC01, and ABC02.

Examples

The following example defines the GPIO00 to GPIO31 ports as both auxiliary input and output ports. The first 16 are usable by test logic that is both internal and external to the block. The last 16 are only used by test logic that is external to the block. The full flexibility is preserved such that each test mode will be able to use N of them as auxiliary output ports and the rest as auxiliary inputs where N can be different for each test mode.

```
DftSpecification(my_chip,rtl) {
    EmbeddedBoundaryScan {
        AuxiliaryInputOutputPorts {
            internal_auxiliary_input_ports : GPIO%2d[0:15] ;
            internal_auxiliary_output_ports : GPIO%2d[0:15] ;
            external_auxiliary_input_ports : GPIO%2d[0:31] ;
            external_auxiliary_output_ports : GPIO%2d[0:31] ;
        }
    }
}
```

EnableGroups

Specifies the creation of enable groups using either the ports in the fanout of a functional enable signal or a specified port list.

Usage

```
DftSpecification(module_name, id) {
    BoundaryScan | EmbeddedBoundaryScan {
        EnableGroups {
            EnableGroup(name) {
                capture_core_signal : on | off ;
                internal_enable_signal : pin_or_net_name ;
                port_list : port_name_pattern, ... ;
                insert_before_port : port_name ;
                insert_after_port : port_name ;
            }
        }
    }
}
```

Description

A wrapper that specifies the creation of enable groups using either the ports in the fanout of a functional enable signal or a specified port list. The properties `insert_before_port` and `insert_after_port` are used to specify the location of the enable cells associated with the group. The property `capture_core_signal` is used to prevent the cell from capturing the core signal during INTEST or during logictest when the boundary scan is used as isolation.

Arguments

- `capture_core_signal : on | off ;`

A property that specifies if the enable boundary-scan cells associated with the group are allowed to capture the core signal during INTEST or during the capture pulse when you reuse it for logictest isolation. See the `max_segment_length_for_logictest` property in the [BoundaryScan](#) wrapper for information about the logictest usage. When specified to off, the enable boundary-scan cell captures itself instead of capturing the core signal. This may be useful if you are using LogicBIST and the functional enable is X during the logictest mode.

- `internal_enable_signal : pin_or_net_name ;`

A property that references an internal signal inside the chip that directly controls the enable pin of a group of output pad cells. Specifying this enable signal is equivalent to listing all the ports controlled by that enable signal in the `port_list` property. The specification of the `internal_enable_pin` and `port_list` properties are mutually exclusive. If the number of output pad cells controlled by the enable signal is larger than the specified `outputs_per_enable_cell` property, the fanout of the enable cell will be split into smaller groups to meet the specified `outputs_per_enable_cell` value. One enable boundary-scan cell will be added per group.

- `port_list : port_name_pattern, ... ;`

A property that associates a group of output or inout ports with a given enable group. The `port_name_pattern` values can include an asterisk "*" as a wildcard and %#d[lb:rb] as a

counter. The # entry is optional and, when specified, is an integer specifying the minimum number of digits the number must have. For example, ABC%2d[0:2] will match ABC00, ABC01, and ABC02.

The specification of the internal_enable_pin and port_list properties are mutually exclusive. If the number of output pad cells specified in the list is larger than the specified outputs_per_enable_cell value, the list will be split into smaller groups to meet the specified outputs_per_enable_cell value. One enable boundary-scan cell will be added per group.

You do not need to specify an enable group for all output and inout ports. For the tri-state inout and output ports not explicitly associated to an enable group, one or more additional enable groups will be inferred. The inferring is done to match the common functional enable signal sourcing a group of pads. A given group can further be split to satisfy the specified outputs_per_enable_cell value described in the following sections:

- BoundaryScan — [outputs_per_enable_cell](#) property
- EmbeddedBoundaryScan — [outputs_per_enable_cell](#) property
- insert_before_port : *port_name* ;
A property that specifies the position of the enable boundary-scan cell. This property can only be used when the pin_order_file property inside the BoundaryScan wrapper is specified. The specification of the insert_before_port property is mutually exclusive with the specification of the insert_after_port property. If neither the insert_before_port nor insert_after_port properties are specified, the enable boundary-scan cell is inserted before the first boundary cell that is associated with a port controlled by the enable cell.
- insert_after_port : *port_name* ;
A property that specifies the position of the enable boundary-scan cell. This property can only be used when the pin_order_file property inside the BoundaryScan wrapper is specified. The specification of the insert_before_port property is mutually exclusive with the specification of the insert_after_port property. If neither the property insert_before_port nor insert_after_port properties are specified, the enable boundary-scan cell is inserted before the first boundary cell that is associated with a port controlled by the enable cell.

Examples

The following example defines three enable groups. The first one is associated with the ports in the fanout of the functional enable signal “core_i/en”. The second one is associated with all ports matching the pattern “OUT*”. The third group is associated with all other remaining ports as it does not specify either the internal_enable_signal nor the port_list property.

```
DftSpecification(my_chip,rtl) {
    BoundaryScan {
        EnableGroups {
            EnableGroup(g1) {
                internal_enable_signal : core1/en ;
            }
            EnableGroup(g2) {
                port_list : OUT* ;
            }
            EnableGroup(g3) {
            }
        }
    }
}
```

InternalBScanCells

Specifies the insertion of internal boundary-scan cells that are not associated with ports but instead are used to control and/or observe internal nodes inside the design.

Usage

```
DftSpecification(module_name, id) {
    BoundaryScan | EmbeddedBoundaryScan {
        InternalBScanCells {
            InternalBScanCell(name) {
                insert_before_port : port_name ;
                insert_after_port : port_name ;
                safe_value : 0 | 1 | X ;
                type : control | observation | both ;
                connection : pin_or_net_name ;
                multiplexing : on | off | auto ;
            }
        }
    }
}
```

Description

A wrapper that specifies the insertion of internal boundary-scan cells that are not associated with ports but instead are used to control and/or observe internal nodes inside the design.

Arguments

- *name*

A string that uniquely identifies the internal boundary-scan cell in the BSDL file. The string starts with a letter and may be followed by any numbers of letters, numbers, or underscores. The string must be unique across all InternalBScanCell wrappers. The name of internal boundary-scan cells are mapped to the cell position inside the boundary scan chain using an attribute called TESSENT_INTERNAL_CELL_LABELS as shown in this example. The two InternalBScanCell wrappers have the names “my_name1” and “my_name2”.

```
-- BSDL local extensions
attribute TESSENT_INTERNAL_CELL_LABELS: BSDL_EXTENSION;
attribute TESSENT_INTERNAL_CELL_LABELS of TOP: entity is
    -- Label Cell
    "((my_name1 , 36 ) , " &
    " (my_name2 , 30 ))";
```

- *insert_before_port : port_name ;*

A property that specifies the position of the internal boundary-scan cell. This property can only be used when the pin_order_file property inside the BoundaryScan wrapper is specified. The specification of the *insert_before_port* property is mutually exclusive with the specification of the *insert_after_port* property. If neither the *insert_before_port* nor *insert_after_port* properties are specified, the internal boundary-scan cell is inserted at the end of the boundary scan chain near *scan_out* in the order they were specified. The location

of the internal boundary-scan cell is reflected in the BSDL file using the TESSENT_INTERNAL_CELL_LABELS attribute.

- `insert_after_port : port_name ;`

A property that specifies the position of the internal boundary-scan cell. This property can only be used when the `pin_order_file` property inside the [BoundaryScan](#) wrapper is specified. The specification of the `insert_after_port` property is mutually exclusive with the specification of the `insert_before_port` property. If neither the property `insert_before_port` nor `insert_after_port` properties are specified, the internal boundary-scan cell is inserted at the end of the boundary scan chain near `scan_out` in the order they were specified. The location of the internal boundary-scan cell is reflected in the BSDL file using the TESSENT_INTERNAL_CELL_LABELS attribute.

- `safe_value : 0 | 1 | X ;`

A property that specifies a safe value for the internal boundary-scan cell. This value is reflected into the BSDL file. If a non-X safe value is specified, the [BoundaryScan](#) signoff and manufacturing pattern set will never load a different value into that register during any of its [RunTest](#) specifications.

- `type : control | observation | both ;`

A property that specifies if the internal boundary-scan cell is to be used to control and/or observe an internal node. [Table 10-6](#) shows the hardware inserted into the design based on the value of the type and multiplexing property.

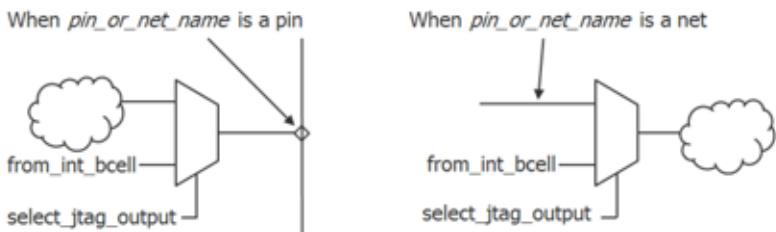

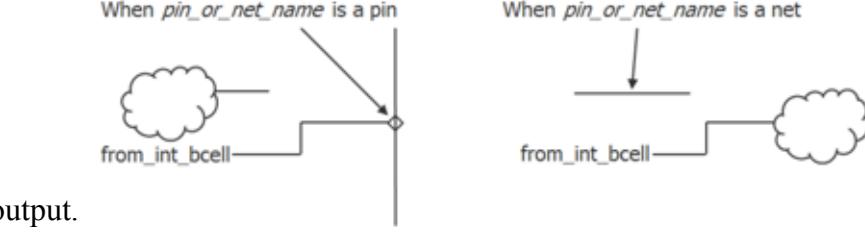

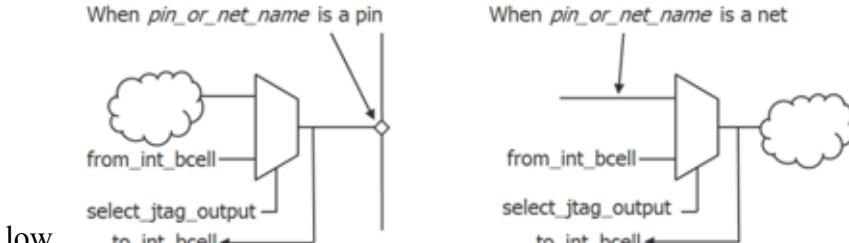

- `connection : pin_or_net_name ;`

A property that specifies the name of a pin or a net to control and/or observe. The `parent_instance` of `pin_or_net_name` will be auto-uniquified if not unique.

- `multiplexing : on | off | auto ;`

A property that is only relevant when the property `type` is set to “control” or “both”. A multiplexer is inserted as shown in [Table 10-6](#). When the value is “auto”, the multiplexer is inserted only when the `has_functional_source` attribute of the specified `pin_or_net_name` is set to “true”. See [Pin](#) and [Net](#) for more information about this attribute.

Table 10-10. Connections to and from Internal Boundary Scan Cells

type	description
control	<p>If multiplexing is specified as “on” or “auto” and the has_functional_source attribute for <i>pin_or_net_name</i> is set to “true”, the driver is intercepted with a multiplexer located in the <i>parent_instance</i> of the <i>pin_or_net_name</i>. A net is intercepted at its source while a pin is intercepted at its destination. The internal boundary-scan cell captures its own output.</p>  <p>If multiplexing is specified as “off” or “auto” and the has_functional_source attribute for <i>pin_or_net_name</i> is set to “false”, the original driver is disconnected and replaced by the signal from the internal boundary-scan cell. The internal boundary-scan cell captures its own output.</p> 
observation	The specified <i>pin_or_net_name</i> is connected to the input of the internal boundary-scan cell.
both	<p>If multiplexing is specified as “on” or “auto” and the has_functional_source attribute for <i>pin_or_net_name</i> is set to “true”, the driver is intercepted with a multiplexer located in the <i>parent_instance</i> of the <i>pin_or_net_name</i>. A net is intercepted at its source while a pin is intercepted at its destination. The observation net is taken after the multiplexer. The functional source of the <i>pin_or_net_name</i> is observable when select_jtag_output is low.</p>  <p>If multiplexing is specified as “off” or “auto” and the has_functional_source attribute for <i>pin_or_net_name</i> is set to “false”, the original driver is disconnected and replaced by the signal from the internal boundary-scan cell. The internal boundary-scan cell captures its own output.</p>

Examples

The following example creates an internal boundary-scan cell that is used to control the u1/pll_reset signal using the boundary scan chain. The specified safe value of 0 ensures this cell will never be loaded with a 1 during any of the [RunTest](#) in the [PatternsSpecification](#) or with any board test patterns created from the BSDL file.

```
DftSpecification(module_name,id) {
    BoundaryScan | EmbeddedBoundaryScan {
        InternalBScanCells {
            InternalBScanCell(mycell) {
                insert_before_port : PortA ;
                safe_value         : 0 ;
                type              : control ;
                connection        : u1/pll_reset ;
                multiplexing      : auto ;
            }
        }
    }
}
```

InternalBscanSegments

Specifies the position of an existing internal boundary scan segment in the boundary scan chain.

Usage

```
DftSpecification(module_name, id) {
    BoundaryScan | EmbeddedBoundaryScan {
        InternalBscanSegments {
            InternalBScanSegment(instance_name) {
                insert_before_port : port_name ;
                insert_after_port : port_name ;
                logical_group_name : logical_group_name ;
            }
        }
    }
}
```

Description

A wrapper that is used to specify the position of an existing internal boundary scan segment in the boundary scan chain. When the BScanSegment contains cells associated with a port of the design, the position of the BScanSegment and its *logical_group_name* is taken from the position and the logical group of the first port associated with the BScanSegment in the *pin_order_file*. In the case of pure internal boundary scan segments, their position and logical grouping name cannot be extracted from associated ports because they are not associated with ports. The logical group name is not used to create logical grouping modules for existing boundary scan segments because they are already grouped into modules. Instead, they are used to refer to the segments that use the *bypass_logical_group* inside the [BondingConfigurations](#) wrapper.

This wrapper is automatically created when the [create_dft_specification](#) command is invoked if a BScanSegment description is found for a module. You simply need to delete this wrapper prior to invoking [process_dft_specification](#) if you do not want it to be part of the boundary scan chain. Refer to the “[set_design_sources -format bscan_lib](#)” command description for information about automatically finding the BScanSegment files without having to explicitly read them in using the [read_core_descriptions](#) command. You specify the module matching options using the [set_module_matching_options](#) command.

Arguments

- *insert_before_port* : *port_name* ;

A property that specifies the position of the internal boundary segment relative to the position of the boundary-scan cell associated with a port. The specification of the *insert_before_port* is mutually exclusive with the specification of the *insert_after_port* property. When neither the *insert_before_port* nor *insert_after_port* properties are specified, the boundary scan segment is placed at the end of the boundary scan chain near the scanout. You can only specify this property if the *pin_order_file* property is used inside the [BoundaryScan](#) wrapper.

- `insert_after_port : port_name ;`

A property that specifies the position of the internal boundary segment relative to the position of the boundary-scan cell associated with a port. The specification of the `insert_before_port` is mutually exclusive with the specification of the `insert_after_port` property. When neither the `insert_before_port` nor `insert_after_port` properties are specified, the boundary scan segment is placed at the end of the boundary scan chain near the scanout. You can only specify this property if the `pin_order_file` property is used inside the `BoundaryScan` wrapper.

- `logical_group_name : logical_group_name ;`

A property used to associate a `logical_group_name` to the existing internal boundary scan segment. This name is not used to create a logical grouping module as the existing boundary scan segment is already grouped into a module. It is used instead to refer to the segment using the `bypass_logical_group` property inside the [BondingConfigurations](#) wrapper.

Examples

The following example defines a design instance as an internal boundary scan segment. It is given a logical group name so that it can be bypassed in some bounding options. A `BscanSegment` definition must exist for the module associated with instance u1/u2.

```
DftSpecification(module_name,id) {
    BoundaryScan {
        InternalBScanSegments {
            InternalBScanSegment(u1/u2) {
                logical_group_name      : seg1 ;
            }
        }
    }
}
```

BondingConfigurations

Specifies different boundary scan chain configurations based on bonding variations of a single die into multiple packages.

Usage

```
DftSpecification(module_name, id) {
    BoundaryScan {
        BondingConfigurations {
            BondingConfiguration(name) {
                enable_signal      : pin_or_net_name ;
                part_number_code   : binary ; // default: 16'h0
                version_code       : binary ; // default: 4'h0
                unused_ports       : port_name_pattern, ... ;
                bypassed_logical_groups : logical_group_name, ... ;
            }
        }
    }
}
```

Description

A wrapper that specifies different boundary scan chain configurations based on bonding variations of a single die into multiple packages. You need to have a one-hot set of decoded signals in which each signal is high for one bonding configuration and low for all the others. In a given bonding configuration, you can choose not to connect some port on the die to package pins. In this case, the boundary-scan cells are described as internal boundary-scan cells in the BSDL file associated with that bonding configuration unless you choose to group those cells in a logical grouping module and specify the module in the list of logical group modules to bypass. You typically need to bypass a segment of the boundary-scan cell when the segment is completely powered down in the given package.

You can also specify a different part_number_code and version_code for each of the bonding configurations. If you are using a third-party TAP controller, the controller must be capturing the part_number code and the version code from ports at the boundary of the TAP controller, and those ports must be described as DataInPorts, as described in the “[Requirements on a TAP to be usable for BoundaryScan](#)” section, and must be part of the CaptureSource of the device_id register.

Arguments

- *name*
A string that uniquely identifies each bonding configuration. This string is used in the name of the BSDL file associated with each bonding configuration.
- *enable_signal* : *pin_or_net_name* ;
A mandatory property that points to a signal inside the design that is high when the given bonding configuration is used and zero for all other bonding configurations.

If you specify an enable _signal, the tool issues the following warning:

```
// Warning: /DftSpecification(car,gate)/BoundaryScan/  
BondingConfigurations/BondingConfiguration(default)/enable_signal  
// You don't need to specify a enable signal. This entry will be  
// ignored.
```

An enable_signal is only needed if you define a bypassed_logical_groups, a part_number_code, or a version_code. A bonding configuration that has at least one of those needs an enable_signal. Conversely, a bonding configuration having none of those does not need one.

- part_number_code : *binary* ;

An optional property that defines the part_number_code to associate with the given bonding configuration. The generation of the part number code per bonding configuration is done inside the boundary scan interface module as shown in [Figure 10-34](#). If you are using a third-party TAP to host the boundary scan chain, it must have a part_number_code DataInPort and that port must be part of the CaptureSource of the device_id register as described in the “[Requirements on a TAP to be usable for BoundaryScan](#)” section.

If this property is not specified, its value is taken from the specified part_number_code property in the Tap wrapper referenced by the ijttag_host_node property of the [BoundaryScan](#) wrapper or from the tied value on the part_number_code DataInPort when using a TAP that already exists in the design.

- version_code : *binary* ;

An optional property that defines which version id code to associate with the given bonding configuration. The generation of the version id code per bonding configuration is done inside the boundary scan interface module as shown in [Figure 10-34](#). If you are using a third-party TAP to host the boundary scan chain, it must have a version_code DataInPort and that port must be part of the CaptureSource of the device_id register as described in the “[Requirements on a TAP to be usable for BoundaryScan](#)” section.

If this property is not specified, its value is taken from the specified version_code property in the Tap wrapper referenced by the ijttag_host_node property of the [BoundaryScan](#) wrapper or from the tied value on the version_code DataInPort when using a TAP that already exist in the design.

- unused_ports : *port_name_pattern*, ... ;

A property that specifies a list of ports that are not contacted in the given bonding configuration but whose boundary-scan cells remain part of the boundary scan chain. Those cells are described as internal boundary-scan cells in the BSDL. If the boundary-scan cells are powered down in the given bonding configuration, you must instead group the boundary-scan cells into one or many logical groups and specify that they are to be bypassed using the bypassed_logical_groups property.

The port_name_pattern can include an asterisk “*” as a wildcard and %#d[lb:rb] as a counter. The # entry is optional and when specified is an integer specifying the minimum

number of digit the number must have. For example, ABC%2d[0:2] will match ABC00, ABC01, and ABC02.

- `bypassed_logical_groups : logical_group_name, ... ;`

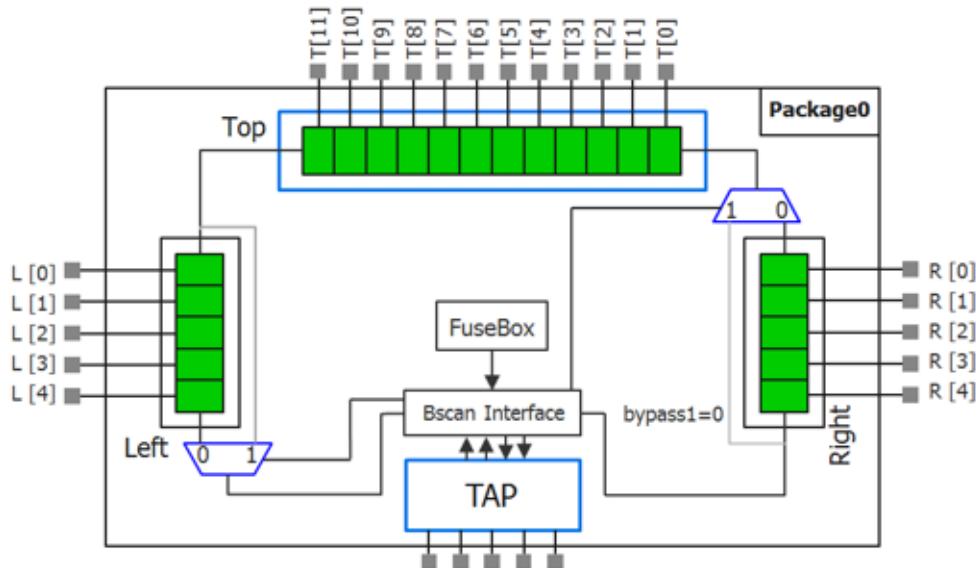

A property used to list one or more logical grouping module that are to be bypassed in the current bonding configurations. You use this option if you want to optimize the length of the boundary scan chain for each bonding configuration, or if the segment is completely powered down in the current bonding configuration. You can choose to declare the boundary-scan cells associated with the non-contacted ports as internal boundary-scan cells using the `unused_ports` property, but this is only possible if the boundary scan chain segment remains alive and powered in the current bonding configuration.

Examples

The following example shows three different bonding configurations.

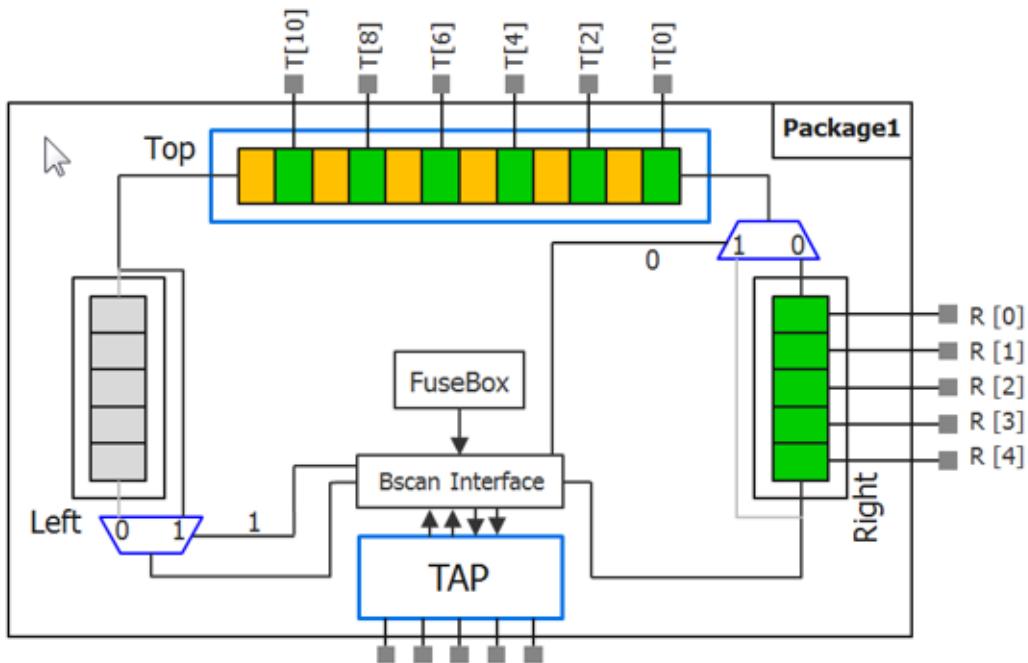

```
DftSpecification(my_chip,rtl) {
    BoundaryScan {
        ijtag_host_node : HostScanInterface(existing_tap) ;
        BondingConfigurations {
            BondingConfiguration (package0) {
                enable_signal           : core/bounding_decode/pkg0 ;
            }
            BondingConfiguration (package1) {
                enable_signal           : core/bounding_decode/pkg1 ;
                unused_ports            : L[*],T1,T3,T5,T7,T9,T11 ;
                part_number_code        : 16'h0001 ;
                bypassed_logical_groups : Left ;
            }
            BondingConfiguration (package2) {
                enable_signal           : core/bounding_decode/pkg2 ;
                unused_ports            : T6,T7,T8,T9,T10,T11 ;
                part_number_code        : 16'h0002 ;
                bypassed_logical_groups : Right ;
            }
        }
    }
}
```

The bonding configuration “package0” has no unused pins and no bypassed logical groups. The boundary scan register contains all boundary-scan cells in the design as shown in [Figure 10-50](#). No boundary-scan cells associated with unused ports are converted to internal boundary-scan cells. The BSDL file may contain internal boundary-scan cells if some were specified with the [InternalBScanCells](#) and [InternalBscanSegments](#) wrappers. Those cells are internal in all configurations unless they are bypassed. The part number code and the version code are not specified for this bonding configuration. Because this example uses a TAP already present in the design, the default values are taken from the tied values present on the `part_number_code` and `version_code` DataInPorts on the TAP where it is instantiated in the design.

Figure 10-50. package0 Bonding Configuration Example

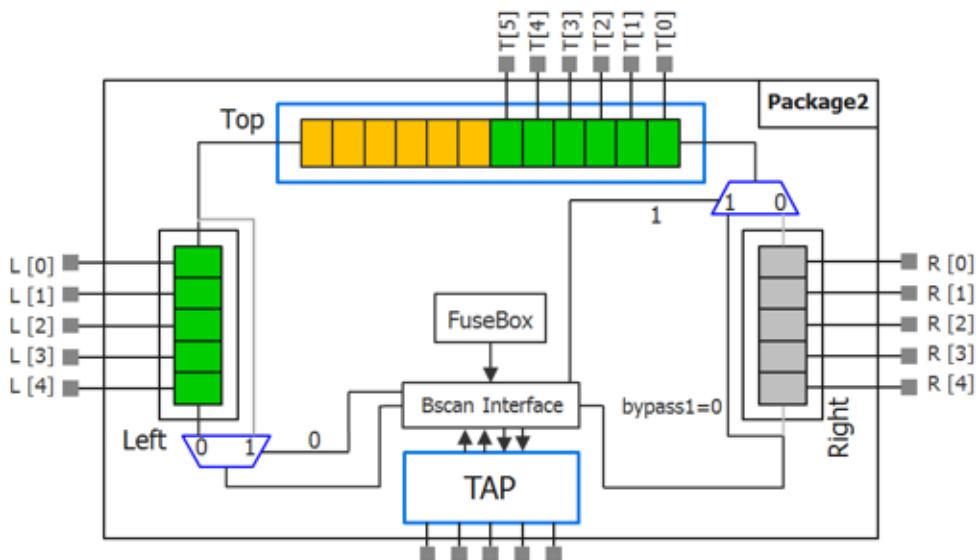

The bonding configuration “*package1*”, shown in [Figure 10-51](#), has several unused pins and a bypassed logical group called “Left”. The bypassed cells are shown in gray and the cells converted to internal cells are shown in orange. A different device_id code is specified for the configuration. Notice that the ports matching L[*] were specified with the unused_ports property. Those ports are already associated with a logical group that is declared as bypassed. This is a redundant specification. The cells associated with the L[*] ports will not be declared as internal boundary-scan cells in the BSDL file because they are bypassed. The cell associated with the ports T1,T3,T5,T7,T9,T11 are declared as internal boundary-scan cells as they are not bypassed.

Figure 10-51. package1 Bounding Configuration Example

The bonding configuration “package2”, shown in [Figure 10-52](#), has several unused pins and one bypassed logical group called “Right”. In this example, a set of fuses is used to program the bonding configuration. The one-hot encoded enable signals could have also been decoded from ports that get tied high and low in each respective package. When you want to simulate the BoundaryScan patterns using the various bonding configurations, you will need to make sure the right bonding configuration is enabled. See the description of the bonding_configuration property inside the BoundaryScan wrapper of the [PatternsSpecification](#) wrapper.

Figure 10-52. package2 Bonding Configuration Example

UserInstructions

Specifies a user instruction and an optional user register that is to be added in the BSDL file.

Usage

```
DftSpecification(module_name, id) {
    BoundaryScan {
        UserInstructions {
            UserInstruction(instr) {           // Repeatable
                tap_host_scan_interface_id : Tap(id)/HostIjtag(id) ;
                instruction_codes       : binary, ... ;
                bsd1_visibility          : public | private ;
                user_register             : user_reg[int] ;
            }
        }
    }
}
```

Description

An optional wrapper that is used to specify a user instruction and an optional user register that is to be added in the BSDL file. The UserInstruction wrapper *instr* name will be listed in the INSTRUCTION_OPCODE section of the BSDL file. If the *instr* is specified as being private, it will also be listed in the INSTRUCTION_PRIVATE section.

If a user register associated with *instr* is specified, it will be listed in the REGISTER_ACCESS section of the BSDL file. UserInstruction wrappers that specify user_register properties must have unique *user_reg* names or use the same *user_reg* name and *int* size.

The opcode(s) for the user instruction can be defined directly using the instruction_codes property, or they can be referenced from those defined in the [Tap/HostIjtag](#) wrapper for the current DftSpecification/[IjtagNetwork](#) using the tap_host_scan_interface_id property. Only one of these methods can be used for each UserInstruction wrapper.

Arguments

- UserInstruction(*instr*)

A repeatable wrapper used to specify the user instruction name. The UserInstruction wrapper *instr* name will be listed in the INSTRUCTION_OPCODE section of the BSDL file and must be a valid BSDL name.

- UserInstruction(*instr*)/tap_host_scan_interface_id : Tap(*id*)/HostIjtag(*id*) ;

A property that specifies the user instruction opcode(s) are to be referenced from those defined in the [Tap/HostIjtag](#) wrapper for the current DftSpecification/[IjtagNetwork](#). The Tap/HostIjtag wrapper must exist and the Tap(*id*) must be the TAP that hosts the boundary scan hardware. This property is mutually exclusive with the instruction_codes property.

- UserInstruction(*instr*)/instruction_codes : *binary*, ... ;

A property that specifies the binary opcode(s) associated with the *instr* user instruction. This property is mutually exclusive with the tap_host_scan_interface_id property.

- UserInstruction(*instr*)/bsdl_visibility : public | private ;

A property that specifies whether the instruction name *instr* is to only be used by the manufacturer, or to be available publicly. The default setting is public. If set to private, the *instr* will be listed in the INSTRUCTION_PRIVATE section of the BSDL file.

- UserInstruction(*instr*)/user_register : *user_reg[int]* ;

An optional property that specifies a user register that is associated with the user instruction *instr*. The parameter *user_reg* specifies the name of the user register and must be a valid BSDL name.

The parameter *int* specifies the size of the user register, and must be specified if the size cannot be determined from the tap_host_scan_interface_id or if the specified register is not one of BOUNDARY, BYPASS or DEVICE_ID. When tap_host_scan_interface_id is specified together with user_register, the parameter *int* will be checked against the selected part of the IJTAG network. If the selected part has a fixed length, it needs to match *int*. If the selected part controls a configurable scan path, or if the length cannot be determined, the user needs to specify the length as *int* in the user_register property. The parameter *int* is optional if the length can be determined from the selected IJTAG network.

The specified *user_reg* will be listed in the REGISTER_ACCESS section of the BSDL file. UserInstruction wrappers that specify user_register properties must have unique *user_reg* names or use the same *user_reg* name and *int* size.

If user_register is not specified, then bsdl_visibility must be set to private.

LogicBist

A wrapper that specifies the information used by the process_dft_specification command to build the Hybrid TK/LBIST IP and insert the IP into the design.

Usage

```
DftSpecification (module_name, id) {
    LogicBist {
        ijtag_host_interface : name ; // default: tied_scan_interface
        Controller(id) {
        }
        NcpIndexDecoder {
        }
    }
}
```

Description

A wrapper that specifies the creation and the optional insertion of Hybrid TK/LBIST controllers in a design.

Arguments

- `ijtag_host_interface : name ;`

This property is used to specify the host scan interface that the Hybrid TK/LBIST controllers will connect to. You can specify the host name as specified by the HostScanInterface parameter within the [IjtagNetwork](#) wrapper with two exceptions: “None” is unsupported. Instead, use the `tied_scan_interface` parameter, which means that all IJTAG signals are tied to 0 and you have to properly reconnect those pins. You can use a post insertion script or do it manually after `process_dft_specification`.

Controller

This wrapper is used to add and specify properties for the Hybrid TK/LBIST controller generated with process_dft_specification.

Usage

```
DftSpecification (module_name, id) {
    LogicBist {
        Controller(id) {
            parent_instance           : name ;
            leaf_instance_name       : name ;
            burn_in                  : on | off ;
            pre_post_shift_dead_cycles : int ; // default: 8
            ControllerChain {
            }
            SingleChainForDiagnosis {
            }
            ShiftCycles {
            }
            CaptureCycles {
            }
            PatternCount {
            }
            WarmupPatternCount {
            }
            NcpOptions {
            }
            Interface {
            }
            Connections {
            }
        }
    }
}
```

Description

Use this wrapper to describe the shared Hybrid TK/LBIST controller instance. When using this wrapper, you must specify the [EDT](#) wrapper.

There is no way to specify multiple LBIST controllers and mapping of Hybrid TK/LBIST blocks to the LogicBIST controller. All EDT blocks specified in the same insertion pass will be hybrid IP connected with this controller.

Arguments

- `parent_instance : name ;`

This property is used to specify the parent instance. This is the name of the instance inside which you instantiate your hybrid IP. By default, the tool chooses the lowest common ancestor of all related EDT blocks.

- `leaf_instance_name : name ;`

This property is used to specify the leaf instance name.

- `burn_in : on | off ;`

This optional property specifies whether to enable burn-in test mode for the LogicBIST IP. The default is off. Refer to “[Burn-In Test Mode](#)” in the *Hybrid TK/LBIST Flow User’s Manual* for details.

- `pre_post_shift_dead_cycles : int ;`

This optional property specifies how many dead cycles, at the shift clock period, will be applied before and after the capture clocks are pulsed. The specified integer can be between 2 and 8, with the default being 8. Reducing the number of pause cycles will reduce the test time but it may also make it harder to achieve timing closure of the test logic. To ensure that the shift and capture signals are staggered an integer value of 1 is not supported. Refer to “[Programmable Shift and Capture Pause Cycles](#)” in the *Hybrid TK/LBIST Flow User’s Manual* for details.

ControllerChain

A wrapper that configures the Hybrid TK/LBIST Controller Chain Mode (CCM).

Usage

```
DftSpecification (module_name, id) {
    LogicBist {
        Controller(id) {
            ControllerChain {
                present : on | off ;
                clock   : enum ; // legal    : tck (edt_clock)
            }
        }
    }
}
```

Description

A wrapper that configures the generation of ATPG patterns that target the Hybrid TK/LBIST logic. See “[Controller Chain Mode](#)” in the *Hybrid TK/LBIST Flow User’s Manual* for complete information.

Arguments

- **present : on | off ;**
This property specifies whether to enable or disable the CCM. When enabled, the tool creates an RTL scan chain so that it can calculate test coverage for the LogicBIST controller and Hybrid TK/LBIST blocks. The default is off.
- **clock : enum ;**
This property specifies whether the tool uses the tck or edt_clock clock during CCM. The default is edt_clock.

SingleChainForDiagnosis

A wrapper used to configure the hybrid TK/LBIST single chain mode logic.

Usage

```
DftSpecification (module_name, id) {
    LogicBist {
        Controller(id) {
            SingleChainForDiagnosis {
                present : on | off ;
                parent_instance : name ;
                leaf_instance_name : name ;
                skip_edt_blocks : on | off ;
            }
        }
    }
}
```

Description

You use this wrapper to configure the hybrid TK/LBIST single chain mode logic. See “[Single Chain Mode Logic](#)” in the *Hybrid TK/LBIST Flow User’s Manual* for complete information.

Arguments

- present : on | off ;

This property determines the “auto” value for the EDT/Controller/[BypassChains](#)/single_bypass_chain property. When the single_bypass_chain property is set to “auto,” it takes the value of the present property.

When the present property is “on” (the default), the EDT/Controller/BypassChains/single_bypass_chain property must be set to either “on” or “auto”. Tesson Shell generates an error if the single_bypass_chain property is off while the present property is on.

Note

Unlike many other options, if this property is set to “off”, then the parent_instance and leaf_instance_name properties are still meaningful. This is because the module controlling LBIST single chain for diagnosis is also responsible for any bypass logic of hybrid EDT blocks. Consequently, it will get instantiated even if the diagnostic logic for LBIST is disabled. Those properties will still determine the name of the module.

- parent_instance : *name* ;

This property is used to specify the parent instance under which the single chain for diagnosis logic will be instantiated. When unspecified, this property inherits its value from the ..parent_instance property.

- leaf_instance_name : *name* ;

This property is used to specify the leaf instance name.

- `skip_edt_clocks : on | off ;`

This property specifies whether to insert a SIB in each EDT block that allows optionally skipping all scan chains in a given EDT block during single chain unload. The default is on. For details, refer to “[Single Chain Mode Diagnosis](#)” in the *Hybrid TK/LBIST Flow User’s Manual*.

ShiftCycles

A wrapper the configures the shift cycles for the hybrid TK/LBIST controller.

Usage

```
DftSpecification (module_name, id) {
    LogicBist {
        Controller(id) {
            ShiftCycles {
                counter_resolution : enum ; // legal : byte bit
                max : int ;
                hardware_default : int ; // default: max
            }
        }
    }
}
```

Description

A wrapper the configures the shift cycles for the hybrid TK/LBIST controller.

Arguments

- counter_resolution : *enum* ;

This parameter specifies whether the shift counter allows shift lengths that operate in multiples of 8 or 1. The default, byte, causes the tool to round up the length of the longest scan chain to the next multiple of 8. When you specify “bit,” the tool applies the number of shifts equal to the length of the longest scan chain.

- max : *int* ;

This property specifies the maximum number of shift cycles for the controller. This is equivalent to the [set_lbist_controller_options](#) command’s “-max_shift_cycle” switch pair.

- hardware_default : *int* ;

This property specifies the default maximum number of shift cycles for the controller. The default is max.

CaptureCycles

A wrapper that configures the capture cycles for the hybrid TK/LBIST controller.

Usage

```
DftSpecification (module_name, id) {
    LogicBist {
        Controller(id) {
            CaptureCycles {
                max           : int ;
                hardware_default : int ; // default: max
            }
        }
    }
}
```

Description

A wrapper that configures the capture cycles for the hybrid TK/LBIST controller.

Arguments

- `max : int ;`

This property specifies the maximum number of capture cycles for the controller. This is equivalent to the [set_lbist_controller_options](#) command's “-max_capture_cycles” switch pair.

- `hardware_default : int ;`

This property specifies the default maximum number of capture cycles for the controller. The default is max.

PatternCount

A wrapper that configures hybrid TK/LBIST pattern counter.

Usage

```
DftSpecification (module_name, id) {
    LogicBist {
        Controller(id) {
            PatternCount {
                max           : int ;
                hardware_default : int ; // default: max
            }
        }
    }
}
```

Description

A wrapper that configures hybrid TK/LBIST pattern counter register.

Arguments

- `max : int ;`

This property specifies the maximum number of patterns for the controller. This is equivalent to the `set_lbist_controller_options` command's “-max_pattern_count” switch pair.

- `hardware_default : int ;`

This property specifies the default maximum number of patterns for the controller. The default is max.

WarmupPatternCount

This wrapper configures the hybrid TK/LBIST warm-up pattern count.

Usage

```
DftSpecification (module_name, id) {
    LogicBist {
        Controller(id) {
            WarmupPatternCount {
                max : int ; // default: 511
                hardware_default : int ; // default: 0
            }
        }
    }
}
```

Description

This wrapper configures the hybrid TK/LBIST warm-up pattern count. See “[Warm-Up Patterns](#)” in the *Hybrid TK/LBIST Flow User’s Manual* for complete information.

Arguments

- `max : int ;`

This property specifies the maximum number of warm-up patterns for the controller. This is equivalent to the `set_lbist_controller_options` command’s “`-max_warmup_pattern_count`” switch pair. The default is 511.

- `hardware_default : int ;`

This property specifies the default maximum number of warm-up patterns for the controller. The default is 0.

NcpOptions

A wrapper that specifies NCP-related hardware options for the LogicBIST controller.

Usage

```
DftSpecification (module_name, id) {
    LogicBist {
        Controller(id) {
            NcpOptions {           // following two properties are mutually exclusive
                count : int ;     // default: 1
                percentage_of_patterns_per_ncp : integer, ... ;
            }
        }
    }
}
```

Description

This wrapper differs from the NcpIndexDecoder wrapper in that NcpOptions specifies NCP-related hardware parameters for the LogicBIST controller whereas you use the NcpIndexDecoder wrapper to configure the index decoder hardware, such as clock waveforms and OCCs.

Specify the NcpOptions wrapper when you are inserting LogicBist and the NCP Index Decoder in different passes. You must specify the count property or the percentage_of_patterns_per_ncp property. The latter property applies the NCPs for the specified percentages of patterns. The count and percentage_of_patterns_per_ncp properties are mutually exclusive.

When you generate the NcpIndexDecoder in the same pass as the LogicBIST controller, Tesson Shell automatically populates the NcpOptions/count parameter from the number of NcpIndexDecoder/Ncp wrappers. In this case, specifying the NcpOptions wrapper results in an error.

Arguments

- **count : int ;**
An integer that specifies to generate a LogicBIST controller that can support up to the specified integer of NCPs. The default is 1. The integer you specify must equal the number of NCPs as specified by the NcpIndexDecoder wrapper.
- **percentage_of_patterns_per_ncp : integer, ... ;**
A repeatable integer that represents a percentage value. This value specifies, as a percentage, the number of times an NCP will be applied every 256 patterns. The first NCP applies to the first integer specified in the percentage_of_patterns_per_ncp list, the second NCP to the second integer, and so on. The number of patterns each NCP is active in (within a 256 pattern range) is stored in the LogicBIST controller's hardware.

Interface

An optional wrapper the specifies the port names on the interface of the LogicBIST controller module.

Usage

```
DftSpecification (module_name, id) {
    LogicBist {
        Controller(id) {
            Interface {
                IjtagScanInterface {
                    tck : port_name; // default: ijtag_tck
                    reset : port_name; // default: ijtag_reset
                    select : port_name; // default: ijtag_sel
                    capture_en : port_name; // default: ijtag_ce
                    shift_en : port_name; // default: ijtag_se
                    update_en : port_name; // default: ijtag_ue
                    scan_in : port_name; // default: ijtag_si
                    scan_out : port_name; // default: ijtag_so
                }
                ControllerChain {
                    enable : port_name; // default: ccm_en
                    scan_in : port_name; // default: ccm_scan_in
                    scan_out : port_name; // default: ccm_scan_out
                    scan_en : port_name; // default: ccm_scan_en
                }
                test_clock : port_name; // default: test_clock
                edt_update : port_name; // default: edt_update
                shift_clock_src : port_name; // default: shift_clock_src
                clock_out : port_name; // default: edt_lbist_clock
                reset_out : port_name; // default: lbist_reset
                enable_out : port_name; // default: lbist_en
                done : port_name; // default: -
                prpg_en : port_name; // default: prpg_en
                misr_en : port_name; // default: misr_accumulate_en
                ijtag_select_out : port_name; // default: edt_sib_en
                scan_en : port_name; // default: scan_en[_in|_out]
            }
        }
    }
}
```

Description

The Interface wrapper is an optional wrapper defined within the LogicBIST controller wrapper that specifies the port names on the interface of the LogicBIST module. You can use this wrapper to rename the listed ports. Each property has a default value as described in the configuration data syntax.

Arguments

- IjtagScanInterface/tck : *port_name* ;

An optional property that specifies the name of the test clock IJTAG control signal. The default is ijtag_tck.

- IjtagScanInterface/reset : *port_name* ;
An optional property that specifies the name of the reset IJTAG control signal. The default is ijtag_reset.
- IjtagScanInterface/select : *port_name* ;
An optional property that specifies the name of the select IJTAG control signal. The default is ijtag_sel.
- IjtagScanInterface/capture_en : *port_name* ;
An optional property that specifies the name of the enable capture IJTAG control signal. The default is ijtag_ce.
- IjtagScanInterface/shift_en : *port_name* ;
An optional property that specifies the name of the enable shift IJTAG control signal. The default is ijtag_se.
- IjtagScanInterface/update_en : *port_name* ;
An optional property that specifies the name of the enable update IJTAG control signal. The default is ijtag_ue.
- IjtagScanInterface/scan_in : *port_name* ;
An optional property that specifies the name of the scan in IJTAG control signal. The default is ijtag_si.
- IjtagScanInterface/scan_out : *port_name* ;
An optional property that specifies the name of the scan out IJTAG control signal. The default is ijtag_so.
- ControllerChain/enable : *port_name* ;
An optional property that specifies the name of the controller chain enable port. This port is only used when DftSpecification/LogicBist/Controller/SingleChainForDiagnosis/present is set to on. The default is ccm_en.
- ControllerChain/scan_in : *port_name* ;
An optional property that specifies the name of the controller chain scan in port. This port is only used when DftSpecification/LogicBist/Controller/SingleChainForDiagnosis/present is set to on. The default is ccm_scan_in.
- ControllerChain/scan_out : *port_name* ;
An optional property that specifies the name of the controller chain scan out port. This port is only used when DftSpecification/LogicBist/Controller/SingleChainForDiagnosis/present is set to on. The default is ccm_scan_out.
- ControllerChain/scan_en : *port_name* ;
An optional property that specifies the name of the controller chain scan enable port. This port is only used when DftSpecification/LogicBist/Controller/SingleChainForDiagnosis/present is set to on. The default is ccm_scan_en.

- **test_clock : *port_name* ;**
An optional property that specifies the name of an input clock port with which to operate the LogicBIST controller. The default is test_clock.
- **shift_clock_src : *port_name* ;**
An optional property that specifies the name of an input clock port with which to operate the LogicBIST controller. The default is shift_clock_src.
- **edt_update : *port_name* ;**
An optional property that specifies the name of an input clock port that connects to the edt_update signal. This port is only created when the clock gater—created by running add_dft_signal shift_capture_clock –create_from_other_signals—is present. The default is edt_update.
- **clock_out : *port_name* ;**
An optional property that specifies the name of an output port for the generated LogicBIST clock. The default is lbist_clock.
- **reset_out : *port_name* ;**
An optional property that specifies the name of an output port that indicates when the synchronous reset of LogicBIST controller occurs. The default is lbist_reset.
- **enable_out : *port_name* ;**
An optional property that specifies the name of an output port that indicates when LogicBIST is enabled. The default is lbist_en.
- **done : *port_name* ;**
An optional property that specifies the name of an output port that indicates when the LogicBIST controller has finished its test. This port is only created when a port name is provided.
- **prpg_en : *port_name* ;**
An optional property that specifies the name of an output port that indicates when the PRPG is active during the scan load/unload. The default is prpg_en.
- **mistr_en : *port_name* ;**
An optional property that specifies the name of an output port that indicates when the MISR is to accumulate the scan unload data. The default is mistr_accumulate_en.
- **ijtag_select_out : *port_name* ;**
An optional property that specifies the name of the IJTAG ToSelectPort that enables the EDT IJTAG network. The default is edt_sib_en.
- **scan_en : *port_name* ;**
An optional property that is used to create the input and output ports that are connected to the source of an intercepted scan enable signal. The tool appends the “_in” and “_out”

suffices to the specified port name to create the input and output ports. The defaults are scan_en_in and scan_en_out.

Examples

The following example renames LogicBIST ports back to their pre-2018.1 release versions for purposes of backwards annotation.

```
DftSpecification(<module_name>,<id>) {
    LogicBist {
        Controller(<id>) {
            Interface {
                IJtagScanInterface {
                    tck      : tck;
                    reset   : sib_reset;
                    select   : sib_en;
                    capture_en : sib_capture_en;
                    shift_en   : sib_shift_en;
                    update_en   : sib_update_en;
                    scan_in     : lbist_scan_in;
                    scan_out    : lbist_scan_out;
                }
                ControllerChain {
                    enable   : ccm_en
                    scan_in  : ccm_scan_in
                    scan_out : ccm_scan_out
                    scan_en  : ccm_scan_en
                }
                test_clock      : edt_clock;
                clock_out       : lbist_clock;
                reset_out       : lbist_reset;
                enable_out      : lbist_en;
                prpg_en         : prpg_en;
                misr_en         : misr_en;
                ijttag_select_out : edt_sib_en;
                scan_en         : scan_en;
                shift_clock_src : shift_clock_src;
            }
        }
    }
}
```

Connections

This wrapper is used to add and specify properties for the hybrid TK/LBIST controller connections.

Usage

```
DftSpecification (module_name, id) {
    LogicBist {
        Controller {
            Connections {
                edt_clock : port_pin_name ;
                    // default: OptionalDftSignal(edt_clock)
                edt_update : port_pin_name ;
                    // default: OptionalDftSignal(edt_update)
                tck : port_pin_name ;
                shift_clock_src : port_pin_name ;
                scan_en_in : port_pin_name ;
                    // default: OptionalDftSignal(scan_en)
                controller_chain_enable : port_pin_name ;
                    // default: control_chain_enable
                controller_chain_scan_in : port_pin_name ;
                    // default: control_chain_scan_in
                controller_chain_scan_out : port_pin_name ;
                    // default: control_chain_scan_out
            }
        }
    }
}
```

Description

This wrapper is used to add and specify properties for the hybrid TK/LBIST controller connections.

Arguments

- `edt_clock : port_pin_name ;`

Note

 When using dft signal for `edt_clock`, it must be sourced from an existing design pin rather than created from other signals. That is, you must specify the `edt_clock` signals with the “`add_dft_signal edt_clock -source_node`” command rather than the “`add_dft_signal edt_clock -create_from_other_signals`” command.

An optional property used to specify a source node to connect the `edt_clock` port to. The node name can be a port or a pin name. The node must already exist in the design with the exception of one case. If the design level, as specified by the `set_design_level` command, is not “chip” and the name corresponds to the name of a scalar port, it is allowed to not exist in the design and it will be created as an input port during insertion. When design level is “chip”, specified port names must already be connected to a pad cell. The connection will automatically be made to the internal side of the input pad buffer. You can specify `OptionalDftSignal(edt_clock)` or `DftSignal(edt_clock)` as the value, and it will be

interpreted to request a connection to the DFT signal `edt_clock` as it was added using the [add_dft_signals](#) command. When using `OptionalDftSignal(edt_clock)`, you will not get an error if the DFT signal `edt_clock` was not added; a connection to the port called “`edt_clock`” will be made instead and the port will be created if not present unless design level is equal to “chip” in which case you will get an error.

- `edt_update : port_pin_name ;`

An optional property used to specify a source node to connect the `edt_update` port to.

The node name can be a port or a pin name. The node must already exist in the design with the exception of one case. If the design level, as specified by the [set_design_level](#) command, is not “chip” and the name corresponds to the name of a scalar port, it is allowed to not exist in the design and it will be created as an input port during insertion.

When design level is “chip”, specified port names must already be connected to a pad cell. The connection will automatically be made to the internal side of the input pad buffer. You can specify `OptionalDftSignal(edt_update)` as the value, and it will be interpreted to request a connection to the DFT signal `edt_update` as it was added using the [add_dft_signals](#) command. When using `OptionalDftSignal(edt_update)`, you will not get an error if the DFT signal `edt_update` was not added; a connection to the port called “`edt_update`” will be made instead and the port will be created if not present unless design level is equal to “chip” in which case you will get an error.

When the property is unspecified, its value defaults to `OptionalDftSignal(edt_update)`.

- `tck : port_pin_name ;`

An optional property used to specify TCK. When the design level is other than “chip”, then by default the value of this property is the `ijtag_tck` pin as specified by the `ijtag_host_interface` parameter. If the design level is “chip”, this parameter defaults to “`tck`”.

- `shift_clock_src : port_pin_name ;`

A mandatory property used to specify the shift clock source. A dash (-) value indicates that the shift clock source is not desired, in which case, only TCK and the `edt_clock` will be allowable shift clock sources.

- `scan_en_in : port_pin_name ;`

An optional property used to specify scan enable for mux-DFF type (input wrapper cells).

- `controller_chain_enable : port_pin_name ;`

An optional property used to specify the controller chain enable.

- `controller_chain_scan_in : port_pin_name ;`

An optional property used to specify the controller chain scan in.

- `controller_chain_scan_out : port_pin_name ;`

An optional property used to specify the controller chain scan out.

NcpIndexDecoder

Decodes the NCP index output of the hybrid TK/LBIST controller into clock sequences to be generated by the Tesson OCCs across all capture procedures.

Usage

```
DftSpecification (module_name, id) {
    LogicBist {
        NcpIndexDecoder {
            parent_instance : instance_name ;
            leaf_instance_name : name ;
            Interface {
                ncp_index : port_name ; // default: ncp_index
                clock_sequence : port_name ; // default: occ%d_clock_sequence
            }
            Connections {
                ncp_index : port_pin_constant_name, ... ;
            }
            Ncp(id) {
                cycle(index) : occ_spec, ... ; // repeatable
            }
        }
    }
}
```

Description

The LBIST NCP index decoder is a simple combinational logic block that decodes the NCP index output of the LBIST controller into clock sequences to be generated by the OCCs across all capture procedures.

Processing the DftSpecification of the LogicBist wrapper using the process_dft_specification command produces the following outputs, which are written into the TSDB directory:

- Verilog RTL for the index decoder.
- Test procedure files for NCP description. It is recommended the timeplate you use during LBIST fault simulation uses the pulse_clock in the timeplates. This way, you can avoid the need for editing the timeplate to add the clock names used in the tool generated NCPs.
- Dofile that describes the mapping between the LBIST NCP index and the NCP names. This file should be sourced during LBIST fault simulation.

See “[NCP Index Decoder](#)” in the *Hybrid TK/LBIST Flow User's Manual* for complete information.

Arguments

- parent_instance : *instance_name* ;

Instance path name of the parent in which the NCP index decoder is instantiated. The default is the top-level of the design.

- `leaf_instance_name : name ;`
Name of the leaf instance.
- `Interface/ncp_index : port_name ;`
Name of the decoder's NCP index input. The default is `ncp_index`.
- `Interface/clock_sequence : port_name ;`
The default is `occ%d_clock_sequence`.
- `Connections/ncp_index : port_pin_constant_name, ... ;`
Points to the LBIST controller's NCP output. The specified pins are connected to the NCP index decoder input. When not specified, the NCP index decoder input pins are tied to "0".
- `Ncp(id)`
Repeatable wrapper that describes a single NCP. A capture procedure could either describe activity in one clock while others are OFF, or across multiple clocks.
- `Ncp(id)/cycle(cycle_number) : occ_spec, ... ;`
Repeatable named property that specifies the clock sequence for a cycle within an NCP.
The `cycle_number` is an integer starting from 0, which corresponds to the first cycle of capture. The clock activity on the first cycle is parallel loaded into the LSB of the OCC shift register, the second cycle onto the next significant bit and so on. When a particular cycle number is omitted, it means there is no clock activity for that cycle. The largest cycle number that can be specified is one less than the width of the OCC control Shift Register. The output NCP contains cycles from 0 till the largest cycle number specified, including empty cycles.

The `occ_spec` is a repeatable list of Tesson OCC specification that can include:

- OCC instance path names.
- OCC module names.
- OCC core names used in TCD.
- OCC controller IDs generated in the same pass.
- Literal string "bscan_occ" to indicate a mini-occ inside boundary scan logic.
- Literal string "sti_occ" to indicate sib(sti) logic.

Ambiguity in specification (for example, a module and a top level instance with same name, or a top level instance and instance leaf name with same names) are resolved in the above order. Avoid potential ambiguity by using the full instance path names.

The tool issues an error if you specify only one `Ncp` wrapper, and it does not generate the NCP index output.

Examples

Example 1

In this example, assume the design has two top level OCC instances named *m8051_gate_tessent_occ_clk1_inst* and *m8051_gate_tessent_occ_clk2_inst* of the same OCC module *m8051_gate_tessent_occ*.

```
DftSpecification {
    LogicBist {
        NcpIndexDecoder {
            Connections {
                ncp_index: m8051_lbist_i/ncp ;
            }
            Ncp(stuck) {
                cycle(0): m8051_gate_tessent_occ ;
                //Specified using module name, refers to both the OCC instances.
            }
            Ncp(clk1_double_pulse) {
                cycle(0): m8051_gate_tessent_occ_clk1_inst ;
                cycle(1): m8051_gate_tessent_occ_clk1_inst ;
            }
            Ncp(clk2_double_pulse) {
                cycle(0): m8051_gate_tessent_occ_clk2_inst ;
                //Note - cycle(1) is omitted, so no clock activity
                cycle(2): m8051_gate_tessent_occ_clk2_inst ;
            }
        }
    }
}
```

Example 2

The following example inserts OCC and the NCP index decoder at the same time. As shown below, you must specify *occ_spec* with the ID as specified for the Occ/Controller that you are generating in the same pass.

```
DftSpecification(m8051, rtl)  {
    Occ {
        Controller(1) {                                     // Controller ID = 1
            clock_intercept_node: NX1g/Z;
        }
        Controller(2) {                                     //Controller ID = 2
            clock_intercept_node: NX2g/Z;
        }
    }
    LogicBist {
        NcpIndexDecoder {
            Ncp(slow) {
                cycle(0): Occ(1);                      // Occ/Controller generated above
                cycle(0): Occ(2);                      // Occ/Controller generated above
            }
            Ncp(NX1_fast) {
                cycle(0): Occ(1);
                cycle(1): Occ(1);
            }
            Ncp(NX2_fast) {
                cycle(0): Occ(2);
                cycle(1): Occ(2);
            }
        }
    }
}
```

LpctType3

As part of the process_dft_specification flow, the LpctType3 DftSpecification syntax defines the configuration of a low pin count test (LPCT) Type3 controller to be generated and inserted into the design.

Usage

```
DftSpecification(module_name, id) {
    LpctType3 {
        Interface {
        }
        Connections {
        }
        Controller {
        }
    }
}
```

Description

You use an LPCT Type3 controller when there is no scan enable at the top level of the design and the design is not using a JTAG TAP controller for test. The LPCT Type3 controller generates the scan enable signal and all EDT specific control signals and you must use it in combination with an EDT wrapper. This controller requires an OCC instrument present in the design. OCC instruments may be specified in the configuration data or added as TCD instruments with the add_core_instances command. The LPCT Type3 controller will use and drive OCCs from a mix of OCC configuration data and TCD instrument instances. It also supports third-party OCCs that are added using the LpctType3/Connections/[ThirdPartyOCC](#) configuration data wrapper.

The inserted LPCT Type3 controller generates the scan enable and all the EDT specific control signals that drive the EDT and OCC controllers. This creates a restriction for interfaces used on the EDT and OCC modules; none of the instruments driven by the LPCT controller can have an IJTAG compatible interface. An error will be reported during validation if an EDT or OCC instrument that has an IJTAG compatible interface and is used in the PDS flow in combination with the LPCT.

The tool generates the RTL files for the LPCT Type3 controller inside the [Tessent Shell Data Base \(TSDB\)](#) when the LpctType3 wrapper is present in the configuration data and the process_dft_specification command is used. During the generation phase, the tool appends entries for the created LPCT files and modules to the synthesis dictionary inside the TSDB instrument container. This allows for the automated synthesis of the LPCT RTL files with the [run_synthesis](#) command.

The LPCT controller is typically used when the design has only 3 top level ports available for “logic test”: a free-running clock, an EDT channel input port, and an EDT channel output port. By default, the data_in connection of the LPCT controller instance is shared with the EDT channel input connection. If pipeline stages are used for EDT input channel connections, there will be no pipeline stages in the data path of the LPCT controller.

For more information, see [LPCT Controller Types](#) in the *TestKompress User's Manual*.

Arguments

None.

Examples

Example 1

This example shows a minimal set of configuration data that will create an LPCT Type3 Controller.

```
DftSpecification(CoreA,rtl1) {
    EDT {
        Controller(1) {
            ijtag_host_interface : none;
            longest_chain_range : 60, 100;
            scan_chain_count : 2;
            input_channel_count : 1;
            output_channel_count : 1;
        }
    }
    OCC {
        ijtag_host_interface : none;
        Controller(1) {
            clock_intercept_node : CLK;
        }
    }
    LpctType3 {
        Controller {
            max_capture_cycles : 5;
        }
    }
}
```

Example 2

In this example, an LPCT Type3 controller is specified and OCC core instances are added.

```

// command: add_core_instances -module CoreA_rtl1_tessent_occ
// Note: Reading TCD file './tsdbA/instruments/CoreA_rtl1_occ.instrument/
CoreA_rtl1_tessent_occ.tcd' from TSDB.
// Added core instance 'CoreA_rtl1_tessent_occ_1_inst'.
// Added core instance 'CoreA_rtl1_tessent_occ_2_inst'.
// Added core instance 'CoreA_rtl1_tessent_occ_3_inst'.
// command: read_config_data -from_string {
    DftSpecification(CoreA,rtl2) +{
        EDT {
            Controller(1) {
                scan_chain_count: 100;
                longest_chain_range: 100,110;
                input_channel_count: 2;
                output_channel_count: 2;
            }
            Controller(2) {
                scan_chain_count: 100;
                longest_chain_range: 100,110;
                input_channel_count: 2;
                output_channel_count: 2;
            }
        }
        LpctType3 {
            Controller {
                max_shift_cycles: auto;
                max_capture_cycles : 5;
                load_unload_cycles : 1, 2 ;
                max_scan_patterns : 100 ;
                max_chain_patterns : 10 ;
            }
        }
    }
}

```

Interface

A wrapper that specifies the port names for the LPCT Type 3 controller module.

Usage

```
DftSpecification(module_name, id) {
    LpctType3 {
        Interface {
            clock : port_name ; // default: lpct_clock
            clock_mux_select : port_name ; // default: lpct_clock_mux_select
            capture_enable : port_name ; // default: lpct_capture_en
            shift_enable : port_name ; // default: lpct_shift_en
            shift_clock : port_name ; // default: lpct_shift_clock
            reset : port_name ; // default: lpct_reset
            scan_enable : port_name ; // default: lpct_scan_en
            data_in : port_name ; // default: lpct_data_in
            test_mode : port_name ; // default: lpct_test_mode
            reset_out : port_name ...; // default: lpct_reset_out
            reset_polarity : active_high | active_low ;
            test_end : port_name ; // default: lpct_test_end
            test_active : port_name ; // default: lpct_test_active
        }
        Connections {
        }
        Controller {
        }
    }
}
```

Description

You can use this wrapper to specify the names of the LPCT Type 3 controller ports. Each property has a default value, as described in the configuration data syntax. You can override the default name if you provide a value to be used for the port names of the LPCT controller module.

Arguments

- **clock : *port_name* ; // default: lpct_clock**
Specifies the name of the input clock for the LPCT controller. The default name is lpct_clock.
- **clock_mux_select : *port_name* ; // default: lpct_clock_mux_select**
Specifies the LPCT clock mux select port name. The default is lpct_clock_mux_select.
- **capture_enable : *port_name* ; // default: lpct_capture_enable**
Specifies the LPCT capture enable port name. The default is lpct_capture_enable.
- **shift_enable : *port_name* ; // default: lpct_shift_en**
Specifies the LPCT shift clock enable port name. The default is lpct_shift_en.

- `shift_clock : port_name ; // default: lpct_shift_clock`
Specifies the LPCT shift clock port name. The default is lpct_shift_clock.
- `reset : port_name ; // default: lpct_reset`
Specifies the LPCT reset port name. The default is lpct_reset.
- `scan_enable : port_name ; // default: lpct_scan_en`
Specifies the LPCT scan enable port name. The default is lpct_scan_en.
- `data_in : port_name ; // default: lpct_data_in`
Specifies the LPCT data in port name. The default is lpct_data_in.
- `test_mode : port_name ; // default: lpct_test_mode`
Specifies the LPCT test mode port name. The default is lpct_test_mode.
- `reset_out : port_name ; // default: lpct_reset_out`
Specifies the LPCT reset output port name. The default is lpct_reset_out.
- `reset_polarity : active_polarity ; // active_high active_low`
An optional switch and literal pair that specifies the activity state for the input reset signal of the generated LPCT controller. The default is active_high.
- `test_end : port_name ; // default: lpct_test_end`
Specifies the LPCT test_end port name. The default is lpct_test_end.
- `test_active : port_name ; // default: lpct_test_active`
Specifies the LPCT test_active port name. The default is lpct_test_active.

Connections

This wrapper specifies the LPCT Type3 controller connections.

Usage

```
DftSpecification(module_name, id) {
    LpctType3 {
        Interface {
        }
        Connections {
            clock      : port_pin_name ; // default: lpct_clock
            reset      : port_pin_name ; // default: lpct_reset
            scan_enable : port_pin_name ;
            data_in     : port_pin_name ; // default: lpct_data_in
            test_mode   : port_pin_name ; // default: lpct_test_mode
            reset_out   : port_pin_name, ... ;
            test_end    : port_pin_name ;
            test_active : port_pin_name ;
            ThirdPartyOCC {
            }
        }
        Controller {
        }
    }
}
```

Description

The connections wrapper for the LPCT Type3 controller identifies its connections, which you specify with port or pin names. When the LPCT Type3 controller is inserted into the chip design top-level, all of the connections with a specified value must have an existing top-level port that is connected to a PAD cell. An error will be reported if this is not the case.

When the LPCT Type3 controller is inserted in a physical block or sub block design, the specified connections are created to the specified ports or pins. If the ports do not exist, they will be created.

Arguments

- `clock : port_pin_name ;`

Required argument that specifies an always-pulse clock for the LPCT. Default clock name is lpct_clock.

- `reset : port_pin_name;`

An optional property that specifies the input reset signal connection for the LPCT controller. The reset pin can be shared with the design's functional reset. This can be either a top-level port or an internal power-on-reset pin. The default reset name is lpct_reset.

You can manually specify the input and output reset connections for the LPCT controller. Use the `reset` property to specify the input reset connection to the controller and the `reset_out` property to specify the connection points that the LPCT controller will reset.

- **scan_enable : *port_pin_name*;**
An optional argument for LPCT controllers, that specifies the list of pins to which the LPCT output scan enable pin is connected.
- **data_in : *port_pin_name*;**
Optional argument that specifies the pin or port connected to the LPCT controller data_in pin. For the LPCT controller, a test sequence and configuration is scanned in through this port. This port is usually shared with the edt_channel input. The default data in name is lpct_data_in.
- **test_mode :*port_pin_name*;**
Optional argument that specifies the pin is a test mode signal used to enable test mode. This signal is not used when sequence detection is used. Default test mode name is lpct_test_mode.
- **reset_out : *port_pin_name*, ...;**
Specifies the output connection, or connections, of the LPCT reset signal sent to the design. The value of this property can be a bus or a list of connection points. The tool makes the specified connections from the output reset pin of the controller and connects the reset port or pin to the input reset pin of the controller.
- **test_end : *port_pin_name*;**
Optional argument that specifies the pin is a test mode signal used to enable test mode. This signal is not used when sequence detection is used.
- **test_active : *port_pin_name*;**
Optional argument that specifies an output signal from that LPCT controller that indicates the LPCT controller is active and controlling the scan test.

ThirdPartyOCC

A wrapper that specifies connections for a third-party OCC. If any of the properties is specified in this wrapper indicates a third-party OCC is used in the design.

Usage

```
DftSpecification(module_name, id) {
    LpctType3 {
        Interface {
        }
        Connections {
            ThirdPartyOCC {
                clock_mux_select : port_pin_name ;// default: lpct_clock_mux_select
                capture_enable   : port_pin_name ; //default: lpct_capture_en
                shift_enable     : port_pin_name ; //default: lpct_shift_en
                shift_clock      : port_pin_name ; //default: lpct_shift_clock
            }
            Controller {
            }
        }
    }
}
```

Description

Third-party wrappers are specified only within the LpctType3/Connections wrapper. Use this wrapper to specify properties for a third-party OCC.

Arguments

- **clock_mux_select : *port_pin_name* ;// default: lpct_clock_mux_select**
An optional argument that specifies the connection to be made to the `clock_mux_select` output of the LPCT controller. This pin is a MUX select signal that selects between the shift clock generated by the LPCT controller and the capture clock. If `clock_mux_select` is high, shift clock is selected; if `clock_mux_select` is low, the capture clock is selected.
- **capture_enable : *port_pin_name* ;// default: lpct_capture_en**
A property that specifies the connection for the `capture_enable` output signal of the LPCT controller.
- **shift_enable : *port_pin_name* ;// default: lpct_shift_en**
A property that specifies the connection for the `shift_enable` output signal of the LPCT controller.
- **shift_clock : *port_pin_name* ;// default: lpct_shift_clock**
A property that specifies the connection for the `shift_clock` signal of the LPCT controller.

Controller

A wrapper used to specify all the LPCT Type3 specific settings.

Usage

```
DftSpecification(module_name, id) {
    LpctType3 {
        Interface {
        }
        Controller {
            max_shift_cycles      : int | auto ;
            max_capture_cycles   : int ;
            load_unload_cycles   : count1, count2 ;
            max_scan_patterns    : int ;
            max_chain_patterns   : int ;
            shift_control_type   : enable | clock | none ;
            TestModeDetect {
            }
            parent_instance       : instance ;
            leaf_instance_name   : instance ;
        }
    }
}
```

Description

The controller wrapper specifies all the LPCT Type3 IP specific settings. There can only be one controller wrapper within the LpctTye3 wrapper, therefore the tool only creates a single LPCT controller during a single process_dft_specification pass.

Arguments

- `max_shift_cycles : integer;`

A property that specifies the maximum number of shift cycles for the LPCT controller. By default the value of this property is set to auto, which indicates that the maximum number of shift cycles is calculated automatically by the tool. The value of this property affects the size of the LPCT shift cycle counter register. If it is manually set, it needs to be large enough so the LPCT shift cycle counter can handle the longest shift length (from all EDT controllers). If is is too small, an error is reported during the validation phase.

- `max_capture_cycles : integer ;`

A property that specifies the maximum number of capture cycles for all test patterns. This is a required property.

- `load_unload_cycles : count1, count2;`

A property that specifies the number of cycles that precede and follow the shift cycles in the load_unload procedure. The value count1 is the number of cycles that precede the shift cycles in the load_unload procedure, while the value for count2 is the number of cycles that follow the shift cycles in the load_unload procedure.

- `max_scan_patterns : integer ;`
A property that specifies the maximum number of scan test patterns generated in the test application.
- `max_chain_patterns : integer;`
A property that specifies the maximum number of chain test patterns generated in the test application.
- `shift_control_type : {enable | clock | none};`
A property that specifies how the LPCT controller generates the shift clock control signal. By default the value of this property is set to enable. The enable value is the only value allowed when using Tessent OCCs. When you use third-party OCCs, the value of this property can be set to any value allowed by the syntax.
- `parent_instance : instance`
A property that specifies the name of the parent instance in which the LPCT is instantiated. By default, the LPCT controller is instantiated on the top level.
- `leaf_instance_name : instance;`
A property that specifies the name of the LPCT controller instance. By default the instance name follows this pattern:
 `${design_name}_ ${design_id}_ tessent_ ${instrument_type}`

TestModeDetect

A wrapper used to configure how the LPCT enters the test mode.

Usage

```
DftSpecification(module_name, id) {
    LpctType3 {
        Interface {
            }
            Connections {
            }
            Controller {
                TestModeDetect {
                    type           : <enum> ; // legal : (signal) sequence
                    input_sequence : <binary_seq>, <cycle_count> ;
                }
            }
        }
    }
}
```

Description

The LPCT controller can enter test mode in one of two ways: by detecting a specific input sequence within a particular number of cycles after test controller reset, or by a signal that indicates test mode. These two ways of entering test mode are mutually exclusive.

Use this wrapper to specify the controller enable type: signal or sequence. By default, the tool will use the test_mode connection from the Connections wrapper to cause the controller to enter test mode. If you select the sequence detection type, you must specify the input sequence that places the LPCT controller into test mode. The test controller enters test mode by detecting a specific sequence within a particular number of cycles or by a signal that indicates test mode.

Arguments

- type : signal | sequence ;

A property that specifies the LPCT controller enable type, sequence or signal. By default, the value is set to signal, indicating that the tool will use the test_mode connection from the Connections wrapper.

When using a test mode signal, test mode will start after the signal is asserted. This signal needs to stay asserted for only one cycle, after which it can be de-asserted at any time. The test session will not end when this signal is de-asserted; instead it will end only after end of test as determined by the pattern counters. In this case, it is your responsibility to ensure test mode will not be entered during functional operation. When this signal is a top level pin, the tool can generate the correct test_setup procedure. When this signal is an internal pin, you must modify the test setup procedure for pattern generation to ensure that the internal test mode signal will be asserted as desired.

To use sequence detection, you specify the input sequence and the number of cycles within which it should be detected during IP creation. Doing this ensures the chip will not enter test

mode during functional operation. To use sequence detection, must specify the input sequence property.

When the input test procedure already has an existing test_setup, the sequence detect period should also consider the additional cycles necessary for applying test_setup.

- **input_sequence** : *binary_seq* , *cycle_count* ;

A property that specifies the binary sequence that triggers the LPCT test mode if it is detected within the number of specified cycles after the LPCT controller has been reset.

MemoryBISR

Specifies the creation and the optional insertion of BISR registers.

Usage

```
DftSpecification(module_name,id) {
    MemoryBISR {
        bisr_segment_order_file : file_name ;
        memory_repair_loading_method : serial | from_read_buffer ;
        memory_library_name_list : mem_lib_name, ... ;
        BisrElement(memory_instance) {
        }
        Interface {
        }
        Controller {
        }
    }
}
```

Description

A wrapper that specifies the creation and the optional insertion of BISR registers. The presence of the controller wrapper adds a controller in the current design. A chip is allowed to have more than one Bisr controller as long as you have a set of fuses for each controller. Refer to “[Built-In Repair Analysis](#)” in the *Tessent MemoryBIST User’s Manual* for a detailed introduction to the topic, including what your memory library needs to include in order to perform Built-In Repair Analysis, and which [Interface](#) your fuse box needs to have to be usable by the controller.

Arguments

- `bisr_segment_order_file : file_name ;`

This property is used to reference a file that contains the power domain and ordering definition of the BISR segments using the syntax shown [Figure 10-53](#). This file is typically auto-generated when the [check_design_rules](#) command runs unless the [set_memory_instance_options -bisr_segment_order_file](#) command was used in which case the specified file is not generated but validated.

This property is typically needed unless the [process_dft_specification](#) command is run with the `-no_insertion` option; if this option is not used, the property is optional.

When the [check_design_rules](#) command runs, a `bisr_segment_order_file` is generated when all of these conditions are met:

- The [set_dft_specification_requirements -memory_test](#) option was specified as “on”.
- The [set_dft_specification_requirements -memory_bisr_chain](#) option was not set to off.
- The [set_memory_instance_options -bisr_segment_order_file](#) option was not specified.

- At least one memory instance exists with a Memory library description that has at least one Memory/.../SpareElement wrapper present *and the* [set_memory_instance_options -use_in_memory_bisr_dft_specification](#) option was not set to “off” for that instance, or, alternatively, at least one block with an ICL file that describes one or more BISR chains is present and the [ignore_for_dft_specification](#) pin attribute is not set to “on” for at least one of the BISR scan-in pins. A BISR scan-in pin as described in ICL has a [ScanInPort](#) that is part of a [ScanInterface](#) with a [tessent_bisr_chain_length Attribute](#) set to a value greater than 0.

The bisr_segment_order_file is created using the format shown in [Figure 10-53](#). If you load a DEF file using the [read_def](#) command, the elements in the OrderedElements wrapper will be ordered so as to minimize wire lengths between them. If you load a UPF or CPF file using the [read_upf](#) or [read_cpf](#) commands, a PowerDomainGroup wrapper will be created for each power domain name that has at least one element. You can also use the [Instance](#) and [Pin](#)-level attribute “bisr_power_domain_name” to define the power domains. When both the “power_domain_name” and the “bisr_power_domain_name” attributes are defined on the same instance, the latter wins. The advantage of the “bisr_power_domain_name” attribute is that it can be set differently on different BISR scan-in pins to associate them to different power domain names. You can also use the attribute to create extra BISR power domains that are not defined in the UPF/CPF files.

When the [check_design_rules](#) command runs and the following conditions are met:

- The [set_dft_specification_requirements -memory_test](#) option was specified as “on”
- The [set_dft_specification_requirements -memory_bisr_chain](#) option was not set to off
- The [set_memory_instance_options -bisr_segment_order_file](#) option was specified to refer to an existing file

The tool validates the referred bisr_segment_order_file to make sure that it lists all existing BISR chain elements and only existing BISR chain elements. An existing BISR chain element is a memory instance with a Memory library description that has at least one Memory/.../SpareElement wrapper (see “[Tessent Core Description](#)” on page 3755) present and the [set_memory_instance_options -use_in_memory_bisr_dft_specification](#) option was not set to “off” for that instance or a BISR scan-in pin on a block having an ICL file describing the BISR chains and the [Pin](#) attribute called “[ignore_for_dft_specification](#)” is not set to “on” on that pin. A BISR scan-in pin is described in ICL and has a [ScanInPort](#) that is part of a [ScanInterface](#) with the [Attribute](#) “[tessent_bisr_chain_length](#)” set to a value greater than 0.

When running the [process_dft_specification](#) command, the validation of the file pointed to by the bisr_segment_order_file property is repeated again to make sure that it lists all existing BISR chain elements and only existing BISR chain elements. If the property is not specified, an empty file is assumed and an error will be generated for all missing existing BISR chain elements.

The format of the BISR segment order file is shown in [Figure 10-53](#). When referring to an instance of a block that has more than one BISR scan segment, you must add the name of the scanin port to distinguish one chain from the other. The <block_instance_name>/<bisr_scanin_port_name> paths must point to pins of an instance with an associated ICL file where the Scanin Port is described as a [ScanInPort](#) that is part of a [ScanInterface](#) with the [Attribute](#) “tessent_bisr_chain_length” set to a value greater than 0. The [extract_icl](#) command automatically sets this attribute when generating an ICL module that contains BISR chains. The BisrModules wrapper is used when the [process_dft_specification](#) command is run with the -no_insertion option and it is desired to generate BISR registers for the memory specified by BisrModules/<modulename>. BisrModules/<modulename> must correspond to a memory core description that is loaded into memory using the [read_core_descriptions](#) command or the [set_design_sources](#) -format tcd_memory command. When running process_dft_specification with the -no_insertion option, the module names of repairable memories must be provided by the user because there is no design information that can be referenced to obtain this information.

Figure 10-53. BISR Segment Order File

```
BisrSegmentOrderSpecification {
    PowerDomainGroup(power_domain_name) { // Repeatable
        OrderedElements {
            memory_instance_name;
            block_instance_name[/bisr_scanin_port_name];
        }
    }
    BisrModules {
        modulename; // Repeatable
    }
}
```

- `memory_repair_loading_method : serial | from_read_buffer ;`

When this property is set to its default value of “serial”, the repair information is read from the fuse box, decompressed and then sent serially to the repair registers located near the memories. The advantages are that a relatively small number of fuses and very few wires are required which simplifies layout. The disadvantage is the longer length of time required to load the repair registers. It might be necessary to reduce the number of repair registers by enabling sharing of repair logic. See the [repair_sharing](#) property, and other related properties, in the [MemoryCluster](#) wrapper of the DftSpecification.

When this property is set to “from_read_buffer”, a multiplexer is inserted between the BISR module and the memory repair ports. This multiplexer allows the repair information to be sourced from either the fuse box read buffer or from the BISR registers. When using the read buffer as the repair source, the repair information is driven from the fuse box read buffer and broadcast to all memory repair ports in parallel. The advantages are that the repair information is available very quickly at the memory inputs and there is no limit on the number of incremental repair sessions. The disadvantages are that the memory repair information is stored in an uncompressed form and a lot of connections are created between the BISR controller and the memories. Therefore, a lot more fuses are required and routing

congestion might occur during layout. For these reasons, it might be necessary to reduce the number of repair registers by enabling sharing of repair logic. See the `repair_sharing` property, and other related properties, in the [MemoryCluster](#) wrapper of the `DftSpecification`.

The multiplexer select signal is connected to a test data register, which is controllable during patterns generation.

When generating the fuse box controller, a new signal call “SerialRepairEnable” is present on the fuse box controller if the design contains BISR chains that support fast BISR loading.

- `memory_library_name_list : mem_lib_name, ... ;`

A property that specifies a list of memory libraries associated with repairable memories in the design. This property is only used and needed if you are running the `process_dft_specification` command with the `-no_insertion` option and the design is not elaborated in memory. Otherwise, the `memory_library_name` is extracted from the design for the memory instances indicated inside the file specified in `bisr_segment_order_file`.

BisrElement

Overrides the settings of the BISR registers and specifies their location.

Usage

```
DftSpecification(module_name, id) {
    MemoryBisr {
        BisrElement(memory_instance) { // repeatable
            parent_instance : relative_instance ;
            parent_instance_anchor : current_design |
                parent_instance_of_memory | attribute_expression ;
        }
    }
}
```

Description

A repeatable wrapper that is used to override settings of the BISR registers for repairable memory instances and specify their insertion into a particular parent instance of the design. If memory instances are matched by multiple BisrElement wrappers due to wildcards, the last BisrElement property in the DftSpecification will override any prior wrappers.

Note

 When relocating the BISR modules inside non-unique design instances, Tessent Shell will attempt to preserve design uniqueness. However, if the relocation of the BISR modules causes non-unique instances to differ, Tessent Shell will unify the design instances in order to satisfy the BISR relocation requirements.

If the BisrElement wrapper is not specified, or if it is specified but has no properties specified within the wrapper, the BISR registers will be inserted adjacent to their respective memory instances.

Arguments

- *memory_instance*
A pattern expression matching repairable memory instances in the design. The wildcard character “*” may be used to select multiple memory instances.
- *parent_instance : relative_instance ;*
A property that specifies a design instance relative to the instance specified with *parent_instance_anchor*. If not specified, the default is a null string which will instantiate the BISR register in the same design hierarchy as specified by the *parent_instance_anchor* property.
- *parent_instance_anchor : current_design | parent_instance_of_memory | attribute_expression ;*
This property is only valid if *parent_instance* is specified. The *parent_instance_anchor* property specifies the starting point, or anchor, for the relative path specified with the

relative_instance value of the *parent_instance* property. The default value of *current_design* specifies the top level of the current design. Specifying *parent_instance_of_memory* will set the anchor one level up in the design hierarchy from the memory instance(s) matched by *memory_instance*. The *attribute_expression*, enclosed in double quotes, is used to find a design instance on which the attribute expression is true. The expression is evaluated beginning with the parent instance of the memory. If the expression is true, this instance is set as the *parent_instance_anchor*. If the expression is false, the next level parent instance is then evaluated. This continues until the expression is true or the top level of the design is reached.

Examples

Example 1

The following example shows how the BISR register instances for the repairable memory instances memA and memB, originally matched by a wildcard pattern, are placed into the desired top-level design locations by subsequent BisrElement wrappers.

```
BisrElement(*) {
    parent_instance_anchor : current_design ;
    parent_instance : block_instC;
}
BisrElement(core_inst*/memA) {
    parent_instance_anchor : current_design ;
    parent_instance : block_instA;
}
BisrElement(core_inst*/memB) {
    parent_instance : block_instB;    // parent_instance_anchor defaults to
}                                // current_design if not specified.
```

If memA and memB instances are located throughout the design hierarchy, the instances located within these blocks will match the subsequent BisrElement *memory_instance* expression:

```
core_instA/memA, core_instB/memA, core_instC/memB, core_instA/memB
```

The final location for the BISR register instances will then be as follows:

```
block_instA          // all matched memA BISR registers
block_instB          // all matched memB BISR registers
block_instC          // all globally matched memory BISR registers
```

Example 2

The following example shows how the BISR register instances for the repairable memory instance memA, which was originally matched by a wildcard pattern, are restored to the same design instance as the memory through a final match for that memory instance:

```
BisrElement(*) {  
    parent_instance_anchor : current_design ;  
    parent_instance : block_instA;  
}  
BisrElement(*/memA) {  
    parent_instance_anchor : parent_instance_of_memory ;  
    parent_instance : "";  
}
```

If memA is located in the design hierarchy at:

```
top/block_instB/memA
```

The final location for the BISR register instances will then be at:

```
top/block_instB           // memA BISR registers adjacent to memA  
block_instA               // BISR registers for all other memories
```

Example 3

This example outlines another use of the parent_instance_of_memory option for the parent_instance_anchor property with a more elaborate parent_instance specification. Assume the design contains a memory instance memA, located in the design hierarchy at:

```
block_instA/c_inst1/d_inst/memA
```

The following BisrElement wrapper is defined to instantiate the BISR registers for memA:

```
BisrElement(*) {  
    parent_instance_anchor : parent_instance_of_memory ;  
    parent_instance : ../../memA_bisr_container_inst;  
}
```

The parent instance of memA is: block_instA/c_inst1/d_inst, which will be the anchor. The parent_instance property may contain “..” sequences to define relative paths from the parent instance anchor. The single “..” sequence in this example moves up one level in hierarchy from the anchor, then appends the instance memA_bisr_container_inst. The final location for memA BISR instances will then be:

```
block_instA/c_inst1/memA_bisr_container_inst
```

Example 4

The following example locates each BISR register at the first parent level that has the “power_domain_island” attribute equal to “pdgA_2”. The evaluation of the expression starts

from the parent instance of each matched memory and works up the design hierarchy. point to attribute filtering equation syntax section for more.

```
BisrElement(*) {  
    parent_instance_anchor : "power_domain_island==pdgA_2" ;  
}
```

If no match is found, the BISR registers will be placed at the top level of the design.

Note that any of the listed [Instance](#) built-in attributes, or any user attributes that are [registered](#) against a design instance, can be used within the *attribute_expression*. Additionally, any of the [Attribute Filtering Equation Syntax](#) relations can be implemented to create more complex expressions.

Interface

Specifies the names of the ports created when connecting the BISR chains to ports of a module of type `sub_block` or `physical_block` as specified using the `set_design_level` command.

Usage

```
DftSpecification(module_name, id) {
    MemoryBisr {
        Interface {
            scan_in           : port_naming ; //Def: %s_bisr_si
            scan_out          : port_naming ; //Def: %s_bisr_so
            capture_shift_clock : port_naming ; //Def: %s_bisr_clk
            shift_en          : port_naming ; //Def: %s_bisr_shift_en
            reset              : port_naming ; //Def: %s_bisr_reset
            parallel_in       : port_naming ; //Def: %s_bisr_parallel_in
            serial_repair_enable: port_naming ;
                                         //Def: %s_bisr_serial_repair_enable
            memory_disable     : port_naming ; //Def: %s_bisr_mem_disable
            memory_chain_select: port_naming ; //Def: %s_bisr_mem_chain_select
        }
    }
}
```

Description

A wrapper that specifies the names of the ports created when connecting the BISR chains to ports of a module of type `sub_block` or `physical_block` as specified using the `set_design_level` command. The “%s_” symbol is required but can be specified anywhere in the string. It is replaced by the power domain name followed by an underscore when the module contains power domain names other than “-”; otherwise it is replaced by an empty string. The ports are only created when the `Controller` wrapper is not specified, in which case the chains are connected to it. The ports are allowed to already be present. If the `has_functional_source` attribute on the `scan_out` port is true, the BISR chain is inserted between the net sourcing the `scan_out` port and the port itself. ICL extract will check that the chains traces back to the specified `scan_in` port. This feature is useful to support multi pass insertion flows.

Arguments

- `scan_in : port_naming ;`

A string that specifies the naming to use for the `scan_in` port. When unspecified, it defaults to the value specified in the `MemoryBisr/ChainInterface/scan_in` property inside the `DefaultsSpecification/DftSpecification` wrappers. See the `get_defaults_value` command description for more details about the company, group, and user defaults specifications.

The string must contain the “%s_” symbol. It is replaced by the power domain name followed by an underscore when the module contains more than one power domain name; otherwise, it is replaced by an empty string.

- `scan_out : port_naming ;`

A string that specifies the naming to use for the `scan_out` port. When unspecified, it defaults to the value specified in the `MemoryBisr/ChainInterface/scan_out` property inside the

[DefaultsSpecification/DftSpecification](#) wrappers. See the [get_defaults_value](#) command description for more details about the company, group, and user defaults specifications.

The string must contain the “%s_” symbol. It is replaced by the power domain name followed by an underscore when the module contains more than one power domain name; otherwise, it is replaced by an empty string.

- `capture_shift_clock : port_naming ;`

A string that specifies the naming to use for the capture_shift_clock port. When unspecified, it defaults to the value specified in the [MemoryBisr/ChainInterface/capture_shift_clock](#) property inside the [DefaultsSpecification/DftSpecification](#) wrappers. See the [get_defaults_value](#) command description for more details about the company, group, and user defaults specifications.

The string must contain the “%s_” symbol. It is replaced by the power domain name followed by an underscore when the module contains more than one power domain name; otherwise, it is replaced by an empty string.

- `shift_en : port_naming ;`

A string that specifies the naming to use for the shift_en port. When unspecified, it defaults to the value specified in the [MemoryBisr/ChainInterface/shift_en](#) property inside the [DefaultsSpecification/DftSpecification](#) wrappers. See the [get_defaults_value](#) command description for more details about the company, group and user defaults specifications.

The string must contain the “%s_” symbol. It is replaced by the power domain name followed by an underscore when the module contains more than one power domain name; otherwise, it is replaced by an empty string.

- `reset : port_naming ;`

A string that specifies the naming to use for the active low reset port. When unspecified, it defaults to the value specified in the [MemoryBisr/ChainInterface/reset](#) property inside the [DefaultsSpecification/DftSpecification](#) wrappers. See the [get_defaults_value](#) command description for more details about the company, group and user defaults specifications.

The string must contain the “%s_” symbol. It is replaced by the power domain name followed by an underscore when the module contains more than one power domain name; otherwise, it is replaced by an empty string.

- `parallel_in : port_naming ;`

A string that specifies the naming to use for the BISR chain parallel input port. This property is only effective when DftSpecification/[MemoryBisr/memory_repair_loading_method](#): from_read_buffer has been specified, otherwise it is ignored. When unspecified, it defaults to the value specified in the [MemoryBisr/ChainInterface/parallel_in](#) property inside the [DefaultsSpecification/DftSpecification](#) wrappers. See the [get_defaults_value](#) command description for more details about the company, group and user defaults specifications.

The string must contain the “%s_” symbol. It is replaced by the power domain name followed by an underscore when the module contains more than one power domain name; otherwise, it is replaced by an empty string.

- **serial_repair_enable : port_naming ;**

A string that specifies the naming to use for the BISR chain loading enable port. This property is only effective when DftSpecification/[MemoryBisr](#)/memory_repair_loading_method: from_read_buffer has been specified, otherwise it is ignored. This port will be connected to the “SerialRepairEnable” output port of the fuse box controller. When unspecified, it defaults to the value specified in the [MemoryBisr](#)/ChainInterface/serial_repair_enable property inside the [DefaultsSpecification](#)/[DftSpecification](#) wrappers. See the [get_defaults_value](#) command description for more details about the company, group and user defaults specifications.

The string must contain the “%s_” symbol. It is replaced by the power domain name followed by the underscore when the module contains more than one power domain name; otherwise it is replaced by an empty string.

- **memory_disable : port_naming ;**

A string that specifies the naming to use for the memory_disable port. When unspecified, it defaults to the value specified in the [MemoryBisr](#)/ChainInterface/memory_disable property inside the [DefaultsSpecification](#)/[DftSpecification](#) wrappers. See the [get_defaults_value](#) command description for more details about the company, group and user defaults specifications.

The string must contain the “%s_” symbol. It is replaced by the power domain name followed by an underscore when the module contains more than one power domain name otherwise, it is replaced by an empty string.

This port is only created when at least one memory instance has a Memory wrapper (see “[Tessent Core Description](#)” on page 3755) with function “bisrSerialData” and a Memory with function “select” in its Memory library description or a child block with this port is present. Such ports are identified in the ICL module as [DataInPorts](#) with the Attribute “tessent_bisr_function” set to “memory_disable”.

- **memory_chain_select : port_naming ;**

A string that specifies the naming to use for the memory_chain_select port. When unspecified, it defaults to the value specified in the [MemoryBisr](#)/ChainInterface/memory_chain_select property inside the [DefaultsSpecification](#)/[DftSpecification](#) wrappers. See the [get_defaults_value](#) command description for more details about the company, group, and user defaults specifications.

The string must contain the "%s_" symbol. It is replaced by the power domain name followed by an underscore when the module contains more than one power domain name; otherwise, it is replaced by an empty string.

This port is only created when at least one memory instance has a Memory wrapper (see “[Tessent Core Description](#)” on page 3755) with function bisrSerialData in its Memory library description or a child block with this port is present. Such ports are identified in the

ICL module as **DataInPorts** with the **Attribute** “tessent_bisr_function” set to “memory_chain_select”.

Examples

The following example defines an interface naming convention that uses capital letters and TS_ as a prefix.

```
DftSpecification(my_design,rtl) {
    MemoryBisr {
        Interface {
            scan_in          : TS_%s_BISR_SI ;
            scan_out         : TS_%s_BISR_SO ;
            capture_shift_clock : TS_%s_BISR_CLK ;
            shift_en         : TS_%s_BISR_SHIFT_EN ;
            reset            : TS_%s_BISR_RESETB ;
            memory_disable   : TS_%s_BISR_MEM_DISABLE ;
            memory_chain_select : TS_%s_BISR_MEM_CHAIN_SEL ;
        }
    }
}
```

Controller

Specifies the creation and optionally the insertion of a BISR loader controller.

Usage

```
DftSpecification(module_name,id) {
    MemoryBisr {
        Controller {
            ijttag_host_node : node_id ;
            parent_instance : inst_name ;
            leaf_instance_name : inst_name ;
            repair_clock_connection : pin_or_port_name ;
            repair_trigger_connection : pin_or_port_name ;
            serial_repair_enable : pin_or_port_name ;//Def: auto

        }
    }
}
```

Description

A wrapper that specifies the creation and optionally the insertion of a BISR loader controller. A controller needs a dedicated set of fuses associated with it and you typically need only one controller per chip. The architecture of the controller is described in the “[The BISR Controller](#)” section of the *Tessent MemoryBIST User’s Manual*.

Arguments

- `ijttag_host_node : node_id ;`

A property that specifies where the BISR controller should attached to the iJTAG network. The string `node_id` must have one of the following formats: HostScanInterface(id), Tap(id)/HostIjtag(id), ScanMux(id)/Input(1|0) or Sib(id). The specified node id must exist in the [IjtagNetwork](#) wrapper of the same [DftSpecification](#) wrapper.

When using the [create_dft_specification](#) command, the BIST controller will be attached to the Sib(sti) node. The Bisr controller is scan-testable and its `test_en` pin must be driven high during any logictest mode. The logictest modes often rely on the fact that memories were repaired prior to running the ATPG patterns when the sync write through feature is used. The `bisr_clock` ports are held low when `ltest_en` is high to make sure the BISR controller can be scan tested without disturbing the unloaded repair solution in the BISR registers.

- `parent_instance : inst_name ;`

A property that specifies the parent instance in which the memory BISR controller instance is to be inserted. When unspecified, it defaults to the top level of the design. When set to “.”, it explicitly points to the top level of the design. You specify this option if you want the memory BISR controller to be instantiated inside a different hierarchy. The parent instance must point to a unique instance; otherwise, it will be unqualified during [process_dft_specification](#).

- `leaf_instance_name : inst_name ;`

An optional property that specifies the memory BISR controller instance name explicitly. The default value is `design_name_design_id_tessent_mbisr_controller_inst`. This property is not used nor needed when the [process_dft_specification](#) command is run with the `-no_insertion` option.

- `repair_clock_connection : pin_or_port_name ;`

A property that defines a functional clock that is going to be free-running during power-up and is to be used to unload the fuse content into the BISR registers. When you point to a top level port, the connection is automatically transferred on the `from_pad` port the input pad buffer when the pad cell is properly described in your cell library.

The distributed architecture and conservative clocking methodology used for self-repair require some care in the selection of the functional repair clock that is used to apply repair during chip power-up. It is recommended that you use a functional clock of 10 MHz or less in that functional mode. Note that all other modes of operation for the BISR controller used for manufacturing test use the TAP clock (TCK), which is also 10 MHz, by default. Using such a low frequency simplifies timing closure. At 10 MHz, self-repair will take approximately 1 ms to execute for a BISR chain with 5000 bits, which is sufficient to repair hundreds of memories. If this time needs to be shortened, you can use a faster functional clock. However, you must consider the following factors when making a decision because they might limit the maximum achievable frequency:

- Clock balancing of the BISR chain

The BISR chain is distributed throughout the chip, and some segments of the BISR chain might be part of pre-designed circuit blocks. Balancing the BISR clock to achieve a higher speed of operation might be difficult.

- Clock edge uncertainty

Retiming registers are inserted between BISR registers so that balancing the BISR clock is not necessary. However, these retiming registers might limit the maximum achievable frequency due to the uncertain time of occurrence of the falling BISR clock edge with respect to its rising edge.

- Distribution of the BISR registers

The BISR chain is distributed throughout the chip, and some segments of the BISR chain might be part of pre-designed circuit blocks. Long wires between BISR registers might limit the maximum achievable frequency. Note that the routing of the

BISR chain is not optimized based on placement unless have read in a DEF file using the [read_def](#) command prior to running the [check_design_rules](#) command.

- **repair_trigger_connection : *pin_or_port_name* ;**

A property that specifies the functional signal that resets the BISR controller and BISR registers and initiates the memory repair. This signal is typically derived from a power-on detector or the power management unit of your device. When you point to a top level port, the connection is automatically transferred on the *from_pad* port of the input pad buffer when the pad cell is properly described in your cell library.

- **serial_repair_enable : *pin_or_port_name* ;**

A property that specifies the input that selects between serial or parallel BISR chain loading. The specified pin or port will be connected to the “SerialRepairEnable” input port of the fuse box controller. When driven with a “0” the BISR chains are loaded in parallel from the read buffer of the fuse box. When driven with a “1”, the fusebox controller initializes the BISR chains serially. This property is required when the [MemoryBisr/memory_repair_loading_method](#) parameter is set to “from_read_buffer”, otherwise it is ignored.

- **programming_voltage_source : *pin_or_port_name* ;**

A property that defines the top-level port or internal voltage source that supplies the programming voltage for the fuse box programming. If the programming voltage is generated using an on-chip charge pump, then specify the voltage output pin of the charge pump. This property must be specified when the *fuse_box_location* property is set to internal. This property is used to make the connection between the specified programming voltage source and the fuse box programming voltage pin. You do not need to specify this property when the *fuse_box_location* property is set to external because the programming voltage source should already be connected to the fuse box interface in the pre-dft inserted design. Refer to “[Connecting the BISR Controller to an External Fuse Box](#)” for further information about external fuse box implementation.

- **programming_voltage_port : *port_name* ;**

An optional property that defines the top-level port that supplies the programming voltage. The voltage port must be identified if it needs to be driven to a specific programming value when the fuses are being programmed. You do not need to specify this property when the *programming_voltage_source* is specified and references a top-level port or when the voltage is generated from an internal charge pump.

- **fuse_box_location : internal | external ;**

A property that specifies if the fuse box is to be instantiated inside the BISR controller, or if it already exists in the design and connections should be made to and from it. It is typically external when the up address range of the fuse box is used by other functional or test modes. Refer to the [ExternalFuseBoxOptions](#) wrapper if your fuse box is external to the controller.

When not specified, this property defaults to the [MemoryBisr/fuse_box_location](#) property found inside the [DefaultsSpecification/DftSpecification](#) wrapper.

- `fuse_box_interface_module : module_name ;`

A property that specifies the module name of the fuse box to instantiate in the design. The module name specified with this property will override any that are inferred from `tcd_fusebox` libraries loaded in the design. If the fuse box module is already instantiated into the design, its associated [FuseBoxInterface](#) wrapper is automatically searched and loaded. See the [set_module_matching_options](#) and the “[set_design_sources -format tcd_fusebox](#)” command descriptions for more information about the searching mechanism.

When the `fuse_box_location` property is set to internal and only one `tcd_fusebox` file is present, the `fuse_box_interface_module` property is inferred from the `tcd_fusebox` if the `fuse_box_interface_module` property is not specified. If multiple `tcd_fusebox` library files are present, then it is required to specify the `fuse_box_interface_module` property in this wrapper.

When the `fuse_box_location` property is set to external and `fuse_box_interface_module` is not specified, the `fuse_box_interface_module` will be inferred from the specified [ExternalFuseBoxOptions/design_instance](#) property. If neither the design instance or `fuse_box_interface_module` properties are specified, and only a single `tcd_fusebox` exists in the design, the `fuse_box_interface_module` will be inferred from this `tcd_fusebox`. If multiple `tcd_fusebox` files are present, an error will result and the user will be required to specify which `fuse_box_interface_module` to use.

Refer to the [FuseBoxInterface](#) wrapper description and “[Connecting the BISR Controller to an External Fuse Box](#)” topic in the *Tessent MemoryBIST User’s Manual* for further information on `tcd_fusebox` usage and DftSpecification requirements.

- `max_fuse_box_programming_sessions : int | unlimited ;`

A property that enables hard incremental repair and specifies how many fuse box programming sessions are to be supported by the controller. You need more than one programming session if you need to test the memories at different times and conditions, and if you want to be able to program the repair fuses after each repair analysis. This is useful for increasing the yield of circuits exhibiting parametric defects under certain process, voltage or temperature conditions. This approach avoids the need to save the repair information of the chip for each intermediate repair solution, and only program the fuse once the cumulative failure map is known. Refer to the [Tessent MemoryBIST User’s Manual](#) for a detailed description of this feature. The hardware cost associated with each fuse box programming session is a register that is as wide as the fuse box address bus, plus an extra flop and some logic gates.

When specifying an integer value, the repair information is compressed before being stored in the fuse box. The number of fuses required to store the repair information is proportional to the integer value.

When specified as ‘unlimited’, the fuse box compression hardware is disabled inside the fuse box controller. This enables the repair solution from the BISR chains to be stored uncompressed inside the fuse box. New repair solutions can be written directly inside the fuse box without affecting the repair solution from previous repair sessions. This allows an unlimited number of self_fuse_box_program autonomous mode programming sessions.

Disabling the compression hardware is also useful in the rare case where more than 50% of the repair registers are expected to be used. The compression algorithm becomes inefficient in that case and might require more fuses than there are bits in the BISR chain.

Note

 When fuse box compression is disabled through the ‘unlimited’ setting, the fuse box size must be greater than or equal to the total number of bits in the BISR chains.

When not specified, this property defaults to the [MemoryBISR](#)/
max_fuse_box_programming_sessions property found inside the [DefaultsSpecification](#)/
[DftSpecification](#) wrapper.

Examples

The following example shows the specification of the controller wrapper. The ijttag_host_node property is linked to Sib(bisr) node. The repair_clock_connection property points to a port of the device. The cell library information will be automatically used to map the connection on the other side of the input pad buffer. The repair_trigger_connection property is used to specify the connection to the power management unit. Because the fuse box is internal, FuseBoxInterface(my_fuse_box_internal) wrapper (see “[Tessent Core Description](#)” on page 3755) is required to have been pre-loaded into memory using the [read_core_descriptions](#) command.

```
DftSpecification(my_design,rtl) {
    IJTAGNetwork {
        HostScanInterface(ijttag) {
            Sib(sti) {
                Sib(bisr) {
                }
            }
        }
    }
    MemoryBISR {
        Controller {
            ijttag_host_node : Sid(bisr) ;
            repair_clock_connection : Clk10Mhz ;
            repair_trigger_connection : pmu/repair_en ;
            programming_voltage_source : VPP ;
            fuse_box_location : internal ;
            fuse_box_interface_module : my_fuse_box_interface ;
        }
    }
}
```

AdvancedOptions

Specifies advanced options for the BISR controller.

Usage

```
DftSpecification(module_name, id) {
    MemoryBISR {
        Controller {
            AdvancedOptions {
                FuseBoxOptions {
                    write_duration : time | 8us ;
                    read_word_size : int | auto ;
                    number_of_fuses_for_repair : int | auto ;
                    align_access_en_with_address : on | off | auto ;
                    programming_method : buffered | unbuffered | auto ;
                }
                repair_word_size : int | auto ;
                max_bisr_chain_length : int | auto ;
                zero_counter_bits : int | auto ;
                bisr_done_connection : pin_name ;
                bisr_pass_connection : pin_name ;
                power_up_chain_select : internal | external ;
            }
        }
    }
}
```

Description

A wrapper that specifies advanced options for the BISR controller. You do not need to specify any of the properties with an auto default value when you have a FuseBoxInterface wrapper (see “[Tessent Core Description](#)” on page 3755) associated with the specified fuse_box_module_name property. The two connection properties are typically used to connect the status signal to the power management unit when different portions of the chip are powered up and down during the normal operation of a device, and those portions have repairable memories that need to be repaired each time the region is turned back on. Refer to the [Tessent MemoryBIST User’s Manual](#) for detailed information about power domains and their impact on memory BISR.

Arguments

- FuseBoxOptions/write_duration : *time* | 8us ;
 A property that specifies the time it takes to program a fuse. When set to auto, the value found inside the associated FuseBoxInterface wrapper is used. If no associated FuseBoxInterface wrapper exists, the default value of “8us” is used. The write duration of the fuse box is the value found in the datasheet of the fuse box.
- FuseBoxOptions/read_word_size : *int* | auto ;
 A property that specifies how many fuses are read in parallel. The fuse box interface module is designed to not reread the fuse box if the next read address it is getting is part of the same word that it just read. This information is needed to properly compute how long it takes to

read the fuse values and estimate the worst case repair time needed when all fuses need to be read.

When set to auto, the value found inside the associated FuseBoxInterface wrapper is used. If no associated FuseBoxInterface wrapper exists, the default value of 1 is used. It is ok to specify a read_word_size value that is actually smaller than the true word size of the fuse box that was read as it will only makes the calculated worst case run time for the power up emulation mode longer. This property does not affect the controller hardware and the true worst case time it takes to power up a domain. However, it is important to not specify a read_word_size that is larger than reality as the power up emulation pattern would be generated with a wait loop that is too short.

- FuseBoxOptions/number_of_fuses_for_repair : *int* | auto ;

A property that defines the number of fuses available for repair in the fuse box. You need to reserve the bottom part of the address space for repair but you may use the upper part for other purposes. When the value is auto, the number of fuses for repair is set to the value of number_of_fuses specified in the Core/FuseBoxInterface wrapper. If no FuseBoxInterface description is available, the value is computed as 2 to the power of the number of address ports specified with the ExternalFuseBoxOptions/ConnectionOverrides/address property.

- FuseBoxOptions/align_access_en_with_address : on | off | auto ;

A property that specifies if the pulse triggering a fuse box access and generated by the BISR controller is expected to be aligned with the address to be read or written or if it is one cycle ahead. The value “on” means that the fuse box interface can only accept a pulse that is aligned with the address. The value “off” means that the fuse box interface can also accept a pulse occurring one cycle ahead of the address allowing a slightly faster fuse box access. For example, a read access can take as little as two clock cycles instead of three for some fuse box interfaces. When set to auto, the value found inside the associated FuseBoxInterface wrapper is used. If no associated FuseBoxInterface wrapper exists, it defaults to on if fuse_box_location is external, and to off if fuse_box_location is internal.

- programming_method : buffered | unbuffered | auto ;

A property that specifies that it is not allowed to program individual fuses at randomly specified addresses. In some fuseboxes, individual fuse bits cannot be addressed directly; all fuse bits must be read or programmed as a group. When this property is set to buffered, a signal called programFB is generated by the BISR controller and connected to the fuse box interface. This signal is used to initiate final fuse box programming. Extra steps are also added to the patterns to transfer and program the fuses during the “self_fuse_box_program” autonomous operation and in the “program” and “read” fuse box access modes. When set to auto, the value found inside the associated FuseBoxInterface wrapper is used. If no associated FuseBoxInterface wrapper exists, it defaults to “unbuffered”.

- repair_word_size : *int* | auto ;

A property that specifies the repair word size which is the number of bits read from the fuse box as soon as one of the bits in the word is a one. Refer to the compression algorithm description in the [Tessent MemoryBIST User’s Manual](#) for more information.

When set to auto, this property is automatically set to match the largest repair word size of all your repairable memories providing the most effective encoding capacity.

- max_bisr_chain_length : *int | auto* ;

A property that specifies the maximum length a BISR chain could have. Unless you are creating a BISR controller without having all BISR chains visible, you do not need to specify this property because the default auto value implies that the controller is built to be capable of loading BISR chains that are as much as four times larger than they currently are, allowing for any number of last minute additions.

- zero_counter_bits : *int | auto* ;

A property that specifies how many bits the zero counter of the encoder must have. This property should never need to be specified as it is automatically set to the log2 of the specified or inferred max_bisr_chain_length property. Refer to the compression algorithm description in the [Tessent MemoryBIST User's Manual](#) for more information about the zero counter.

- bisr_done_connection : *pin_name* ;

A property that specifies a connection to be made from the done status port of the BISR controller to the power management unit. This done status port indicates that all enabled power domains are programmed. See the done_to_pmu_connection property inside the [PowerDomainOptions](#) wrapper to know how to connect each power domain-specific done status port to the power management unit.

- bisr_pass_connection : *pin_name* ;

A property that specifies a connection to be made from the pass status port of the BISR controller to the power management unit. This pass status port indicates that no errors happened while reading the fuse and loading the enabled BISR chains.

- power_up_chain_select : *internal | external* ;

This property changes the default BISR chain select output on the fuse box controller when performing a power-up or a calculate_bisr_chain_length pattern. This property is used for designs that contain memories with serial repair interfaces that do not perform a complete reset of their internal BISR chain during an asynchronous reset from the fuse box controller. Certain TSMC repairable memories implement such a BISR reset mechanism.

When power_up_chain_select is set to internal, the fuse box controller selects the internal BISR chains when performing the chain length calculation. However, if the memory's internal BISR chain does not reset completely, this will cause the BISR chain length calculation to fail. It is recommended to use the "internal" chain when possible in order to verify the internal chains every time the chip is powered up.

When set to external, the external BISR register is used to calculate the BISR chain length during power up. This register is guaranteed to reset completely and ensures that the BISR chain length calculation succeeds.

Examples

The following example connects the done and pass status ports to pins of the power management unit.

```
DftSpecification(my_design,rtl) {
    MemoryBisr {
        Controller {
            AdvancedOptions {
                bisr_done_connection      : pmu/global_bisr_done ;
                bisr_pass_connection      : pmu/global_bisr_pass ;
            }
        }
    }
}
```

ExternalFuseBoxOptions

Specifies options relative to an external fuse box and its interface.

Usage

```
DftSpecification(module_name, id) {
    MemoryBisr {
        Controller {
            ExternalFuseBoxOptions {
                design_instance      : inst_name ;
                multiplexing         : on | off | auto ;
                ConnectionOverrides {
                    bisr_en          : pin_name, ... ;
                    clock             : pin_name ;
                    select            : pin_name ;
                    reset             : pin_name ;
                    access_en         : pin_name ;
                    write_en          : pin_name ;
                    write_duration_count : pin_name ;
                    read_buffer_select : pin_name ;
                    read_buffer_output : pin_name ;
                    write_buffer_transfer : pin_name ;
                    address           : pin_name ;
                    done              : pin_name ;
                    read_data          : pin_name ;
                }
            }
        }
    }
}
```

Description

A wrapper that specifies options relative to the external fuse box and its interface. This wrapper is only used when the `fuse_box_location` property in the `DftSpecification/MemoryBisr/Controller` wrapper is set to external. The `ConnectionOverrides` wrapper is used to define connections between the external fuse box and BISR controller. These connections can also be specified in the `tcd_fusebox FuseBoxInterface` module library. When defining connections in the `ConnectionOverrides` wrapper, it is mandatory to specify the following properties:

- `done`
- `read_data`
- `write_en`
- `select`
- `access_en`
- `address`
- `write_duration_count`

Refer to the `fuse_box_location` and `fuse_box_interface_module` property descriptions, the [FuseBoxInterface](#) wrapper description and the “[Connecting the BISR Controller to an External Fuse Box](#)” topic in the *Tessent MemoryBIST User’s Manual* for further details.

Arguments

- `design_instance : inst_name ;`

A property that is only specified when the `DftSpecification/MemoryBISR/Controller` `fuse_box_interface_module` property is not specified. The `fuse_box_interface_module` will be inferred from the `design_instance` property. If neither the `design_instance` or `fuse_box_interface_module` properties are specified, and only a single `tcd_fusebox` exists in the design, the `fuse_box_interface_module` will be inferred from this `tcd_fusebox`. If multiple `tcd_fusebox` files are present, an error will result and the user will be required to specify which `fuse_box_interface_module` to use.

- `multiplexing : on | off | auto ;`

A property that specifies if the connection to the external fuse box should be multiplexed or not. The connection must be multiplexed if it is also used by some other circuitry. If it is multiplexed, a 2-to-1 multiplexer local to the connection end point is inserted and the select is driven by the `bisr_en` signal. When the property is set to `auto`, the multiplexer is only inserted if the `has_functional_source` Pin attribute of the specified `pin_name` in the connection is set to true. See “[Pin](#)” on page 3094.

- `ConnectionOverrides/bisr_en : pin_name ;`

A property that specifies one or many connections to create from the `bisr_en` port to any pins in the circuit. This signal is typically used as a select of multiplexers when the fuse box is shared with other circuitry and the multiplexer is already inside the interface.

- `ConnectionOverrides/clock : pin_name ;`

A property that specifies where to connect the clock signal for the fuse box interface. This property is used when you do not have a `FuseBoxInterface` wrapper associated with a `fuse_box_module_interface` property, or if the clock connection needs to be made to any place other than the ports of the fuse box interface module. For a description of the clock signal on the fuse box interface, refer to the [FuseBoxInterface](#) wrapper description.

- `ConnectionOverrides/select : pin_name ;`

A property that specifies where to connect the select signal for the fuse box interface. This property is used when you do not have a `FuseBoxInterface` wrapper associated with a `fuse_box_module_interface` property, or if the select connection needs to be made to any place other than the ports of the fuse box interface module. For a description of the select signal on the fuse box interface, refer to the [FuseBoxInterface](#) wrapper description.

- `ConnectionOverrides/reset : pin_name ;`

A property that specifies where to connect the reset signal for the fuse box interface. This property is used when you do not have a `FuseBoxInterface` wrapper associated with a `fuse_box_module_interface` property, or if the reset connection needs to be made to any

place other than the ports of the fuse box interface module. For a description of the reset signal on the fuse box interface, refer to the [FuseBoxInterface](#) wrapper description.

- ConnectionOverrides/access_en : *pin_name* ;

A property that specifies where to connect the access_en signal for the fuse box interface. This property is used when you do not have a FuseBoxInterface wrapper associated with a fuse_box_module_interface property, or if the access_enable connection needs to be made to any place other than the ports of the fuse box interface module. For a description of the access_enable signal on the fuse box interface, refer to the [FuseBoxInterface](#) wrapper description.

- ConnectionOverrides/write_en : *pin_name* ;

A property that specifies where to connect the write_en signal for the fuse box interface. This property is used when you do not have a FuseBoxInterface wrapper associated with a fuse_box_module_interface property, or if the write_enable connection needs to be made to any place other than the ports of the fuse box interface module. For a description of the write_enable signal on the fuse box interface, refer to the [FuseBoxInterface](#) wrapper description.

- ConnectionOverrides/write_duration_count : *pin_name* ;

A property that specifies where to connect the write_duration_count signal for the fuse box interface. This property is used when you do not have a FuseBoxInterface wrapper associated with a fuse_box_module_interface property, or if the write_duration_count connection needs to be made to any place other than the ports of the fuse box interface module. For a description of the write_duration_count signals on the fuse box interface, refer to the [FuseBoxInterface](#) wrapper description.

If the write_duration_count pins are a series of numbered scalar ports, you can use the %<integer>d[msb:lsb] symbol to specify them. For example, wcount%2d[31:0] will connect to the scalar ports called wcount31 to wcount00.

- ConnectionOverrides/read_buffer_select : *pin_name* ;

A property that specifies where to connect the read_buffer_select signal for the fuse box interface. This property is used when you do not have a FuseBoxInterface wrapper associated with a fuse_box_module_interface property, or if the read_buffer_select connection needs to be made to any place other than the ports of the fuse box interface module. For a description of the read_buffer_select signal on the fuse box interface, refer to the [FuseBoxInterface](#) wrapper description.

- ConnectionOverrides/read_buffer_output : *pin_name* ;

A property that specifies where to connect the read_buffer_output signals for the fuse box interface. This property is used when you do not have a FuseBoxInterface wrapper associated with a fuse_box_module_interface property, or if the read_buffer_output connections need to be made to any place other than the ports of the fuse box interface module. For a description of the read_buffer_output signal on the fuse box interface, refer to the [FuseBoxInterface](#) wrapper description.

If the `read_buffer_output` pins are a series of numbered scalar ports, you can use the `%<integer>d[msb:lsb]` symbol to specify them. For example `RB%2d[12:0]` will connect to the scalar ports called RB12 to RB00.

- `ConnectionOverrides/write_buffer_transfer : pin_name ;`
A property that specifies where to connect the `write_buffer_transfer` signal for the fuse box interface. This property is used when you do not have a `FuseBoxInterface` wrapper associated with a `fuse_box_module_interface` property, or if the `write_buffer_enable` connection needs to be made to any place other than the ports of the fuse box interface module. For a description of the `write_buffer_transfer` signal on the fuse box interface, refer to the [FuseBoxInterface](#) wrapper description.
- `ConnectionOverrides/address : pin_name ;`
A property that specifies where to connect the address signals for the fuse box interface. This property is used when you do not have a `FuseBoxInterface` wrapper associated with a `fuse_box_module_interface` property, or if the address connection needs to be made to any place other than the port of the fuse box interface module. For a description of the address signals on the fuse box interface, refer to the [FuseBoxInterface](#) wrapper description.
If the address pins are a series of numbered scalar ports, you can use the `%<integer>d[msb:lsb]` symbol to specify them. For example `add%2d[13:0]` will connect to the scalar ports called add13 to add00.
- `ConnectionOverrides/done : pin_name ;`
A property that specifies where to connect the `done` signal from the fuse box interface. This property is used when you do not have a `FuseBoxInterface` wrapper associated with a `fuse_box_module_interface` property, or if the `done` connection needs to be made from any other place than the ports of the fuse box interface module. For a description of the `done` signal on the fuse box interface, refer to the [FuseBoxInterface](#) wrapper description.
- `ConnectionOverrides/read_data : pin_name ;`
A property that specifies where to connect the `read_data` signal for the fuse box interface. This property is used when you do not have a `FuseBoxInterface` wrapper associated with a `fuse_box_module_interface` property, or if the `read_value` connection needs to be made from any place other than the port of the fuse box interface module. For a description of the `read_value` signal on the fuse box interface, refer to the [FuseBoxInterface](#) wrapper description.

Examples

The following examples uses the `design_instance` property to specify which instance of the fuse box module is to be used by the BISR controller. This is only needed in the rare case that the design contains more than one instance of the module specified by the `fuse_box_interface_module` property. The clock connection is overridden and connects to the input of a clock buffer instead of to the pin of the fuse box interface module.

```
DftSpecification(my_design,rtl) {
    MemoryBisr {
        Controller {
            ExternalFuseBoxOptions {
                design_instance : fuse_box_inst1 ;
                ConnectionOverrides {
                    clock          : clock_buf/A ;
                }
            }
        }
    }
}
```

PowerDomainOptions

Specifies options specific to the power domains.

Usage

```
DftSpecification(module_name, id) {
    MemoryBisr {
        Controller {
            PowerDomainOptions {
                power_domain_priority_order : power_domain_name, ... ;
                PowerDomainName(power_domain_name) {
                    enable_from_pmu_connection : pin_or_net_name ;
                    busy_to_pmu_connection : pin_or_net_name ;
                    done_to_pmu_connection : pin_or_net_name ;
                    ChainConnectionOverride {
                        to_scan_in : port_or_pin_name ;
                        from_scan_out : port_or_pin_name ;
                        capture_shift_clock : port_or_pin_name ;
                        shift_en : port_or_pin_name ;
                        reset : port_or_pin_name ;
                        memory_disable : port_or_pin_name ;
                        memory_chain_select : port_or_pin_name ;
                    }
                }
            }
        }
    }
}
```

Description

A wrapper that specifies options specific to the power domains. The `power_domain_priority_order` property is used to specify in which order the power domains are prioritized during the power up sequence.

You should order the list such that the power domains that must be programmed first are listed first. You use the `PowerDomainName` wrapper to specify connections between the controller and the power management unit. The `power_domain_name` used to identify the `PowerDomainName` wrappers must match the value of the `bisr_power_domain_name` attribute associated with memory and BISR segment instances. For more details about the usage of the `bisr_power_domain_name` attribute, see the description of the [MemoryBisr](#) wrapper.

Arguments

- `power_domain_priority_order : power_domain_name, ... ;`

A property that lists the power domain names in the order they must be programmed during power up. The power domains that must be powered-up faster than the others should be specified at the beginning of the list. If you are not using the `-no_insertion` mode of the [process_dft_specification](#) command and a memory and BISR segment instance have a `bisr_power_domain_name` attribute value that is not found in the list, an error is generated. An error is also generated if the list includes a `power_domain_name` that is not associated with any memory or BISR segment instances, unless the `ChainConnectionOverride` wrapper

is specified in the corresponding PowerDomainName wrapper. See [Example 2](#) for an example usage of the ChainConnectionOverride wrapper.

- PowerDomainName/enable_from_pmu_connection : *pin_or_net_name* ;
A property that specifies a connection from the power management unit to the power domain-specific enable signal. Refer to the [Tessent MemoryBIST User's Manual](#) for more information about the signals between the power management unit and the BISR controller.
- PowerDomainName/busy_to_pmu_connection : *pin_or_net_name* ;
A property that specifies a connection to the power management unit from the power domain-specific BISR busy signal. Refer to the [Tessent MemoryBIST User's Manual](#) for more information about the signals between the power management unit and the BISR controller.
- PowerDomainName/done_to_pmu_connection : *pin_or_net_name* ;
A property that specifies a connection to the power management unit from the power domain-specific BISR done signal. Refer to the [Tessent MemoryBIST User's Manual](#) for more information about the signals between the power management unit and the BISR controller.
- PowerDomainName/ChainConnectionOverride/to_scan_in : *port_or_pin_name* ;
A property that overrides the scan_in connection for the chain associated with the power domain name. You use this property when you are creating and instantiating the BISR controller in a module in which the chains are either pre-connected or do not exist at all. See the [Example 2](#) for an example usage. You must override all connections for a given power domain name as soon as you override one. When using the ChainConnectionOverride wrapper to connect the BISR controller to top-level ports, there cannot be a mix of pre-connected BISR chains and top-level connections at the same time.
- PowerDomainName/ChainConnectionOverride/from_scan_out : *port_or_pin_name* ;
A property that overrides the scan_out connection for the chain associated with the power domain name. You use this property when you are creating and instantiating the BISR controller in a module in which the chains are either pre-connected or do not exist at all. See the [Example 2](#) for an example usage. You must override all connections for a given power domain name as soon as you override one. When using the ChainConnectionOverride wrapper to connect the BISR controller to top-level ports, there cannot be a mix of pre-connected BISR chains and top-level connections at the same time.
- PowerDomainName/ChainConnectionOverride/capture_shift_clock : *port_or_pin_name* ;
A property that overrides the capture_shift_clock connection for the chain associated with the power domain name. You use this property when you are creating and instantiating the BISR controller in a module in which the chains are either pre-connected or do not exist at all. See [Example 2](#) for an example usage. You must override all connections for a given power domain name as soon as you override one. When using the ChainConnectionOverride wrapper to connect the BISR controller to top-level ports, there cannot be a mix of pre-connected BISR chains and top-level connections at the same time.

- PowerDomainName/ChainConnectionOverride/shift_en : *port_or_pin_name* ;
A property that overrides the shift_en connection for the chain associated with the power domain name. You use this property when you are creating and instantiating the BISR controller in a module in which the chains are either pre-connected or do not exist at all. See [Example 2](#) for an example usage. You must override all connections for a given power domain name as soon as you override one. When using the ChainConnectionOverride wrapper to connect the BISR controller to top-level ports, there cannot be a mix of pre-connected BISR chains and top-level connections at the same time.
- PowerDomainName/ChainConnectionOverride/reset : *port_or_pin_name* ;
A property that overrides the reset connection for the chain associated with the power domain name. You use this property when you are creating and instantiating the BISR controller in a module in which the chains are either pre-connected or do not exist at all. See [Example 2](#) for an example usage. You must override all connections for a given power domain name as soon as you override one. When using the ChainConnectionOverride wrapper to connect the BISR controller to top-level ports, there cannot be a mix of pre-connected BISR chains and top-level connections at the same time.
- PowerDomainName/ChainConnectionOverride/memory_disable : *port_or_pin_name* ;
A property that overrides the memory_disable connection for the chain associated with the power domain name. You use this property when you are creating and instantiating the BISR controller in a module in which the chains are either pre-connected or do not exist at all. See [Example 2](#) below for an example usage. You must override all connections for a given power domain name as soon as you override one. When using the ChainConnectionOverride wrapper to connect the BISR controller to top-level ports, there cannot be a mix of pre-connected BISR chains and top-level connections at the same time. The specification of the memory_disable connection overrides remains optional because this is an optional connection that is only used if your memories have serial repair access as described in the *Memory BISR User's Manual*.
- PowerDomainName/ChainConnectionOverride/memory_chain_select : *port_or_pin_name* ;
A property that overrides the memory chain select connection for the chain associated with the power domain name. You use this property when you are creating and instantiating the BISR controller in a module in which the chains are either pre-connected or do not exist at all. See [Example 2](#) for an example usage. You must override all connections for a given power domain name as soon as you override one. When using the ChainConnectionOverride wrapper to connect the BISR controller to top-level ports, there cannot be a mix of pre-connected BISR chains and top-level connections at the same time.

Examples

Example 1

The following example defines the priority order for the power domain names A, B, and C where power domain A has highest priority and C has the lowest priority. The connections per power domain are also specified.

```
DftSpecification(my_design,rtl) {
    MemoryBisr {
        Controller {
            PowerDomainOptions {
                power_domain_priority_order : A,B,C ;
                PowerDomainName(A) {
                    enable_from_pmu_connection : pmu/bisr_en_A ;
                    busy_to_pmu_connection : pmu/bisr_busy_A ;
                    done_to_pmu_connection : pmu/bisr_done_A ;
                }
                PowerDomainName(B) {
                    enable_from_pmu_connection : pmu/bisr_en_B ;
                    busy_to_pmu_connection : pmu/bisr_busy_B ;
                    done_to_pmu_connection : pmu/bisr_done_B ;
                }
                PowerDomainName(C) {
                    enable_from_pmu_connection : pmu/bisr_en_C ;
                    busy_to_pmu_connection : pmu/bisr_busy_C ;
                    done_to_pmu_connection : pmu/bisr_done_C ;
                }
            }
        }
    }
}
```

Example 2

The following example defines explicit connections for the chains associated with the power domain names. This syntax is used when constructing and inserting a BISR controller into a design in which the chains are not visible. In this example, the BISR controller is inserted into a module that will be used in many designs. The module already contains the power management unit and an instance of the fuse box interface module called fuse_2k module. The list of power domain names and the max chain length and repair word size values are specified because their values cannot be extracted from the chains because they do not exist yet.

```

DftSpecification(my_design,rtl) {
    MemoryBisr {
        Controller {
            ijttag_host_node : Sib(bisr) ;
            repair_clock_connection : bisr_clk ;
            repair_trigger_connection : pmu/bisr_trigger ;
            fuse_box_location : external ;
            fuse_box_interface_module : fuse_2k ;
        }
        repair_word_size : 8 ;
        max_bisr_chain_length : 4000 ;
        bisr_done_connection : pmu/bisr_done ;
        bisr_pass_connection : pmu/bisr_pass ;
    }
    PowerDomainOptions {
        power_domain_priority_order : A,B,C ;
        PowerDomainName(A) {
            enable_from_pmu_connection : pmu/bisr_en_A ;
            busy_to_pmu_connection : pmu/bisr_busy_A ;
            done_to_pmu_connection : pmu/bisr_done_A ;
            ChainConnectionOverride {
                to_scan_in : A_bisr_si ;
                from_scan_in : A_bisr_so ;
                capture_shift_clock : A_bisr_clk ;
                shift_en : A_bisr_se ;
                reset : A_bisr_rst ;
                memory_disable : A_bisr_md ;
                memory_chain_select : A_bisr_csel ;
            }
        }
        PowerDomainName(B) {
            enable_from_pmu_connection : pmu/bisr_en_B ;
            busy_to_pmu_connection : pmu/bisr_busy_B ;
            done_to_pmu_connection : pmu/bisr_done_B ;
            ChainConnectionOverride {
                to_scan_in : B_bisr_si ;
                from_scan_in : B_bisr_so ;
                capture_shift_clock : B_bisr_clk ;
                shift_en : B_bisr_se ;
                reset : B_bisr_rst ;
                memory_disable : B_bisr_md ;
                memory_chain_select : B_bisr_csel ;
            }
        }
        PowerDomainName(C) {
            enable_from_pmu_connection : pmu/bisr_en_C ;
            busy_to_pmu_connection : pmu/bisr_busy_C ;
            done_to_pmu_connection : pmu/bisr_done_C ;
            ChainConnectionOverride {
                to_scan_in : C_bisr_si ;
                from_scan_in : C_bisr_so ;
                capture_shift_clock : C_bisr_clk ;
                shift_en : C_bisr_se ;
                reset : C_bisr_rst ;
                memory_disable : C_bisr_md ;
            }
        }
    }
}

```

}

MemoryBist

Specifies the creation and the optional insertion of memory BIST controllers in a design.

Usage

```
DftSpecification(module_name, id) {
    MemoryBist {
        ijtag_host_node : node_id ;
        Controller(id)
    }
    ReusedController(id) {
    }
    BistAccessPort {
    }
    TCKInjectionPoints {
    }
}
```

Description

A wrapper that specifies the creation and the optional insertion of memory BIST controllers in a design.

The presence of the MemoryBist wrapper within the DftSpecification adds one or more controllers to the current design. Refer to the [Tessent MemoryBIST User's Manual](#) to get started with the MemoryBist insertion flow.

Arguments

- *ijtag_host_node* : *node_id* ;
A required property that specifies the ScanInterface that is hosting the memory BIST controllers. The *node_id* is of the form “Sib(*id*)” when the **DftSpecification** is created using the [create_dft_specification](#) command. However, the *node_id* is allowed to point to any valid host scan interface: [Tap/HostIjtag](#), [Sib\(*id*\)](#), or [HostScanInterface/Interface\(*id*\)](#).

Controller

A wrapper that defines a new memory BIST controller. The *id* value uniquely identifies the controller. The *id* value is reflected in the module names associated with that controller.

Usage

```
DftSpecification(module_name, id) {
    MemoryBist {
        Controller(id) {
            parent_instance           : inst_path ;
            leaf_instance_name        : inst_name ;
            clock_domain_label        : label ;
            clock_period               : time ;
            AdvancedOptions           { // *DefSpec
            }
            AlgorithmResourceOptions   { // *DefSpec
            }
            RepairOptions              { // *DefSpec
            }
            DiagnosisOptions           { // *DefSpec
            }
            Step                      { // Mutually exclusive with
            }                           // MemoryCluster wrapper
            MemoryCluster(cluster_id) { // Mutually exclusive with
            }                           // Step wrapper
        }
    }
}
```

Description

A wrapper that defines a new memory BIST controller. The *id* value uniquely identifies the controller. The *id* value is reflected in the module names associated with that controller.

Arguments

- parent_instance : *inst_path* ;

An optional property that specifies where the memory BIST controller is instantiated in the design. When set to “.”, it points to the top level of the design. When unspecified, it defaults to a null string that is interpreted as the common instance ancestor of all memories tested by the controller. See the description of the [get_common_parent_instance](#) command to see how the common ancestor is computed.

This property is not used nor needed when the [process_dft_specification](#) command is run with the -no_insertion option.

- leaf_instance_name : *inst_name* ;

An optional property that specifies the memory BIST controller instance name explicitly. By default, an instance name is automatically generated by appending the “_inst” string to the controller module name, which itself defaults to the following:

design_name_design_id_tessent_mbist_controller_id_controller

This property is not used nor needed when the [process_dft_specification](#) command is run with the -no_insertion option.

- `clock_domain_label : label ;`

A property that specifies the label (see [add_clocks](#)) of the clock domain used by the memory BIST controller and all the associated memories. Any memory tested by the controller that has a clock port sourced by a different clock domain will have a multiplexer added in its interface module to inject the clock used by the controller when running memory BIST.

This property is not used nor needed when the [process_dft_specification](#) command is run with the -no_insertion option and the design is not present. When running in -no_insertion mode without the design loaded in memory, specify the `clock_period` property instead. This is needed to correctly create the synthesis script.

- `clock_period : time ;`

A property that is only used when [process_dft_specification](#) is run with the -no_insertion option and the design with the memory instances is not loaded into the tool. In this case, the `clock_domain_label` property cannot be specified and instead the `clock_period` property is used. When the design is present, the clock period used in the synthesis script is extracted from the period of the clock referred to by the `clock_domain_label` property. In -no_insertion mode, there may be no design present with defined clocks to refer to. In this case, you use the `clock_period` property to specify at which rate the given controller is meant to operate.

Also note that when the `clock_domain_label` property is not specified, the information needed to control the insertion of the clock multiplexers inside the memory interface modules is missing. You are therefore responsible for adding those multiplexers where needed when you insert the controller inside your design such that all memory clocks are driven by the clock used by the controller during memory BIST.

AdvancedOptions

Specifies advanced options for the memory BIST controller.

Usage

```
DftSpecification(module_name,id) {
    MemoryBist {
        Controller(id) {
            AdvancedOptions {
                algorithm : algo_name ; // *DefSpec
                // default: from_library
                operation_set : opset_name ;
                // default: from_library
                extra_algorithms : algo_name, ... ;
                extra_operation_sets : opset_name, ... ;
                functional_debug_mode : on | off ; // *DefSpec
                pipeline_controller_outputs : on | off ; // *DefSpec
                observation_xor_size : 1..8 | off ; // default:3
                selective_parallel_memory_test : on | off ; // *DefSpec
                shared_comparators_per_go_id : int | all ;
                //default: 1 *DefSpec
                use_multicycle_paths : on | off ; // *DefSpec
                gate_bist_clock_in_functional_mode : off |
                    with_clock_gating_cell | with_clock_mux; // *DefSpec
                min_misr_segment_bits : 24 | 256 ; // *DefSpec
            }
        }
    }
}
```

Description

A wrapper that specifies advanced options for the memory BIST controller.

Arguments

- `algorithm : algo_name ;`

An optional property that specifies the name of an algorithm. This value serves as the default value for the [Step](#)/algorithm property when it is not specified in the [Step](#) wrapper. When unspecified, it defaults to “from_library”. See the [Step](#)/algorithm property description to understand the meaning of the default value.

The allowed list of algorithm names already existing in the tool is LVAddressInterconnect, LVBitSurroundDisturb, LVCheckerboard1X1, LVCheckerboard4X4, LVColumnBar, LVDataInterconnect, LVGalColumn, LVGalPat, LVGalRow, LVMarchCMinus, LVMarchLA, LVMarchX, LVMarchY, LVMasest, LVRowBar, LVWalkingPat, ReadOnly, March, SMarchCHKB, SMarchCHKBci, SMarchCHKBcil, and SMarchCHKBbcd. Those algorithm are documented in the “[Mentor Graphics Library of Algorithms](#)” section of the *Tessent MemoryBIST User’s and Reference Manual*.

You can also define and name your own algorithm using the Algorithm wrapper.

- `operation_set : string ;`

An optional property that specifies the name of an operation set. This value serves as the default value for the [Step/operation_set](#) property when it is not specified in the [Step](#) wrapper. When unspecified, it defaults to “from_library”. See the [Step/operation_set](#) property description to understand the meaning of the default value.

The allowed list of operation set names already existing in the tool is Async, AsyncWR, Sync, SyncWR, SyncWRvcd, clockedAsync, clockedAsyncWR, and rom. Those operation sets are documented in the [Built-In OperationSet](#) section of the *Tessent MemoryBIST User’s and Reference Manual*.

You can also define and name your own operation set using the [OperationSet](#) wrapper.

- `extra_algorithms: algo_name, ... ;`

An optional property that specifies the names of additional algorithms that are to be built into the controller such that they can later be selected at run time. The algorithms can be explicitly listed or defined using a regular expression.

The allowed list of algorithm names already existing in the tool is LVAddressInterconnect, LVBitSurroundDisturb, LVCheckerboard1X1, LVCheckerboard4X4, LVColumnBar, LVDataInterconnect, LVGalColumn, LVGalPat, LVGalRow, LVMarchCMinus, LVMarchLA, LVMarchX, LVMarchY, LVMases, LVRowBar, LVWalkingPat, ReadOnly, March, SMarchCHKB, SMarchCHKBci, SMarchCHKBcil, and SMarchCHKBvcd. Those algorithm are documented in the [Mentor Graphics Library of Algorithms](#) section of the *Tessent MemoryBIST User’s and Reference Manual*.

- `extra_operation_sets: opset_name, ... ;`

An optional property that specifies the names of additional operation sets that can be built into the controller such that they can later be selected at run time. The operation set names can be explicitly listed or defined using a regular expression.

The allowed list of operation set names already existing in the tool is Async, AsyncWR, Sync, SyncWR, SyncWRvcd, clockedAsync, clockedAsyncWR, and rom. Those operation sets are documented in the [Built-In OperationSet](#) section of the *Tessent MemoryBIST User’s and Reference Manual*.

You can also define and name your own operation set using the [OperationSet](#) wrapper.

- `functional_debug_mode: on | off ;`

An optional property that specifies that the necessary setup chain muxing and controller ports are generated to allow functional system debug. Provides read and write access to any BISTable memory with a negligible impact on area. For more information, see the [“Functional Debug Memory Access” Appendix](#) in *Tessent MemoryBIST User’s Manual for Use with Tessent Shell*.

- `pipeline_controller_outputs : on | off ;`

A property that specifies the insertion of one pipeline stage on all BIST outputs from the memory BIST controller. The pipeline stage is added for all controller steps and memories

under test. The pipeline flip-flops are instantiated in the controller module. This property facilitates timing closure on paths from the controller.

- `observation_xor_size : 1..8 | off ;`

A property that specifies the number of signals combined in an XOR tree for observing the address and control ports of the memories in a memoryBIST interface during logic test. If not specified, a default value of 3 is used. When the off value is specified, no observation logic for logic test is inserted into the interface modules.

- `selective_parallel_memory_test: on | off ;`

A property that specifies whether or not specific memories are to be enabled during memory BIST. The compare status of any disabled memories will remain at the pass status throughout the test and will not contribute to the global pass/fail status. In addition, disabled memory inputs with port function Select and WriteEnable are forced to their inactive value. The memories to be enabled for memory BIST are selected at runtime using the `enable_memory_list` property in the PatternsSpecification/Patterns/TestStep/MemoryBist/Controller/[AdvancedOptions](#) wrapper.

- `shared_comparators_per_go_id : int | all ;`

A property that specifies the number of comparators to share a given go_id register located in the controller. You can use this feature to manage the area overhead by reducing the number of registers used to log the comparator status. However, using a value other than 1 complicates and lengthens diagnosis with bit level resolution as the test needs to be repeated for as many times as there are comparators sharing a common go_id register.

The value should be set to 1 to enable reading complete memory words in a single read operation. Also, the MemoryBist/Controller/[AlgorithmResourceOptions](#)/data_register_bits property should be set to an appropriate value based on the complexity of the patterns to be written to memory. For complete control of the write data, this property should be set to the number of bits of the widest memory tested by the controller.

Specifying the value “all” infers that there will be one go_id register for all comparators located in the controller.

- `use_multicycle_paths : on | off ;`

A property that specifies whether or not multi-cycle paths are declared in the generated SDC and STA scripts. Omitting those greatly simplifies the SDC constraints but limits the speed at which the controller can operate as all timing paths needs to be closed as if they were all single-cycle paths when the timing exceptions are not declared.

- `gate_bist_clock_in_functional_mode : off | with_clock_gating_cell | with_clock_mux;`

An optional property that disables the clock input to the memory BIST controller and interfaces during the functional mode of operation. This will reduce clocking activity in the chip, saving power. The value “with_clock_mux” inserts a multiplexer with the 0 input tied low in the functional clock tree. Specifying “with_clock_gating_cell” will explicitly request the clock gating library cell to gate the bist clock.

- min_misr_segment_bits : 24 | 256 ;

A property that specifies the number of bits contained within each segment that composes the MISR. When the default setting of 24 is specified, the MISR will be composed of 24-bit and 32-bit segments. The tool will select the combination of segments, based on ROM word size, to minimize the total length of the MISR. A setting of 256 will only utilize 256-bit segments for the MISR and reduce aliasing. The 256 setting is only supported for programmable controllers.

AlgorithmResourceOptions

Specifies properties related to memory BIST controller hardware to support custom algorithm implementation.

Usage

```
DftSpecification(module_name, id) {
    MemoryBist {
        Controller(id) {
            AlgorithmResourceOptions { // *DefSpec
                soft_instruction_count : int ; // default: 0
                data_register_bits : int | auto ;
                counter_a_bits : int | auto ;
                delay_counter_bits : int | auto ;
                preserve_microcode_initial_values : on | off ;
                soft_algorithm_address_min_max : on | off ;
                max_data_inversion_address_bit_index : int | max_index ;
                                                // default: 0
                a_equals_b_command_allowed : on | off ;
                address_segment_x0_y0_allowed : on | off ;
                max_x0_segment_bits : 1 | auto ;
                max_y0_segment_bits : 1 | auto ;
            }
        }
    }
}
```

Description

A wrapper that specifies the amount of hardware to include into the memory BIST controller to support custom algorithm implementation. The more you add, the more flexible your algorithms can be but the more hardware it takes to implement the controller.

This entire wrapper can be specified in the [DefaultsSpecification/DftSpecification/MemoryBist](#) wrapper such that it gets created as you want when you run the [create_dft_specification](#) command.

Arguments

- `soft_instruction_count : int;`

Specifies the number of instructions you want available for programming your soft programmable algorithms. The default value is 0 which means that only algorithms hardened into the controller will be usable.

The `soft_instruction_count` property specifies the number of instruction words that will be implemented in the microprogram memory of the soft programmable controller. The number of bits per instruction word depends on many factors such as the logical address map, number of operations, and the number of instructions.

The soft programmable controller supports the downloading of programmable algorithms at run time. You can load any soft algorithm at run time using the `apply_algorithm` property inside the `MemoryBist/Controller/AdvancedOptions` wrapper of the [PatternsSpecification](#).

The number of instructions in the soft algorithm must not exceed the value specified for this property.

Specifying the soft_instruction_count property is a trade-off between the amount of instructions your custom soft programmed algorithm can have and area. If a large number of instructions is specified, there is a high cost in hardware to implement the microprogram memory. However, if the number of instructions is small, the types of algorithms that can be implemented is significantly reduced.

- `data_register_bits : int | auto ;`

The data_register_bits property allows you to specify the number of bits in the write and expect data registers. The number of bits in the write and expect data registers can represent the entire width of the memory data bus or a segment of the memory data bus. If the data register size is wider than the memory data bus width, the data pattern will be truncated to fit the bus width. If the data register size is narrower than the memory data bus width, the data pattern will be replicated to fill the bus width. The default value of auto means 2 bits if the hard-coded algorithms are limited to SMarch, SMarchCHKB, SMarchCHKBci, SMarchCHKBcil, and SMarchCHKBvcd. If other algorithms are built into the controller, the default value is the number of bits on the widest memory tested by the controller.

- `counter_a_bits : int | auto ;`

The optional counter_a_bits property specifies the width of the general purpose CounterA counter. The maximum width that can be specified is 64 bits. The default value of auto gets converted to an integer that is the largest of the following:

Number of counter bits required to count the number of rotate commands to move a bit across the length of the data register.

Number of counter bits required to count the number of rotate commands to move a bit across the length of the Z address register plus the Y address register plus the X address register.

- `delay_counter_bits : int | auto ;`

The optional delay_counter_bits property specifies the number of bits in the general purpose DelayCounter. The default auto value for delay_counter_bits gets converted into an integer based on the MemoryType property of the Memory library wrapper—see “[Tessent MemoryBIST Library Algorithms](#)” in the *Tessent MemoryBIST User's Manual*. If the controller only test memories of type SRAM or ROM, the auto value gets converted to 0. If the controller tests one or more memories of type DRAM, the auto value gets converted to a number large enough to meet the refresh requirements of the DRAM memories taking into account the period of the clock used by the controller.

- `preserve_microcode_initial_values : on | off ;`

When the property is specified to on and the memory BIST controller is soft programmable (the property soft_instruction_count is greater than 0) and at least one of the memories tested by the controller is a multi-port memory other than a 1R1W configuration, the

`preserve_microcode_initial_values` property inserts shadow registers for the following controller registers:

X, Y, and Z segments of Address Register A

X, Y, and Z segments of Address Register B

Write data register

Expect data register

When a soft-coded algorithm is applied at runtime, the microcode values are loaded once into the soft programmable controller at the start of the test. The shadow registers replicate the initial values of the registers above. For multi-port memory testing, the algorithm is applied for each test port. Since the soft-coded algorithm is not reloaded for each test port, the microcode initial values must be preserved as the actual registers might be manipulated during the algorithm execution.

Depending on the memory word width and the number of words, the shadow registers might add significant area overhead to the soft programmable controller. An alternative approach is to specify this property to off and use the `freeze_test_port` property inside the [AdvancedOptions](#) wrapper to apply the soft-coded algorithm to one specific test port of the multiport memory at a time.

- `soft_algorithm_address_min_max : on | off ;`

The `soft_algorithm_address_min_max` property allows the user to specify a user defined address count range in the soft algorithms. This must be set to on if any of the following properties will be specified in the soft algorithm:

- `load_bank_address_min`
- `load_bank_address_max`
- `load_column_address_min`
- `load_column_address_max`
- `load_row_address_min`
- `load_row_address_max`

- `max_data_inversion_address_bit_index : int | max_index ;`

The `max_data_inversion_address_bit_index` property determines the size of the multiplexer used by the `invert_data_with_row_bit` and `invert_data_with_column_bit` properties inside the `DataGenerator` wrapper of custom Algorithm wrapper—see “[Defining a Custom Algorithm](#)” in the *Tessent MemoryBIST User’s Manual*. The address bit selection logic inside the memory BIST controller creates critical paths that may affect timing closure when synthesizing at high clock frequencies. You should only specify a non-zero value for this property unless you intend to use the `invert_data_with_row_bit` or

invert_data_with_row_bit property with values other than r[0] and c[0] respectively. When unspecified, this property defaults to 0. Valid values are as follows:

integer — limits the highest bit index of the row and column address that can be specified for the invert_data_with_row_bit and invert_data_with_column_bit properties. Valid values are from 0 to N.

max_index — allows any row or column address bits to be selected for write or expect data register inversion.

- a_equals_b_command_allowed : on | off ;

The a_equals_b_command_allowed property specifies whether the comparator that is used for the address_a_equals_b property (used in the InstructionData wrapper) is generated inside the memory BIST controller—see “[Instruction/AdvancedOptions](#)” in the *Tessent MemoryBIST User’s Manual*. The presence of the address comparator in the memory BIST controller creates critical paths that may affect timing closure when synthesizing at high clock frequencies. It is recommended to set the pipeline_controller_outputs property (see [AdvancedOptions](#)) property to on when this property is set to on. If you do not intend to define custom algorithms that use the address_a_equals_b property, the property should be set to off to facilitate timing closure.

When a_equals_b_command_allowed is set to off, custom algorithms cannot use the address_a_equals_b feature. That is, the address_a_equals_b property must be off in all InstructionData wrappers—see “[Instruction/DataCommands](#)” in the *Tessent MemoryBIST User’s Manual*.

- address_segment_x0_y0_allowed : on | off ;

The address_segment_x0_y0_allowed property allows the row and column address counters to be further segmented. The row address counter may be sub-divided into a X1 address counter and a X0 address counter. The column address counter may be sub-divided into a Y1 address counter and a Y0 address counter. The algorithm can use these address segments to achieve complex address count sequences. The size of the individual address segment is configured through the properties max_x0_segment_bits and max_y0_segment_bits in the algorithm.

- max_x0_segment_bits : 1 | auto ;

The optional max_x0_segment_bits property specifies the limit of the X0 address segment size.

When max_x0_segment_bits is set to 1, the address counter logic is modified so that all critical single-cycle paths to the other registers of the memory BIST controller are removed. Corresponding multi-cycle constraints are added to relax these paths during synthesis, timing analysis, and layout. This facilitates the timing closure of the controller hardware when operating at high clock frequency and when incrementing/decrementing the address in consecutive clock cycles of custom algorithms. The value of 1 for max_x0_segment_bits is suitable for all Mentor Graphics library algorithms.

Setting max_x0_segment_bits to Auto allows the implementation of address sequences incrementing or decrementing the address by 2 or more in custom algorithms. The address

can be incremented or decremented in consecutive cycles of custom algorithms but the presence of additional critical single-cycle paths might limit the maximum operational speed of the controller, especially for soft-programmable controllers which allow all possible X0 address segment sizes. If a hard-programmable controller is implemented, the tool automatically determines the maximum size of the X0 address segment required. This allows to minimize area and the number of critical single-cycle paths.

Please refer to the description of `column_address_count_enable` and `row_address_count_enable` in the [Cycle/AdvancedSignals](#) wrapper properties for additional usage conditions concerning the implementation of custom algorithms requiring the address to be incremented/decremented in consecutive clock cycles.

The following usage conditions apply:

- Refer to the `row_address_count_enable` usage conditions for the `max_x0_segment_bits` property usage when implementing custom algorithms requiring the address to be incremented/decremented in consecutive clock cycles.
- `max_y0_segment_bits : 1 | auto ;`

The optional `max_y0_segment_bits` property specifies the limit of the Y0 address segment size.

When `max_y0_segment_bits` is set to 1, the address counter logic is modified so that all critical single-cycle paths to the other registers of the memory BIST controller are removed. Corresponding multi-cycle constraints are added to relax these paths during synthesis, timing analysis, and layout. This facilitates the timing closure of the controller hardware when operating at high clock frequency and when incrementing/decrementing the address in consecutive clock cycles of custom algorithms. The value of 1 for `max_y0_segment_bits` is suitable for all Mentor Graphics library algorithms.

Setting `max_y0_segment_bits` to Auto allows the implementation of address sequences incrementing or decrementing the address by 2 or more in custom algorithms. The address can be incremented or decremented in consecutive cycles of custom algorithms but the presence of additional critical single-cycle paths might limit the maximum operational speed of the controller, especially for soft-programmable controllers which allow all possible Y0 address segment sizes. If a hard-programmable controller is implemented, the tool automatically determines the maximum size of the Y0 address segment required. This allows to minimize area and the number of critical single-cycle paths.

Please refer to the description of `column_address_count_enable` and `row_address_count_enable` in the [Cycle/AdvancedSignals](#) wrapper properties for additional usage conditions concerning the implementation of custom algorithms requiring the address to be incremented/decremented in consecutive clock cycles.

The following usage conditions apply:

- Refer to the `column_address_count_enable` usage conditions for the `max_y0_segment_bits` property usage when implementing custom algorithms requiring the address to be incremented/decremented in consecutive clock cycles.

MemoryCluster

Specifies the controller properties to generate a memory BIST controller to test memories that use a shared bus interface.

Usage

```
DftSpecification(module_name, id) {
    MemoryBist {
        Controller(id) {
            MemoryCluster(cluster_id) {
                instance_name : instance_name ;
                memory_cluster_library_name : library_name ;
                pipeline_cluster_inputs : on | off ; // *DefSpec
                pipeline_cluster_outputs : on | off ; // *DefSpec
                memory_access_level : auto | logical | physical ;
                                         // *DefSpec
                repair_analysis_present : auto | off ; // *DefSpec
                max_repair_group_size : unlimited |
                                         {int[kilobits | megabits]} ;
                                         // *DefSpec
                repair_group_scope : logical_memory |
                                     physical_memory | controller ;
                                         // *DefSpec
                repair_sharing : on | off ;
            }
        }
    }
}
```

Description

A wrapper that specifies the controller properties to generate a memory BIST controller to test memories that use a shared bus interface. The [MemoryCluster](#) and [Step](#) wrappers are mutually exclusive. The shared bus interface provides common access to multiple memories. Please refer to the [Tessent MemoryBIST User's Manual](#) for further details.

Arguments

- **instance_name** : *instance_name* ;
A property that specifies the instance path of a memory cluster that will be connected to a shared bus memory BIST controller
- **memory_cluster_library_name** : *library_name* ;
An optional property that specifies the cluster library template name that will be used to generate a shared bus memory BIST controller. This is only needed if you wish to generate a memory BIST controller without insertion.
- **pipeline_cluster_inputs** : on | off ;
A property that specifies whether the memory cluster inputs from the memory BIST controller will be pipelined with a single pipelining stage to help with meeting timing closure.

- pipeline_cluster_outputs : on | off ;

A property that specifies whether the memory cluster outputs to the memory BIST controller will be pipelined with a single pipelining stage to help with meeting timing closure.

- memory_access_level : auto | logical | physical ;

A property that specifies the view of all memories in the memory cluster that the memory BIST controller operates on. The memories accessed through the shared bus interface are called logical memories. A logical memory is an address space composed of one or more physical memories.

When the value is set to logical, the physical composition of the logical memory is irrelevant. All memories that form the logical memory are tested in one pass of the test algorithm. Repair and diagnosis information will be reported with respect to the address space and I/O of the logical memory. You use this option if each logical memory contains one physical memory. It is also suitable if you want to implement repair sharing for the physical memories that you integrate into the logical memory.

When the value is set to physical, each physical memory composing a logical memory is tested independently of each other. This option provides repair and diagnosis resolution mapped to the physical memories but it increases the area overhead.

When the value is set to auto, the access level is determined for each logical memory from the specification of its logical library. The auto value is converted to physical if all of the following conditions are met: (a) the logical memory contains one or more physical memories—at least one PhysicalToLogicalMapping wrapper is present, (b) the logical memory defines no repair—the RedundancyAnalysis wrapper is not present, and (c) the logical memory defines no address segmentation —the AddressCounter wrapper is not present.

- repair_analysis_present : auto | off ;

A property that specifies if repair analysis logic is generated for the indicated Shared Bus memory cluster. If this property is set to auto and the Shared Bus logical or physical memory's library descriptions (as specified by memory_access_level) contain at least one RedundancyAnalysis/SpareElement wrapper, the repair analysis logic is generated. Refer to the “[RedundancyAnalysis](#)” section in the *Tessent MemoryBIST User's Manual* manual for more information.

- max_repair_group_size : unlimited | {int[kilobits | megabits]} ;

A property that specifies the total memory size limit on a shared bus memory group when repair sharing is enabled with [set_memory_instance_options](#). This property is used during logical/physical memory expansion when the [process_dft_specification](#) command is run. The default value of “unlimited” indicates that any number of compatible shared bus memories can be assigned to repair groups. The int[units] pair specifies the maximum size allowed for a repair group. Any shared bus memory that would cause this limit to be exceeded will be assigned to a different repair group.

- repair_group_scope : logical_memory | physical_memory | controller ;

A property used to specify how repair grouping is conducted during logical/physical memory expansion for shared bus memories when the [process_dft_specification](#) command is run and repair sharing is enabled with [set_memory_instance_options](#).

The selected value impacts the repair grouping as follows:

- logical_memory — Specifies the repair groups are restricted to compatible physical memories **within** a logical memory without exceeding the size specified by the max_repair_group_size property in the MemoryCluster wrapper.
- physical_memory — Specifies the repair group is restricted within a physical memory. Memories with multiple [RowSegment](#) and/or [ColumnSegment](#) wrappers will be considered as having a single RowSegment and/or ColumnSegment wrapper for redundancy analysis as long as the memory size does not exceed the size specified by the max_repair_group_size property in the MemoryCluster wrapper.
- controller — Specifies the repair group is restricted to all memories tested by the controller. The repair group cannot contain memories tested by other controllers. Memories are automatically assigned to repair groups as long as the memory size does not exceed the size specified by the max_repair_group_size property in the MemoryCluster wrapper.

- repair_sharing : on | off ;

A property that will globally enable and disable repair sharing for shared bus memories that have “-repair_sharing auto” specified, which is the default. The “-repair_sharing” value can be changed from “auto” for a memory instance with the [set_memory_instance_options](#) command.

RepairOptions

Provides repair-related options and properties.

Usage

```
DftSpecification(module_name, id) {
    MemoryBist {
        Controller(id) {
            RepairOptions {
                fuse_set_extraction_sequence : address_before_fuse_map | fuse_map_before_address ;
                row_bira_location : controller | follow_comparators ;
            }
        }
    }
}
```

Description

The RepairOptions wrapper specifies what to shift out and monitor with repairable memories, as well as the spare allocation method to use.

Arguments

- **fuse_set_extraction_sequence** : address_before_fuse_map | fuse_map_before_address ;
A property that defines the setup chain sequence of the Column/IO BIRA registers that report the faulty column address and the IO decode value. This property specifies whether the faulty column address or the IO decode value will be shifted out first when the repair analysis information is extracted from the memory BIST controller. Valid values are as follows:
 - AddressBeforeFuseMap — the faulty column address will be shifted out before the IO decode value. The MSB of the IO decode register connects to the LSB of the faulty column address register.
 - FuseMapBeforeAddress — the IO decode value will be shifted out before the faulty column address. The MSB of the faulty column address register connects to the LSB of the IO decode register.
- **row_bira_location** : controller | follow_comparators ;
A property that specifies where the Row BIRA module will be located. The Row BIRA module can be located in the same module as the comparators or it can be forced to be inside the memory BIST controller.
When shared comparators are used (comparator_location:shared_in_controller), the Row BIRA module is always located inside the memory BIST controller. However, when local comparators are used (comparator_location:per_interface), the Row BIRA module can be placed inside the interface or inside the controller.

For a memory BIST controller with several memories with Row BIRA, placing the Row BIRA module inside the controller results in a reduction of area due to the sharing of common redundancy analysis logic and pipelining stages.

DiagnosisOptions

Specifies the diagnosis options that affect diagnostic hardware generation for the memory BIST controller.

Usage

```
DftSpecification(module_name, id) {
    MemoryBist {
        Controller(id) {
            DiagnosisOptions { *DefSpec
                comparator_selection_mux : on | off | auto ;
                go_status : auto | per_memory ;
                StopOnErrorOptions {
                    failure_limit : int | off ;
                }
            }
        }
    }
}
```

Description

A wrapper that specifies the diagnosis options that affect diagnostic hardware generation for the memoryBIST controller.

Arguments

- **comparator_selection_mux** : on | off | auto ;

A property that specifies whether bit-level diagnostic resolution is maintained when local_comparators_per_go_id or shared_comparators_per_go_id is set to a value greater than 1. The valid values are:

on — specifies that a multiplexer is inserted at the input of each go_id register to select the output of only one comparator at a time and provide bit-level diagnostic resolution when the local_comparators_per_go_id or shared_comparators_per_go_id property is set to a value greater than 1.

off — specifies that bit-level diagnostic resolution is not required.

auto — infers “on” when the StopOnErrorOptions/failure_limit property is not set to “off”; otherwise, infers “off”.

- **go_status** : auto | per_memory ;

A property that specifies how a pass/fail status per individual memory is generated for the current controller.

The per-memory status register allows you to determine which memories failed without having to examine the individual compare status registers (GO_ID bits). The valid values are:

auto — a per-memory pass/fail status register is generated when memories with redundancy are present for the current MemoryBIST controller. If there are no

memories with redundancy for the current controller, then the per-memory status register is not added. This is the default value.

per_memory — A per-memory pass/fail status register is added for all memories on the current MemoryBIST controller, even if there are no memories with redundancy.

- **StopOnErrorOptions/failure_limit:** *int* | off ;

A property that specifies the maximum number of failures that the memory BIST controller can log in the Stop-On-Nth-Error mode of diagnosis. The default value becomes 4096 when the controller tests at least one memory of type SRAM or DRAM. It becomes “off” when the controller tests only memories of type ROM. The error counter is no longer used for ROM diagnosis as it was in the LV flow. Instead the functional debug mode is used to perform ROM diagnosis.

Step

Specifies the properties for memory BIST steps.

Usage

```
DftSpecification(module_name,id) {
    MemoryBist {
        Controller(id) {
            Step { // repeatable
                algorithm : algo_name ;           // *DefSpec
                operation_set
                comparator_location
                bist_data_in_pipelining
                bist_data_out_pipelining
                MemoryInterface(id) {
                    instance_name
                    memory_library_name
                    repair_analysis_present
                    repair_group_name
                    scan_bypass_logic
                    local_comparators_per_go_id
                    rom_content_file
                    output_enable_control
                    observation_xor_size
                }
                ReusedMemoryInterface(id) {
                    instance_name
                    reused_interface_id
                    repair_group_name
                }
            }
        }
    }
}
```

Description

A wrapper that specifies the properties for memory BIST steps. These properties are used to generate specific controllers' configurations. The [Step](#) and [MemoryCluster](#) wrappers are mutually exclusive. See also “[Tessent Core Description](#)” on page 3755 for Memory wrapper details.

Arguments

- algorithm : algo_name | [from_library](#) ;

The ram_algorithm property specifies the name of the algorithm that is applied to all memories tested in this step. If the “from_library” value is used, the algorithm specified in the Memory library description of all memories tested by the controller in the given Step is used. An error is generated if the “from_library” value is used and the memories tested by the controller in the given Step do not have the same value for the algorithm property.

- `operation_set : opset_name ;`

The `operation_set` property specifies the name of the operation set that is applied to all memories tested in this step. If the “from_library” value is used, the OperationSet specified in the Memory library description of all memories tested by the controller in the given Step is used. An error is generated if the “from_library” value is used and the memories tested by the controller in the given Step do not have the same value for the `OperationSet` property.

- `comparator_location : shared_in_controller | per_interface ;`

The `comparator_location` property specifies where comparators for the memory BIST controller are placed, with the default being the placement of the comparators in the memory interface. Using the `per_interface` value greatly reduces the routing area needed to bring the BIST data signals from the memory interfaces to the controller. You also get per memory diagnostic resolution in go-nogo tests even when the controller has more than one step when the comparators are inside the interfaces. You can use the `local_comparators_per_goid` property to reduce the area overhead.

- `bist_data_in_pipelining : on | off | int;`

The `bist_data_in_pipelining` property defines the number of pipeline stages to be added to all BIST inputs in the memory interface. Setting the value “on” is equivalent to 1 pipeline stage. You can use this property to facilitate timing closure on paths from the controller. The dedicated pipeline flip-flops allow the layout tool to place the flip-flops at the optimal distance for each memory. Typically, a single pipeline stage is sufficient. The `MemoryBist/Controller/AdvancedOptions/pipeline_controller_outputs` option is much less costly and is typically good enough to meet timing. The pipeline registers are added in the memory interface on the BIST signals from the controller. Some signals propagate to the memory while other signals are internal to the memory interface or controller and control the test execution. Examples of test signals that are pipelined when `bist_data_in_pipelining` is specified are address and control to the memory, write data pattern, expect data pattern, compare enable, and checkerboard pattern enable.

When using the `bist_data_in_pipelining` property, you do not need to update any operation set because the pipelining is taken into account when writing to and reading from the memory.

- `bist_data_out_pipelining : on | off | per_port;`

A property that specifies whether the BIST data from the memory to the comparators will be pipelined with a single pipelining stage. The pipelining stage is inserted in the memory interface. The valid values and their effects are as follows:

`on` — pipelines the BIST data out to the comparators. You specify `on` if the BIST data output does not have time to propagate to the comparator. Pipelining might be required when the comparators are located in the memory BIST controller due to the physical distance between the memory controller and memory interface.

`off` — does not pipeline the BIST data out.

`per_port` — pipelines the BIST data out per memory output port. For multi-port memories, the data from each output port is multiplexed into a single BIST data out to

the comparators. You specify `per_port` to insert separate pipelining flip-flops on each data output port before the multiplexer.

- `MemoryInterface(id)/instance_name : inst_name ;`

A property that specifies the instance name of the memory interface associated with the given memory. This property is required when running the [process_dft_specification](#) command without the `-no_insertion` option. In this case, the value of the `tcd_memory_name Instance` attribute attached to the instance defines the Memory library associated to that instance. When you use the `-no_insertion` flow, the elaborated design that contain the instantiated memories is optional. When the design is not present, the Memory library associated with the `MemoryInterface` is defined using the `memory_library_name`.

- `MemoryInterface(id)/memory_library_name : mem_lib_name ;`

A property that specifies the name of the memory library associated with the memory tested by the memory interface. This property is only used and needed if you are running the [process_dft_specification](#) command with the `-no_insertion` option and the design is not elaborated in memory. Otherwise, the `memory_library_name` is extracted from the `tcd_memory_name` attribute attached to the instance referenced by the `MemoryInterface(id)/instance_name` property.

- `MemoryInterface(id)/repair_analysis_present : auto | off ;`

A property that specifies whether repair analysis logic is generated for the memory tested by the memory interface. If set to `auto` and the memory library description associated to the memory tested by the memory interface contains at least one `RedundancyAnalysis/SpareElement` wrapper, the repair analysis logic is generated. See “[Tessent Core Description](#)” on page 3755 for `RedundancyAnalysis` wrapper information.

- `MemoryInterface(id)/repair_group_name : none | group_name ;`

A property that specifies the group name for the memory interfaces that will share a `BIRA/BISR` module. This property is automatically filled in when the [create_dft_specification](#) command is run and repair sharing is enabled with [set_memory_instance_options](#). The user can update this property to manually change the repair group assignments.

- `MemoryInterface(id)/scan_bypass_logic : async_mux | none | sync_mux | from_library ;`

A property that specifies when and how memories are bypassed during scan testing. Bypassing memories enables testing of the user interface logic to and from these embedded memories as well as to and from the memory `BIST` controller and memory interface circuitry.

If the specified value for `MemoryInterface(id)/scan_bypass_logic` equals “`sync_mux`”, “`async_mux`” or “`none`”, it overrides the `TransparentMode` property in the Memory library description. If the value is not specified or set to “`from_library`”, the value in the Memory library file takes effect.

Valid values are as follows:

`async_mux` — inserts an additional multiplexer on the memory interface `DataOut` ports so that data is directly transferred from the `DataIn` ports to the `DataOut` ports. This

setting enables combinational ATPG tools to test the interface between the user logic and the memory. It is not recommended for at-speed testing because the timing paths are not consistent with the functional mode.

sync_mux — inserts an additional multiplexer and flip-flop on the interface DataOut ports that enable ATPG tools to test the interface between the user logic and the memory without having to enable testing through the memory. This mode is very efficient for ATPG and provides very consistent timing paths between test and functional modes.

none — specifies that no bypass logic will be added in the memory interface. Specify None if you have a bidirectional data bus or the memory implements internal bypass logic.

from_library — specifies that the bypass logic will be generated according to the TransparentMode property setting of the Memory library file.

- **MemoryInterface(id)/local_comparators_per_go_id : int | all ;**

A property that specifies the number of comparators to share with a given go_id register located in the interface. You can use this feature to manage the area overhead by reducing the number of registers used to log the comparator status. However, using a value other than 1 complicates and lengthens diagnosis with bit-level resolution as the test needs to be repeated as many times as there are comparators sharing a common go_id register.

The value should be set to 1 to enable reading complete memory words in a single read operation. Also, the MemoryBist/Controller/[AlgorithmResourceOptions](#)/data_register_bits property should be set to an appropriate value based on the complexity of the patterns to be written to memory. For complete control of the write data, this property should be set to the number of bits of the widest memory tested by the controller.

The default value is 1. Specifying the value “all” infers that there will be one go_id register for all comparators associated with a memory.

- **MemoryInterface(id)/rom_content_file : file_path ;**

A property that specifies the location of the ROM content file. The path is absolute or relative to the working directory. This property is mandatory when the memory tested by the memory interface is of type ROM. The ROM content file is used to compute the signatures associated with all algorithms applicable to ROMs and built into the controller. See the [Step](#)/Algorithm property and the [AdvancedOptions](#)/extra_algorithms to understand which algorithm gets built into the controller.

- **MemoryInterface(id)/output_enable_control : always_on | system ;**

The output_enable_control property should only be specified when the design is not elaborated. Otherwise, it is recommended to let Tesson Shell analyze the design and infer the proper output_enable_control setting based on design connectivity. When the design contains many non-unique instances of the same memory interface with different output enable connection configurations, Tesson Shell will apply the value that accommodates all memory instances.

The `output_enable_control` property is used to determine the type of data output stage (2-state or 3-state) when generating the memory interface modules, as well as the logic that controls the output enable ports of the memory and interface modules. When set to `always_on`, a 2-state output multiplexer is generated. When set to `system`, a 3-state multiplexer is generated.

Specifying The `output_enable_control` Based on Design:

Set `output_enable_control` to `always_on` when the memory output enable port is tied to a constant value in the functional design. This maintains the memory data output drivers (tri-state) into an always on state. The memory BIST interface generated for this memory intercepts the data output with a standard 2-state mux and drives the values from the bypass registers during scan if the memory bypass is selected during scan. Else, the interface will select the memory output during functional mode or when applying multi-load scan patterns to memory. This will not cause any net contention with other memories in the design, and is the most common situation.

Set `output_enable_control` to `system` when the memory output enable port is driven by functional logic. This is typically the case when many memories are connected to the same data bus. It is assumed that the functional logic enables a single memory output at any time and avoids bus contentions. The memory BIST interface generated for this memory must also have a 3-state output. During scan mode, the memory interface observes the memory output enable signal and either enables the output drivers from the memory interface (when memory bypass is enabled), or the memory output drivers (when applying multi-load scan patterns to memory).

- `MemoryInterface(id)/observation_xor_size : auto | off ;`

A property that specifies whether or not to insert scan observation points for the address and control ports in the memory interface. The `auto` setting combines the signals based on the `observation_xor_size` property in the `MemoryBist/Controller/AdvancedOptions` wrapper. The `off` setting disables the observation logic insertion. The default setting is `auto`.

- `ReusedMemoryInterface(id)/instance_name : inst_name ;`

A property that is used to associate a memory interface module with another memory instance. You can use this wrapper when the memory instance has the same module name as the one for which the reused memory interface is for. The `create_dft_specification` command will use this wrapper when the parent module of the memory instance is not unique to avoid having to uniquify the parent module during insertion. It will also use this wrapper when the memory instance is inside a generate loop to avoid having to unroll the loop during insertion. This property is optional when the `process_dft_specification` command is run with the `-no_insertion` option.

- `ReusedMemoryInterface(id)/reused_interface_id : [ctrl_id:]mem_interface_id ;`

A property that specifies the memory interface that is to be reused by the given memory instance. The value is the id of the controller wrapper, a colon, and the id of the `memory_interface` wrapper that is reused. The id of the controller and the colon is optional when the reused `MemoryInterface` belongs to the same controller as the `ReusedMemoryInterface` wrapper.

- ReusedMemoryInterface(id)/repair_group_name : none | *group_name* ;

A property that specifies the group name for the reused memory interfaces that will share a BIRA/BISR module. This property is automatically filled in when the [create_dft_specification](#) command is run and repair sharing is enabled with [set_memory_instance_options](#). The user can update this property to manually change the repair group assignments.

ReusedController

Specifies the insertion of the second instance of a memory BIST controller.

Usage

```
DftSpecification(module_name,id) {
    MemoryBist {
        ReusedController(id) { // repeatable
            parent_instance : inst_path ;
            leaf_instance_name : inst_name ;
            clock_domain_label : name ;
            reused_controller_id : id ;
            Step { //repeatable
                MemoryInterface(id) { // repeatable
                    instance_name : name ;
                }
            }
            MemoryCluster(cluster_id) {
                instance_name : name ;
            }
        }
    }
}
```

Description

A wrapper that specifies the insertion of the second instance of a memory BIST controller. The [create_dft_specification](#) command uses this wrapper when it detects that two controllers test the exact same set of memory modules and that the common ancestor of each of those two sets are repeated instances of a single module. To avoid having to lift the controller into a unique location or having to uniquify the repeated module, the memory BIST controller module is reused. The ReusedController/Step and ReusedController/MemoryCluster wrappers are mutually exclusive.

Arguments

- **parent_instance : *inst_path* ;**
An optional property that specifies where the memory BIST controller is instantiated in the design. When unspecified, it defaults to a null string which is interpreted as the common instance ancestor of all memories tested by the controller. See the description of the [get_common_parent_instance](#) command to see how the common ancestor is computed.
- **leaf_instance_name : *inst_name* ;**
An optional property that specifies the memory BIST controller instance name explicitly. By default, an instance name is automatically generated by appending the “_inst” string to the module name. This property must be identical in all Controller/ReusedController wrapper which have their parent_instance specified or inferred to point to instances of the same repeated module.

- `clock_domain_label : name ;`
A property that specifies the label (see [add_clocks](#)) of the clock domain used by the memory BIST controller and all the associated memories. Any memory tested by the controller which has a clock port sourced by a different clock domain will have a multiplexer added in its interface module to inject the clock used by the controller when running memory BIST.
- `reused_controller_id : id ;`
A property that specifies the id of a controller wrapper that is to be reused.
- `Step/MemoryInterface(id)/instance_name : name ;`
A property that specifies the instance name of the memory to be tested by the given memory interface in the given [Step](#).
- `MemoryCluster(cluster_id)/instance_name : name ;`
A property that specifies the instance name of the memory cluster to be tested by the given controller.

BistAccessPort

A wrapper that specifies where the memory BIST BIST Access Port (memory BIST BAP) module is instantiated in the design.

Usage

```
DftSpecification(module_name, id) {
    MemoryBist {
        BistAccessPort {
            parent_instance      : inst_path ;
            leaf_instance_name   : inst_name ;
        }
    }
}
```

Description

The BistAccessPort wrapper provides the capability to locate the memory BIST BAP instance at a specified location in the design hierarchy. The memory BIST BAP provides control signals to memory BIST controllers, collects their GO and DONE status signals and provides access to their internal registers. A memory BIST BAP is inserted for each pass when doing multi-pass insertion.

Arguments

- **parent_instance** : *inst_path*

An optional property that specifies the hierarchical path where the memory BIST BAP module is instantiated in the design.

When unspecified, it defaults to a null string that is interpreted as the common instance ancestor of all memory controllers driven by the memory BIST BAP. See the description of the [get_common_parent_instance](#) command to see how the common ancestor is computed. When *inst_path* is specified as “.”, the memory BIST BAP is instantiated in the top module of the design.

This property is not used or needed when the [process_dft_specification](#) command is run with the -no_insertion option.

- **leaf_instance_name** : *inst_name*

An optional property that specifies the memory BIST BAP instance name explicitly. By default, an instance name is automatically generated by appending the “_inst” string to the memory BIST BAP module name, which itself defaults to the following:

design_name_design_id_tessent_mbist_bap

The *design_id* is specified with the [set_context](#) -design_identifier command for the current design.

This property is not used or needed when the [process_dft_specification](#) command is run with the -no_insertion option.

TCKInjectionPoints

Specifies the locations in the design where a mux will be inserted to inject TCK onto the functional clock trees for TCK mode implementation.

Usage

```
DftSpecification(module_name, id) {
    MemoryBist {
        TCKInjectionPoints {
            ClockMux (mux_id) {
                leaf_instance_name : instance_name ;
                node : node_name ;
            }
        }
    }
}
```

Description

The TCKInjectionPoints wrapper defines the locations where muxes will be inserted to inject TCK. The TCK that will be injected is the one used by the specified [MemoryBist/ijtag_host_node](#). These muxes will be controlled by the DFT signal “tck_select”, which is asserted as needed during patterns steps by setting the [Patterns tck_clock_only](#) property to “on”.

Arguments

- `leaf_instance_name : instance_name ;`

A string property that specifies the leaf instance name of the mux. A prefix is added to the specified *instance_name* as follows:

`<persistent_clock_cell_prefix>_tck_mux_instance_name`

If this property is not specified, it defaults to:

`<persistent_clock_cell_prefix>_tck_mux_<design_name>_<dft_spec_id>_<mux_id>_inst`

The “*dft_spec_id*” string is the “*id*” specified in the DftSpecification wrapper, and the “*mux_id*” is the string specified in the ClockMux wrapper. Tessent Shell checks for name conflicts before instantiating the mux and, if needed, applies the unification suffix specified by the [set_insertion_options](#) command.

- `node : node_name ;`

A required property that specifies the location of a port, pin or net name to be intercepted with a mux instance.

OCC

The OCC DftSpecification syntax defines the configuration of the OCC to be generated and inserted into the design.

Usage

```
DftSpecification(module_name, id) {
    OCC {
        ijtag_host_interface      : host_name | none;
        capture_trigger            : auto | shift_en | capture_en;
        static_clock_control       : auto | off | [internal | external | both];
        capture_window_size        : int ; // default: 3
        type                      : standard | parent | child;
        internal_clock_gater       : on | off | auto;
        shift_only_mode            : on | off | auto;
        kill_clock_mode             : on | off | auto;
        include_clocks_in_icl_model : on | off ;
        leaf_instance_name          : instance_name ;
        Interface {
        }
        Connections {
        }
        Controller(id) {
        }
    }
}
```

Description

The OCC DftSpecification syntax defines the configuration of the OCC to be generated and inserted into the design.

In modern designs, OCC circuits are commonly used to manage clocks during test. Such clock controllers can generate slow-speed or at-speed clock sequences under the control of ATPG process. Tesson OCC is an implementation of a clock controller created by Tesson Shell that has been designed to meet the requirements of scan test for ATPG, Logic BIST, EDT, and Low Pin Count Test.

The OCC follows the `use_rtl_synchronizer_cell` property to decide if a real or an RTL cell synchronizer cell is used. The OCC also follows the `use_rtl_synchronizer_cell` property to use a synchronizer cell with or without a reset port. The use of the asynchronous reset removes the need to add extra shift cycles in the parallel load simulations even when you have capture clocks which are slower than the shift clock.

Note

 The Sync cell is instantiated with the following leaf instance prefix:

*persistent_cell_prefix*test_ntc_

where *persistent_cell_prefix* is specified using the [persistent_cell_prefix](#) property of the DftSpecification wrapper. You can use this special prefix to locate them in the design if you want to disable their notification during logic test Verilog simulations.

Refer to “[On-Chip Clock Controller Design Description](#)” and the “[OCC schematic](#)” in the *Tessent Scan and ATPG User’s Manual* for more information.

Note

 The standard OCC is the recommended OCC for use in hierarchical cores. For more information, see “[Core OCC Recommendation](#)” in the *Tessent Scan and ATPG User’s Manual*.

Arguments

- *ijtag_host_interface* : *host_name* ;

A property that specifies the host scan interface to which the clock controllers will be connected. The default value is “none” which means that the static controls are primary inputs on the control. With the “none” value, you can use the Connections/
[StaticExternalControls](#) wrapper to specify where to connect them. If you are using IJTAG with all its advantages with respect to the test_setup automation, use the [create_dft_specification -sti_sib_list](#) switch with a value of “Occ” to have the DftSpecification created with an Sib ready to host the OCC controllers. You then point to it using “Sib(Occ)” as the *ijtag_host_interface* value.

- *capture_trigger* : *enum* ;

A property that specifies whether *shift_en* or *capture_en* is used as the trigger to generate programmable capture pulses. The *capture_en* version is used when some internal test logic generates a separate *capture_en* signal, such as the LPCT or LBIST controller.

The default is auto.

Choose one from the following:

auto — Automatically determines whether *shift_en* or *capture_en* is used as the trigger. When the OCC wrapper is used with a LogicBist or an LpcfType3 wrapper in the same insertion pass (that is, the wrappers are present in the same DftSpecification) auto resolves to the *capture_en* value; otherwise it resolves to *shift_en*.

capture_en — The OCC controllers will infer the *capture_en* port.

shift_en — The OCC controllers will infer the *shift_en* port.

- static_clock_control : *enum* ;

A property that specifies whether capture clock generation is available outside of ATPG control.

There is a dependency between this property and the [StaticExternalControls](#) wrapper's static_clock_control_mode property. By default the OCC wrapper's static_clock_control property defaults to off; you must set this property to a value other than off in order to generate the static clock control pins on the OCC module.

Choose one from the following:

auto — When both OCC and LogicBIST are included in the same insertion pass (that is, the wrappers are present in the same DftSpecification), auto resolves to external when LogicBIST is present; otherwise, it resolves to off.

off — Capture clock generation is only under ATPG control, specifically static programmability. This is the default.

internal — Non-ATPG control capture clock generation is available through an IJTAG TDR in the OCC (static programmability).

external — Non-ATPG control capture clock generation is available through OCC input pins.

both — Combination of internal and external.

- capture_window_size : *int* ;

A property that specifies the maximum possible number of clock pulses the OCC can generate. During pattern generation, the OCC can be configured to produce a smaller number of pulses than this specified value. The default is 3, and the range is 2 to 6.

- type : standard | parent | child ;

A property that specifies what type of controller to build.

Choose one from the following:

standard — Request the creation of a standard OCC which has the ability to inject the shift clock and allows controlling which clock pulse goes through based on the control flip-flops. The fast_clock input can be free-running asynchronous clocks. See “[Fast Capture Mode Operation](#)” in the *Tessent Scan and ATPG User’s Manual* for a schematic drawing of this OCC type.

child — Request the creation of a child OCC which does not include a multiplexer along the clock path to inject the shift clock. The child OCC lets the clock go through when scan_en is high. When scan_en is low, the clock input pulses for a constant number of pulses and the child OCC lets zero or more pulses go through based on the value of its control flip-flops. Typically, an OCC of type parent is at the base of the clock sourcing the clock input of the child OCC. See “[Child OCC On-Chip Controller Logic Schematic](#)” in the *Tessent Scan and ATPG User’s Manual* for a schematic drawing of this OCC type.

parent — Request the creation of a parent OCC which has the ability to operate in standard mode or in parent mode. In parent mode, the OCC injects the shift clock at

the base of the clock in shift mode. When `scan_en` is low, it lets a programmable constant set of clock pulses go through. The parent OCC typically feeds the clock input of child OCC which are the ones that enable the scan-based test pattern generation tool to control which clock pulses go through or not. See “[Parent On-Chip Controller Logic Schematic](#)” in *Tessent Scan and ATPG User’s Manual* for a schematic drawing of this OCC type.

- `internal_clock_gater` : `on | off | auto` ;

A property that specifies if the OCC of type “child” has the clock gater inside the OCC module or if it is to only output the enable signal to be used by a clock gater already present at the base of the clock tree. It can only be set to off when type is “child”. When left at the default value of “auto”, it is interpreted as to mean off when the `clock_intercept_node` property is left empty and the `clock_enable_pin` property refers to the name of a pin.

- `shift_only_mode` : `on | off | auto` ;

A property that specifies the addition of a new port on the OCC controller that is used to activate the shift only mode in the OCC. The default is auto.

This property is “on” if you added the `ext_ltest_en` DFT signal using the [add_dft_signals](#) command. Otherwise, this property is “off”.

For more information, refer to “[Shift Mode](#)” in the *Tessent Scan and ATPG User’s Manual*.

- `kill_clock_mode` : `on | off | auto` ;

A property that specifies the addition of a new port on the OCC controller that is used to activate the clock gater on the fast_clock path such that the clock can be gated off during functional mode. The value of the `kill_clock_en` port is a don’t care when the OCC is active.

When the DFT signal `occ_kill_clock_en` is added, the auto value is interpreted as On, and the `kill_clock_en` port is automatically sourced by the `occ_kill_clock_en` DFT signal making it easy to activate this feature using the [set_static_dft_signal_values](#) command.

Use this property to re-use the clock gater inside the OCC during functional mode to kill the functional clock. You can also use this property during hierarchical test mode. When running the internal logic test modes on a core, you can save power inside the other cores that are not running by disabling their clocks using the following command and switch:

```
set_static_dft_signal_values occ_kill_clock_en 1 \
    -instances inactive_core_instances
```

To achieve the same results during MemoryBIST patterns, you use the `DftControlSettings` wrapper.

- `include_clocks_in_icl_model` : `on | off` ;

An optional property used to specify if the input and output clock ports as well as the optional TCK multiplexer to be described in the ICL model of the OCC. A TCK multiplexer is inserted inside the OCC when the `ijtag_host_node` property is not specified to none. The TCK mux must be described in ICL if you want to use the `tck_clock_only` property in Patterns file and the TCK clock is injected with the OCC controller.

- `leaf_instance_name : instance_name ;`

A property that specifies the leaf instance name for the clock controller.

Interface

This wrapper specifies the port names on the interface of the OCC module. When a particular property is not used, the tool default port naming will be used.

Usage

```
DftSpecification(module_name, id) {
    OCC {
        Interface {
            scan_en      : port_name ; // default: scan_en
            capture_en   : port_name ; // default: capture_en
            slow_clock   : port_name ; // default: slow_clock
            fast_clock   : port_name ; // default: fast_clock
            clock        : port_name ; // defualt: clock
            clock_out    : port_name ; // default: clock_out
            clock_en_out : port_name ; // default: clock_en_out
            scan_in      : port_name ; // default: scan_in
            scan_out     : port_name ; // default: scan_out
            clock_sequence: port_name ; // default: clock_sequence[%d]
            IJtagScanInterface {
            }
            StaticExternalControls {
            }
        }
    }
}
```

Description

This wrapper specifies the port names on the interface of the OCC module. When a particular property is not used, the tool default port naming will be used.

Arguments

- **scan_en : *port_name* ;**
Scan enable port name. The default is scan_en.
- **capture_en : *port_name* ;**
Optional capture enable port name, used only when capture_trigger is set to capture_en. The default is capture_en. The default connection for capture_en is tie-0.
In LPCT usage, this tied pin is driven exclusively by the LPCT controller. In LBIST usage, this pin is multiplexed between LBIST capture enable during LBIST mode and inverted scan enable during ATPG mode.
- **slow_clock : *port_name* ;**
Slow clock input. This port provides the shift clock during shift mode and clock source during slow capture mode. In LPCT or LBIST applications, this is connected to a free running clock. The default is slow_clock. This port is not present when the type property is set to child.

- `fast_clock : port_name ;`
Fast clock input. This port is connected to the functional clock source and provides the source clock during fast capture mode. The default is `fast_clock`. This port is not present when the type property is set to child.
- `clock : port_name;`
A clock input that only exist when the type property is set to “child”. This clock carries the shift clock durign shift mode and the capture clock during capture mode. An OCC of type parent is typically used at the source of the clock feeding the OCC of type child.
- `clock_out : port_name ;`
Test clock output pin that delivers shift clock during shift and programmable capture clock during capture. The default is `clock_out`.
- `clock_en_out : port_name;`
A port that is only present for OCC of type “child”. It is used to control the `test_en` port of a clock gater situated at the based of the clock tree. This output is typically only used when the `internal_clock_gater` property is off.
- `scan_in : port_name ;`
Scan input for the shift register inside OCC. This pin will be declared as a scan sub-chain input for scan insertion. The default is `scan_in`.
- `scan_out : port_name ;`
Scan output for the shift register inside OCC. This pin will be declared as a scan sub-chain output for scan insertion. The default is `scan_out`.
- `clock_sequence : port_name ;`
Used for LogicBIST non-ATPG control of the OCC. The default is `clock_sequence[%d]`.

IjtagScanInterface

This wrapper specifies the names of ijtag interface ports of the OCC module. This wrapper is used only when the OCC uses IJTAG.

Usage

```
DftSpecification(module_name, id) {
    OCC {
        Interface {
            IjtagScanInterface {
                tck           : port_name      ; // default: ijtag_tck
                reset         : port_name     ; // default: ijtag_reset
                select        : port_name     ; // default: ijtag_sel
                capture_en   : port_name     ; // default: ijtag_ce
                shift_en     : port_name     ; // default: ijtag_se
                update_en    : port_name     ; // default: ijtag_ue
                scan_in      : port_name     ; // default: ijtag_si
                scan_out     : port_name     ; // default: ijtag_so
                reset_polarity: active_polarity; // legal : active_high
                                         // active_low
            }
        }
    }
}
```

Description

This wrapper specifies the names of ijtag interface ports of the OCC module. This wrapper is used only when the OCC uses IJTAG.

Arguments

- **tck : *port_name* ;**
IJTAG control signal. The default is ijtag_tck.
- **reset : *port_name* ;**
IJTAG control signal. The default is ijtag_reset.
- **select : *port_name* ;**
IJTAG control signal. The default is ijtag_sel.
- **capture_en : *port_name* ;**
IJTAG control signal. The default is ijtag_ce.
- **shift_en : *port_name* ;**
IJTAG control signal. The default is ijtag_se.
- **update_en : *port_name* ;**
IJTAG control signal. The default is ijtag_ue.

- `scan_in : port_name ;`
Scan interface pins for the IJTAG scan path that will be connected to the specified IJTAG host scan interface. The default is `ijtag_si`.
- `scan_out : port_name ;`
Scan interface pins for the IJTAG scan path that will be connected to the specified IJTAG host scan interface. The default is `ijtag_so`.
- `reset_polarity : active_polarity ;`
Active state of the `ijtag` reset signal, to be used during IJTAG network insertion. This specifies only the active state inside the OCC. The default is `active_low`.

StaticExternalControls

This wrapper specifies the names of static signals when ijtag is not used. When using IJTAG, these signals are available as TDR bits inside the OCC.

Usage

```
DftSpecification(module_name, id) {
    OCC {
        Interface {
            StaticExternalControls {
                test_mode : port_name; //test_mode
                fast_capture_mode : port_name; //fast_capture_mode
                parent_mode : port_name; //parent_mode
                capture_cycle_width : port_name; //capture_cycle_width[%d]
                static_clock_control_mode : port_name; //static_clock_control_mode
                shift_only_mode : port_name; //shift_only_mode
                kill_clock_en : port_name; //kill_clock_en
            }
        }
    }
}
```

Description

This wrapper specifies the names of static signals when ijtag is not used. When using IJTAG, these signals are available as TDR bits inside the OCC.

Arguments

- **test_mode : *port_name* ;**
Signal to specify non-Functional mode. The default value is test_mode. This port is only created when the [ijtag_host_interface](#) property is set to “none”.
- **fast_capture_mode : *port_name* ;**
Signal to choose between fast and slow capture modes. The source of the programmable clock output will be the fast_clock OCC input when this signal is 1 or the slow_clock OCC input when this signal is 0. The default value is fast_capture_mode. This port is only created when the [ijtag_host_interface](#) property is set to “none” and the [type](#) property is “standard” or “parent”.
- **parent_mode : *port_name* ;**
Signal used to enable the parent mode of the controller. The default value is parent_mode. This port is only created when the [ijtag_host_interface](#) property is set to “none” and the [type](#) property is “parent”.
- **capture_cycle_width : *port_name* ;**
Provides pattern generation time configurability of the capture width size up to the maximum specified. This is a vector port with log2(capture_width_size) bits. The default value is “capture_cycle_width”. This port is only created when the [ijtag_host_interface](#) property is set to “none”.

- static_clock_control_mode : *port_name* ;

Control signal to decide whether the programmable clock sequence is under ATPG control or not. When this pin is 0, the clock sequence is shifted in as part of scan loading. When this pin is 1, the clock sequence is parallel loaded from the OCC clock sequence. The default value is static_clock_control_mode. This port is only created when the [ijtag_host_interface](#) property is set to “none”.

- shift_only_mode : *port_name* ;

Signal used to enable the [shift_only_mode](#) port on the OCC controller. The default value is “shift_only_mode”. The port is only created when the [OCC](#) wrapper [shift_only_mode](#) property is set to or interpreted as “on”.

- kill_clock_en : *port_name* ;

Signal used to enable the [kill_clock_mode](#) port on the OCC controller that is used to activate the clock gater on the fast_clock path such that the clock can be gated off during functional mode. The default value is “kill_clock_en”. The port is only created when the [OCC](#) wrapper [kill_clock_mode](#) property is set to or interpreted as “on”.

Connections

This wrapper specifies the design port or pin to which the OCC pins should be connected. When specified, this globally overrides the default connection specified for this port type. These are the global specifications.

Usage

```
DftSpecification(module_name, id) {
    OCC {
        Connections {
            scan_en      : port_pin_name | DftSignal(scan_en) | ;
                           OptionalDftSignal(scan_en);
            capture_en   : port_pin_name | 0;
            slow_clock   : port_pin_name | DftSignal(shift_capture_clock) | ;
                           OptionalDftSignal(shift_capture_clock);
            clock_sequence : port_pin_constant_name, ...; // default: 0
            StaticExternalControls {
            }
        }
    }
}
```

Description

This wrapper specifies the design port or pin to which the OCC pins should be connected. When specified, this globally overrides the default connection specified for this port type. These are the global specifications.

Arguments

- **scan_en** : *port_pin_name* | *DftSignal(scan_en)* | *OptionalDftSignal(scan_en)*;
An optional property used to specify a source node to connect the *scan_en* port to.
The node name can be a port or a pin name. The node must already exist in the design with the exception of one case. If the design level, as specified by the [set_design_level](#) command, is not “chip” and the name corresponds to the name of a scalar port, it is allowed to not exist in the design and it will be created as an input port during insertion.
When design level is “chip”, specified port names must already be connected to a pad cell. The connection will automatically be made to the internal side of the input pad buffer. You can specify *OptionalDftSignal(scan_en)* or *DftSignal(scan_en)* as the value, and it will be interpreted to request a connection to the DFT signal *scan_en* as it was added using the [add_dft_signals](#) command. When using *OptionalDftSignal(scan_en)*, you will not get an error if the DFT signal *scan_en* was not added; a connection to the port called “*scan_en*” will be made instead and the port will be created if not present unless design level is equal to “chip” in which case you will get an error. When the property is unspecified, its value defaults to *OptionalDftSignal(scan_en)*.

- `capture_en : port_pin_name ;`

Optional capture enable port name, used only when capture_trigger is set to capture_en. The default is 0.

- `slow_clock : port_pin_name ;`

An optional property used to specify a source node to connect the slow_clock port to.

The node name can be a port or a pin name. The node must already exist in the design with the exception of one case. If the design level, as specified by the [set_design_level](#) command, is not “chip” and the name corresponds to the name of a scalar port, it is allowed to not exist in the design and it will be created as an input port during insertion.

When design level is “chip”, specified port names must already be connected to a pad cell. The connection will automatically be made to the internal side of the input pad buffer. You can specify OptionalDftSignal(shift_capture_clock) or DftSignal(shift_capture_clock) as the value, and it will be interpreted to request a connection to the DFT signal shift_capture_clock as it was added using the [add_dft_signals](#) command. When using OptionalDftSignal(shift_capture_clock), you will not get an error if the DFT signal shift_capture_clock was not added; a connection to the port called “slow_clock” will be made instead and the port will be created if not present unless design level is equal to “chip” in which case you will get an error. When the property is unspecified, its value defaults to OptionalDftSignal(shift_capture_clock).

- `clock_sequence : port_pin_constant_name, ...; // default: 0`

Used for LogicBIST non-ATPG control of the OCC. The default is 0. When a constant value is provided, you should provide a sequence of bit values to be connected. For example, when capture_window_size is equal to 3, provided value should be of form ‘111’, ‘110’, ‘001’.

StaticExternalControls

This wrapper specifies the names of static signals when ijtag is not used. When using IJTAG, these signals are available as TDR bits inside the OCC.

Usage

```
DftSpecification(module_name,id) {
    OCC {
        Connections {
            StaticExternalControls {
                test_mode : port_pin_name | 0 | 1;
                fast_capture_mode : port_pin_name | 0 | 1;
                parent_mode : port_pin_name | 0 | 1;
                capture_cycle_width : port_pin_name | 0 | 1, ... ;
                static_clock_control_mode : port_pin_constant_name | 0 | 1;
                shift_only_mode : port_name ;
                    // default: DftSignalOrTiedLow(ext_ltest_en)
                kill_clock_en : port_name;
                    // default: DftSignal(occ_kill_clock_en)
            }
        }
    }
}
```

Description

This wrapper specifies the names of static signals when the [ijtag_host_interface](#) property is set to “none”. When the [ijtag_host_interface](#) property refers to an IJTAG host node, these signals are available as TDR bits inside the OCC.

Arguments

- **test_mode** : *port_pin_name* | 0 | 1;
Signal that is used to activate the OCC. When this signal is 0, the OCC is not activated and simply lets the *fast_clock*/clock input go through unaltered. The default is 0.
- **fast_capture_mode** : *port_pin_name* | 0 | 1;
Signal to choose between fast and slow capture modes. The source of the programmable clock output will be the *fast_clock* OCC input when this signal is 1 or the *slow_clock* OCC input when this signal is 0. The default value is 0. This port is not present for OCC of type “child”.
- **parent_mode** : *port_pin_name* | 0 | 1 ;
Signal used to activate the parent mode of an OCC of type “parent”. When equal to 0, the OCC operates in standard mode. The default value is 0.
- **capture_cycle_width** : *port_pin_name* | 0 | 1, ... ;
Provides pattern generation time configurability of the capture width size up to the maximum specified. Constant throughout the test, that is ATPG cannot change it on a per pattern basis.

- static_clock_control_mode : *port_pin_constant_name* | 0 | 1 ;

Control signal to decide whether the programmable clock sequence is under ATPG control or not. When this pin is 0, the clock sequence is shifted in as part of scan loading. When this pin is 1, the clock sequence is parallel loaded from the OCC external_clock_control pins. The default is 0. This port only exists when the [static_clock_control](#) property is set to external or both.

- shift_only_mode : *port_name* ;

DFT signal used to activate the [shift_only_mode](#). The default connection is DftSignalOrTiedLow([ext_ltest_en](#)).

- kill_clock_en : *port_name* ;

DFT signal used to activate the [kill_clock_mode](#) such that the clock gater on the fast_clock path such that the clock can be gated off during functional mode. The default is DftSignal([occ_kill_clock_en](#)).

Controller

This wrapper specifies the connections to the controller.

Usage

```
DftSpecification(module_name, id) {
    OCC {
        Controller(id) {
            clock_intercept_node      : port_pin_name ;
            clock_enable_pin          : pin_name;
            clock_enable_pin_polarity : active_high | active_low | auto;
            parent_instance           : instance_name ;
            leaf_instance_name        : instance_name ;
            type                      : standard | child | parent;
            internal_clock_gater     : on | off | auto;
            shift_only_mode           : on | off | auto;
            kill_clock_mode           : on | off | auto;
            Connections {
            }
        }
    }
}
```

Description

This wrapper specifies the connections to the controller.

Arguments

- **clock_intercept_node** : *port_pin_name* ;

A property that specifies the design port or pin to which the OCC clock output pin will be attached. The value of the “has_functional_source” attribute of the port or pin specified by this property impacts the connectivity of the OCC fast clock port. See the `fast_clock` property description in “OCC/Controller/[Connections](#)”.

- **clock_enable_pin** : *pin_name*;

A property that specifies the `test_en` pin of a clock gater situated at the base of the clock tree which the OCC of type `child` uses to control the clock during scan-based test pattern generation. This property can only be used when the `type` property is set to “`child`”. When the `clock_enable_pin` property is used and the `clock_intercept_node` property is left blank, the `internal_clock_gater` is inferred to `off` when it has a value of “`auto`”.

- **clock_enable_pin_polarity** : `active_high` | `active_low` | auto;

This property controls the active polarity of the `clock_en_port`. You only need to specify this property when you are creating the OCC without doing the insertion ([process_dft_specification](#) is used with the `-no_insertion` switch) and the `clock_enable_pin` is not pointing to the `test_en` pin of an integrated clock gater cell. When it is pointing to the `test_en` pin of an integrated clock gater cell, the active polarity is automatically extracted from the cell information.

- `parent_instance : instance_name ;`

This property specifies the design instance in which the OCC is instantiated. By default, the OCC is placed at the same hierarchical level as the `clock_intercept_node`.

- `leaf_instance_name : instance_name ;`

This property inherits its value from the OCC wrapper `leaf_instance_name` property if not specified locally.

- `type : standard | child | parent;`

This property inherits its values from the `../type` property when it is not specified locally. Its meaning is identical to how it is described in the `../type` property section.

- `internal_clock_gater : on | off | auto;`

This property inherits its values from the `../internal_clock_gater` property when it is not specified locally. Its meaning is identical to how it is described in the `../internal_clock_gater` property section.

- `shift_only_mode : on | off | auto;`

This property inherits its value from the `../shift_only_mode` property when it is not specified locally.

- `kill_clock_mode : on | off | auto;`

This property inherits its value from the `../kill_clock_mode` property when it is not specified locally.

Connections

This wrapper specifies the design port or pin to which the OCC pins should be connected.

Usage

```
DftSpecification(module_name, id) {
    OCC {
        Controller(id) {
            Connections {
                scan_en      : port_pin_name | DftSignal(scan_en) |;
                OptionalDftSignal(scan_en);
                capture_en   : port_pin_name | 0;
                slow_clock   : port_pin_name | DftSignal(shift_capture_clock) |
                OptionalDftSignal(shift_capture_clock)
                fast_clock   : port_pin_name ;
                clock        : port_pin_name ;
                clock_sequence: port_pin_constant_name, ... ; // default: 0
                StaticExternalControls {
                }
            }
        }
    }
}
```

Description

This wrapper specifies the design port or pin to which the OCC pins should be connected.

Arguments

- `scan_en : port_pin_name ;`

An optional property used to specify a source node to connect the `scan_en` port to.

The node name can be a port or a pin name. The node must already exist in the design with the exception of one case. If the design level, as specified by the `set_design_level` command, is not “chip” and the name corresponds to the name of a scalar port, it is allowed to not exist in the design and it will be created as an input port during insertion.

When design level is “chip”, specified port names must already be connected to a pad cell. The connection will automatically be made to the internal side of the input pad buffer. You can specify `OptionalDftSignal(scan_en)` or `DftSignal(scan_en)` as the value, and it will be interpreted to request a connection to the DFT signal `scan_en` as it was added using the `add_dft_signals` command. When using `OptionalDftSignal(scan_en)`, you will not get an error if the DFT signal `scan_en` was not added; a connection to the port called “`scan_en`” will be made instead and the port will be created if not present unless design level is equal to “chip” in which case you will get an error.

When the property is unspecified, its value is inherited from the [../Connections/scan_en](#) property which itself defaults to `OptionalDftSignal(scan_en)` when unspecified.

- `capture_en : port_pin_name ;`

Optional capture enable port name, used only when capture_trigger is set to capture_en. The default is 0.

- `slow_clock : port_pin_name ;`

An optional property used to specify a source node to connect the shift_capture_clock port to.

The node name can be a port or a pin name. The node must already exist in the design with the exception of one case. If the design level, as specified by the `set_design_level` command, is not “chip” and the name corresponds to the name of a scalar port, it is allowed to not exist in the design and it will be created as an input port during insertion.

When design level is “chip”, specified port names must already be connected to a pad cell. The connection will automatically be made to the internal side of the input pad buffer. You can specify `OptionalDftSignal(shift_capture_clock)` or `DftSignal(shift_capture_clock)` as the value, and it will be interpreted to request a connection to the DFT signal `shift_capture_clock` as it was added using the `add_dft_signals` command. When using `OptionalDftSignal(shift_capture_clock)`, you will not get an error if the DFT signal `shift_capture_clock` was not added; a connection to the port called “`slow_clock`” will be made instead and the port will be created if not present unless design level is equal to “chip” in which case you will get an error.

When the property is unspecified, its value is inherited from the `../Connections/shift_capture_clock` property which itself defaults to `OptionalDftSignal(shift_capture_clock)` when unspecified.

- `fast_clock : port_pin_name ;`

This property is used to specify a connection for the `fast_clock` input port of the OCC. When making this connection, the tool considers the value of the “`has_functional_source`” attribute of the port or pin specified by the `clock_intercept_node` and whether or not the `fast_clock` property is specified. There are four cases:

- Case 1 — The specified `clock_intercept_node` has a functional source, meaning its “`has_functional_source`” attribute set to true, and the `fast_clock` property is not specified. The OCC intercepts the specified `clock_intercept_node` so that the specified port/pin drives the OCC `fast_clock` port and the OCC `clock_output` drives all the sinks previously driven by the specified pin.
- Case 2 — The port or pin specified by `clock_intercept_node` has no functional source and the `fast_clock` property is specified. The OCC is inserted such that its `fast_clock` pin is connected to the port/pin specified by the `fast_clock` property and its `clock_out` pin is connected to the port/pin specified by the `clock_intercept_node` property.
- Case 3 — The specified `clock_intercept_node` has its “`has_functional_source`” attribute set to true, and the `fast_clock` property is specified. The OCC is inserted so

that its fast_clock pin is connected to the port/pin specified by the fast_clock property and the OCC clock_out pin drives the logic previously connected to the port/pin specified by the clock_intercept_node property.

- Case 4 — The clock_intercept_node port does not have a functional source and fast_clock is not specified. In this case, the tool reports an error.
- clock : port_pin_name ;

This property is used to specify a connection for the clock input port of the OCC which only exists on OCC of type “child”. This port is connected to a functional clock source and provides the source clock during both shift and capture mode. Used only when the clock_intercept_node property points to a pin that has no functional source (specifically, its has_functional_source attribute is false).

- clock_sequence : port_pin_constant_name, ... ;

Used for LogicBIST non-ATPG control of the OCC. The default is 0. When a constant value is provided, you should provide a sequence of bit values to be connected. For example, when capture_window_size is equal to 3, provided value should be of form ‘111’, ‘110’, ‘001’.

Examples

Example 1

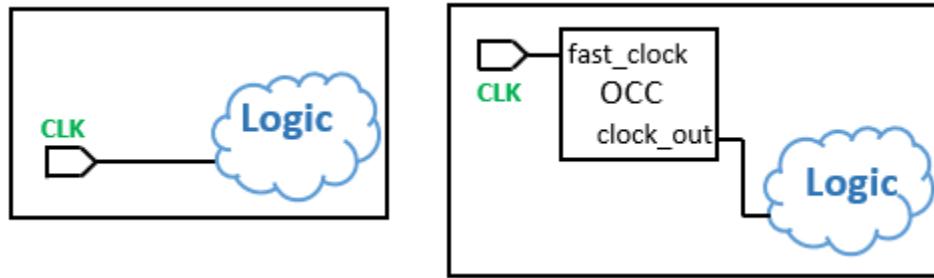

This example shows the case when the specified clock_intercept_node has a functional source and the fast_clock option is not specified for the OCC controller.

The OCC/Controller property clock_intercept_node specifies the CLK port (highlighted in green). The OCC/Controller/Connections fast_clock property is not used.

```
DftSpecification(design1, gates) {
    OCC {
        Controller(NX1) {
            clock_intercept_node: CLK;
        }
    }
}
```

Figure 10-54 shows a design before and after OCC insertion. The OCC is inserted so that port specified by clock_intercept_node, CLK (highlighted in green), is connected to the OCC fast_clock port and the OCC clock_out port is connected to the logic previously connected to CLK.

Figure 10-54. Case 1 — clock_intercept_node Has Functional Source and fast_clock Not Specified

Example 2

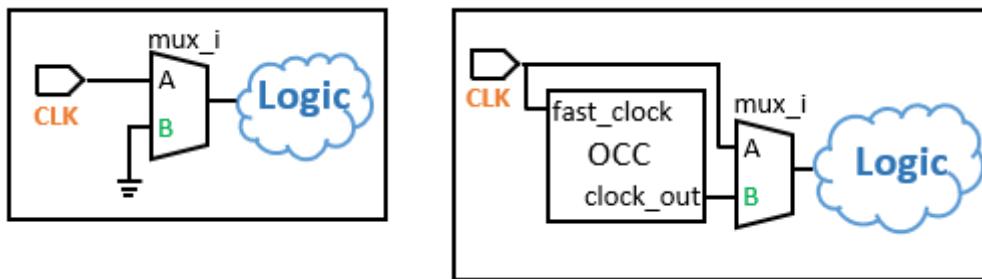

This example shows case 2 when the specified controller_intercept_node does not have a functional source and the fast_clock option is specified for the OCC controller. One example for this case is when you are using a MUX outside the OCC to switch between the functional clock and the test clock.

The specification shows that the clock_intercept_node is a pin on MUX, mux_i/B (highlighted in green), which is tied low. It also shows that the OCC/Controller/Connections fast_clock property is set to CLK (highlighted in orange).

```
DftSpecification(design1, gates) {
    OCC {
        Controller(NX1) {
            clock_intercept_node: mux_i/B;
            Connections {
                fast_clock : CLK;
            }
        }
    }
}
```

Figure 10-55 shows that, before OCC insertion, CLK was connected to mux_i/A and mux_i/B is tied low. After insertion, the CLK port (highlighted in orange) is still connected to mux_i/A. It is also connected to the OCC fast_clock port. The OCC clock_out pin is connected to mux_i/B (highlighted in green).

Figure 10-55. No Functional Source and fast_clock Specified

Note

 An error is reported if the clock_intercept_node does not have a functional source and fast_clock is not specified.

Example 3

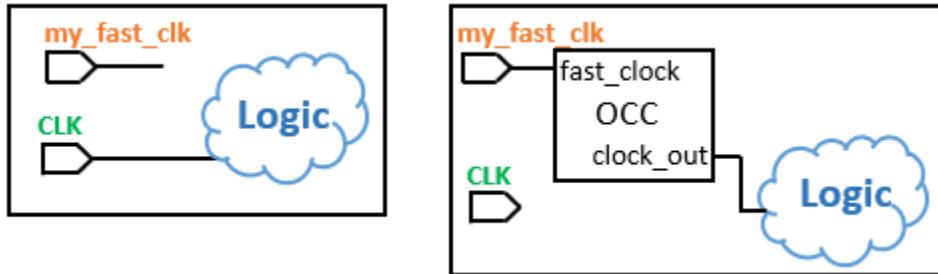

This example shows the case when the specified clock_intercept_node has a functional source and the fast_clock option is specified for the OCC controller.

The OCC/Controller property clock_intercept_node specifies the CLK port (highlighted in green). The OCC/Controller/Connections fast_clock property specifies the my_fast_clock port (highlighted in orange).

```
DftSpecification(design1, gates)  {
    OCC {
        Controller(NX1) {
            clock_intercept_node: CLK;
            Connections {
                fast_clock : my_fast_clock;
            }
        }
    }
}
```

Figure 10-56 shows that before OCC insertion the clock_intercept_node, CLK (highlighted in green) is connected to logic. It also shows the fast_clock specified port, my_fast_clock (highlighted in orange). After OCC insertion my_fast_clock is connected to the fast_clock input of the OCC and the clock_out port of the OCC drives the logic previously connected directly to CLK.

Figure 10-56. Case 3 - Functional Source and fast_clock Specified

StaticExternalControls

This wrapper specifies the names of static signals when ijtag is not used.

Usage

```
DftSpecification(module_name, id) {
    OCC {
        Controller(id) {
            Connections {
                StaticExternalControls {
                    test_mode : port_pin_name | 0 | 1;
                    fast_capture_mode : port_pin_name | 0 | 1;
                    parent_mode : port_pin_name | 0 | 1;
                    capture_cycle_width : port_pin_name | 0 | 1, ... ;
                    static_clock_control_mode : port_pin_constant_name | 0 | 1;
                    shift_only_mode : port_name;
                    kill_clock_en // default: DftSignalOrTiedLow(ext_ltest_en)
                      : port_name;
                    // default: DftSignal(occ_kill_clock_en)
                }
            }
        }
    }
}
```

Description

This wrapper specifies the names of static signals when ijtag is not used.

Arguments

- `test_mode : port_pin_name ;`

This property inherits its value from the `../Connections/StaticExternalControls/test_mode` property when unspecified. It has the exact same usage as described in the `../Connections/StaticExternalControls/test_mode` section. You specify it here if you want a different connection for this controller.

- `fast_capture_mode : port_pin_name ;`

This property inherits its value from the `../Connections/StaticExternalControls/fast_capture_mode` property when unspecified. It has the exact same usage as described in the `../Connections/StaticExternalControls/fast_capture_mode` section. You specify it here if you want a different connection for this controller.

- `parent_mode : port_pin_name ;`

This property inherits its value from the `../Connections/StaticExternalControls/parent_mode` property when unspecified. It has the exact same usage as described in the `../Connections/StaticExternalControls/parent_mode` section. You specify it here if you want a different connection for this controller.

- capture_cycle_width : *port_pin_name*, ... ;

This property inherits its value from the ../../Connections/StaticExternalControls/[capture_cycle_width](#) property when unspecified. It has the exact same usage as described in the ../../Connections/StaticExternalControls/[capture_cycle_width](#) section. You specify it here if you want a different connection for this controller.

- static_clock_control_mode : *port_pin_constant_name* ;

This property inherits its value from the ../../Connections/StaticExternalControls/[static_clock_control_mode](#) property when unspecified. It has the exact same usage as described in the ../../Connections/StaticExternalControls/[static_clock_control_mode](#) section. You specify it here if you want a different connection for this controller.

- shift_only_mode : *port_name* ;

This property inherits its value from the ../../Connections/StaticExternalControls/[shift_only_mode](#) property and has the exact same usage. You specify it here if you want a different connection for this controller. The default is DftSignalOrTiedLow(ext_ltest_en).

- kill_clock_en : *port_name* ;

This property inherits its value from the ../../Connections/StaticExternalControls/[kill_clock_en](#) property and has the exact same usage. You specify it here if you want a different connection for this controller. The default DftSignal(occ_kill_clock_en).

RtlCells

A wrapper that is used to specify the name of the ports to use when creating RTL cells.

Usage

```
DftSpecification(module_name,id) {
    RtlCells {
        And2|Or2|ClkAnd2|ClkOr2 {
            input0 : string ; // default: a
            input1 : string ; // default: b
            output : string ; // default: y
        }
        Buf|Inv|ClkBuf|ClkInv {
            input : string ; // default: a
            output : string ; // default: y
        }
        Mux2|ClkMux2 {
            input0 : string ; // default: a
            input1 : string ; // default: b
            select : string ; // default: s
            output : string ; // default: y
        }
        ClkGateAnd|ClkGateOr {
            clock_in : string ; // default: clk
            functional_enable : string ; // default: fe
            test_enable : string ; // default: te
            clock_out : string ; // default: clkg
        }
        PosedgeDff|NegedgeDff {
            data_in : string ; // default: d
            clock_in : string ; // default: clk
            data_out : string ; // default: q
        }
        PosedgeDffReset|NegedgeDffReset {
            reset : string ; // default: rn
            reset_polarity : string ; // active_high | active_low
            data_in : string ; // default: d
            clock_in : string ; // default: clk
            data_out : string ; // default: q
        }
        PosedgeDffSet|NegedgeDffSet {
            set : string ; // default: sn
            set_polarity : string ; // active_high | active_low
            data_in : string ; // default: d
            clock_in : string ; // default: clk
            data_out : string ; // default: q
        }
        PosedgeSynchronizer {
            data_in : string ; // default: d
            clock_in : string ; // default: clk
            data_out : string ; // default: q
        }
        PosedgeSynchronizerReset {
            reset : string ; // default: rn
            reset_polarity : string ; // active_high | active_low
            data_in : string ; // default: d
            clock_in : string ; // default: clk
            data_out : string ; // default: q
        }
    }
}
```

Description

A wrapper that is used to specify the name of the ports to use when creating RTL cells. A set of RTL cells is created when the `use_rtl_cells` property of the **DftSpecification** wrapper defaults to on or is specified as on. The list of cells is dependent on the need of the instruments being created, and the list requested in the `force_creation_of_rtl_cells : cell_type, ... ;` command.

Arguments

- `And2|Or2|ClkAnd2|ClkOr2/input0 : string ;`
A property that specifies the name of the first input of the And or Or cell. For the Clock version, this input is the input to which the clock signal is connected. The default string is “a”.
- `And2|Or2|ClkAnd2|ClkOr2/ input1 : string ;`
A property that specifies the name of the second input of the And or Or cells. For the Clock version, this input is the input to which the data signal is connected. The default string is “b”.
- `And2|Or2|ClkAnd2|ClkOr2/ output : string ;`
A property that specifies the name of the output of the And or Or cells. The default string is “y”.
- `Buf|Inv|ClkBuf|ClkInv/input : string ;`
A property that specifies the name of the input of the Buffer or Inverter cells. The default string is “a”.
- `Buf|Inv|ClkBuf|ClkInv/output : string ;`
A property that specifies the name of the output of the Buffer or Inverter cells. The default string is “y”.
- `Mux2|ClkMux2/input0 : string ;`
A property that specifies the name of input0 of the multiplexer cells. The default string is “a”.
- `Mux2|ClkMux2/input1 : string ;`
A property that specifies the name of input1 of the multiplexer cells. The default string is “b”.
- `Mux2|ClkMux2/select : string ;`
A property that specifies the name of the select input of the multiplexer cells. The default string is “s”.
- `Mux2|ClkMux2/output : string ;`
A property that specifies the name of the output of the multiplexer cells. The default string is “y”.

- **ClkGateAnd|ClkGateOr/clock_in : string ;**
A property that specifies the name of the clock input of the clock gating cells. The default string is “clk”.
- **ClkGateAnd|ClkGateOr/functional_enable : string ;**
A property that specifies the name of the functional enable input of the clock gating cells. The default string is “fe”.
- **ClkGateAnd|ClkGateOr/test_enable : string ;**
A property that specifies the name of the test enable input of the clock gating cells. The default string is “te”. The input is used to disable the gating during scan test.
- **ClkGateAnd|ClkGateOr/clock_out : string ;**
A property that specifies the name of the gated clock output of the clock gating cells. The default string is “clkg”.
- **PosedgeDff|NededgeDff/data_in : string ;**
A property that specifies the name of the data input of the DFF cells. The default is “d”.
- **PosedgeDff|NededgeDff/clock_in : string ;**
A property that specifies the name of the clock input of the DFF cells. The default is “clk”.
- **PosedgeDff|NededgeDff/data_out : string ;**
A property that specifies the name of the data output of the DFF cells. The default is “q”.
- **PosedgeDffReset | NededgeDffReset/reset : string ;**
A property that specifies the name of the reset of the DFF cells. The default is “rn”.
- **PosedgeDffReset | NededgeDffReset/reset_polarity : string ;**
A property that specifies the name of the reset polarity of the DFF cells. The default is “active_low”.
- **PosedgeDffReset | NededgeDffReset/data_in : string ;**
A property that specifies the name of the data input of the DFF cells. The default is “d”.
- **PosedgeDffReset | NededgeDffReset/clock_in : string ;**
A property that specifies the name of the clock input of the DFF cells. The default is “clk”.
- **PosedgeDffReset | NededgeDffReset/data_out : string ;**
A property that specifies the name of the data output of the DFF cells. The default is “q”.
- **PosedgeDffSet | NededgeDffSet/set : string ;**
A property that specifies the name of the set of the DFF cells. The default is “sn”.
- **PosedgeDffSet | NededgeDffSet/set_polarity : string ;**
A property that specifies the name of the set polarity of the DFF cells. The default is “active_low”.

- PosedgeDffSet | NegedgeDffSet/*data_in* : *string* ;
A property that specifies the name of the data input of the DFF cells. The default is “d”.
- PosedgeDffSet | NegedgeDffSet/*clock_in* : *string* ;
A property that specifies the name of the clock input of the DFF cells. The default is “clk”.
- PosedgeDffSet | NegedgeDffSet/*data_out* : *string* ;
A property that specifies the name of the data output of the DFF cells. The default is “q”.
- PosedgeSynchronizer/*data_in* : *string* ;
A property that specifies the name of the data input of the synchronizer cells. The default is “d”.
- PosedgeSynchronizer/*clock_in* : *string* ;
A property that specifies the name of the clock input of the synchronizer cells. The default is “clk”.
- PosedgeSynchronizer/*data_out* : *string* ;
A property that specifies the name of the data output of the synchronizer cells. The default is “q”.
- PosedgeSynchronizerReset/*reset* : *string* ;
A property that specifies the name of the reset of the synchronizer reset cells. The default is “rn”.
- PosedgeSynchronizerReset/*reset_polarity* : *string* ;
A property that specifies the name of the reset polarity of the synchronizer reset cells. Choose either active_high or active_low. The default is “active_low”.
- PosedgeSynchronizerReset/*data_in* : *string* ;
A property that specifies the name of the data input of the synchronizer reset cells. The default is “d”.
- PosedgeSynchronizerReset/*clock_in* : *string* ;
A property that specifies the name of the clock input of the synchronizer reset cells. The default is “clk”.
- PosedgeSynchronizerReset/*data_out* : *string* ;
A property that specifies the name of the data output of the synchronizer reset cells. The default is “q”.

Examples

This example specifies the port name for the clock multiplexer cell.

```
DftSpecification(modA,rtl) {
    RtlCells {
        ClockMux {
            input0 : I0 ;
            input1 : I1 ;
            select : S0 ;
            output : O ;
        }
    }
}
```

PatternsSpecification Configuration Syntax

This chapter describes the configuration data syntax used inside Tesson Shell to specify patterns to be applied to DFT components that are inserted into a design.

This chapter covers the [BoundaryScan](#), [MemoryBist](#), [MemoryBisr](#), [LogicBist](#), and [SdfInfo](#) wrappers as they exist inside the PatternsSpecification wrapper. Using this syntax, it is possible to specify a wide variety of patterns specifications, in a single wrapper or in multiple PatternsSpecification wrappers, to generate verification test benches used for simulation and tester patterns used for chip manufacturing.

PatternsSpecification	3570
Patterns	3576
SimulationOptions	3580
AdvancedOptions	3585
TestStep	3590
ICLNetworkVerify	3655
ProcedureStep	3659
EnableGroupInfo	3669
SdfInfo	3671
LoadBoardInfo	3674
TesterInterface	3676
Loopbacks	3679
ACLoopbacks	3681
InSystemTest	3683

PatternsSpecification

Defines a series of Patterns wrapper for a given view of a design.

Usage

```
PatternsSpecification(design_name, design_id, pattern_id) {
    usage                      : simulation | manufacturing_test ;
    manufacturing_patterns_format : format, ... ; // default: Stil
    compress_pattern_files       : boolean // default: on
    SimulationOptions {
        testbench_module_name     : format_string ;
        logic_bist_debug          : off | bist_registers_and_clock_verify |
                                    // setup_and_clock_verify |
                                    // setup_and_clock_verify_one_per_ncp;
        verify_internal_data_pins : boolean ; // default: off
    }
    AdvancedOptions {
        parameter_file           : file_path ;
        Parameters {
            parameter_name         : parameter_value ;
        }
        procfile_name             : file_path ;
        ireset_in_test_setup_proc : on | off ;
        no_initialization        : on | off ;
        ConstantPortSettings {
            port_name              : 0 | 1 ;
        }
    }
    Patterns(patterns_name) {
    }
    PatternsGroup(group_name) {
        AdvancedOptions {
            // same as ../AdvancedOptions
        }
        Patterns(patterns_name) {
        }
    }
    EnableGroupInfo(enable_group_info_id) {
    }
    SdfInfo(sdf_info_id) {
    }
    LoadBoardInfo (load_board_info_id) {
    }
    InSystemTest {
    }
}
```

Description

The PatternsSpecification wrapper defines a series of Patterns wrapper for a given view of a design. The Patterns wrapper can be declared directly at the top level or grouped into PatternsGroup wrappers.

The pattern specification uniquely identifies a design view of a design by using the *design_name* and *design_id* values. The [create_patterns_specification](#) command sets the

pattern_id value to signoff or manufacturing based on the usage arguments. The *pattern_id* can later be modified to create various PatternsSpecifications. For example, you can create a patterns specification targeted for wafer probe test, final test, and board level test. The number of tester channels and power available in each test setup typically varies and patterns need to be adjusted accordingly.

Arguments

- *design_name*

A string that identifies the PatternsSpecification for a specific design. This string is automatically populated by the [create_dft_specification](#) command to match the name of the current design. Refer to the description of the [process_patterns_specification](#) command to understand which PatternsSpecification gets processed.

- *design_id*

A string that identifies the PatternsSpecification for a specific *design_id* of the current design. If this string is missing from the “get_context -design_id” command and switch, it is automatically populated by the [create_patterns_specification](#) command with the value of the [tessent_design_id](#) attribute found in the top ICL module. Refer to the description of the [process_patterns_specification](#) command to understand which PatternsSpecification the tool processes.

- *pattern_id*

A string that distinguishes multiple PatternsSpecifications for a specific *design_name* and *design_id* from each other. The [create_patterns_specification](#) command populates this string with signoff and manufacturing but this string can be changed to any value to differentiate different patterns specifications from each other. For example, you can create a system_test version that is derived from the manufacturing one and include only the tests that can be operated through the TAP controller.

- usage : [simulation](#) | [manufacturing_test](#) ;

A property that specifies whether the PatternsSpecification is to be used to generate simulation test benches or manufacturing test patterns. The patterns are converted to Verilog test benches when the usage is specified as “simulation” and to the specified [manufacturing_patterns_format](#) when the usage is specified as “manufacturing_test”. Some settings are checked against this usage specification such as the “reduced_address_count” property in the [MemoryBist](#) wrapper.

- [manufacturing_patterns_format](#) : *format*, ... ;

A property that specifies one or more formats for the patterns files to generate when usage is specified as “manufacturing_test”.

The property supports the following formats:

- CTL
- FJTDL

- MITDL
- STIL — The default.
- STIL2005
- SVF — Because of inherent limitations of SVF, you *cannot* specify this format at the same time as other formats.
- TITDL
- TSTL2
- WGL
- WGL_LSI

For a description of these formats, see the description of the *format_switch* argument to the [write_patterns](#) command.

- `compress_patterns_file : on | off ;`

A property that specifies whether the patterns files are to be compressed when written to disk. When the property is specified to on, the file will have the extension “.gz” to signify that it is compressed.

- `testbench_module_name : format_string ;`

A property that specifies the top-level module name in the Verilog test bench file. You can use this property to give a different test bench module name for each test bench so that more than one test bench can be compiled in a single work area of a Verilog simulator at the same time.

The default is TB. The string can also include %d which will be replaced by the name of the current design, or %p which will be replaced by the name of the Patterns wrapper. Using a unique name for the test bench allows you to use a common signal name file to display signals in your simulator including alias name definitions you may have created. The [run_testbench_simulations](#) command uses a separate directory to compile each test bench so keeping the testbench_module_name as TB is optimal and recommended.

- `logic_bist_debug : off | bist_registers_and_clock_verify | setup_and_clock_verify | setup_and_clock_verify_one_per_ncp ;`

A property that causes the tool to provide extra data to help you debug LogicBIST simulation mismatches. Refer to “[Pattern Mismatch Debugging](#)” in the *Hybrid TK/LBIST User’s Manual* for details. The valid values are:

- off — The tool does not provide extra data for debugging.
- bist_registers_and_clock_verify — The simulation generates a mismatch showing when the PRPG, MISR, and low-power registers (if present) diverge from their expected values. This can help reduce debug time because it identifies the scan pattern at which the register(s) begin to diverge.

- `setup_and_clock_verify` — The tool creates a LogicBIST pattern that verifies that the controller is setup correctly, and then it applies 256 serial patterns to exercise the full NCP count range. During this test, the tool reduces the shift length to decrease the simulation runtime. Because of the reduced shift length, the MISR signature is not examined at the end of the pattern. If a clock does not generate the expected number of pulses for a given NCP, the tool generates a simulation mismatch.
- `setup_and_clock_verify_one_per_ncp` — The same as `setup_and_clock_verify`, except the tool only applies a single scan pattern for each NCP.
- `AdvancedOptions/parameter_file : file_path ;`
A property that specifies the name of a file containing parameters used to configure the `write_patterns` command. For a description of the available parameters, see the “[Parameter File Format and Keywords](#)” on page 3937.
- `AdvancedOptions/Parameters/parameter_name : parameter_value ;`
A wrapper that specifies parameter-value pairs used to configure the `write_patterns` command. A parameter specified in this wrapper overrides the same parameter specified in the specified `parameter_file`. For a description of the available parameters, see the “[Parameter File Format and Keywords](#)” on page 3937.
- `AdvancedOptions/procfile_name : file_path ;`
A property that specifies a procfile name that contains a `test_setup` and/or a `test_end` procedure.

The `file_path` must have one of the following formats:

- A simple file name with no directory path. In this case, the file must exist beside the ICL file.
- A null string. In this case, no procfile is used.
- An absolute path starting with a “/”.
- A relative path starting with “./” or “..”. In this case, the file must exist relative to the current working directory.
- `AdvancedOptions/ireset_in_test_setup_proc : on | off ;`
A property which, when set to “on”, will suppress the “iReset” being issued before the first pattern set generated for the Patterns wrapper being processed.
A `test_setup` procedure must be provided in the procfile specified by the “`procfile_name`” property in the same `AdvancedOptions` wrapper.
It is your responsibility to put appropriate events into the `test_setup` procedure that will reset the IJTAG network. The effect of the `ireset_in_test_setup_proc` being on is to add the `-ireset_in_test_setup_proc` to the `open_pattern_set` command for the first pattern set generated by for the Patterns wrapper.

- AdvancedOptions/no_initialization : on | off ;

A property that specifies creating the initialization cycle in the pattern file. The default is off.

If defined, the value of no_initialization property becomes the default value for the property in the following wrappers:

- PatternsSpecification/PatternsGroup/AdvancedOptions
- PatternsSpecification/Patterns/AdvancedOptions

This property maps directly to the [write_patterns](#) -noinitialization command and switch when the patterns are written out by [process_patterns_specification](#).

- AdvancedOptions/ConstantPortSettings/port_name : 0 | 1 ;

A data wrapper that specifies the ports that must be held constant throughout the entire pattern set. This list is typically empty and is not populated by the [create_patterns_specification](#) command. Input ports that were constrained prior to running extract_icl are automatically reported in the ICL file, and they are automatically forced accordingly when the [process_patterns_specification](#) command is called.

- PatternsGroup(*group_id*)

A wrapper that groups a set of Patterns wrappers. The group_id value is a unique string containing only letters, numbers, and underscores that identifies the group. This option makes it convenient to fold that group into the GUI when using the [add_config_tab](#) command. It also enables you to select that group in the GUI to validate or process all Patterns wrappers found inside the group.

You can also do this from the dofile using the [process_patterns_specification](#) command with the -config_object option referring to a PatternsGroup wrapper.

Examples

The following example shows a PatternsSpecification wrapper for module “MyDesign”, design_identifier “rtl”, and pattern_id set to signoff. The AdvancedOptions/Parameters wrapper is used to specify the SIM_PRECISION parameter. You typically do not need to set this parameter as it is automatically set to provide accuracy of each clock period to within 1%. For example, a Patterns wrapper using a clock with a period of 4.5 ns and 450 ps will automatically have a resolution of 1 ps such that the 450 ps half period of 225 ps can be expressed with more than 2 ps or 1% accuracy. It is shown here as an example in case you wanted to set a higher precision.

```
PatternsSpecification(MyDesign,rtl,signoff) {
    usage : simulation ;
    AdvancedOptions {
        Parameters {
            SIM_PRECISION : 1ps ;
        }
    }
}
```

[create_patterns_specification](#)
[process_patterns_specification](#)

Patterns

Defines a complete set of Patterns steps each of which is meant to be run as one entity during simulation or manufacturing test.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    Patterns(patterns_name) {
        tester_period : time ;
        tck_clock_only : on | off ;
        tck_off_state : 0 | 1 ;
        tck_ratio : ratio ;
        load_board_info : load_board_info_id ;
        timeplate : timeplate_name ;
        DftControlSettings {
            icl_inst_path : 1 | 0 ;
        }
        ClockPeriods {
            pin_name : tester | time ; // repeatable
        }
        AdvancedOptions {
        }
        SimulationOptions {
        }
        ICLNetworkVerify(id) { // mutually exclusive with ProcedureStep and
        } // and TestStep wrappers
        ProcedureStep(procedure_step_name) { //repeatable
        }
        TestStep(step_name) { //repeatable
        }
    }
}
```

Description

The Patterns wrapper defines a complete set of Patterns steps each of which is meant to be run as one entity during simulation or manufacturing test. When the PatternsSpecification/usage property is set to manufacturing_test, it is possible to split separate steps into multiple patterns file such that test program events such as VDD bumping or PMU measurements can be inserted in the middle of the patterns. See the AdvancedOptions/split_patterns_file property description in the [ProcedureStep](#) and [TestStep](#) wrappers for more information about patterns file splitting.

Arguments

- tester_period : *time* ;

A property that sets the tester period for the given pattern set. Clocks defined as “tester” in the ClockPeriods wrapper will operate at the specified tester period. The TCK clock operates at the specified tester period divided down by the specified tck_ratio property.

- tck_clock_only : on | off ;

A property that specifies that all instruments in this Patterns wrapper should run with a TCK clock.

Note

 The tck_clock_only property will only have an effect on Patterns containing MemoryBIST tests.

This property will instruct the IJTAG solver to find a way to sensitize clock muxes and OCC on the clock paths to inject a TCK source. If there is no way to inject TCK from a TCKPort, an error will be issued. The test can still be run at TCK if the traced functional ClockPorts are set as “tester_period” in the ClockPeriods wrapper. The patterns will then assume that TCK will be injected on those functional clock ports from outside the design.

The TCK injection needs to be present in the ICL descriptions of the OCC modules in order to be understood and used by the IJTAG solver. To make sure the OCC ICL is complete, you must set the OCC wrapper property [include_clocks_in_icl_model](#) to “on” before processing the DftSpecification with the [process_dft_specification](#) command.

- `tck_off_state : 0 | 1 ;`

A property that specifies the off value of the TCK clock. By default, the off value is 0. See the description of the [open_pattern_set](#) command for a description of the TCK waveform based on the `tck_off_state` and the `tck_ratio` values.

- `tck_ratio : ratio;`

A property that specifies the ratio of the period of TCK with respect to the tester period. By default, the ratio is 1. See the description of the [open_patterns_set](#) command for a description of the TCK waveform based on the `tck_off_state` and the `tck_ratio` values.

This value is set correctly by the [create_patterns_specification](#) command when it uses tester clocks to bring down the period of TCK to the appropriate value.

- `load_board_info : load_board_info_id ;`

A property used to reference a [LoadBoardInfo](#) wrapper. The tester interface and loopbacks specified in the pointed LoadBoardInfo wrapper will be considered in the patterns and the Verilog test bench will be created to reflect those if it is generated.

- `timeplate : timeplate_name ;`

A property that specifies the timeplate the tool uses to override the default timeplate assumed when generating the pattern. The timeplate is loaded from a procfile as specified from the PatternsSpecification/Patterns/[AdvancedOptions](#)/procfile_name property.

- `DftControlSettings/signal : 1 | 0 ;`

A data wrapper that specifies the values of static dft signals of type `global_dft_control` that were created during the DFT step using the [add_dft_signals](#) command. By default, all dft control signals of type `global_dft_control` are set to their reset value unless you explicitly specify them in the DftControlSettings wrapper.

To report the available static dft signals that have the `global_dft_control` type, use the “[report_static_dft_signal_settings -all](#)” command when the ICL is elaborated.

See [Example 2](#) to understand how this wrapper is auto populated by the `create_patterns_specification` command.

When the `create_patterns_specification` creates a Patterns wrapper, it will often automatically fill out the `DftControlSettings` wrapper with some DFT signals. For every active physical block instance, all DFT signals which were registered with a `-defaults_value_in_all_test` that is different than its `-reset_value` are set to their specified `-defaults_value_in_all_test` values. When creating memoryBIST patterns, the `nonscan_test` DFT signal is also set.

- `ClockPeriods/pin_name : tester | time ;`

A data wrapper that specifies the clocks that are to be started for the given pattern set. When the value “tester” is used for a given clock, the clock is started as a free-running synchronous clock operating at the tester period. When the value is of type time, the clock is started as an asynchronous clock with its period set to the specified time value. Those asynchronous clocks are present in the simulation test benches but only appear as annotations near the top of the patterns file when the usage is `manufacturing_test`. The test engineer is expected to start the asynchronous clock with tester-specific commands. This is an example annotation that appears in a stil file to report the asynchronous clocks:

```
Ann { * Begin_async_clocks * }
Ann { *   clk = period: 16.00ns * }
Ann { * End_async_clocks * }
```

If a controller used in the current Patterns wrapper issues an iClock command on its clock port and the port traces to a top-level port that is not declared in the `ClockPeriods` wrapper, you will get an error as shown here:

```
// Error: Unable to trace the iClock
// 'core_rtl_tessent_mbist_c2_controller_inst.BIST_CLK' to a
// valid clock source. Traced the system clock to clock source
// 'clk'. The source of an iClock command must be driven by a
// primary input port of ICL type ClockPort that has been declared
// as a clock source with the add_clocks command.
```

To fix this type of error, you can either add missing `DftControlSettings` to configure the clock multiplexing, or you can add the missing clock port in the `ClockPorts` wrapper.

Examples

Example 1

The following example illustrates a Patterns wrapper that operates the tester and tck at 100ns. The example creates two asynchronous clocks that are needed by the memory BIST controllers operated in TestStep TS0 and TS1.

```
PatternsSpecification(design_name, design_id, pattern_id) {
    Patterns(patterns_name) {
        tester_period      : 100ns ;
        ClockPeriods {
            Clka : 4.5ns ;
            clkb : 5ns ;
        }
        TestStep(TS0) {
            MemoryBist {
                ...
            }
        }
        TestStep(TS1) {
            MemoryBist {
                ...
            }
        }
    }
}
```

Example 2

This example shows how to deal with clock port cloning that may happen during layout. Imagine you had a clock port called clka on your core and after layout this clock port was split into eight ports where the original clock port drive a small percent of the original fanout and the seven new ports clka_1 to clka_7 drives the rest. You need to have this new clock toggling in the test bench whenever clka was toggling. The following example script takes the [PatternsSpecification](#) created by [create_patterns_specification](#) and clones the clka entry in all ClockPeriods wrapper it is already found. The new entries in the ClockPeriods wrapper tells [process_patterns_specification](#) to also start those clocks.

```
set spec [create_patterns_spec]
set new_clka_ports [get_name_list [get_ports clka_*]]
set ClockPeriods_wrappers [get_config_elements ClockPeriods -in $spec -hier]

foreach_in_collection ClockPeriods_wrapper $ClockPeriods_wrappers {
    if {[get_config_value clka -in $ClockPeriods_wrapper -exists]} {
        set period [get_config_value clka -in $ClockPeriods_wrapper]
        foreach new_clka_port $new_clka_ports {
            add_config_element $new_clka_port -in $ClockPeriods_wrapper -value $period
        }
    }
}
```

SimulationOptions

Specifies properties that affect the creation of the simulation test benches.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    Patterns(patterns_name) {
        SimulationOptions {
            testbench_module_name      : format_string ; // default: TB
            monitor_internal_clock_pins : boolean ; // default: on | off
            sdf_info                  : sdf_info_id ;
            emulate_bisr_chains_in_lower_physical_blocks : boolean ;
                                         // default: auto
            logic_bist_debug          : off | bist_registers_and_clock_verify |
                                         setup_and_clock_verify |
                                         setup_and_clock_verify_one_per_ncp;
            LowerPhysicalBlockInstances {
                instance_name : full | graybox | interface ; //repeatable
            }
            TopModules {
                module_name   : file_path ; // repeatable
            }
            SimulationMacros {
                macro_name    : value ;      // repeatable
            }
            NonContactedTestOptions {
                default inout pad decay time : time ;
                PadDecayTimes {
                    port_name   : time ;      // repeatable
                }
            }
        }
    }
}
```

Description

Specifies properties that affect the creation of the simulation test benches.

Arguments

- testbench_module_name : *format_string* ;

A property that specifies the top-level module name in the Verilog test bench file. You can use this property to give a different test bench module name for each test bench so that more than one test bench can be compiled in a single work area of a Verilog simulator at the same time.

The default is TB. The string can also include %d which will be replaced by the name of the current design, or %p which will be replaced by the name of the Patterns wrapper. Using a unique name for the test bench allows you to use a common signal name file to display signals in your simulator including alias name definitions you may have created. The run_testbench_simulations command uses a separate directory to compile each test bench so keeping the testbench_module_name as TB is optimal and recommended.

- monitor_internal_clock_pins : boolean ;

A property that specifies whether the simulation test bench is to monitor the internal clock pins. When specified to on, those pins that have an iClock defined in the PDL are monitored to make sure the right frequency reaches them in simulation. The expected period is computed by the iClock command. The ICL clock pin names are converted to design pin names using the value of the tessent_design_instance property that the tool added to the ICL instances during ICL extraction.

Note

 During layout, ungrouping very often makes internal clock monitoring unusable as the design hierarchy is required to find the internal clock pins. If this happens you must either turn this property off or use a Verilog `define macro to turn off the monitoring, see the “[Clock Monitoring During Simulation](#)” section under the [run_testbench_simulations](#) command for an example of the available macros.

If this property is not specified, it defaults to the value defined in the wrapper `.././SimulationOptions`. This means the PatternsSpecification/SimulationOptions when there is no intermediate PatternsGroup wrapper or PatternsSpecification/PatternsGroup/SimulationOptions otherwise.

- sdf_info : [sdf_info_id](#) ;

A property used to reference a [SdfInfo](#) wrapper. The SDF file identified in the SdfInfo wrapper will be applied to the design when doing the simulation of this pattern set.

- emulate_bisr_chains_in_lower_physical_blocks : on | off | [auto](#) ;

A property that specifies whether the tool should create behavioral code in a side Verilog module (see “[patterns](#)” on page 3774) to emulate the behavior of the BISR segments within the child physical block instances. The valid values are:

[auto](#) — BISR chain emulation is only enabled for those child physical block instances listed in the LowerPhysicalBlockInstances wrapper with a value of “interface” or “graybox”. This is the default.

on — BISR chain emulation is enabled for all child physical block instances. The emulation logic overrides the BISR segments inside the child block instance even if the full view of the child physical block instance has been loaded.

off — BISR chain emulation is disabled for all child physical block instances.

The tool uses hierarchical forces and observe commands to emulate the behavior of the BISR segments on the port of the child physical block instance. This enables you to simulate the BISR operation at the top level if you are using interface or graybox models for the child physical block instances. To use the full simulation model for all instances of a sub physical block module, you can specify the string “`+define+Full_<PhysicalBlockModuleName>`” on the simulator command line; this strips out the behavioral code associated with the block name.

- `logic_bist_debug : off | bist_registers_and_clock_verify | setup_and_clock_verify | setup_and_clock_verify_one_per_ncp ;`

A property that causes the tool to provide extra data to help you debug LogicBIST simulation mismatches. Refer to “[Pattern Mismatch Debugging](#)” in the *Hybrid TK/LBIST User’s Manual* for details. The valid values are:

`off` — The tool does not provide extra data for debugging.

`bist_registers_and_clock_verify` — The simulation generates a mismatch showing when the PRPG, MISR, and low-power registers (if present) diverge from their expected values. This can help reduce debug time because it identifies the scan pattern at which the register(s) begin to diverge.

`setup_and_clock_verify` — The tool creates a LogicBIST pattern that verifies that the controller is setup correctly, and then it applies 256 serial patterns to exercise the full NCP count range. During this test, the tool reduces the shift length to decrease the simulation runtime. Because of the reduced shift length, the MISR signature is not examined at the end of the pattern. If a clock does not generate the expected number of pulses for a given NCP, the tool generates a simulation mismatch.

`setup_and_clock_verify_one_per_ncp` — The same as `setup_and_clock_verify`, except the tool only applies a single scan pattern for each NCP.

- `LowerPhysicalBlockInstances/instance_name : full | graybox | interface ;`

A data wrapper that specifies which view of the lower physical block instances is to be used for this simulation. By default, the interface view (the one containing only the port definition of the instance) is used. If the pattern set operates controllers or instruments found inside some lower physical block instances, the full view of those instances needs to be used. The Patterns wrapper created by the [create_patterns_specification](#) command automatically adds the correct instances that correspond to the controller that it added in the given pattern set. You only need to edit this property if you chose to modify the group of controllers the given patterns wrapper operates on. It is possible to use the graybox value only when a graybox file is available for a lower physical block instance when generated with the “[write_design -tsdb -graybox](#)” command and switch. Selecting this value will generate a simulation testbench for the [ICLNetworkVerify](#) wrapper that automatically excludes all ICL instances that are not used for scan (ICL module attribute [keep_active_during_scan_test](#) is false).

- `TopModules/module_name : file_path ;`

Many modules can be added to the simulation of the parent [Patterns\(pattern_name\)](#) wrapper in which the SimulationOptions/TopModules resides. For each module `module_name`, the file `file_path` in which this module is found is required and only Verilog files are allowed. During the simulation of the Patterns, the file specified by `file_path` is compiled at the same time as the test bench and then, the module `module_name` will be loaded during simulation.

This is equivalent to doing the following on the [run_testbench_simulations](#) command line:

```
run_testbench_simulations -select <pattern_name> \
    -extra_top_modules [list <module_name> ...] \
    -extra_verilog_files [list <file_path> ...] \
    ...
```

Since the TopModules can be specified on a per Patterns basis, it allows for finer control of the simulation process but without having to call the [run_testbench_simulations](#) command for each Patterns(*pattern_name*).

- SimulationMacros/*macro_name* : *value* ;

Each macro *macro_name* and optional value *value* specified in this wrapper translate to the command line argument '+define+...' when the test bench and top modules are compiled during simulation.

For example, for the following wrapper inside a parent [Patterns\(pattern_name\)](#)/SimulationOptions wrapper:

```
SimulationMacros {
    enable_faults;
    fault_type : 2;
}
```

Translate to the following command line arguments when compiling the test bench and top modules:

```
+define+enable_faults
+define+fault_type=2
```

This is equivalent to doing the following on the [run_testbench_simulations](#) command line:

```
run_testbench_simulations -select <pattern_name> \
    -simulation_macro_definitions [list enable_faults fault_type=2] \
    ...
```

Since the SimulationMacros can be specified on a per Patterns basis, it allows for finer control of the simulation process but without having to call the [run_testbench_simulations](#) command for each Patterns(*pattern_name*).

- NonContactedTestOptions/default inout pad decay time : *time* ;

A property that specifies the default inout port decay time that is utilized in [leakage_non_contacted](#) testing. Unique port decay times can be specified in the PadDecayTimes wrapper.

- NonContactedTestOptions/PadDecayTimes/*port_name* : *time* ;

A repeatable property that specifies an inout port name and pad decay time. These attributes are utilized in [leakage_non_contacted](#) testing. If not specified, the port decay time will default to the default inout pad decay time.

[process_patterns_specification](#)

AdvancedOptions

Specifies special advanced properties that affect various aspects of the pattern set.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    Patterns(patterns_name) {
        AdvancedOptions {
            parameter_file           : file_path ;
            Parameters {
                parameter_name : parameter_value ; // repeatable
            }
            include_all_power_pins   : on | off | auto ;
            include_only_used_pins   : on | off | auto ;
            exclude_initial_ireset_from_patterns : on | off ;
            skip_test_setup          : on | off ;
            skip_test_end            : on | off ;
            procfile_name            : file_name ;
            ireset_in_test_setup_proc : on | off ;
            no_initialization       : on | off ;
            // defaults to ../../AdvancedOptions/procfile_name
            ConstantPortSettings {
                // cumulates and overrides constant port settings in
                // ../../AdvancedOptions
                port_name             : 0 | 1 ;
            }
        }
    }
}
```

Description

The AdvancedOptions wrapper is used to specify special advanced properties that affect various aspects of the pattern set.

See the [LoadBoardInfo](#) wrapper description and `load_board_info` property for more control over load board contacted ports and loopbacks.

Arguments

- `parameter_file : file_path ;`
A property that specifies the name of a file containing parameters used to configure the `write_patterns` command. For a description of the available parameters, see the “[Parameter File Format and Keywords](#)” on page 3937. When the property is not specified, the value of the `../../AdvancedOptions/parameter_file` property is used.
- `Parameters/parameter_name : parameter_value ;`
A wrapper that specifies parameter-value pairs used to configure the `write_patterns` command. A parameter specified in this wrapper overrides the same parameter specified in the specified `parameter_file`. For description of the available parameters, see the “[Parameter File Format and Keywords](#)” on page 3937, The list of parameters found in this wrapper are added to any parameter specified in the `../../AdvancedOptions/Parameters` wrapper.

- `include_all_power_pins : on | off | auto ;`

A property that specifies whether or not to include power and ground ports in the patterns file. The power and ground ports are specified using the “`set_attribute_value -name function -value power | ground`” command. When set to auto, the power and ground ports are included in the simulation test benches but excluded from the manufacturing patterns file because the power and ground pins are not driven by the tester channels but directly from the load board.

Depending on its value, this property takes control of the value of the parameter `ALL_EXCLUDE_POWER_GROUND`, which can be set directly in the Parameters wrapper.

- The `ALL_EXCLUDE_POWER_GROUND` parameter keyword is used only when the `include_all_power_pins` property is set to auto (the default) or is not set.
- The `ALL_EXCLUDE_POWER_GROUND` parameter keyword is overridden when the `include_all_power_pins` property is set to on or off.
- `include_only_used_pins : on | off | auto ;`

A property that specifies whether to include all non-power or ground ports in the patterns file or only the one that are actually used in the current pattern set. The used port list is the list of ports explicitly forced or sampled at least once in the pattern set.

Depending on its value, this property takes control of the value of the parameter `ALL_EXCLUDE_UNUSED`, which can be set directly in the Parameters wrapper.

- When set to auto, the property defaults to on when the usage property (see [PatternsSpecification](#)) is `manufacturing_test`; otherwise, it defaults to off.
- The `ALL_EXCLUDE_UNUSED` parameter keyword is used only when the `include_only_used_pins` property is set to auto (the default) or is not set.
- The `ALL_EXCLUDE_UNUSED` parameter keyword is overridden when the `include_only_used_pins` property is set to on or off.

See [LoadBoardInfo](#) wrapper description and `load_board_info` property for more control over load board contacted ports and loopbacks.

- `exclude_initial_ireset_from_patterns : on | off ;`

A property that specifies whether or not to include an asynchronous reset of the IJTAG network in the manufacturing patterns. When set to “off”, the manufacturing patterns will begin with an asynchronous reset of the IJTAG network. When set to “on”, the pattern will begin the execution while assuming that the IJTAG network is in a reset state.

When this property is set to “on”, the IJTAG network must have been restored to its reset state otherwise the execution of the current pattern will fail. In order to bring back the IJTAG network to a reset state, a previous pattern must have been generated with the [TestStep](#)/AdvancedOptions/network_end_state : reset and executed before the current pattern is executed.

This property is typically used when running the memoryBIST pre-repair patterns and memoryBISR fuse programming patterns when implementing the memory repair flow. It is important to disable the initial IJTAG reset in these patterns in order to preserve any memory repair information that was calculated in previous patterns.

Note that this property removes the initial IJTAG reset from the manufacturing patterns only. When generating simulation testbenches, the initial IJTAG reset is applied in order to ensure a valid IJTAG network state during simulation.

- `skip_test_setup : on | off ;`

A property that specifies that the optional `test_setup` procedure that was loaded from the identified procfile using the [Patterns](#)/`profile_name` property is to be skipped from the current patterns file. If you do that, the pattern set is no longer self contained. In manufacturing test, the `test_setup` pattern must be applied to the device once and the state of the device that was obtained by the `test_setup` procedure, and on which the current pattern set depends on, must be maintained by the tester before running the current pattern set. This typically involves maintaining the power to the device and the value of input pins when switching from one pattern set to the next.

- `skip_test_end : on | off ;`

A property that specifies that the optional `test_end` procedure that was loaded from the identified procfile using the [Patterns](#)/`profile_name` property command is to be skipped from the current patterns file

- `procfile_name : file_path ;`

A property that specifies a procfile name that contains a `test_setup` and/or a `test_end` procedure. This property, when unspecified, takes its value from the `../..AdvancedOptions/profile_name` property found in the [PatternsSpecification](#) or PatternsGroup wrapper.

The `file_path` must have one of the format:

- It must be a null string. In this case, no profile is used.
- It must be an absolute path starting with a “/”.
- It must be a relative path starting with “./”. In this case, the file must exist relative to the current working directory.
- It must be a simple file name with no directory path. In this case, the file must exist beside the ICL file.
- `ireset_in_test_setup_proc : on | off ;`

A property which, when set to “on”, will suppress the “iReset” being issued before the first pattern set generated for the Patterns wrapper being processed.

A `test_setup` procedure must be provided in the procfile specified by the “`procfile_name`” property in the same AdvancedOptions wrapper.

It is your responsibility to put appropriate events into the `test_setup` procedure that will reset the IJTAG network.

The effect of the “ireset_in_test_setup_proc” being “on” is to add the “-ireset_in_test_setup_proc” to the “open_pattern_set” command for the first pattern set generated by for the Patterns wrapper. See the [open_pattern_set](#) command for more information.

- no_initialization : on | [off](#) ;

A property that specifies creating the initialization cycle in the pattern file. The default is off. This property, when unspecified, takes its value from the property specified in the following wrapper:

[PatternsSpecification](#)/AdvancedOptions

- ConstantPortSettings/port_name : 0 | 1 ;

A data wrapper that specifies the ports that must be held constant throughout the entire pattern set. This list is typically empty. The ConstantPortSettings wrapper can be used in the [BSDL-only flow](#) (also refer to [BoundaryScan](#) for further information). Input ports that were constrained prior to running [extract_icl](#) are automatically reported in the ICL file and they are automatically forced when [process_patterns_specification](#) is called. Port settings listed in this wrapper accumulate and replace the port settings defined in [..../AdvancedOptions/ConstantPortSettings](#) wrapper found in the [PatternsSpecification](#) and [PatternsGroup](#) wrappers.

If you have used [add_dft_signals](#) scan_en to define top level ports as DFT signals of type scan_en, the [create_patterns_specification](#) command will automatically add the scan enable ports to the AdvancedOptions/ConstantPortSettings wrapper such that they are automatically asserted off during the pattern generation. If you have other scan enable ports not identified with the [add_dft_signals](#), you need to add them yourself in the [create PatternsSpecification](#) using this script:

```
set spec [create_patterns_specification]
# Get a collection object to the
# 'ConstantPortSettings' wrapper
set ConstantPortSettings \
[get_config_value -in $spec -object \
AdvancedOptions/ConstantPortSettings]

# Add entries to 'ConstantPortSettings'
# wrapper for some ports that must be
# forced to '0'.
set scan_en_port_list {se1 se2}
foreach scan_en $scan_en_port_list {
    add_config_element $scan_en \
        -in $ConstantPortSettings -value 0
}
```

Examples

The following example uses the include_only_used_pins property to only include the used ports. The generated stil file will exclude the unused ports. By default, all ports would have been listed in the patterns file even if they had no activity.

```
PatternsSpecification(my_design, final, manufacturing) {
    usage : manufacturing_test ;
    manufacturing_patterns_format : stil ;
    Patterns(mbist1) {
        AdvancedOptions {
            include_only_used_pins : on ;
        }
    }
}
```

TestStep

Inserts a test step in the pattern set.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    Patterns(patterns_name) {
        TestStep(step_name) {
            AdvancedOptions {
                force_voltage(pin_name) : voltage ; // repeatable
                split_patterns_file : on | off ;
                network_end_state : keep | reset | initial ;
                IjtagRetargetingOptions {
                    merge_irunloop_only : on | off ;
                }
            }
            BoundaryScan {
            }
            MemoryBist {
            }
            MemoryBisr {
            }
            LogicBist {
            }
        }
    }
}
```

Description

The TestStep wrapper is used to insert a test step in the pattern set. The test step includes the selection of Boundary Scan tests, MemoryBIST or LogicBIST tests.

Arguments

- *step_name*
A string that uniquely identifies the step within a pattern set. All procedure_step_name and test_step_name strings must be unique within a Patterns wrapper. The string is only allowed to contains letters, numbers, and underscores.
- AdvancedOptions/force_voltage(*pin_name*) : *voltage* ;
A repeatable property that specifies that the current test step needs a special voltage to be applied on a specific port of the device. This is typically used in TestStep where MemoryBisr is used to program the fusebox. The property does not actually force the voltage. It only generates a special annotation near the top of the patterns file to let the test engineer know that test program commands are needed to supply the needed voltage on the given port. As soon as a single force_voltage property is specified, the split_patterns_file : on; property is implied to allow the insertion of the test program commands needed to apply the voltage values.

Below is an example of the special annotation inside a stil file:

```
Ann { * Before applying this pattern, the following actions are required: * }
Ann { * - Apply +0.25V on port PA * }
Ann { * - Apply -0.25V on port PB * }
```

- AdvancedOptions/split_patterns_file : on | off ;

A property that causes the pattern set to be split into multiple files. The file containing the previous patterns is closed and a new one is created for the current step. The file name is the name of the Patterns wrapper initially. When a step with split_patterns_file set to on is reached, the new file name consists of the name of the Patterns wrapper concatenated with an underscore to the name of the TestStep wrapper as shown here:

```
<pattern_name>_<test_step_name>
```

The split patterns file contains a special annotation near the top of the file that reads like this:

```
Ann { * This pattern file requires some actions taken on the ATE. * }
Ann { * This pattern assumes it is following another one: * }
Ann { * the power and clocks must be kept alive between * }
Ann { * the two patterns and all pins kept their state. * }
```

- AdvancedOptions/network_end_state : keep | reset | initial ;

A property that specifies the action to take at the end of the TestStep. The options for this property are named the same and perform the identical functions as the close_pattern_set command's arguments. For details, see the [close_pattern_set](#) command.

- IjtagRetargetingOptions/merge_irunloop_only : on | off ;

A property that specifies if iApply statements of concurrent iCalls are allowed to be merged during the processing of an iMerge block. This property and its options perform the identical function as “set_ijtag_retargeting_options [-merge_irunloop_only](#)”. Refer to the [set_ijtag_retargeting_options](#) command for more information.

Examples

The following example defines two TestStep wrappers in series. The first one runs memory BIST controllers while the second ones runs a MemoryBisr controller.

```
PatternsSpecification(mychip, gate, signoff) {
    Patterns(P1) {
        TestStep(TS1) {
            MemoryBist {
                Controller(corea.ctrl1) {
                }
                Controller(corea.ctrl2) {
                }
            }
        }
        TestStep(TS2) {
            MemoryBisr {
                Controller(ctrl1) {
                }
            }
        }
    }
}
```

BoundaryScan

Specifies the boundary scan tests to be generated.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    Patterns(patterns_name) {
        TestStep(step_name) {
            BoundaryScan {
                bsdl_file : file_path ;
                bsdl_package_directories : dir_path | auto ;
                enable_group_info : enable_group_info_id, ... ;
                bonding_configuration : name ;
                pin_action_verbosity : on | off ;
                active_control_cells : unlimited | integer ;
                RunTest(test) {
                }
            }
        }
    }
}
```

Description

The BoundaryScan wrapper specifies the boundary scan tests to be generated.

As illustrated in its syntax, the BoundaryScan specification consists of RunTest wrappers and properties that will affect all RunTest wrappers.

The repeatable RunTest wrapper defines the tests to be generated in the current pattern set. At least one RunTest wrapper is required, and no more than one BoundaryScan wrapper may be specified per TestStep wrapper.

Arguments

- bsdl_file : *file_path* ;

A property that specifies the path and filename of the Boundary Scan Description Language (BSDL) file to be used for BSDL-only flow pattern generation. In the BSDL-only pattern generation flow, only the BSDL file is required. You do not need to specify the BSDL file if it can be found in an instrument container in the TSDB directory. Packages can optionally be specified in the BSDL file and included with the bsdl_package_directories argument. For more information, refer to “[BSDL-Only Flow](#)” in the *Tessent BoundaryScan User’s Manual*.

Note

 In the BSDL-only flow, it may not be possible to use the [run_testbench_simulations](#) command since the data needed to run this command may not be available.

- `bsdl_package_directories : dir_path | auto ;`

A property that specifies a single path, or a list of paths to the package include directories. If `dir_path` is not specified, or if `auto` is specified, the path is assumed to be the same directory where the BSDL file is located.

- `enable_group_info : enable_group_info_id, ... ;`

A property that specifies one or more `EnableGroupInfo` wrappers to use for the boundary scan patterns. If more than one `EnableGroupInfo` wrapper is specified, the tool automatically extends the test to multiple sequential tests that enable each `EnableGroupInfo` wrapper separately.

All enable cells not part of the listed enable groups, whether they are part of a not listed enable group or part of no enable group, are added to a new artificial group and tested all simultaneously.

If an `EnableGroupInfo(enable_group_info_id)` wrapper is not found in the `PatternsSpecification` wrapper, the tool generates an error listing the `enable_group_info_ids` that are available. If the user specifies “`enable_group_info : *;`”, the tool automatically adds all available `enable_group_info_ids` to this property.

- `bonding_configuration : name ;`

A property that selects which bonding configuration the current patterns will be generated for. You must specify this property if your Tessent BoundaryScan hardware was generated with one or more `BondingConfigurations`. The name string must refer to a valid `BondingConfigurations(name)`. Tessent Shell will search for the corresponding BSDL file `<design_name>_<name>.bsdl` in the TSDB.

This property cannot be used if `bsdl_file` is specified.

- `pin_action_verbosity : on | off ;`

A property that enables you to specify whether your simulator displays comments each time a pin is compared to a specific value during test bench simulation. Be aware that adding comments for each output comparison increases pattern storage size.

- `active_control_cells : unlimited | integer ;`

A property that specifies how many enable boundary-scan cells can be active simultaneously during the clamp and output tests. Valid integer values are 1 or greater.

A large value generates a shorter overall test. Using a small value reduces the noise of simultaneously switching outputs created by test fixtures and package inductance.

If the `enable_group_info` property is specified and the integer is smaller than the number of control cells in an `enable_group`, the `enable group` will be split up and run sequentially in smaller groups of integer cells simultaneously.

Examples

The following example shows the PatternsSpecification of a standard set of 1149.1 tests with a reduction in the patterns storage size due to turning off pin action verbosity and a reduction in switching activity due to limiting the number of simultaneously active control cells.

```
PatternsSpecification(CHIP,signoff) {
    Patterns(std_test) {
        TestStep(TS1) {
            BoundaryScan {
                pin_action_verbosity: off ;
                active_control_cells: 1 ;
                RunTest(test_logic_reset){}
                RunTest(inst_reg){}
                RunTest(id_Reg){}
                RunTest(bypass_reg){}
                RunTest(bscan_reg){}
                RunTest(input){}
                RunTest(sample){}
                RunTest(highz){}
                RunTest(output_clamp){}
            }
        }
    }
}
```

RunTest

Defines a TAP or IO test to be run.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    Patterns(patterns_name) {
        TestStep {
            BoundaryScan {
                RunTest(test_name) {
                    AdvancedOptions {
                        checker_board : on | off ;
                    }
                    NonContactedPinOptions {
                        LeakageOptions {
                            logic_level : both | iih | iil ;
                            number_of_cycles : int ; default: 0
                        }
                        TriStateEnableOptions {
                            test_path : both | local | global ;
                            logic_level : both | high | low ;
                            number_of_rti_cycles : integer ; // default: 1
                        }
                    }
                    CellCompares {
                        cell_number : 0 | 1 | x ; // repeatable
                    }
                    CellSettings {
                        cell_number : 0 | 1 ; // repeatable
                    }
                    MaskedPins {
                        pin_name : normal | masked ; // repeatable
                    }
                    PinSettingsOverride {
                        pin_name : 0 | 1 | z ; // repeatable
                    }
                    PinComparesOverride {
                        pin_name : 0 | 1 | x ; // repeatable
                    }
                }
            }
        }
    }
}
```

Description

The RunTest wrapper defines a TAP or IO test to be run. Using the sub-wrappers in the RunTest wrapper, you can customize pin or cell options that will apply to this test only. This wrapper needs to be repeated once for every test type you want to run.

Arguments

- *test_name*

A string that specifies the type of test to run.

The valid values for *test_name* and a description of each test type follow:

Value	Description
bscan_reg	Ensures the boundary scan data register responds properly to the TAP state machine, and that the boundary scan register can be loaded. This algorithm uses the SAMPLE instruction, shifting data through the boundary scan chain only. Testing whether the boundary scan chain can actually capture and update data to the pins is performed as part of the input and output algorithms, and is therefore not included as part of the bscan_reg algorithm.
bypass_reg	Ensures that the data register state machine is functioning properly and that the bypass register can be loaded. This algorithm scans through the bypass register each time, comparing the bypass register capture value to 0. The algorithm also steps through all possible state transitions associated with a data register scan operation. If the TAP does not track states of the FSM (finite state machine) properly, the 11110 pattern will not appear on TDO in subsequent data register scan operations. The algorithm performs a final check of the bypass operation codes by scanning a 11111 pattern through the bypass register using every instruction opcode documented in the BSDL file as selecting the Bypass register.
clamp	This test verifies the CLAMP instruction. It consists of creating various clamp states and verifying that the output and the bidirectional pins are in the correct states. The clamp test exercises each boundary-scan cell with each pin driven in the high and the low state. In addition, the clamp test performs a scan-through test of the bypass register. The execution is conditional on the existence of the TAP CLAMP instruction code.
controlr	This test verifies that all controlr cells are reset to their disable state after a TAP controller reset. Execution is conditional upon the presence of at least one controlr cell.
disabled_outputs	This test disables all pads in the EXTEST mode by scanning a disabling value in all their enable cells. Tests the output for high impedance. Execution is conditional on the presence of at least one control cell or one open drain/source pad.
dot6_ac_00	This test measures AC parameters Vhyst_edge and Thyst on contacted 1149.6 input pins by applying a valid logic 0 to the input pins and expecting to capture a logic 0. This test applies AC waveforms to contacted inputs and uses the EXTEST_PULSE code.

Value	Description
dot6_ac_01	<p>This test measures AC parameters V_{hyst_edge} and T_{hyst} on contacted 1149.6 input pins by applying an invalid logic 0 to the input pins and expecting to capture a logic 1. This test applies AC waveforms to contacted inputs and uses the EXTEST_PULSE code.</p> <p>This test is meant for manufacturing patterns and will never pass simulation because it assumes that the test receiver will react correctly to an invalid 0 or 1.</p>
dot6_ac_10	<p>This test measures AC parameters V_{hyst_edge} and T_{hyst} on contacted 1149.6 input pins by applying an invalid logic 1 to the input pins and expecting to capture a logic 0. This test applies AC waveforms to contacted inputs and uses the EXTEST_PULSE code.</p> <p>This test is meant for manufacturing patterns and will never pass simulation because it assumes that the test receiver will react correctly to an invalid 0 or 1.</p>
dot6_ac_11	<p>This test measures AC parameters V_{hyst_edge} and T_{hyst} on contacted 1149.6 input pins by applying a valid logic 1 to the input pins and expecting to capture a logic 1. This test applies AC waveforms to contacted inputs and uses the EXTEST_PULSE code.</p>
dot6_ac_input	<p>This test verifies the AC operation of the 1149.6 receivers. It performs the following tasks:</p> <ul style="list-style-type: none"> Applies a checkerboard pattern to contacted AC input/bidirectional pins. Disables all output/bidirectional pads. Applies a valid AC waveform to contacted input and inout pins. Tests the “no transition” detection capability, if present, by applying two consecutive test patterns while keeping the AC pin level constant. If the pad contains either a Low-Pass filter or an embedded High-Pass filter, the absence of transition in the second pattern will make its corresponding boundary-scan cell capture its default value. Uses both EXTEST_PULSE and EXTEST_TRAIN codes.
dot6_ac_output	<p>This test verifies the AC operation of the 1149.6 transmitters and loopbacks. It performs the following tasks:</p> <ul style="list-style-type: none"> Enables all AC output pads. Ignores and turns off all non-AC pads, if possible. Uses both AC and DC loopbacks if present. Uses both EXTEST_PULSE and EXTEST_TRAIN codes. Alternatively disables and enables ACSelect cells. Runs the test on one Enable Group at a time. Strobes AC waveforms on all AC contacted outputs.

Value	Description
dot6_ac_select_cells	<p>This test verifies that the netlist properly implements the AC grouping described in the BSDL. Only one ACSelect cell is enabled at a time, and its action is verified by checking that all AC output pins in its fanout properly toggle during the RunTestIdle state when the EXTEST_PULSE instruction is loaded.</p> <p>This test is necessary only during netlist verification in the design flow. In manufacturing, the dot6_ac_output test ensures that all AC select cells are properly operating by enabling or disabling them all at once.</p>
dot6_dc_00	<p>This test measures DC parameters Vthreshold and Vhyst_level on contacted 1149.6 input pins by applying a valid logic 0 to the input pins and expecting to capture a logic 0. All AC pad drivers are disabled for this test.</p>
dot6_dc_01	<p>This test measures DC parameters Vthreshold and Vhyst_level on contacted 1149.6 input pins by applying an invalid logic 0 to the input pins and expecting to capture a logic 1. All AC pad drivers are disabled for this test.</p> <p>This test is meant for manufacturing patterns and will never pass simulation because it assumes that the test receiver will react correctly to an invalid 0 or 1.</p>
dot6_dc_10	<p>This test measures DC parameters Vthreshold and Vhyst_level on contacted 1149.6 input pins by applying an invalid logic 1 to the input pins and expecting to capture a logic 0. All AC pad drivers are disabled for this test.</p> <p>This test is meant for manufacturing patterns and will never pass simulation because it assumes that the test receiver will react correctly to an invalid 0 or 1.</p>
dot6_dc_11	<p>This test measures DC parameters Vthreshold and Vhyst_level on contacted 1149.6 input pins by applying a valid logic 1 to the input pins and expecting to capture a logic 1. All AC pad drivers are disabled for this test.</p>
dot6_dc_input	<p>This 1149.6 test verifies the behavior of all 1149.6 AC input pins when operating in EXTEST mode. Just as the non-AC (in other words, DC) pins “input” test, this pattern applies zero and one logic values at the AC pins and checks that their 1149.6 test-receiver’s associated bscan cells capture the same value. In addition, whenever the target tester supports it, the test will also verify that all AC pins can reliably detect invalid input voltage levels sitting in between the “zero” and “one” threshold voltages.</p>

Value	Description
dot6_dc_output	This 1149.6 test is equivalent to the existing output IO test for normal DC pads. Just as in the output test, the dot6_dc_output test applies checkerboard values, activates output cells one enable group at a time, and uses load board loopbacks as well as IO internal loopbacks. In addition, this test also covers 1149.6-specific features such as coupling capacitors discharge time, ACSelect cells, and output inversion during the RunTestIdle state of the TAP.
highz	This test verifies the operation of the HIGHZ instruction code. The pattern loads the HIGHZ code into the TAP, driving all output and bidirectional pins into high-impedance states. Note that this test actually executes the following three tests: disabled_outputs, highz_mode, and controlr.
highz_mode	<p>This test disables all pads via the TAP HIGHZ instruction code. It tests all outputs for high impedance.</p> <p>The execution is conditional to the existence of a TAP HIGHZ instruction code.</p>
id_reg	Ensures that the ID register is responding properly to the TAP data register state machine. This algorithm compares the capture values of the device ID and status registers whenever a data register scan operation is performed. The algorithm steps through all possible state transitions associated with a data register scan operation. The execution is conditional to the existence of a TAP IDCODE instruction code.
iih	Presets input pins so that the tester can drive the pins to their high values and measure the current of these pins. The tester stops the test to measure current, then resumes the test.
iil	Presets input pins so that the tester can drive the pins to their low values and measure the current of these pins. The tester stops the test to measure current, then resumes the test.
input	<p>This test verifies that the boundary-scan cells perform a proper capture of input data using standard IEEE-1149.1 timing. It tests all input, observe-only, and clock boundary-scan cells when the TAP instruction register is loaded with the EXTEST instruction code. In addition, it also tests the input direction of all bidirectional cells. The test turns off all pad drivers, including the bidirectional ones, and applies alternate EVEN and ODD checkerboard patterns to all input and bidirectional contacted pins that have tester control capabilities. Cells are pre-loaded with their pin state's opposite value. All non-X cell captured values are compared at TDO including those resulting from the following:</p> <p>Cells capturing themselves or a constant value in EXTEST mode.</p> <p>When a pin is tied to a constant value by the load board.</p> <p>The presence of an internal or external pull-up or pull-down resistor at the output of an uncontrollable bidirectional pin.</p>

Value	Description
inst_reg	<p>This test verifies that the instruction register can be loaded. The two least significant bits are compared to “01” on every instruction register scan operation. This algorithm steps through all possible state transitions associated with an instruction register scan operation.</p> <p>If the TAP does not track states of the FSM (finite state machine) properly, the standard 01 bits of the instruction register do not appear in a subsequent instruction register operation.</p>
leakage_non_contacted	<p>This test will drive a value to an inout port and observe the value after a specified number of cycles.</p> <p>The leakage_non_contact test can only be used if there are non-contacted inout ports. These non-contacted inout ports can be described in the PatternsSpecification/LoadBoardInfo/TesterInterface wrapper with port properties of control:none and observation:none set.</p> <p> Note: The Verilog test bench will pass only if you specify the pad decay time in the SimulationOptions/NonContactedTestOptions/PadDecayTimes wrapper with a time greater than that specified in the NonContactedPinOptions/LeakageOptions/number_of_cycles property.</p>
tristate_enable_non_contacted	<p>This test verifies if the pad driver of a bidirectional non-contacted pad can be disabled by the force_disable signal and the local enable signal. The RunTest/NonContactedPinOptions/TriStateEnableOptions wrapper defines the types of tests to run (global or local) and their parameters. This wrapper can only be used with the tristate_enable_non_contacted test.</p> <p>The pad decay times should be defined in the SimulationOptions/NonContactedTestOptions/PadDecayTimes wrapper for the testbench.</p>

Value	Description
output	<p>This test verifies that the boundary-scan cells perform a proper capture of output data using standard IEEE 1149.1 timing. It also checks the preload functionality of the SAMPLE/ PRELOAD instruction. In addition, it tests output and bidirectional boundary-scan cells when the TAP instruction register is loaded with the EXTEST instruction. Output and bidirectional pad drivers are turned on sequentially on a per group basis so as not to exceed the values specified with the active_control_cells property. All enabled output and bidirectional cells are loaded alternatively with EVEN and ODD checkerboard patterns. The output and bidirectional pins are strobed if they are both contacted and observable. All non-X values captured by the boundary-scan cells are compared at TDO, including the ones from the following:</p> <ul style="list-style-type: none"> Cells capturing themselves or a constant value in EXTEST mode. Enabled bidirectional boundary-scan cells that capture the pin state in EXTEST mode. Disabled bidirectional boundary-scan cells that have an internal or external pull-up/pull-down resistor. Input pins driven by a load board loopback from an output or bidirectional pin. Input cell captured value for all enabled bidirectional pads controlled by the combination of one output and one input or sample boundary-scan cell.
output_clamp	<p>This test runs the output test with an added short clamp test. During the output test, after each load of the boundary-scan register and each strobing of the enabled output and input pins, the following is performed:</p> <ul style="list-style-type: none"> The TAP instruction register is reprogrammed with the CLAMP instruction code. The test verifies whether the BYPASS register is selected. The output pins are strobed again to verify that they are to retain the initial output state value in CLAMP mode. The TAP instruction register is then reprogrammed with the EXTEST instruction, and the output test resumes from there.
sample	<p>This test verifies that the boundary-scan cells perform a proper capture of input data, like the input test, with the exception of the bidirectional pins. This algorithm uses the SAMPLE instruction code instead of the EXTEST instruction code which means the pad drivers of bidirectional pins cannot be turned off.</p>
test_logic_reset	<p>This test verifies that the TAP is being reset properly. Note that the boundary scan chain contains safe data values, and that either the EXTEST or SAMPLE instruction is active.</p>

Value	Description
voh	Presets output pins so that the tester can drive the pins to their high values and measure the voltage of these pins. The tester stops the test to measure voltage, then resumes the test.
vol	Presets output pins so that the tester can drive the pins to their low values and measure the voltage of these pins. The tester stops the test to measure voltage, then resumes the test.

- AdvancedOptions/checker_board : on | off ;

A property that enables or disables applying checkerboard vectors. Valid settings are as follows:

on	Enables checkerboard vectors which alternate logic zeroes and ones from one pin to the next, following the order of the boundary-scan register. This increases the chances of detecting short-circuits between two adjacent pins. Default IO test vectors are checkerboard.
off	Disables checkerboard, therefore applying boundary-scan load vectors made of all zeroes or all ones. This leads to easier debugging and simplifies usability.

This property affects the following tests: input, output, clamp, sample, dot6_ac_input, dot6_dc_input, dot6_ac_output, dot6_dc_output, and dot6_ac_select_cells.

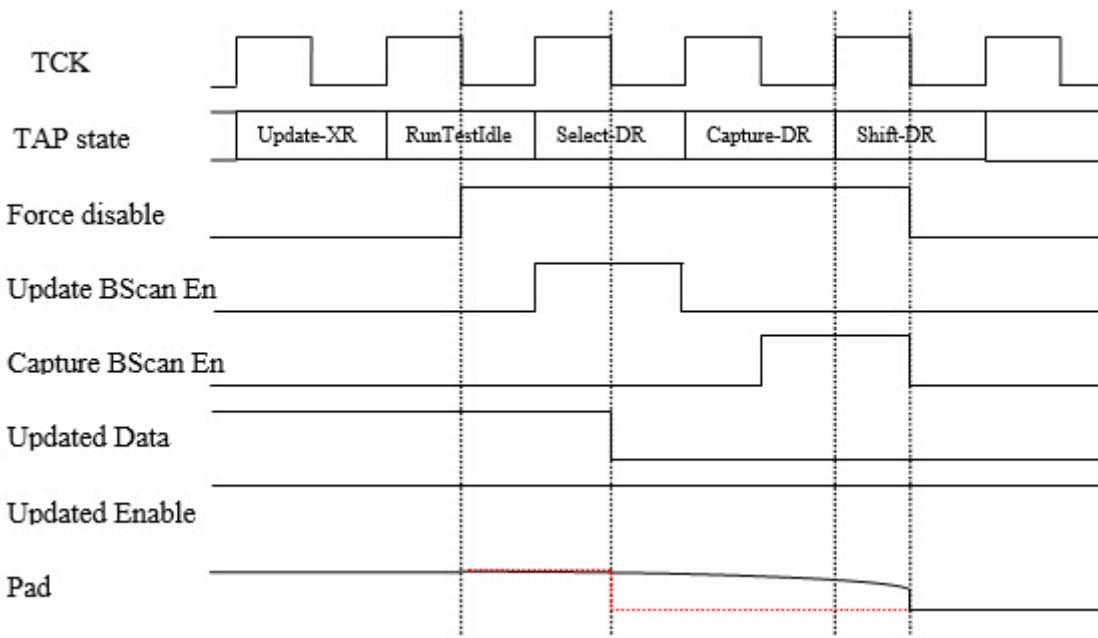

If the value is set to off, individual boundary-scan load vectors are still named EVEN and ODD in the output test bench. However, EVEN will mean logic 0 for all IO pins and ODD will mean logic 1 for all IO pins.

- NonContactedPinOptions/LeakageOptions/logic_level : both | iih | iil ;
A property that specifies the logic levels to be tested with the leakage_non_contacted test. This property can only be used with the leakage_non_contacted test. Specifying iih tests the leakage current with a value of 1 driven on the inout port. Specifying iil tests the leakage current with a value of 0 driven on the inout port. The default value of “both” with test the leakage current with both a 0 and 1 value driven.
- NonContactedPinOptions/LeakageOptions/number_of_cycles : *int* ;
A property that specifies the number of wait cycles between driving the test value and checking the value on a non-contacted inout port. This property can only be used with the leakage_non_contacted test. The default value is “0”. The specified wait time should be smaller than the pad decay time specified for the ports that are tested. The pad decay time is specified in the PatternsSpecification/Patterns/[SimulationOptions](#)/NonContactedTestOptions/PadDecayTimes wrapper.
- NonContactedPinOptions/TriStateEnableOptions/test_path : both | local | global ;
A property that specifies whether the global or the local test is created. By default, both tests are created.

The global test charges the pads with the value specified in the TriStateEnableOptions/logic_level property, and loads the data bscan cell with the opposite value. The update element is not strobed, so the value is not applied to the pad, as shown in [Figure 10-57](#) below. The force_disable signal is asserted, tri-stating the pad, and remains active until the pad state is captured. The updated data, set to the opposite state, is loaded in the SelectDR TAP state, which is done 1.5 cycles before the capture occurs. If the force_disable signal is not able to disable the pad driver because of a faulty circuit, the pad will be driven with the opposite value and that value will be captured, as shown with the red dotted line.

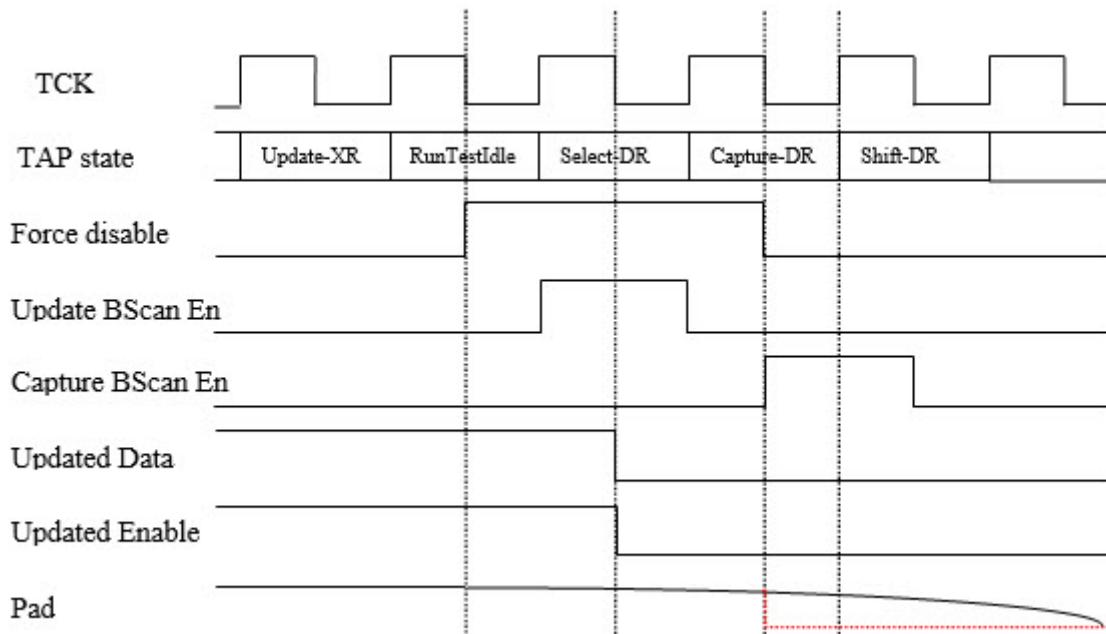

The timing in [Figure 10-57](#) reflects the default setting of “1” for TriStateEnableOptions/number_of_rti_cycles. By using larger settings, the number of cycles between disabling the pad driver and capturing the value can increased. This can be used to test the amount of time the pad can hold a charged value. The pad decay time, or the time a pad can hold a value, is defined in the PatternsSpecification/Patterns/[SimulationOptions](#)/NonContactedTestOptions/PadDecayTimes wrapper.

Figure 10-57. Timing Diagram of the Global tristate_enable_non_contacted Test

The local test charges the pads with the value specified in the TriStateEnableOptions/logic_level property, and loads the data bscan cell with the opposite value. Additionally, the enable cell is loaded with the pad disable value. The update element is not strobed, so the value is not applied to the pad, as shown in [Figure 10-58](#) below. The force_disable signal is asserted, tri-stating the pad as is done with the global test. The updated data (opposite) and enable (disable value), is loaded in the SelectDR TAP state, which is done 1.5 cycles before the capture occurs. Force disable is released in the CaptureDR TAP state, leaving only the enable cell, loaded with the pad disable value, to tri-state the pad. If the enable cell is not able to disable the pad driver because of a faulty circuit, the pad will be driven with the opposite value and that value will be captured, as shown with the red dotted line in the figure.

Figure 10-58. Timing Diagram of the Local tristate_enable_non_contacted Test

- NonContactedPinOptions/TriStateEnableOptions/logic_level : both | high | low ;
A property that specifies the logic level that is used to pre-charge the pads for local and global tristate_enable_non_contacted tests. By default, tests are created for both high and low levels.
- NonContactedPinOptions/TriStateEnableOptions/number_of_rti_cycles : *integer* ;
A property that specifies the number of cycles the tristate_enable_non_contacted global test will remain in the RunTestIdle TAP state. This determines how long the pad will remain undriven before the value is captured 1.5 cycles later. The default value is 1, or one cycle.
- CellCompares/cell_number : 0 | 1 | X ;
A property that enables you to override one or more boundary-scan cells' expected captured values for all scan operations performed during the test. The cell_number is a valid boundary-scan cell number as listed in the BOUNDARY_REGISTER Attribute section of the BSDL file of the design. A setting of X instructs Tessent Shell to ignore the captured and shifted out value of this boundary-scan cell, and a setting of 0 or 1 will instruct it to compare the captured and shifted out value of this boundary-scan cell to this logical value.
- CellSettings/cell_number : 0 | 1 ;
A property that enables you to override the value to be shifted into one or more specific boundary-scan cells for all scan operations performed during the test. The cell_number is a valid boundary-scan cell number as listed in the BOUNDARY_REGISTER Attribute section of the BSDL file of the design. A setting of 0 instructs Tessent Shell to shift in and update the logic 0 value in the specified boundary-scan cell, and a setting of 1 instructs Tessent Shell to shift in and update the logic 1 value in the specified boundary-scan cell.

For the specified cells, the CellSettings wrapper overrides the value for all shift-in and update operations that will be performed during execution of the test specified by `test_name` of the RunTest wrapper. Comparisons of captured pin values are not adjusted accordingly and will have to be comprehended with the appropriate CellCompares and PinComparesOverride settings. Typically, this wrapper is used to force a static value on an output or bidirectional pin of the DUT.

- `MaskedPins/pin_name : masked | normal ;`

A property that specifies that one or more pins will be masked during the IO tests. Any failure related to these pins or to associated boundary-scan cells is not reported during execution of the test. The `pin_name` is a valid port name on the current design.

- `PinSettingsOverride/pin_name : 0 | 1 | Z ;`

A property that specifies a constant value for one or more input or bidirectional pins. The `pin_name` is a valid name of a top-level port (primary input or bidirectional pin). A value of 0, 1, or Z indicates that a logic 0, logic 1, or Z value, respectively, is forced on the pin. This property setting overrides the pin value that the test normally applies.

- `PinComparesOverride/pin_name : 0 | 1 | X ;`

A property that specifies for Tessent Shell to compare one or more output or bidirectional pins to a given value. The `pin_name` is a valid name of a top-level port (primary output or bidirectional pin). A value of 0 or 1 indicates that a logic 0 or logic 1 value, respectively, is compared on the primary pin. A value of X indicates that no value is compared on the primary pin. This property setting overrides the compare value that the test normally applies.

It is recommended to use this wrapper to list all output2 pins that cannot be tri-stated to a compare value of X for highz, highz_mode, disabled_outputs and controlr tests.

Examples

The following example shows a configuration that tests the TAP controller hosting the boundary scan, and a separate set of patterns to test the boundary scan:

```
PatternsSpecification(CHIP,signoff) {
    Patterns(TAP_test) {
        TestStep(TS1) {
            BoundaryScan {
                RunTest(test_logic_reset){}
                RunTest(inst_reg){}
                RunTest(id_Reg){}
                RunTest(bypass_reg){}
            }
        }
    }
    Patterns(bscan_test) {
        TestStep(TS1) {
            BoundaryScan {
                RunTest(bscan_reg){}
                RunTest(input) {
                    AdvancedOptions {
                        checker_board: off ;
                    }
                }
                RunTest(input) {
                    AdvancedOptions {
                        checker_board: on ;
                    }
                }
                RunTest(output_clamp){}
                RunTest(sample){}
                RunTest(highz) {
                    PinComparesOverride {
                        OUT5 : X ;
                        OUT6 : X ;
                    }
                }
            }
        }
    }
}
```

    }
}
```

Description

The LogicBIST wrapper specifies the LogicBIST tests to be generated.

As shown in the syntax above, the LogicBIST specification consists of one or more CoreInstance wrappers that contain the properties that determine how the Hybrid TK/LBIST core is to be run.

Arguments

- **CoreInstance(*icl_instance_name*)**
A required property that specifies the ICL instance to the core containing the Hybrid TK/LBIST controller. If the controller is in the root module, then you specify “.”.
- **run_mode : hw_default | run_time_prog | burn_in ;**
A property that specifies whether the Hybrid TK/LBIST controller runs with the default settings or with scanned-in settings. When set to run_time_prog, the default, the controller is scanned through the IJTAG network to set up the controller according to the properties specified in the CoreInstance wrapper. When set to hw_default, the controller uses hard-coded values that were determined during the DFT process. When set to burn_in, the controller runs continuously for the amount of time specified by the burn_in_time property.

- `burn_in_time : tvalue ;`

An optional switch and time-delay value pair that specifies how long the LogicBIST wafer-level burn-in test should run. You can specify the time values using the following units. The default is 1s.

- s - seconds
- ms - milliseconds
- us - microseconds
- ns - nanoseconds
- ps - picoseconds

- `mode_name : mode_name ;`

A property that selects which LogicBIST mode should be used from the [logic_test_cores](#) directory within the TSDB. During fault simulation, you can change the mode by using the `set_current_mode` command. If the TSDB only contains one mode, the tool will use that mode. If the TSDB contains more than one mode, you must specify which mode to use.

- `mistr_comparisons : int ;`

A property that enables you to specify the number of times the MISR is compared during the LogicBIST run. The number of MISR compares cannot exceed the number of patterns being run, as specified by the `begin_pattern` and `end_pattern` properties. If `DiagnosisOptions/extract_flop_data` is on, the `mistr_comparisons` property specifies the number of times the contents of the scan chains will be scanned. The default is 1.

- `begin_pattern : int | last_pattern ;`

A property that specifies the first LogicBIST pattern to apply. The default is 0.

- `end_pattern : int | last_pattern ;`

A property that specifies the last LogicBIST pattern to apply. The default is `last_pattern`.

- `warmup_pattern_count : int ;`

A property that specifies the first N patterns of a LogicBIST pattern to be masked in order to allow the voltage in the chip to stabilize. When a warm-up value is specified, the PRPG will be seeded with pattern `begin_pattern - N` and the MISR will hold the `begin_pattern` seed until the warm-up patterns are completed. The default is 0.

- `shift_clock_select: shift_clock_src | ltest_clock | tck ;`

A property that specifies the clock input for the Hybrid TK/LBIST controller.

- `DiagnosisOptions/extract_flop_data : on | off ;`

A property that enables the diagnostic mode in which the state of the circuit is frozen after the application of the last pattern and is then the contents of each flip-flop that is serially scanned out via the IJTAG network. The default is off.

Examples

Example 1

The following example shows the PatternsSpecification for a top-level Hybrid TK/LBIST controller in the module CHIP. The single pattern consists of two TestSteps that require the clocks clk100, clk150, and clk200 to be active at the periods shown. The first TestStep runs a total of 8 patterns, beginning with pattern 0. After the last pattern (7) runs, the MISR signature is scanned out and compared. The second TestStep runs only pattern 7, but after the pattern is complete the flip-flop data is scanned out and compared.

```
PatternsSpecification (CHIP,signoff) {
    Patterns (LogicBist) {
        ClockPeriods {
            clk100 : 10ns ;
            clk150 : 6.66667ns ;
            clk200 : 5ns ;
        }
        TestStep (serial_load) {
            LogicBist {
                CoreInstance(CHIP) {
                    run_mode      : run_time_prog ;
                    begin_pattern : 0 ;
                    end_pattern   : 7 ;
                }
            }
        }
        TestStep (diagnostic) {
            LogicBist {
                CoreInstance(CHIP) {
                    run_mode      : run_time_prog ;
                    begin_pattern : 7 ;
                    end_pattern   : 7 ;
                    DiagnosisOptions {
                        extract_flop_data : on ;
                    }
                }
            }
        }
    }
}
```

Example 2

The following example runs the Hybrid TK/LBIST controller from pattern 512 to 524. With 3 misr_comparisons the pattern will be broken up into 3 runs, where the first runs patterns 512 to 515, the second runs patterns 516 to 519, and the last runs patterns 520 to 524. In addition, because warmup_pattern_count is set to 8, the 3 misr_comparisons runs are effectively running patterns 504 to 515, 508 to 519, and 512 to 524, but those 8 warm-up patterns will not contribute to the calculated MISR signatures.

```
PatternsSpecification(top,gate,signoff) {
    Patterns(LogicBist_m8051_1) {
        ClockPeriods {
            refclk : 10.00ns ;
        }
        TestStep(serial_load) {
            LogicBist {
                CoreInstance(m8051_wrap_inst_m8051_inst1) {
                    run_mode : run_time_prog ;
                    begin_pattern : 512 ;
                    end_pattern : 524 ;
                    misr_comparisons : 3 ;
                    warmup_pattern_count : 8 ;
                }
            }
        }
    }
}
```

Example 3

The following example runs the Hybrid TK/LBIST controller in wafer-level burn-in mode for 24 hours (86400 seconds).

```
PatternsSpecification(top,gate,signoff) {
    Patterns(LogicBist_m8051_1) {
        ClockPeriods {
            refclk : 10.00ns ;
        }
        TestStep(serial_load) {
            LogicBist {
                CoreInstance(m8051_wrap_inst_m8051_inst1) {
                    run_mode : burn_in ;
                    burn_in_time : 86.4e+3s;
                }
            }
        }
    }
}
```

MemoryBisr

Controls BISR circuitry in your design.

Usage

```
PatternsSpecification(design_name,design_id, pattern_id) {  
    Patterns(pattern_name) {  
        TestStep(name) {  
            MemoryBisr {  
                run_mode : bisr_chain_access | autonomous | fuse_box_access ;  
                Controller() {  
                }  
            }  
        }  
    }  
}
```

Description

The MemoryBisr wrapper is used for controlling BISR circuitry in your design.

At the block or sub-block design level, the [Controller](#) wrapper and run_mode property are used to verify the operation of BISR chains even though the chains may not yet be connected to a BISR controller.

At the chip design level, all parameters are used to verify the operation of BISR controller itself and its connections to the BISR chains and fuse box.

Arguments

- run_mode : bisr_chain_access | autonomous | fuse_box_access ;

A property used for BISR verification at the chip top, block, or sub-block level specifying the mode of operation of the BISR circuitry. The property must be specified because there is no default value for it. At the block and sub-block level, only the bisr_chain_access mode is valid. All modes are valid at the chip top level when the chains are connected to a BISR controller. The following table describes the three available modes.

bisr_chain_access	<p>Enables access to BISR chains. At the block/sub-block level, BISR chains are typically directly connected to top-level ports. At the chip top level, the BISR controller enables access to the BISR chains using the TDI and TDO top-level TAP ports.</p> <p>Several options are available to transfer repair information from BIRA modules to BISR registers, and serially load/unload user-defined values in selected BISR chains. These options are explained in the BisrChainAccessOptions wrapper description.</p>
-------------------	--

<u>autonomous</u>	In this mode, the controller operation does not require any data patterns from the tester. Several autonomous options are available to compress/decompress repair information, program/read fuses, and manipulate BISR chains. These options are explained in the AutonomousOption wrapper description.
fuse_box_access	Specifies that the BISR controller enables access to the fuse box using the TDI and TDO top-level 1149.1 TAP ports. The two valid operations in this mode are <i>program</i> and <i>read</i> . These are explained in the FuseBoxAccessOptions wrapper description.

Examples

Examples for the various BISR run modes can be found at the end of the [BisrChainAccessOptions](#), [AutonomousOption](#), and [AutonomousOption](#) wrapper descriptions.

Controller

Specifies the inclusion of a memory BISR controller into the test patterns.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    Patterns(pattern_name) {
        TestStep(name) {
            MemoryBISR {
                Controller(icl_instance_name) {
                    power_domain_group_labels      : pdg_label, ... ;
                    test_time_multiplier          : real ; // default 1
                    fuse_box_write_duration       : time ; // default 7ms
                    fuse_box_read_duration        : time ; // default 200ns
                    fuse_box_init_duration        : time // default 1us
                    inhibit_buffer_to_fuse_tranfer : on | off ;
                    AutonomousOptions {
                    }
                    BisrChainAccessOptions {
                    }
                    FuseBoxAccessOptions {
                    }
                }
            }
        }
    }
}
```

Description

The Controller wrapper specifies the inclusion of a memory BISR controller into the test patterns and allows specifying properties that are applicable to all run modes selectable in the [MemoryBist](#) wrapper such as the selection of power domain groups. Options specific to the selected run mode are part of the corresponding wrapper.

Arguments

- *icl_instance_name*

Specifies the instance name of a module found in an ICL model. The ICL instance name corresponds to the instance of the module in the design at the time the BISR logic was inserted. The ICL instance name provides a fixed reference to this logic even if the circuit hierarchy might change during the layout process. At the block/sub-block level when the chain are not yet connected to a controller, the *icl_instance_name* is specified as “.”. and identifies the block/sub-block itself. At the chip top level, it identifies the BISR controller module. The list of available memory BIST controller instances can be found using this command:

```
get_icl_instances -filter
{tessent_instrument_type==mentor::memory_bisr &&
tessent_instrument_subtype==controller}
```

The [create_patterns_specification](#) command automates the creation of the Controller wrapper for each instance in the design.

- `power_domain_group_labels : pdg_label, ... ;`

A property that specifies the power domain group(s) on which to perform the BISR operations. The default value is an asterisk (*) which is equivalent to enumerating all power domain group labels, including the default group assigned to all memories that were not explicitly assigned a label. This special group is designated with a hyphen (-).

Note the following usage conditions:

If these settings apply:	Then the power_domain_group_labels setting must be:
<code>MemoryBisr/run_mode : bisr_chain_access</code>	An asterisk (*) or One or more power domain group label(s)
<code>MemoryBisr/run_mode: autonomous</code> <code>MemoryBisr/Controller/AutonomousOptions/operation : verify_fuse_box</code> or <code>MemoryBisr/Controller/AutonomousOptions/operation : power_up_emulation</code> or <code>MemoryBisr/Controller/AutonomousOptions/operation : clear_bisr_chain</code>	An asterisk (*) or One or more power domain group label(s)
<code>MemoryBisr/run_mode: autonomous</code> <code>MemoryBisr/Controller/AutonomousOptions/operation : self_fuse_box_program</code>	An asterisk (*) or all power domain group labels

- `test_time_multiplier : real ;`

A property that specifies a multiplier to extend or shorten the memory BISR run time. The final run time is equal to the original test time (as calculated by Tesson Shell) multiplied by the `test_time_multiplier` factor. The default is 1.

This property is typically used when the test clock runs slower than expected by BISR. As a result, the memory BISR controller may not have completed its test within the allocated time when polled by the ATE. The `test_time_multiplier` property thus extends the computed test time; this is usually as a temporary measure (until the clock periods described in the [Patterns/ClockPeriods](#) wrapper is used).

- `fuse_box_write_duration : time ;`

A property that controls the duration of the pause cycle when the BISR controller is writing into the fuse box. This property is rarely used and overrides the value already specified by

the [AdvancedOptions/write_duration](#) property of the fuse box interface. The fuse box data sheet should provide the fuse write duration delay. The time value is a real number followed by the unit without a space in between. Valid time units are s, ms, us, ns, and ps. The default time unit is ns. The fuse box write duration default is 7ms.

- `fuse_box_read_duration : time ;`

A property that controls the duration of a read access from the fuse box. The time value is a real number followed by the unit without a space in between. Valid time units are s, ms, us, ns, and ps. The default time unit is ns. The fuse box read duration default is 200ns.

- `fuse_box_init_duration : time ;`

Specifies the initial delay required prior to accessing the fuse box. The time value is a real number followed by the unit without a space in between. Valid time units are s, ms, us, ns, and ps. The default time unit is ns. The fuse box init duration default is 1 us.

- `inhibit_buffer_to_fuse_transfer : on | off ;`

A property that prevents the automatic programming of the fuse values that are stored in a buffer located in the fuse box interface at the end of a `SelfFuseBoxProgram` or `FuseBoxAccess` programming test step. If the `inhibit_buffer_to_fuse_transfer` property is set to “on” inside a `self_fuse_box_program` or `fuse_box_access` programming `TestStep` wrapper, the contents of the fuse box interface buffer is not transferred to the fuse box (specifically, fuse programming is not executed). Setting this property to on enables additional fuse values to be written to the buffer in subsequent test steps before final programming is executed.

Examples

Examples for the various BISR options can be found at the end of the [BisrChainAccessOptions](#), [AutonomousOption](#), and [AutonomousOption](#) wrapper descriptions.

AutonomousOption

Sets options that control the autonomous mode of the BISR controller.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    Patterns(pattern_name) {
        TestStep(name) {
            MemoryBisr {
                Controller(instance) {
                    AutonomousOptions {
                        operation : mode ;
                        enable_bira_capture : on | off ;
                        select_read_buffer : on | off | auto ;
                        max_repair_count : integer | all ;
                    }
                }
            }
        }
    }
}
```

Description

The AutonomousOptions wrapper sets options that control the autonomous mode of the BISR controller. In Autonomous mode, the controller operation does not require any data patterns from the tester and the state of the GO and DONE outputs is updated at the end of the operation.

Several autonomous options are available to compress and decompress repair information, program and read fuses, and manipulate BISR chains. The content of the AutonomousOptions wrapper is used when you specify the MemoryBisr/run_mode property as “autonomous”.

Arguments

- **operation : mode ;**

A property that specifies one of the following operation modes:

calculate_bisr_chain_length	In this mode, the BISR controller measures the length of the selected BISR chains by shifting a single “1” through the chains. The fuse box controller counts the number of shifts needed for the “1” to propagate through the chains and initializes the BISR chain length registers with the calculated value. These registers are also initialized using the same method when running the power_up_emulation operation. The fuse box is not read from for this operation. The initialization of the BISR chain length registers must be executed before running the following autonomous mode operations: rotate_bisr_chain, self_fuse_box_program, and verify_fuse_box.
-----------------------------	---

clear_bisr_chain	Clears all flip-flops in the BISR chain without calculating the BISR chain length. This enables quick initialization of the memory repair inputs when performing memory BIST verification.
power_up_emulation	Simulates a power-up event. During this mode, the BISR controller first calculates the BISR chain length using the method outlined for calculate_bisr_chain_length and then reads and decompresses the repair information from the fuse box into the selected BISR chain(s). All inputs to the BISR controller are provided by IJTAG in this mode. The functional inputs of the BISR controller (clock, repair enable and PDGenable signals) are not used in that mode and can be in any state.
rotate_bisr_chain	Performs a BISR chain rotation autonomously. This operation is used to shift the contents of the BISR chain inside memories with internal repair registers. When the enable_bira_capture property is set to on, a BIRA-to-BISR transfer is performed prior to the BISR chain rotation.
self_fuse_box_program	When the BISR chain contains the repair information for all memories, the BISR controller rotates the BISR chain, compresses its content, and writes the compressed values to the fuse box. If the GO and DONE signals of the BISR controller are high when the test step completes, the initial BISR chain content is preserved. When multiple power domain groups are present, their BISR chains are processed in a single controller run.
verify_fuse_box	Verifies the decompressed content of the fuse box against the content of the BISR chain, one bit at a time. The BISR chain is shifted as the decompressed content of the fuse box is shifted in and compared with the BISR chain output. The BISR controller GO signal goes high at the end of the test if the decompressed data from the fuse box exactly matches the content of the BISR chain.

- enable_bira_capture : on | off ;

A property that enables BISR registers to capture the repair information contained in the corresponding BIRA registers in the rotate_bisr_chain mode. When set to on, the BIRA value is loaded into the BISR register on the first BISR clock cycle before shifting the BISR chain. When set to off, loading of the BIRA values is disabled.

- select_read_buffer : on | off | auto ;

This property is only used if the [MemoryBisr/memory_repair_loading_method](#) parameter is set to “from_read_buffer”. The select_read_buffer property is used to select between serial or parallel loading of the BISR chains during the power-up emulation autonomous mode of the fuse box controller. When selecting the read buffer output, the BISR chain initialization

is much faster than the serial method since the repair values are driven to the memory repair ports using parallel connections. If enable_bira_capture is enabled the parallel repair values are also captured into the BISR registers for validation purposes. When select_read_buffer is set to “off”, the repair values from the fuse box are shifted serially in the BISR registers.

The default “auto” value resolves to “on” if the fuse box controller does support fast BISR loading and the run_mode for the current test step is “power_up_emulation”. Otherwise, the “auto” value resolves to “off”.

- max_repair_count : *integer* | all ;

A property that specifies the maximum number of repairs your test bench will perform. This property is used only in simulation mode with fault injection. Because you know how many faults you injected and how many repairs this represents, you can specify max_repair_count to reduce the simulation time. Valid integer values are 1 or greater. A setting of “all” means that the runtime is calculated as the time needed to write 50% of the fuse box locations, assuming the other 50% will be zeros. A *test_time_multiplier* : *real* ; property can be specified with a value varying between 1 and 2 to adjust the test time to adjust the maximum percentage of programmed fuses, although this should rarely be necessary.

Examples

The following example will cause the fuse box controller to find the repair information for the specified power domain in the fuse box, read it, decompress it and load the result in the BISR chain associated to power domain named “PDG_A”. The BISR chain length is also calculated.

```
TestStep(power_up_emulation_step) {
    MemoryBisr {
        run_mode : autonomous ;
        Controller(FB_INST1) {
            power_domain_group_labels : PDG_A ;
            AutonomousOptions {
                operation : power_up_emulation ;
            }
        }
    }
}
```

BisrChainAccessOptions

Specifies the options that control BISR chain operations.

Usage

```
PatternsSpecification(design_name,design_id, pattern_id) {
    Patterns(pattern_name) {
        TestStep(name) {
            MemoryBisr {
                Controller(icl_instance_name) {
                    BisrChainAccessOptions {
                        enable_rotation : on | off ;
                        enable_bira_capture : on | off ;
                        select_read_buffer : on | off ;
                        select_bisr_registers : internal | external ;
                        default_read_value : pattern ;
                        default_write_value : pattern ;
                        BisrRegisterAccessOptions(icl_instance_name) {
                            read_value(range) : pattern ;
                            write_value(range) : pattern ;
                        }
                    }
                }
            }
        }
    }
}
```

Description

The BisrChainAccessOptions wrapper specifies the options that control BISR chain operations.

This wrapper can be used at all design levels (specifically, top, block or sub-block level). To use the BisrChainAccessOptions wrapper, you must specify [MemoryBisr/run_mode](#) : `bisr_chain_access`.

You specify access to individual BISR registers using the BisrRegisterAccessOptions. Any `read_value` or `write_value` specified in this wrapper overrides the `default_read_value` and `default_write_value` specified in the BisrChainAccessOptions wrapper.

Arguments

- `enable_rotation : on | off` ;

A property that enables the rotation of the BISR selected chain(s). This property is typically used in combination with `enable_bira_capture : on` and `select_bisr_registers : external` to transfer repair information from BIRA registers to external and internal BISR registers. This property can only be specified when the chains are not yet connected to a controller. When you are at a level where the chains are connected to a controller, rotation of the BISR chains must be performed using the `rotate_bisr_chain` autonomous mode described in the [AutonomousOption](#) wrapper.

- `enable_bira_capture : on | off ;`

A property that enables BISR registers to capture the repair information contained in the corresponding BIRA registers. When set to on, the BIRA values are loaded into the BISR registers on the first BISR clock cycle before shifting the BISR chain(s). When set to off, loading of the BIRA values is disabled. When set to on, `select_bisr_registers` should be set to external. The `enable_rotation` property can be set to on to enable the transfer of BIRA registers to internal BISR registers, or it can be set to off if the objective is to simply inspect the values contained in the BIRA registers.

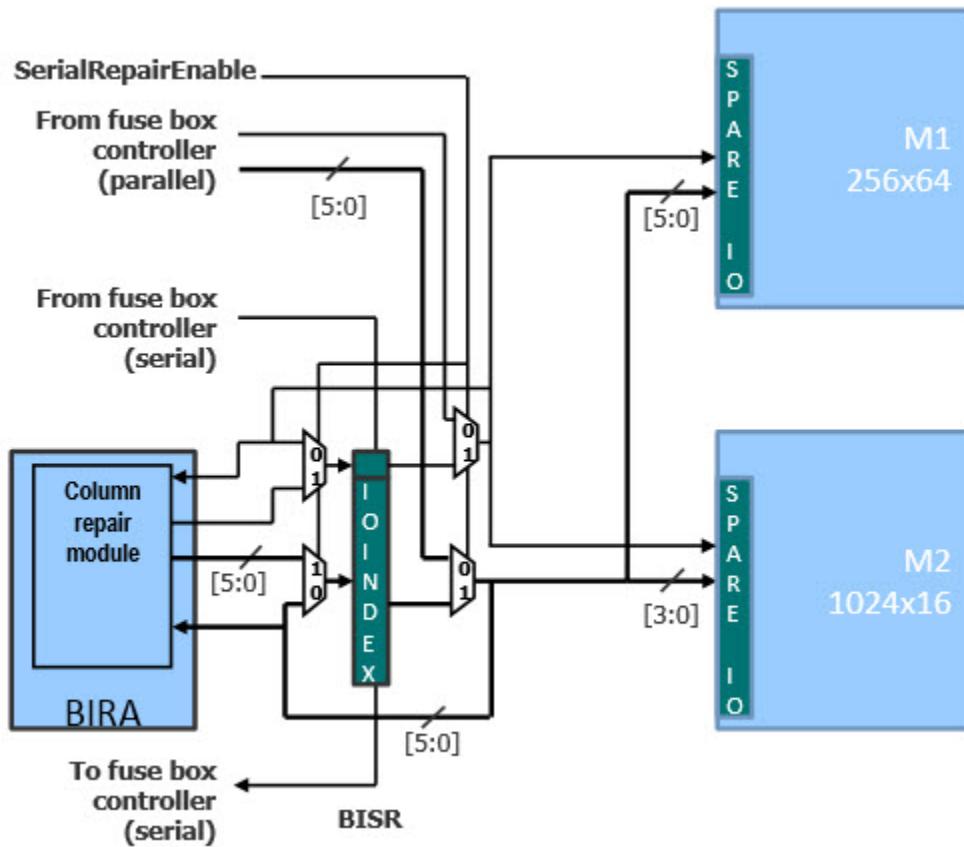

- `select_read_buffer : on | off ;`

This property is only used if the [MemoryBisr/memory_repair_loading_method](#) parameter is set to “from_read_buffer”.

When `select_read_buffer` is set to on, the `SerialRepairEnable` signal driving the multiplexers shown in [Figure 10-59](#) below is set to “0”. This will allow the parallel inputs driven by the fuse box read buffer output to reach the memory repair ports. Additionally, if the `enable_bira_capture` property is enabled, the parallel repair inputs will also be captured inside the BISR registers at the beginning of the shift cycle and scanned out.

When `select_read_buffer` is set to off, the `SerialRepairEnable` signal driving the multiplexers is set to “1”. This will allow the repair values from the BISR register outputs to drive the memory repair ports. When `enable_bira_capture` is enabled in this case, the values from the BIRA engine will be captured inside the BISR registers at the beginning of the shift cycle.

Figure 10-59. Fast BISR Muxing

When select_read_buffer is enabled at a block level, the primary inputs of the block are captured. For block level, an iProc is needed that provides iForcePort statements on the primary inputs of the block to emulate read buffer values. This prevents unknown values from being captured into the BISR registers. The iProc shown below provides an example implementation:

```
iTopProc ReadBuffer{} {
    iForcePort ReadBufferParallelPortName 0
    iApply
}
```

- `select_bisr_registers : internal | external ;`

A property that specifies whether the internal BISR register of memories with a serial BISR interface, or part of a shared bus, are scanned out during the BISR scan chain access. When set to internal, the property can be used to confirm the values actually loaded in internal BISR registers in a preceding test step.

- `default_read_value: pattern ;`

A property that sets default compare values for all BISR registers of the selected BISR chain(s). The BisrRegisterAccessOptions/read_value property can be used to override the compare pattern for specific BISR registers. By default, the all_x pattern is selected

indicating that all bits of all BISR registers will be ignored until specified otherwise in the patterns specification. Similarly, the all_one and all_zero patterns indicate that all bits will be compared to 1 and 0 respectively. A binary bit pattern can also be specified for comparison. The leading_one pattern indicates that the bit of each BISR register closest to its serial output will be compared to 1 and all others to 0. This pattern is useful for verifying the correct operation of BISR chains. The valid values are:

<i>binary</i>	During an iRead operation, the BISR chain range is compared against the specified bit pattern.
<u>all_x</u>	During an iRead operation, the BISR chain values are not compared.
all_one	Compares all BISR register bits against all 1s during an iRead operation.
all_zero	Compares all BISR register bits against all 0s during an iRead operation.
leading_one	The leading one symbol corresponds to a value of 1 followed by 0s (100...00).

- default_write_value : *pattern*;

A property that sets default values to be scanned in all BISR registers of the selected BISR chain(s). The BisrRegisterAccessOptions/write_value property can be used to override the write value for specific bits. By default, the all_x pattern is selected indicating that none of the bits need to be set to a particular value. In that case, the last value scanned in during a BISR chain access will be used to set each bit. The all_one and all_zero patterns indicate that all bits will be set to 1 and 0 respectively. The bits can also be set to a specified binary bit pattern. The all_x pattern is used as the default because BISR chains are usually reset before being exercised for the first time. It is therefore not necessary to explicitly write a value in order to initialize all bits of the BISR chain to 0. The leading_one pattern indicates that the bit of each BISR register closest to its serial output will be set to 1 and all others to 0. This pattern is useful for verifying the correct operation of BISR chains.

<i>binary</i>	During an iWrite operation, the BISR chain range is written with the specified bit pattern.
<u>all_x</u>	During an iWrite operation, the test bench will scan in the same values of those that were previously shifted in this shift register.
all_one	Writes 1's in all BISR bits during an iWrite operation.
all_zero	Writes 0's in all BISR bits during an iWrite operation.
leading_one	The leading one symbol corresponds to a value of 1 followed by 0s (100..00).

- *icl_instance_name*

Specifies the instance name of one or several BISR registers found in an ICL model of the circuit. The selected BISR registers must be part of the selected BISR chain(s) identified by the power_domain_group_labels property. Multiple BISR registers can be specified using wildcards within the name. The ICL instance names correspond to the instance name of BISR registers in the design at the time the BISR logic was inserted. The ICL instance name provides a fixed reference to this logic even if the circuit hierarchy might change during the layout process. To report the available BISR registers, use the [report_bisr_repair_register_icl_instances](#) command.

- *read_value(range) : pattern;*

A property that sets an expected value on specific bits of the selected BISR registers. This property is used only for verification and serves no purpose in the manufacturing flow. The range entry represents a bit index or range of bit indices of BISR registers within the selected BISR chain(s). Bit 0 is closest to the serial output of the BISR register. Entries for range are:

range	Description
<i>integer</i>	Reads the specified bit index of the BISR chain.
<i>integer:integer</i>	Reads the range of bit indices specified by the two integers.
<i>all_bits</i>	Reads all bits of the BISR registers within the selected chain(s).
<i>max_index:integer</i>	<i>max_index</i> is replaced by the most significant bit index value of the BISR registers within the selected chain(s). Reads the range of bit indices between the most significant bit and the index specified by <i>integer</i> .
<i>max_index</i>	Reads the most significant bit of the selected BISR chain(s).

The binary value for pattern is a bit pattern of a determined length—for example 8'b10001101. The bit length defined must match the index length defined by range or an error is generated. The all_zero pattern indicates that all bits of the selected BISR registers will be compared to 0. Similarly, the all_one and all_x patterns indicate that selected BISR register bits will be compared to 1 and x respectively. The leading_one pattern indicates that the bit within a range of BISR registers closest to its serial output will be compared to 1 and all others to 0. Values for pattern are:

<i>binary</i>	During an iRead operation, the BISR chain range is compared against the specified bit pattern. The length of range and pattern must match or an error is generated.
---------------	---

all_x	During an iRead operation, the BISR chain values are not compared.
all_one	Compares the BISR register bits against all 1s during an iRead operation.
all_zero	Compares the BISR register bits against all 0s during an iRead operation.
leading_one	During an iRead operation, compares the BISR register bits against a value of 1 followed by 0s (100...00) starting at the bit within the range closest to the BISR chain serial output.

- `write_value(range) : binary;`

A property that sets values to be scanned into specific bits of the selected BISR registers. For memories with a serial BISR interface, both the internal and external BISR registers are set to the same value. This property is used only for verification and serves no purpose in the manufacturing flow. The range entry represents a bit index or range of bit indices of BISR registers within the selected BISR chain(s). Bit 0 is closest to the serial output of the BISR register. Entries for range are:

range	Description
<i>integer</i>	Writes the specified bit index of the BISR chain.
<i>integer:integer</i>	Writes the range of bit indices specified by the two integers.
all_bits	Writes all bits of the BISR registers within the selected chain(s).
<i>max_index:integer</i>	<i>max_index</i> is replaced by the most significant bit index value of the BISR registers within the selected chain(s). Writes the range of bit indices between the most significant bit and the index specified by <i>integer</i> .
<i>max_index</i>	Writes the most significant bit of the selected BISR chain(s).

The binary value for pattern is a bit pattern of a determined length—for example 8'b10001101. The bit length defined must match the length index defined by range or an error is generated. The all_zero and all_one patterns indicate that all bits of the selected BISR registers will be written with 0s and 1s respectively. The all_x patterns indicate that the selected BISR register bits will be written with the same values that were previously

shifted in. The `leading_one` pattern indicates that the bit within the range of BISR registers closest to its serial output will be compared to 1 and all others to 0. Values for patterns are:

<code>binary</code>	During an iWrite operation, the BISR chain range is written with the specified bit pattern. The length of range and pattern must match or an error is generated.
<code>all_x</code>	During an iWrite operation, the test bench will scan in the same values of that were previously shifted in this BISR chain range.
<code>all_one</code>	Writes 1s in the BISR chain range during an iWrite operation.
<code>all_zero</code>	Writes 0s in the BISR chain range during an iWrite operation.
<code>leading_one</code>	During an iWrite operation, writes a value of 1 followed by 0s (100...00) starting at the bit within the range closest to the BISR chain serial output.

To use the `write_value` property, the [BisrChainAccessOptions/enable_rotation](#) property must be set to off.

Examples

Example 1

The following example has two TestStep wrappers. Both test steps operate on the BISR chain identified with label PDG_A. The `leading_one` pattern is loaded in all BISR registers in the first step and read back in the second one.

```
TestStep(write_leading_one) {
    MemoryBisr {
        run_mode      : bisr_chain_access ;
        Controller(FB_INST1) {
            power_domain_group_labels : PDG_A ;
            BisrChainAccessOptions {
                default_write_value   : leading_one ;
            }
        }
    }
}
TestStep(read_leading_one) {
    MemoryBisr {
        run_mode      : bisr_chain_access ;
        Controller(FB_INST1) {
            power_domain_group_labels : PDG_A ;
            BisrChainAccessOptions {
                default_read_value    : leading_one ;
            }
        }
    }
}
```

Example 2

The following example has two TestStep wrappers. Both test steps operate on the BISR chain identified with label PDG_A. The first step loads a value of 0 in all bits of the BISR chain except for a portion of the specified BISR register. The second step confirms that all values have been loaded correctly and the BISR chain is functional. These steps could be followed by another one running memory BIST to verify that the repair solution loaded in the BISR register is valid.

```
TestStep(write_selected_BISR_reg) {
    MemoryBisr {
        run_mode : bisr_chain_access ;
        Controller(FB_INST1) {
            power_domain_group_labels : PDG_A ;
            BisrChainAccessOptions {
                default_write_value : all_zero ;
                BisrRegisterAccessOptions (BISR_reg_inst3) {
                    write_value(15:8): 8'b10001101 ;
                }
            }
        }
    }
}

TestStep(read_selected_BISR_reg) {
    MemoryBisr {
        run_mode : bisr_chain_access ;
        Controller(FB_INST1) {
            power_domain_group_labels : PDG_A ;
            BisrChainAccessOptions {
                default_read_value : all_zero ;
                BisrRegisterAccessOptions (BISR_reg_inst3) {
                    read_value(15:8): 8'b10001101 ;
                }
            }
        }
    }
}
```

FuseBoxAccessOptions

Specifies the options used to read and write (or program) fuses to the fuse box.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    Patterns(pattern_name) {
        TestStep(name) {
            MemoryBISR {
                Controller(instance) {
                    FuseBoxAccessOptions {
                        operation : program | read ;
                        read_address(range) : 0 | 1 | X ; //repeatable
                        write_address : range ; //repeatable
                    }
                }
            }
        }
    }
}
```

Description

The FuseBoxAccessOptions wrapper specifies the options used to read and write (program) fuses in the fuse box. Fuse addresses are scanned in using the ScanIn and ScanOut ports of the IJTAG network (which is typically a TAP controller at the chip level). To use the FuseBoxAccessOptions wrapper, you must specify MemoryBISR/run_mode : fuse_box_access.

Arguments

- **operation : program | read ;**

A property that specifies the type of access method the BISR controller executes on the fuse box. When set to read, the BISR controller executes a read operation on the fuse box according to the read_address property setting. When set to program, the BISR controller writes a logic 1 value to the address specified with the write_address property.

- **read_address(range) : 0 | 1 | X ;**

A property that reads the content at the specified fuse box address and compares the content against logic 0 or 1. To disable the compare, set the property to X. The default is to compare all addresses to 0 that correspond to the value of an unprogrammed fuse. The range specifies the address within the fuse box. The range can be a single address, an address range, or a comma-separated list of the two formats. All addresses must be an integer varying from 0 to number_of_fuses as defined by the [AdvancedOptions/number_of_fuses_for_repair](#) property in the [DftSpecification](#). Its value is either explicitly defined or calculated by default to be (2address_bits - 1) where address_bits is the width of the address port specified in the FuseBoxInterface wrapper. The “max_address” and “max_repair_address” strings can be used to specify a range. The “max_address” string represents the last address of the fuse box whereas the “max_repair_address” string represents the last address dedicated to memory repair which is determined by the value of number_of_fuses_for_repair defined in the [AdvancedOptions/FuseBoxOptions](#) wrapper or calculated by default to be the same as

number_of_fuses. For example, the range “max_address: 0” selects all bits of the fuse box whereas “max_repair_address: 0” selects the lower portion of the fuse box dedicated to memory repair. The read_address property can be repeated several times within the FuseBoxAccessOptions wrapper. If an address is specified in more than one property, the last specification will prevail. To use this property, the operation property must be set to read.

- write_address : *range* ;

A property that writes logic 1 into the specified fuse box address which is an integer. The range can be a single address, an address range, or a comma-separated list of the two formats. All addresses must be an integer varying from 0 to number_of_fuses as defined by the [AdvancedOptions/number_of_fuses_for_repair](#) property in the [DftSpecification](#). Its value is either explicitly defined or calculated by default to be (2address_bits -1) where address_bits is the width of the address port specified in the FuseBoxInterface wrapper. The “max_address” and “max_repair_address” strings can be used to specify a range. The “max_address” string represents the last address of the fuse box whereas the “max_repair_address” string represents the last address dedicated to memory repair which is determined by the value of number_of_fuses_for_repair defined in the [AdvancedOptions/FuseBoxOptions](#) wrapper or calculated by default to be the same as number_of_fuses. For example, the range “max_address: 0” selects all bits of the fuse box whereas “max_repair_address: 0” selects the lower portion of the fuse box dedicated to memory repair. The write_address property can be repeated several times within the FuseBoxAccessOptions wrapper. To use this property, the operation property must be set to program.

Examples

The following example has three TestStep wrappers. The first one verifies that the fuse box has never been written before (that is, all fuses have a value of 0). The second one writes 1 in a few selected locations. The third TestStep reads back a portion of the fuse box and verifies that the locations written in the second TestStep contain the value 1.

```
TestStep(read_all0s) {
    MemoryBisr {
        run_mode : fuse_box_access ;
        Controller(FB_INST1) {
            FuseBoxAccessOptions {
                // Not necessary to specify read_address.
                // Default is to read all addresses and compare to 0.
                // Equivalent to specifying read_address(max_address:0):0 ;
                operation : read ;
            }
        }
    }
}
TestStep(write_selected_locations) {
    MemoryBisr {
        run_mode : fuse_box_access ;
        Controller(FB_INST1) {
            FuseBoxAccessOptions {
                operation : program ;
                // Write a 1 to 7 locations
                // 5:9 is equivalent to 5, 6, 7, 8, 9
                write_address : 2, 5:9, 12 ;
            }
        }
    }
}
TestStep(verify_first_16_locations) {
    MemoryBisr {
        run_mode : fuse_box_access ;
        Controller(FB_INST1) {
            FuseBoxAccessOptions {
                operation : read ;
                // Restrict the address range to the first 16 addresses
                // Set the expected value to 0
                read_address(15:0) : 0 ;
                // Override the expected value for the locations written in
                // previous step
                read_address(2, 5:9, 12) : 1 ;
            }
        }
    }
}
```

MemoryBist

Specifies the use of MemoryBist in the current TestStep.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    Patterns(pattern_name) {
        TestStep(name) {
            MemoryBist {
                run_mode : mode ;
                parallel_retention_time : time | off ;
                reduced_address_count : on | off ;
                AdvancedOptions {
                    retention_test_phase : all_phases | start_to_pause |
                                            pause_to_pause | pause_to_end ;
                    memory_reset : on | off ;
                    preserve_bist_inputs : on | off ;
                }
                DiagnosisOptions {
                    extract_diagnosis_data : on | off | auto ;
                    preserve_fuse_register_values : on | off ;
                }
                Controller(instance) {
                }
            }
        }
    }
}
```

Description

A wrapper that specifies the use of MemoryBist in the current TestStep.

This wrapper can be specified once for each TestStep wrapper. The MemoryBist specification consists of one AdvancedOptions wrapper, one DiagnosisOptions wrapper, and one or more Controller wrapper(s). These three wrappers can be specified in any order.

The repeatable Controller wrapper is used to define the inclusion of the given controller instance in the current TestStep, and allows specifying additional options that are specific to the instance. The properties specified outside the Controller wrapper apply to all Controllers.

The AdvancedOptions wrapper contains advanced options influencing how memory BIST is carried out. The DiagnosisOptions wrapper defines options related to memory BIST diagnosis.

Arguments

- `run_mode : mode ;`

A property that specifies the run mode to use with the controllers. The valid modes and their meaning are:

<u>hw_default</u>	Specifies that the memory BIST controllers use the default (hardcoded) settings. This run mode requires the least amount of configuration for the memory BIST controllers to launch tests.
<code>run_time_prog</code>	Specifies that the memory BIST controllers run the BIST test using the scanned-in settings prior to test execution. Individual memory BIST controllers are first accessed and configured before they all execute tests in parallel.
<code>increment_failure_limit</code>	Automatically advances the optional failure limit counter. This mode is useful for creating Stop-On-Error test patterns for bitmap applications.
<code>check_repair_needed</code>	Specifies that the repair analysis status registers need to be examined after BIST completes. The status registers report the pair status of the memories with built-in redundancy. This mode requires at least one tested memory to have repair analysis features defined in its Memory library description. This is indicated by the presence of a RedundancyAnalysis wrapper. See “ Tessent Core Description ” on page 3755.

- `parallel_retention_time : time | off ;`

A property that specifies the retention pause between algorithm sub-phases when performing parallel static retention testing. The time value is a real number followed by the unit without a space in between. Valid time units are s, ms, us, ns, and ps. The default time unit is ns. Specifying a time value for a controller testing only ROM will result in an error.

- `reduced_address_count : on | off ;`

A property that enables the memory BIST controller to be run on the four corners of the common memory address space. This property is useful for checking the proper functionality of the BIST controller without having to simulate the test of the entire memory space. Static timing analysis is required in the full chip context to verify that the timing between the controllers and the memories is valid. Note that the full address space should be simulated on the assembly module before it is merged into the chip.

This property supports the `hw_default` or `run_time_prog` run modes.

Patterns created for signoff usage with the [create_patterns_specification](#) command set the `reduced_address_count` property to on for memory BIST controllers with RAMs only. Memory BIST controllers with ROMs will ignore this property and execute a full address count.

When this property is enabled and the memory BIST controller contains a step with multiple memories, the controller runs all algorithm phases of the test on just the following four addresses:

- RowMin, ColMin
- RowMax, ColMin
- RowMin, ColMax
- RowMax, ColMax

If the memory has only row address bits, the reduced address range would be these two locations:

- RowMin
- RowMax
- AdvancedOptions/retention_test_phase : all_phases | start_to_pause | pause_to_pause | pause_to_end ;

A property that specifies whether the memory BIST controller applies the entire selected library algorithm or only a sub-phase of it. Specifying a phase value other than all_phases for a controller only testing ROM will result in an error.

This property is typically not used because specifying a time value with the parallel_retention_time property described above automates the sequential execution of the start_to_pause, pause_to_pause, and pause_to_end phases with the specified pause time inserted between them. This retention_test_phase enables you to define the step explicitly into three TestSteps where each TestStep runs a different phase. Valid values are as follows:

all_phases	Indicates that the controller applies the entire selected algorithm.
start_to_pause	Indicates that the controller applies only the portion of the selected algorithm that ends at the first static retention test pause. This value corresponds to the application of the checkerboard pattern.
pause_to_pause	Indicates that the controller applies only the portion of the selected algorithm that runs from the first static retention pause to the second static retention test pause. This value corresponds to the application of the inverse checkerboard pattern.
pause_to_end	Indicates that the controller applies only the portion of the selected algorithm that runs from the second static retention pause and onward.

- AdvancedOptions/memory_reset : on | off ;
- A property that instructs memory BIST controllers to only clear the memories and to skip the remaining phases of the library algorithm. The controllers clear memories by writing a value of 0 to all memory locations. You can only set this property to on when the algorithms used are limited to the following: SMarch, SMarchCHKB, SMarchCHKBci, SMarchCHKBcil, or SMarchCHKBvcd. Specifying an on value when other algorithms are used results in an error. Specifying an off value causes the full algorithm to be executed. The

memories are populated with zeros at the end of the algorithm since the last phase executed writes a value of 0 to all memory locations.

- AdvancedOptions/preserve_bist_inputs : on | off ;

A property that specifies that the memory interface multiplexers will continue to select the BIST inputs during and after the test has finished. Memories are under functional control except for the memories undergoing test by the test algorithm. When set to on, the memories will remain under BIST control for the duration of the TestStep until the property is set to off in a subsequent TestStep. One application of this property is to maintain the BIST inputs to the memory between pattern TestSteps. Another application of this property is to allow the memory to be refreshed by the controller upon completion of all algorithms in the test.

- DiagnosisOptions/extract_diagnosis_data : on | off | auto ;

A property that enables the sampling of internal registers of the memory BIST controller after the BIST run is completed. This property is useful when the Stop-On-Nth-Error diagnosis feature is enabled using failure_limit. The internal register values are only meaningful if the controller has stopped at the requested failure number and the DONE status signal is 0. Furthermore, the internal register values require post-processing to provide diagnostic information on the detected failures. The default value of auto resolves to on when failure_limit is not off, otherwise it resolves to off.

- DiagnosisOptions/preserve_fuse_register_values : on | off ;

A property that specifies if the repair analysis registers preserve their values from a previous test step. This inhibits the loading of the BISR register values into the repair analysis registers when a new test step begins. This property supports the hw_default or run_time_prog run modes.

Examples

The following example runs a memory BIST in reduced address space.

```
PatternsSpecification(top,rtl,signoff) {
    Patterns(MemoryBist_P1) {
        tester_period : 100ns ;
        TestStep(mem_test) {
            MemoryBist {
                run_mode : run_time_prog ;
                reduced_address_count : on ;
                Controller(core_inst1_top_rtl_tessent_mbist_c1_controller_inst) {
                    ...
                }
            }
        }
    }
}
```

Controller

Specifies the inclusion of a MemoryBIST controller instance in the TestStep.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    Patterns(pattern_name) {
        TestStep(name) {
            MemoryBist {
                Controller(instance) {
                    parallel_retention_group : integer ;
                    AlgorithmSetupOverrides {
                    }
                    AdvancedOptions {
                    }
                    RepairOptions {
                    }
                    DiagnosisOptions {
                    }
                    MemoryInterface(memory_id) {
                    }
                    DramOptions {
                    }
                }
            }
        }
    }
}
```

Description

A wrapper that specifies the inclusion of a MemoryBIST controller instance in the TestStep.

This wrapper is repeated for each controller instance that is to be run in this TestStep. All MemoryBIST controller instances are set up serially but run in parallel.

Arguments

- *instance*

A string that specifies the ICL instance name of the MemoryBIST controller. The list of available MemoryBIST controller instances can be found using this command:

```
get_icl_instances -filter
{tessent_instrument_type==mentor::memory_bist &&
tessent_instrument_subtype==controller}
```

The [create_patterns_specification](#) command automates the creation of the Controller wrapper for each instance in the design.

- *parallel_retention_group : integer ;*

A property that specifies the group number associated with the controller. The group number is a numeric label for the controller group. Each controller group consists of all controllers with the same parallel_retention_group property value. When performing a parallel static retention test on controller groups, the controller groups are run sequentially

so as to minimize the peak power requirement while maintaining the ability to bring all controllers from all groups to the pause state and perform a single retention pause and, optionally, a single voltage bump for all memories in the chip.

The controller group execution order is determined from the order of appearance of the group numbers. The following usage conditions apply:

- This property is meaningful only if the parallel_retention_time property in the MemoryBist wrapper specifies a time greater than zero.
- When performing a parallel static retention test on controller groups, all three algorithm sub-phases (start_to_pause, pause_to_pause, and pause_to_end) are applied. In this case, the AdvancedOptions/retention_test_phase property in the MemoryBist wrapper is ignored.

Examples

The following example assigns the first MemoryBIST controller to a group number 0. It will thus be enabled first for a retention test of 1 second:

```
TestStep(mem_test) {
    MemoryBist {
        run_mode : hw_default ;
        parallel_retention_time : 1s ;
        Controller(core_inst1_top_rtl_tessent_mbist_c1_controller_inst) {
            parallel_retention_group : 0 ;
            (...)
        }
    }
}
```

AlgorithmSetupOverrides

The AlgorithmSetupOverrides wrapper groups the DataGenerator and AddressGenerator wrappers, which define the initial values of the address and data pattern prior to the execution of the test algorithm.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    Patterns(pattern_name) {
        TestStep(name) {
            MemoryBist {
                Controller(instance) {
                    AlgorithmSetupOverrides {
                        load_counter_a_start_count : int ; //defalut: 0
                        AddressGenerator {
                            AddressRegisterA | AddressRegisterB {
                                load_bank_address : binary_address | auto ;
                                load_column_address : binary_address | auto ;
                                load_row_address : binary_address | auto ;
                            }
                        }
                        DataGenerator {
                            load_write_data : binary_data | auto ;
                            load_expect_data : binary_data | auto ;
                            invert_data_with_row_bit : r[x] | none ;
                            invert_data_with_column_bit : c[x] | none ;
                        }
                    }
                }
            }
        }
    }
}
```

Description

The AlgorithmSetupOverrides wrapper groups the DataGenerator and AddressGenerator wrappers, which require initialization prior to execution of the algorithm microprogram. The specified values override the values defined in the selected algorithm.

Using the AlgorithmSetupOverrides wrapper requires selecting an algorithm using the `apply_algorithm` property inside the `MemoryBist/Controller/AdvancedOptions` wrapper of the `PatternsSpecification`. Additional usage conditions apply to the `AddressGenerator` wrapper. Changing the initial value of any address register or of `CounterA` require setting the `AdvancedOptions/functional_debug_mode` property to on.

For more information, see the “[Functional Debug Memory Access](#)” appendix in *Tessent MemoryBIST User’s Manual for Use with Tessent Shell*.

Arguments

- `load_counter_a_start_count : int ;`
An optional property that specifies the startcount or starting count value for the CounterA general purpose module. The default value is “0”. The integer specified for `load_counter_a_start_count` must be in the range [0:2ⁿ-1], where *n* is the number of bits in CounterA, specified by the `counter_a_bits` property in the DftSpecification/MemoryBist/Controller/[AlgorithmResourceOptions](#) wrapper.
- `AddressGenerator/AddressRegisterA | B/load_bank_address : binary_address | auto ;`
An optional property that specifies a binary value to be loaded into the *BankAddress* for the named AddressRegisterA or AddressRegisterB. The value loaded into the *BankAddress* is the initial value of the bank address prior to execution of the microprogram. The value set with this property overrides the `load_bank_address` value defined in the memory library [Algorithm](#) wrapper for the named AddressRegisterA or AddressRegisterB. The width of *binary_address* must be equivalent to the number of bank address bits specified in the Core/Memory/[AddressCounter](#) wrapper of the memory library file. The property defaults to a *binary_address* equivalent to the lowest starting bank address of all memories tested in the controller step.
- `AddressGenerator/AddressRegisterA | B/load_column_address : binary_address | auto ;`
An optional property that specifies a binary value to be loaded into the *ColumnAddress* for the named AddressRegisterA or AddressRegisterB. The value loaded into the *ColumnAddress* is the initial value of the column address prior to execution of the microprogram. The value set with this property overrides the `load_column_address` value defined in the memory library [Algorithm](#) wrapper for the named AddressRegisterA or AddressRegisterB. The width of *binary_address* must be equivalent to the number of column address bits specified in the Core/Memory/[AddressCounter](#) wrapper of the memory library file. The property defaults to a *binary_address* equivalent to the lowest starting column address of all memories tested in the controller step.
- `AddressGenerator/AddressRegisterA | B/load_row_address : binary_address | auto ;`
An optional property that specifies a binary value to be loaded into the *RowAddress* for the named AddressRegisterA or AddressRegisterB. The value loaded into the *RowAddress* is the initial value of the row address prior to execution of the microprogram. The value set with this property overrides the `load_row_address` value defined in the memory library [Algorithm](#) wrapper for the named AddressRegisterA or AddressRegisterB. The width of *binary_address* must be equivalent to the number of row address bits specified in the Core/Memory/[AddressCounter](#) wrapper of the memory library file. The property defaults to a *binary_address* equivalent to the lowest starting row address of all memories tested in the controller step.
- `DataGenerator/load_write_data : binary_data | auto ;`
An optional property that specifies a binary value to load into the *WriteData* register. The value loaded into the *WriteData* register is the initial value of the write data prior to

execution of the microprogram. The value loaded with this property overrides the `load_write_data` value defined in the memory library [DataGenerator](#) wrapper.

- `DataGenerator/load_expect_data : binary_data | auto ;`

An optional property that specifies a binary value to load into the *ExpectData* register. The value loaded into the *ExpectData* register is the initial value of the expect data prior to execution of the microprogram. The value loaded with this property overrides the `load_expect_data` value defined in the memory library [DataGenerator](#) wrapper.

- `DataGenerator/invert_data_with_row_bit : r[x] | none ;`

An optional property that enables you to specify a row address bit that will invert the applied write and expect data registers. The applied write and expect data registers are inverted when the specified row address bit is a “1”, and not inverted when the row address bit is a “0”. The specified value overrides the value defined in the selected algorithm. The default value of “none” specifies that no row bit is selected to invert the write and expect data registers. The specified `r[x]` index must select a valid row address bit where `x` is in the range of “0” to the number of row address bits, minus one. The number of row address bits is specified in the Core/Memory/[AddressCounter](#) wrapper of the memory library file.

- `DataGenerator/invert_data_with_column_bit : c[x] | none ;`

An optional property that enables you to specify a column address bit that will invert the applied write and expect data registers. The applied write and expect data registers are inverted when the specified column address bit is a “1”, and not inverted when the column address bit is a “0”. The specified value overrides the value defined in the selected algorithm. The default value of “none” specifies that no column bit is selected to invert the write and expect data registers. The specified `c[x]` index must select a valid column address bit where `x` is in the range of “0” to the number of column address bits, minus one. The number of column address bits is specified in the Core/Memory/[AddressCounter](#) wrapper of the memory library file.

Examples

For examples and further information, see the “[Functional Debug Memory Access](#)” appendix in *Tessent MemoryBIST User’s Manual for Use with Tessent Shell*.

AdvancedOptions

Specifies advanced test options for the selected memory BIST controller instance.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    Patterns(pattern_name) {
        TestStep(name) {
            MemoryBist {
                Controller(instance) {
                    AdvancedOptions {
                        apply_algorithm : algo_name ;
                        apply_operation_set : opset_name ;
                        enable_memory_list : memory_id, ... ;
                        freeze_step : off | integer ;
                        freeze_test_port : off | integer ;
                        functional_debug_mode : on | off ;
                        test_time_multiplier : real ;
                        test_execution_cycles : integer | auto ;
                        MemoryClusterOptions {
                            configuration_data(interface_id) : binary | auto;
                        }
                    }
                }
            }
        }
    }
}
```

Description

A wrapper that specifies advanced test options for the selected memory BIST controller instance.

The AdvancedOptions wrapper includes the MemoryClusterOptions wrapper which provides additional options specific to Shared Bus memory clusters.

Arguments

- `apply_algorithm : algo_name ;`

A property that selects a test algorithm to apply to one or more memory BIST controller steps. The specified algorithm overrides the default algorithm associated with the controller step.

- The algorithm name must match either a Mentor Graphics library built-in algorithm name or a user-defined algorithm name that was built into the memory BIST controller in the DFT insertion phase. For the soft-programmable controller, the algorithm name may also match a user-defined algorithm specified in the [MemoryOperationsSpecification](#) that was loaded prior to pattern generation.
- This property requires setting the MemoryBist/run_mode property to run_time_prog.

- `apply_operation_set : opset_name ;`

A property that selects a hard-coded operation set to apply to one or more memory BIST controller steps. The specified operation set overrides the default operation set associated with the controller step.

- The operation set name must match either a Mentor Graphics library built-in operation set name or a user-defined operation set name that was built into the memory BIST controller in the DFT insertion phase.
- This property requires setting the MemoryBist/run_mode property to run_time_prog.

- `enable_memory_list : memory_id, ... ;`

An optional property that specifies one or more memories to enable during parallel testing within a controller step. Selection of more than one memory must be specified as a comma separated list of memory ID's. If the property is not specified, all memories are enabled. A warning will be issued if all memories are not enabled for testing in the current pattern. The memory_id is a valid memory ID specified by the Step/MemoryInterface wrapper within the MemoryBist wrapper in the [DftSpecification](#) and must belong to the BIST controller step specified by the freeze_step property. The MemoryBist/run_mode property must be set to run_time_prog.

- `freeze_step : off | integer ;`

A property that specifies for the memory BIST controller to run only a single [Step](#) defined in the [DftSpecification](#). The freeze_step property enables you to diagnose specific failures. Controller steps are numbered sequentially starting with 0. To specify a single controller step, you must set the MemoryBist/run_mode property to run_time_prog. When the freeze_step property is off, the memory BIST controller tests across all steps implemented in the memory BIST controller, and the results are accumulated across the entire BIST run.

- `freeze_test_port : off | integer ;`

A property that specifies a test port on which to freeze the memory BIST controller so that you can diagnose specific failures. At least one memory in the [TestStep](#) wrapper much have multiple test ports. To use this property, you must set the MemoryBist/run_mode property to run_time_prog. When the freeze_test_port property is off, the memory BIST controller executes the steps for all test port combinations implemented in the [MemoryBist](#) controller in the [DftSpecification](#), and the results are accumulated across the entire BIST run.

- `functional_debug_mode : on | off ;`

An optional property that enables a mode on the Tessent MemoryBIST controller to allow functional system debug. The functional_debug_mode property in the DftSpecification/ MemoryBist/Controller/[AdvancedOptions](#) wrapper must have been set to “on” to create necessary hardware for this property. For more information, see the “[Functional Debug Memory Access](#)” appendix in *Tessent MemoryBIST User’s Manual for Use with Tessent Shell*.

- `test_time_multiplier : real ;`

A property that specifies a multiplier to extend or shorten the memory BIST run time. The final run time is equal to the original test time (as calculated by Tesson Shell) multiplied by the `test_time_multiplier` factor. The default is 1.

This property is typically used when the test clock runs slower than expected by BIST. As a result, the memory BIST controller may not have completed its test within the allocated time when polled by the ATE. Specifying a value greater than 1 thus extends the computed test time; this is usually as a temporary measure (until the clock periods described in the [Patterns/ClockPeriods](#) wrapper is used).

- `test_execution_cycles : integer | auto ;`

A property that specifies the number of clock cycles required to execute the algorithm. A setting of `auto` means that the pattern generation tool automatically computes the number of test execution cycles. In most cases this is sufficient; however, this property gives you the option to specify an absolute number of clock cycles. This accommodates extreme cases where the automatically-generated number is not accurate. Note that, in general, correcting the calculated test time with the `test_time_multiplier` property is preferable because it is less error-prone.

- `MemoryClusterOptions/configuration_data(interface_id) : binary | auto ;`

A repeatable wrapper that specifies options related to Shared Bus memory clusters.

The `MemoryClusterOptions` wrapper is used in the `MemoryBist/Controller` wrapper.

A repeatable property that specifies a binary value to be applied to the interface port identified by `interface_id`. The binary value follows Verilog syntax (for example, `3'b101`). If specified, it overrides the default ConfigurationData value from the memory cluster library file (which corresponds to the default “`auto`” value).

The value specified for this property is used for all controller steps executed in the `TestStep`. If the value is not compatible with all steps, the `AdvancedOptions/freeze_step` must also be specified.

Examples

Example 1

The following example illustrates the use of the `apply_operation_set` property to override the operation set to syncWR. This new operation set is applied to all [Steps](#). The `apply_algorithm` property is not used which means the default algorithm to each Controller/Step is used.

```
PatternsSpecification(top,rtl,signoff) {
    Patterns(MemoryBist_P1) {
        tester_period : 100ns ;
        TestStep(mem_test) {
            MemoryBist {
                run_mode : run_time_prog ;
                Controller(core_inst1_top_rtl_tessent_mbist_c1_controller_inst) {
                    AdvancedOptions {
                        apply_operation_set : SyncWR ;
                    }
                }
            }
        }
    }
}
```

Example 2

The following example illustrates how to specify multiple specific memories for parallel testing within a controller through the enable_memory_list property.

Two memories, M1 and M3, are specified as a Tcl list for set_config_value on the enable_memory_list property:

```
SETUP> set_config_value PatternsSpecification(top,rtl,signoff) /
    Patterns(P1)/TestStep(run)/MemoryBist/Controller(c1)/AdvancedOptions/
    enable_memory_list [list M1 M3]
```

The specification can be examined with report_config_data on the AdvancedOptions wrapper:

```
SETUP> report_config_data PatternsSpecification(dashboard,rtl,signoff) /
    Patterns(P1)/TestStep(run)/MemoryBist/Controller(c1)/AdvancedOptions

    AdvancedOptions {
        enable_memory_list : M1, M3;
    }
SETUP>
```

The specification properties for enable_memory_list can be retrieved as a Tcl list with the get_config_data command:

```
SETUP> get_config_value PatternsSpecification(dashboard,rtl,signoff) /
    Patterns(P1)/TestStep(run)/MemoryBist/Controller(c1)/AdvancedOptions/
    enable_memory_list
M1 M3
SETUP>
```

DiagnosisOptions

Provides diagnosis-related options and properties.

Usage

```
PatternsSpecification(design_name,design_id, pattern_id) {
    Patterns(pattern_name) {
        TestStep(name) {
            MemoryBist {
                Controller(instance) {
                    DiagnosisOptions {
                        compare_go : on | off ;
                        compare_go_id : on | off ;
                        compare_memory_go : on | off ;
                        compare_misr : on | off ;
                        comparator_id_select : integer | all | none ;
                        StopOnErrorOptions {
                            failure_limit : integer | auto_increment | off ;
                            data_compare_time_slots : all | even | odd ;
                        }
                    }
                }
            }
        }
    }
}
```

Description

A wrapper that provides diagnosis-related options and properties.

Arguments

- compare_go : on | off ;

A property that specifies that the pass/fail (GO) controller port is checked at the end of the test. This operation provides the composite pass/fail results from all comparators in the controller. You need to disable the compare on the global pass/fail (GO) signal for some of the patterns needed in the memory self repair flow as documented in the [Tessent MemoryBIST User's Manual](#). You also can use this for legacy controllers containing incorrect ROM signatures in the hardware. When you set this property to on, you typically set the compare_go_id property and the compare_misr property to on.

- compare_go_id : on | off ;

A property that specifies that the compare status registers (GO_ID bits) are scanned and examined at the end of the test. This operation identifies which comparator failed but not necessarily the step in which it failed. This property is meaningful when at least one RAM is tested by the memory BIST controller. It is ignored on controllers testing only memories of type ROM.

Note

 If you are not using the automation provided by Tessent SiliconInsight, you can find out which memory instance failed when the [Step/comparator_location](#) property was set to `shared_in_controller` in the [DftSpecification](#) by running the test with a `freeze_step` property set for each of the steps in the memory BIST configuration file.

When the [RepairOptions/check_repair_status](#) property is set to `non_repairable`, the behavior of the `compare_go_id` property is disabled for repairable memories with local comparators. The GO_ID registers for non-repairable memories or repairable memories with shared comparators are always sampled when `compare_go_id` is set to `on`.

- `compare_memory_go : on | off ;`

A property that enables examining the pass/fail status register of the individual memories at the end of the pattern execution. The per-memory status register must be present in the memory BIST controller hardware in order to use this property. Refer to the [DftSpecification DiagnosisOptions/go_status](#) property description for information on incorporating the per-memory status register.

- `compare_misr : on | off ;`

A property that specifies the ROM MISRs are to be examined at the end of the test. This property is ignored when the controller is testing only memories of type SRAM or DRAM. By default, the MISR signature stored in the TSDB will be used to compare the MISR register content. You may specify a different value using the [MemoryInterface/expected_rom_signature](#) property.

- `comparator_id_select : all | none | integer ;`

A property that specifies the individual status of the comparators in the controller to be routed to the compare status controller port. Valid values are as follows:

<code>all</code>	Selects the global controller comparator status signal.
<code>none</code>	Selects a constant logical 1, which implies the comparison result will be forced to consistently pass.
<code>integer</code>	A value between 1 and the number of shared comparators implemented in the controller. The number of shared comparators equals the maximum memory word size of all memories with the <code>Step/comparator_location</code> property set to <code>shared_in_controller</code> in the DftSpecification . The value of 1 corresponds to bit 0 of the memory data word.

These usage conditions apply:

- This property is only meaningful when the controller was generated with the [DiagnosisOptions/comparator_selection_mux](#) property set to `on` in the [DftSpecification](#).

- StopOnErrorOptions/failure_limit : *integer* | auto_increment | off ;

A property that enables Stop-On-Error (SOE) and specifies the number of failures that the memory BIST controller detects before stopping and capturing all relevant information.

This property has two usage scenarios. To learn more about how to use this property, refer to the “Stop-On-Nth-Error Approach” section of the “Tessent MemoryBIST Diagnosis” chapter in the [Tessent MemoryBIST User’s Manual](#). Valid values are:

<i>integer</i>	Specifies the number of failures that the controller detects before stopping and capturing. The value is loaded in the SOE counter and, if present, the failure limit counter.
auto_increment	Specifies that the stop-on-error counter is loaded with the value of the failure limit counter as it was set in a previous step, where run_mode was set to increment_failure_limit.
off	

These usage conditions apply:

- The DftSpecification/MemoryBist property [DiagnosisOptions/StopOnErrorOptions/failure_limit](#) was not set to off.
- When you set the failure_limit property to a non-zero value, you should set [DiagnosisOptions/extract_diagnosis_data](#) to on within the MemoryBist wrapper.

Note

 When the failure limit is reached and the test stops, it is normal for the Done bit to fail because the test did not successfully complete (it aborted at some point).

To run diagnosis on a single memory:

- Set the MemoryBist/[AdvancedOptions/freeze_step](#) property to the step number that corresponds to the memory to diagnose.
- Use the MemoryBist/[AdvancedOptions/enable_memory_list](#) property to select a single memory. It requires that the [AdvancedOptions/selective_parallel_memory_test](#) property in the DftSpecification/MemoryBist wrapper was not set to off.
- StopOnErrorOptions/data_compare_time_slots : all | even | odd ;

A property that selects the clock cycles in which StrobeDataOut is enabled during a read operation. This property should be used when running Stop-on-Nth-Error diagnosis on memories that have StrobeDataOut enabled on consecutive clock cycles during a read operation. The Stop-On-Error diagnosis mode needs two clock cycles upon detecting an error before freezing the state of the memory BIST controller and memory interfaces. This property guarantees that the state of the controller is properly preserved when using

operation sets containing a read operation with consecutive StrobeDataOut signals. Valid values are:

<u>all</u>	Enables StrobeDataOut on all clock cycles during Stop-On-Error Diagnosis mode.
even	Enables StrobeDataOut only on the odd clock cycles during Stop-On-Error Diagnosis mode.
odd	Enables StrobeDataOut only on the even clock cycles during Stop-On-Error Diagnosis mode.

To use this option, the failure_limit property value must be a positive integer or set to auto_increment.

Examples

The following example extracts diagnosis data from a memory, m11, tested in the third controller step (specifically, step 2). Since the memory is normally tested concurrently, two other memories, m12 and m13, are disabled when diagnosing the memory of interest:

```
PatternsSpecification(top,rtl,signoff) {
    Patterns(MemoryBist_P1) {
        tester_period : 100ns ;
        TestStep(mem_test) {
            MemoryBist {
                run_mode : run_time_prog;
                reduced_address_count : off ;
                DiagnosisOptions {
                    extract_diagnosis_data : on ;
                }
                Controller(core_inst1_top_rtl_tessent_mbist_c1_controller_inst) {
                    AdvancedOptions {
                        freeze_step : 2 ;
                        enable_memory_list : m11 ;
                    }
                    DiagnosisOptions {
                        StopOnErrorHandler {
                            failure_limit : auto_increment ;
                        }
                    }
                }
            }
        }
    }
}
```

RepairOptions

Provides repair-related options and properties.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    Patterns(pattern_name) {
        TestStep(name) {
            MemoryBist {
                Controller(instance) {
                    RepairOptions {
                        check_repair_status      : non_repairable | on | off ;
                        extract_repair_fuse_map : on | off ;
                        spare_element_priority : row | column ;
                    }
                }
            }
        }
    }
}
```

Description

The RepairOptions wrapper specifies what to shift out and monitor with repairable memories, as well as the spare allocation method to use. For Memory wrapper details, see “[Tessent Core Description](#)” on page 3755.

Arguments

- RepairOptions/check_repair_status : non_repairable | on | off ;

A property that specifies that the repair analysis status registers are examined after the BIST run is completed. The status registers identify whether the memories with built-in redundancy require no repair, is repairable or is unrepairable. Valid values are:

on	Specifies that the repair analysis status registers are sampled and compared against the zero (0) value.
<u>off</u>	Specifies that the repair analysis status registers are not sampled.
non_repairable	Specifies that only the non-repairable flag of the status register is sampled.

At least one memory tested by the controller must have repair analysis defined in its Memory library description. This feature is useful for separating the bad or unrepairable devices from the good or repairable devices during manufacturing test. For further details on repair status, refer to the “[BIRA Repair Status Bits Checking](#)” topic in the *Tessent MemoryBIST User’s Manual For Use with Tessent Shell* manual.

- RepairOptions/extract_repair_fuse_map : on | off ;

A property that specifies that the repair analysis fuse registers are examined after the BIST run is completed. The fuse registers contain the repair information for memories with

built-in redundancy. When set to on, the repair analysis fuse registers are sampled and compared against the zero (0) value. Note that at least one memory tested by the controller must have repair analysis defined in its Memory library description. When set to off, the repair analysis fuse registers are not sampled.

Note

 The content of the fuse registers are lost after performing this operation. This option should be set to “off” if you plan to perform a BIRA to BISR transfer.

- RepairOptions/spare_element_priority : column | row ;

A property that specifies the type of spare element to be allocated first upon failures. This is used only for memories with redundant row and column elements. To find a repair solution for a faulty memory initially declared as unrepairable, try changing the repair strategy by selecting a different spare_element_priority setting. Valid values are:

column	<p>Specifies that all single-bit errors are repaired by redundant column or IO elements; multi-bit errors are automatically repaired by spare row elements. If the number of faults exceeds the number of redundant columns or IO elements, the remaining redundant row elements are allocated for these faults. This is the most flexible solution because it automatically allocates redundant row elements for multi-bit failures while allocating redundant column or IO elements for single-bit failures.</p> <p>A redundant column or IO element cannot repair a multi-bit failure. If only a redundant column or IO element is available when a multi-bit error is detected, the repair status will be unrepairable.</p>
row	<p>Specifies that redundant rows are allocated for all errors (single-bit and multi-bit). The redundant column/IO elements are only allocated for the remaining faults after all redundant rows are allocated.</p>

Examples

The following example extracts the repair status and repair solution from all repairable memories.

```
PatternsSpecification(top,rtl,signoff) {
    Patterns(MemoryBist_P1) {
        tester_period : 100ns ;
        TestStep(mem_test) {
            MemoryBist {
                run_mode : run_time_prog ;
                Controller(core_inst1_top_rtl_tessent_mbist_c1_controller_inst) {
                    RepairOptions {
                        check_repair_status : on ;
                        extract_repair_fuse_map : on ;
                    }
                }
            }
        }
    }
}
```

MemoryInterface

Specifies test options for the memory associated with the selected memory interface.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    Patterns(pattern_name) {
        TestStep(name) {
            MemoryBist {
                Controller(instance) {
                    MemoryInterface(memory_id) { //repeatable
                        expected_rom_signature : binary | auto;
                        rom_content_file       : file_name;
                        comparator_id_select   : all | none | integer;
                    }
                }
            }
        }
    }
}
```

Description

A wrapper that specifies memory-specific options.

Arguments

- *memory_id*

A string that identifies a given memory interface. The id is one of the ids defined in the [Step/MemoryInterface](#) and [Step/ReusedMemoryInterface](#) wrappers inside the [DftSpecification](#).

- *expected_rom_signature* : `binary` | `auto` ;

A property that specifies the ROM signature value to be compared to. This property is useful when the ROM content has changed and the ROM signatures were not updated into the [instruments](#) directory in the TSDB (see “[Tessent Shell Data Base \(TSDB\)](#)” on page 3763). A value of “auto” selects the signature calculated from the file referenced by *rom_content_file*. Refer to the *rom_content_file* argument description for more information on how the ROM MISR signature is specified.

- *rom_content_file* : *file_name* ;

A property that specifies a ROM content file from which the MISR signature is calculated. If *expected_rom_signature* is set to “auto”, and the specified file is readable, the [process_patterns_specification](#) command will calculate the MISR signature from the file, and apply the new MISR signature in the simulation test bench or manufacturing test pattern.

When generating manufacturing test patterns, a ROM signatures file, named *design_name_design_id.rom_signatures_manufacturing*, will be stored next to the patterns specification file in the TSDB. The ROM signatures file contains the MISR signatures calculated by the [process_patterns_specification](#) command for each combination of the

ROM instance and its ROM content file. Note that the ROM signatures file is not created when generating simulation test benches.

The ROM signature file may be referenced if the ROM content file is unavailable during subsequent runs to generate manufacturing patterns or to perform diagnosis using Tesson SiliconInsight. The tool can automatically process the ROM signatures file and retrieve the stored MISR signatures to create the manufacturing patterns. Guidance on where the MISR signature source is obtained, given the existence and validity of ROM content and signature files and settings for the `expected_rom_signature` argument, are provided in [Table 10-11](#) below.

Table 10-11. ROM MISR Signature Source

expected_rom_signature Value	rom_content_file Value	ROM signatures file	MISR Signature Source
<i>binary</i>	N/A	N/A	Use <code>expected_rom_signature</code> value
<i>auto</i>	Specified and readable	N/A	Calculate from <code>rom_content_file</code>
<i>auto</i>	Specified and Not Readable	Readable	Retrieve from ROM signatures file. If no match, results in an error.
		Not readable	Results in an error
<i>auto</i>	Not Specified	Readable	Retrieve from ROM signatures file. If no match, use signature calculated from DftSpecification <code>rom_content_file</code> during MBIST insertion.
		Not readable	Use signature calculated from DftSpecification <code>rom_content_file</code> during MBIST insertion.

- `comparator_id_select : all | none | integer ;`

A property that specifies the individual status of the comparators in the memory interface to be routed to the compare status controller port. Valid values are as follows:

<code>all</code>	Selects the interface's global comparator status signal.
<code>none</code>	Selects a constant logical 1, which implies the comparison result will be forced to consistently pass.

<i>integer</i>	A value between 1 and the number of comparators implemented for this memory. The number of comparators equals the memory word size. The value 1 corresponds to bit 0 of the memory data word.
----------------	---

These usage conditions apply:

- This property is only meaningful when the controller was generated with the [DiagnosisOptions/comparator_selection_mux](#) property set to on in the [DftSpecification](#).

Examples

The following example extracts the MISR register of memory m1 after the test and compares the MISR register content against the hex value 24'h010204:

```
PatternsSpecification(top,rtl,signoff) {
    Patterns(MemoryBist_P1) {
        tester_period : 100ns ;
        TestStep(rom_test) {
            MemoryBist {
                run_mode : run_time_prog ;
                Controller(core_inst1_top_rtl_tessent_mbist_c1_controller_inst) {
                    DiagnosisOptions {
                        compare_misr : on ;
                        compare_go   : off ;
                    }
                    MemoryInterface(m1) {
                        expected_rom_signature : 24'h010204 ;
                    }
                }
            }
        }
    }
}
```

DramOptions

Provides DRAM AutoRefresh options and properties.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    Patterns(pattern_name) {
        TestStep(name) {
            MemoryBist {
                Controller(instance) {
                    DramOptions {
                        run_time_refresh_interval : time | off | auto ;
                        idle_time_refresh_interval : time | off | auto ;
                    }
                }
            }
        }
    }
}
```

Description

The DramOptions wrapper enables you to specify the DRAM AutoRefresh properties that are applied during and after algorithm execution. AutoRefresh can be disabled, or enabled with default or user specified durations between consecutive AutoRefresh operations. AutoRefresh is disabled by default.

The run_time_refresh_interval property specifies the duration between AutoRefresh operations during algorithm execution. The idle_time_refresh_interval property specifies the duration between AutoRefresh operations after algorithm test execution is completed.

Arguments

- run_time_refresh_interval : *time* | *off* | *auto* ;

The run_time_refresh_interval property enables you to specify if AutoRefresh operations are to be automatically performed on a DRAM during the execution of the algorithm. Valid values are:

Table 10-12. DramOptions Parameter Values

<i>time</i>	AutoRefresh is enabled and the real number <i>time</i> specifies the duration between AutoRefresh operations. Valid values for specifying the units for <i>time</i> are as follows: <ul style="list-style-type: none"> • <i>s</i> — specifies the refresh interval in seconds. • <i>ms</i> — specifies the refresh interval in milliseconds. • <i>us</i> — specifies the refresh interval in microseconds. • <i>ns</i> — specifies the refresh interval in nanoseconds. • <i>ps</i> — specifies the refresh interval in picoseconds.
<i>off</i>	The AutoRefresh operations are disabled. This is the default configuration.

Table 10-12. DramOptions Parameter Values (cont.)

auto	AutoRefresh is enabled and the default duration is used between AutoRefresh operations. The default duration is the lowest value of all the RetentionTimeMax properties in the Memory library files divided by the maximum number of memory rows.
------	---

- `idle_time_refresh_interval : time | off | auto ;`

The `idle_time_refresh_interval` property enables you to specify if AutoRefresh operations are to be automatically performed on a DRAM after the test execution completes. Valid parameter values are shown in [Table 10-12](#) above.

Examples

The following example shows a `DramOptions` wrapper that specifies an elapsed time of 250 milliseconds between consecutive AutoRefresh operations for both during and after algorithm execution:

```
PatternsSpecification (top,rtl,signoff) {
    Patterns (MemoryBist_P1) {
        tester_period : 100ns ;
        TestStep (mem_test) {
            MemoryBist {
                Controller (core_inst1) {
                    DramOptions {
                        run_time_refresh_interval : 250ms ;
                        idle_time_refresh_interval : 250ms ;
                    }
                }
            }
        }
    }
}
```

ICLNetworkVerify

Specifies the creation of a structural pattern to verify the proper operation of the IJTAG Network.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    Patterns(patterns_name) {
        ICLNetworkVerify(id) {
            verify_scan_path : on | off ;
            verify_internal_data_pins : on | off ;
            VerifyOnlyIclModules {
                name_patterns ; // repeatable
            }
            ExcludeIclModules {
                name_patterns ; // repeatable
            }
            VerifyOnlyIclInstances {
                name_patterns ; // repeatable
            }
            ExcludeIclInstances {
                name_patterns ; // repeatable
            }
            ExcludeIclScanRegisters {
                name_patterns ; // repeatable
            }
            ExcludeIclDataPins {
                name_patterns ; // repeatable
            }
        }
    }
}
```

Description

A wrapper that is used to specify the creation of a structural pattern to verify the proper operation of the IJTAG Network. In simulation, the pattern is useful for identifying mismatches between the ICL and Verilog model views. In manufacturing test, it covers manufacturing defects that can exist in the IJTAG network circuitry.

When the property verify_scan_path is on, the patterns are created by tracing backward from all ScanOutPorts and configuring all ScanMuxes found along the way to exercise all scan configurations. On the first scan load, the predictable captured values of the ScanRegisters are compared and the scan registers are loaded with all 0s with a single 1 closest to ScanIn. The ScanRegister is then parked in pause state and then unloaded to make sure the same data comes out, making sure the ScanRegisters are actually the length documented in the ICL model.

When verify_internal_data_pins is on, the internal DataOutPorts are forced and those values observed using ScanRegisters unloading. The internal DataInPorts are controlled using ScanRegisters loading and the resulting value directly observed on the internal DataInPorts. This feature is only usable in simulation and is useful for finding mismatches between the circuits and their ICL descriptions.

Arguments

- `verify_scan_path : on | off ;`

A property that specifies whether the patterns is to verify the integrity of the scan paths. When the property is on, the patterns are created by tracing backward from all ScanOutPorts and configuring all ScanMuxes found along the way to exercise all scan configurations. On the first scan load, the predictable captured values of the ScanRegisters are compared and the scan registers are loaded with all 0s with a single 1 closest to ScanIn. The ScanRegister is then parked in pause state and then unloaded to make sure the same data comes out, making sure the ScanRegisters are actually the length documented in the ICL model. The opposite pair of patterns are also applied as shown here:

```
load 100000...000 expect captures values described in ICL
load 000000...000 expect 100000...000
load 011111...111 expect captures values described in ICL
load 111111...111 expect 011111...111
```

- `verify_internal_data_pins : on | off ;`

A property that specifies whether the patterns is to verify that data can be properly controlled at the internal DataInPorts and observed from the internal DataOutPorts. When the property is on, the internal DataOutPorts are forced and those values observed using ScanRegisters unloading. The values on internal DataInPorts are controlled using ScanRegisters loading and the resulting value directly observed on the internal DataInPorts. This feature is only usable in simulation and is useful for finding mismatches between the circuits and their ICL descriptions.

Note that ICL Extraction sets the `tessent_design_instance` attribute to the pre-synthesis instance names whenever those names are available. During the creation of the data pin verification patterns, the actual design instance names are ignored. The verification pattern generator only uses the `tessent_design_instance` attribute to obtain the references to the design pins. Consequently, the rtl design files provided to ICL extraction must be used during the simulation of the verification patterns, at least in case that the synthesis modifies the design hierarchy (for example, because of “generate” loops). In order to obtain data pin verification patterns which can be simulated using the synthesized netlist with instance names that have been modified by synthesis, you either have to modify the `tessent_design_instance` attributes accordingly or run ICL Extraction based on the synthesized netlist from the beginning (without providing rtl files to the tool).

- `VerifyOnlyIclModules/name_patterns ;`

A Data wrapper used to specify that the test should only focus on a set of ICL modules. The `name_patterns` are glob patterns matching ICL module names instantiated below the current ICL design.

- `ExcludeIclModules/name_patterns ;`

A Data wrapper used to specify that the test should exclude a set of ICL modules. The `name_patterns` are glob patterns matching ICL module names instantiated below the current ICL design. ICL modules having the `tessent_ignore_during_icl_verification` (see [icl_module](#)) attribute set to on are automatically excluded. Use this attribute on ICL

modules which are not truly IJTAG compliant and cannot pass the structural test performed in this test. One such example is the Tesson memory BIST controller. Because of its asynchronous interface, its BIST_CLOCK must be toggling at least 4 time faster than TCK to enable proper shift operation. This dependency on the ClockPort is not documented in ICL such that ICLNetworkVerify does not know to enable the source of the clock port. Such modules are tested as part of the memory BIST operations. They are also tested during scan test as the memory BIST controllers are scan testable.

- VerifyOnlyIclInstances/*name_patterns* ;

A Data wrapper used to specify that the test should only be performed on set of ICL instances. The *name_patterns* are glob patterns matching ICL instances found below the current ICL design.

- ExcludeIclInstances/*name_patterns* ;

A Data wrapper used to specify that the test should exclude a set of ICL instances. The *name_patterns* are glob patterns matching ICL instances found below the current ICL design. ICL instances having the tessent_ignore_during_icl_verification attribute set to on are automatically excluded.

- ExcludeIclScanRegisters/*name_patterns* ;

A Data wrapper used to specify that the test should exclude a set of ICL Scan Register. The *name_patterns* are glob patterns matching ICL instances found below the current ICL design. ICL Scan Registers having the tessent_ignore_during_icl_verification attribute set to on are automatically excluded. This wrapper is only used when verify_scan_path is set to on.

- ExcludeIclDataPins/*name_patterns* ;

A Data wrapper used to specify that the test should exclude a set of ICL DataPorts. The *name_patterns* are glob patterns matching ICL DataPorts found below the current ICL design. This wrapper is only used when the verify_internal_data_pins option is set to on. DataInPorts and DataOutPorts that have the tessent_ignore_during_icl_verification attribute set to on in their ICL definition are automatically excluded. This switch is only used when the [create_icl_verification_patterns -data_pin_test](#) option is set to on.

Examples

Example 1

The following example specifies the creation of the ICL network verification patterns set. The ExcludedIclModules wrapper was used to exclude all ICL Module matching abc*.

Alternatively, the attribute tessent_ignore_during_icl_verification could have been set to true in the ICL module to exclude it automatically.

```
ICLNetworkVerify {
    ExcludedIclModules {
        abc* ;
    }
}
```

Example 2

The following example demonstrates creating one ICLNetworkVerify step using the signoff for the sub-physical regions and using the to replace what is being done in the default manufacturing pattern specification generated.

```
Patterns(ICLNetwork) {
    ICLNetworkVerify(top) {
        // Testing ICL scan registers outside all physical blocks
        ExcludeIclInstances {
            m8051_wrap_inst_m8051_inst1;
            m8051_wrap_inst_m8051_inst2;
            piccpu_inst1;
        }
    }
    ICLNetworkVerify(top_1) {
        // Testing ICL scan registers,
        // including those in physical block ICL instance
        // 'm8051_wrap_inst_m8051_inst1'
        ExcludeIclInstances {
            m8051_wrap_inst_m8051_inst2;
            piccpu_inst1;
        }
    }
    ICLNetworkVerify(top_2) {
        // Testing ICL scan registers,
        // including those in physical block ICL instance
        // 'm8051_wrap_inst_m8051_inst2'
        ExcludeIclInstances {
            m8051_wrap_inst_m8051_inst1;
            piccpu_inst1;
        }
    }
    ICLNetworkVerify(top_3) {
        // Testing ICL scan registers,
        // including those in physical block ICL instance 'piccpu_inst1'
        ExcludeIclInstances {
            m8051_wrap_inst_m8051_inst1;
            m8051_wrap_inst_m8051_inst2;
        }
    }
}
```

As shown, the ICLNetworkVerify(`top`) excludes all sub-physical blocks instances. Then, in turn, each sub-physical block instance is *not* excluded in subsequent ICLNetworkVerify(`<design_name>_<n>`) wrappers.

A comment is added outside each ExcludedInstances wrapper that explains the objective of this particular ICLNetworkVerify wrapper.

ProcedureStep

Inserts arbitrary procedure steps into the pattern set.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    Patterns(patterns_name) {
        ProcedureStep(procedure_step_name) {
            svf_file : file_path ;
            maintain_model_state_from_svf : on | off ;
            run_before_dft_control_settings : on | off ;
            iCall(iproc_name_path) { // repeatable
                iProcArguments {
                    argument_name : argument_value ; // repeatable
                }
            }
            wait_time : time ;
            tester_cycles : integer ;
            tck_cycles : integer ;
            AdvancedOptions {
                force_voltage(pin_name) : voltage ; // repeatable
                split_patterns_file : on | off ;
                network_end_state : keep | reset | initial ;
            }
        }
    }
}
```

Description

The ProcedureStep wrapper is used to insert arbitrary procedure steps into the pattern set. The events of the procedure step consist of a test sequence expressed as a SVF (serial vector format) file or as an iProc followed by a pause of arbitrary length.

The example that follows is an ICL module that describes a programmable clock divider. If this ICL was visible when the [process_dft_specification](#) command was issued, a TDR was inserted to provide controllability of the DataInPorts from the IJTAG network. The ICL module defines the relationship between the clk_out and clk_in as well as the default division ratio between them. The DataInPort rst can be used to reset the divider and the DataInPort ratio[1:0] can be used to program the division ratio. As described in the Description section of the [add_clocks](#) command, an add_clocks command will automatically be inferred when elaborating the design in the DFT context.

Notice how the “rst” ICL port has the [tessent_use_in_dft_specification](#) attribute set to “auto_no_pi”. When unspecified, this attribute defaults to “auto”. With “auto”, the input pin will be intercepted or sourced by a DataOutPort of a TDR if the port is seen to not already be sourced by a valid DataOutPort or a primary input port. When you set it to “auto_no_pi”, the pin will be equipped with a local IJTAG control even if it is seen to already be sourced by a primary input. You want to use the “auto_no_pi” value for ports like this “rst” port because they are often sourced by a system level reset port. Even though it is possible to toggle the system reset to reset the clock divider, the effect of the reset pulse will be felt by the entire system and you

may affect already running parts of the circuit. When you provide local controllability, it becomes possible to reset the clock divider without affecting the rest of the chip. See the description of [create_dft_specification](#) for more information about how DataInPorts are handled during DFT insertion.

If you add the [tessent_default_procedure_name](#) and optionally the [tessent_default_procedure_parameters](#) in the ToClockPort as shown below, the [create_patterns_specification](#) will automatically add the ProcedureStep to iCall the procedure with the specified parameters if it sees the clock of the memoryBIST controller going through this ToClockPort. It is critical that all elements you specify in the ToClockPort be consistent. The default proc and parameters must program the ToClockPort to behave as its Source, FreqDivider and FreqMultiplier properties indicates.

If the [create_patterns_specification](#) command sees that multiple cascaded modules need to be initialized, it will initialize them in separate ProcedureStep such that the element feeding the other is initialized first. See [Example 2](#) where a PLL is initialized first followed by the clock divider in its fanout.

```
Module clk_div {
    Attribute keep_active_during_scan_test = "true" ;
    ClockPort clk_in ;
    ToClockPort clk_out {
        Attribute tessent_default_procedure_name = "init" ;
        Attribute tessent_default_procedure_parameters = "ratio 4" ;
        Source clk_in ;
        FreqDivider 4 ;
    }
    DataInPort rst {
        //This attribute makes sure the pin will be intercepted by
        //create_dft_specification even if the pin is sourced by a PI.
        //Because the rst pin is often shared with many other things
        //in the chip, the local interception makes sure the clock divider can
        //be reset by its iProc without affecting the rest of the design.
        Attribute tessent_use_in_dft_specification = "auto_no_pi";
    }
    DataInPort ratio[1:0] ;
}
```

The basic PDL iProcs to program the divider is shown here:

```
iProcsForModule clk_div
iProc init {{ratio 4}} {
    iClock clk_in
    iWrite rst 0b1
    iWrite ratio [expr int(log($ratio)/log(2))]
    iApply
    iWrite rst 0b0
    iApply
    iRunLoop 8 -sck clk_in
    iClockOverride clk_out -freqDivider $ratio
}
```

The iProc accepts a ratio argument that defaults to 4, and uses this value to program the divider. Once the divider is programmed, the [iClockOverride](#) command is issued to reflect that the division ratio has been changed. The later [iClock](#) commands that trace to this ToClockPort will see the overridden value. The basic PDL iProc shown above is correct in terms of the PDL commands but lacks the Tcl code needed to validate the ratio argument.

The enhanced procedure shown below has the proper validation code. The code at the top validates the ratio value and gives an error message when incorrect. When the iProc is called within a ProcedureStep wrapper, the iProc will be called with a parameter that defines the validation_dict argument containing an entry for each parameter. In the example below, the entry “iproc_parameters ratio” is defined and contains the name of the property inside the ProcedureStep that defines its value. You can use this property to attach the error message to the property using the [add_config_message](#) command as shown below.

Finally, the validation_dict argument contains an entry called “validate_only”. It is expected that the code “if {[dict get \$validation_dict validate_only]} {return}” exists in the iProc such that the iProc can be called with this entry set to 1 during the validation step of the [process_patterns_specification](#) command in order to run the validation code without actually running the PDL command. When the argument called “validation_dict” is not present, the iProc is not run when you call the [process_patterns_specification](#) command with the -validate_only option. This means that incorrect values of arguments passed to iProcs from a ProcedureStep wrapper will only be detected when you run the [process_patterns_specification](#) command without the -validate_only option and the error message will only show up in the transcript and won’t be attached to the property objects in the GUI.

```
iProcsForModule clk_div
iProc init {{ratio 4} {validation_dict {validate_only 0}}} {
    ##### Validation part #####
    if {$ratio ni {1 2 4 8}} {
        set err "Illegal value '$ratio' for option 'ratio'. Must be 1, 2, 4, or
8. Default is 4."
        if {[dict exists $validation_dict iproc_parameters ratio]} {
            add_config_message -display $err \
                -config [dict get $validation_dict iproc_parameters ratio]
        } else {
            display_message $err
        }
        return -code error
    }
    if {[dict get $validation_dict validate_only]} {
        # Skip PDL part
        return
    } ##### PDL part #####
    iClock clk_in
    iWrite rst 0b1
    iWrite ratio [expr int(log($ratio)/log(2))]
    iApply
    iWrite rst 0b0
    iApply
    iRunLoop 8 -sck clk_in
    iClockOverride clk_out -freqDivider $ratio
}
```

Arguments

- *procedure_step_name*

A string that uniquely identifies the step within a pattern set. All of the procedure_step_name and test_step_name names must be unique within a Patterns wrapper. The string is only allowed to contains letters, numbers, and underscores.

- *svf_file :file_path ;*

A property that specifies a file that defines an SVF sequence to be included in the ProcedureStep. The svf_file and iCall(iproc_name_path) properties are mutually exclusive.

There are limitations on what can be in the svf_file. See [import_patterns_from_svf](#) command for a complete list. If the svf_file includes a reset of the Mentor Graphics TAP, then the Mentor Graphics TAP must be left in the Run-Test-Idle state (at the end of the svf_file). An example of this use model is if the svf_file contents must be run to provide access to the Mentor Graphics TAP.

The file_path must have one of the following formats:

- A simple file name with no directory path. In this case, the file must exist beside the ICL file.
- A null string. In this case, no procfile is used.
- An absolute path starting with a “/”.

- A relative path starting with “./” or “../”. In this case, the file must exist relative to the current working directory.
- `maintain_model_state_from_svf : on | off ;`
An optional property that specifies how the SVF reader operates. When set to off, the reader operates in “blackbox mode”, in that it will not apply the SDR (Scan Data Register) and SIR (Scan Instruction Register) commands to the internal state of the IJTAG network, nor will it check if the internal state of the IJTAG network matches the length of the provided SDR/SIR data. The default value is on.
- `run_before_dft_control_settings : on | off ;`
The ProcedureStep/TestStep steps are always relative to each other in the order in which they appear in the PatternsWrapper. The settings described in the DftControlSettings wrappers are always applied first no matter where the wrapper is positioned.
In some situations, you may need to run one or more custom ProcedureStep before the DftControlSettings can be applied, for example powering up a section of the device. Specifying the `run_before_dft_control_settings` on the N first ProcedureStep wrapper will run them in their current relative order before the DftControlSettings are applied.
An error is generated if you have a TestStep or a ProcedureStep with `run_before_dft_controling_settings` set to off above a ProcedureStep with `run_before_dft_controling_settings` set to on.
- `iCall(iproc_name_path)`

A Wrapper that specifies the hierarchical ICL path to an iProc to be called. For example, an iProc named “reset” which has been registered against an ICL module mod1 that is instantiated as “mod1_inst” in the ICL is referenced as `iCall(mod1_inst.reset)`. The iCall wrapper and svf_file properties are mutually exclusive.

When many `iCall(iproc_name_path)` wrappers exists in a ProcedureStep wrapper, the associated iCalls are processed in an ‘iMerge -begin ... iMerge -end’ block so that their operations are performed in parallel. When there is only one iCall in the wrapper, it is not processed within an iMerge block. If the iProcs you want to iCall within a ProcedureStep wrapper contains instructions that are incompatible with the merging procedure (for example, `iApply -end_in_pause`), make sure to include it by itself inside one ProcedureStep wrapper to avoid it being process in an iMerge block.

The iProc for the ICL module must have been sourced into the tool prior to executing the [process_patterns_specification](#) command; otherwise, an error will be generated.

Note

 If your store your iProcs in a file called XXX.pdl and an ICL module was read in from a file called XXX.icl and the two files existed in the same directory, the content of the file XXX.pdl will be collected during ICL extraction and stored into a file called <design_name>. pdl inside the TSDB. This file will be auto loaded when ICL is elaborated, removing the need for you to manually source the iProcs before they can be referenced by the iCall() wrapper.

- `iCall(iproc_name_path)/iProcArguments/argument_name : argument_value ;`

A Data wrapper that specifies argument-values pairs that specifies one or more arguments to pass to the iProc identified with the `iproc_name` property. The `argument_name` must exactly match the name of an argument of the actual iProc. Tesson Shell generates an error if the argument does not exist. The order of the arguments is not important as long as they formally match those defined for the iProc.

The `argument_value` is automatically passed to the iProc in the right position.

Tesson Shell generates an error if a required argument of the iProc is missing from the `iProcArguments` wrapper.

If an optional argument is not specified, the default value of that argument is passed to the iProc when called.

Consider the following example containing the declaration of an iProc called “reset”:

```
iProc reset { initial_delay {final_delay 10us} } {...}
```

The following configuration data:

```
iCall(mod1_inst.reset) {
    iProcArguments {
        initial_delay : 1us;
    }
}
```

results in the following call to the iProc because the value of `final_delay` is optional and defaults to 10 us:

```
iCall mod1_inst.reset 1us 10us
```

The following configuration data results in an error because the `initial_delay` argument is required:

```
iCall(mod1_inst.reset) {
    iProcArguments {
        final_delay : 22us;
    }
}
```

If you have an iProc that uses “args” as an argument, and you want to pass a series of option-value pairs to the args option, you use the following syntax:

```
iProcArguments {
    args : "option1 value1
            option2 value2
            optionN valueN";
}
```

- `wait_time : time ;`

A property that specifies a wait loop at the end of the procedure step. The `wait_time` property is mutually exclusive to the `tester_cycles` and `tck_cycle` properties. It expresses a

wait loop in term of times. The specified time value is divided by the tester_period value and the ceiling value is used to create a wait loop.

- tester_cycles : *integer* ;

A property that specifies a wait loop at the end of the procedure step. The tester_cycles property is mutually exclusive to the wait_time and tck_cycle properties. It expresses a wait loop in term of tester_cycles. The specified integer value is used to create a wait loop.

- tck_cycles : *integer* ;

A property that specifies a wait loop at the end of the procedure step. The tck_cycles property is mutually exclusive to the wait_time and tester_cycles properties. The specified integer value is multiplied by the tck_ratio value to create a wait loop.

- AdvancedOptions/force_voltage(*pin_name*) : *voltage* ;

A repeatable property that specifies that the current test step needs a special voltage to be applied on a specific port of the device. This property is typically used in TestStep when MemoryBisr is used to program the fusebox. The property does not actually force the voltage. It only generates a special annotation near the top of the patterns file to let the test engineer know that test program commands are needed to supply the needed voltage on the given port. As soon as a single force_voltage property is specified, the split_patterns_file : on; property is implied to allow the insertion of the test program commands needed to apply the voltage values.

Here is an example of the special annotation inside a stil file:

```
Ann {* Before applying this pattern, the following actions are
      required: *}
Ann {*} - Apply +0.25V on port PA {}}
```

```
Ann {*} - Apply -0.25V on port PB {}}
```

- AdvancedOptions/split_patterns_file : on | off ;

A property that splits the pattern set into multiple files. The file containing the previous patterns is closed and a new one is created for the current step. The file name is the name of the Patterns wrapper initially. When a step with split_patterns_file set to on is reached, the new file name consists of the name of the Patterns wrapper concatenated with an underscore to the name of the TestStep wrapper as shown here:

```
<pattern_name>_<test_step_name>
```

The split patterns file contains a special annotation near the top of the file that reads like this:

```
Ann {*} This pattern file requires some actions taken on the ATE. *
Ann {*} This pattern assumes it is following another one: *
Ann {*} the power and clocks must be kept alive between *
```

```
Ann {*} the two patterns and all pins kept their state. {}}
```

- AdvancedOptions/network_end_state : `keep` | `reset` | `initial` ;

A property that specifies the action to take at the end of the ProcedureStep. The options for this property are named the same and perform the identical functions as the `close_pattern_set` command's arguments. For details, see the [close_pattern_set](#) command.

Examples

Example 1

The following example shows a Patterns wrapper containing a single ProcedureStep that consists of an initial pause of 4 milliseconds followed by the call of an iProc called “run” on the ICL instance “core1_i1.instrumenta_i1”. The parameter mode is passed to the iProc with a value equal to “random”.

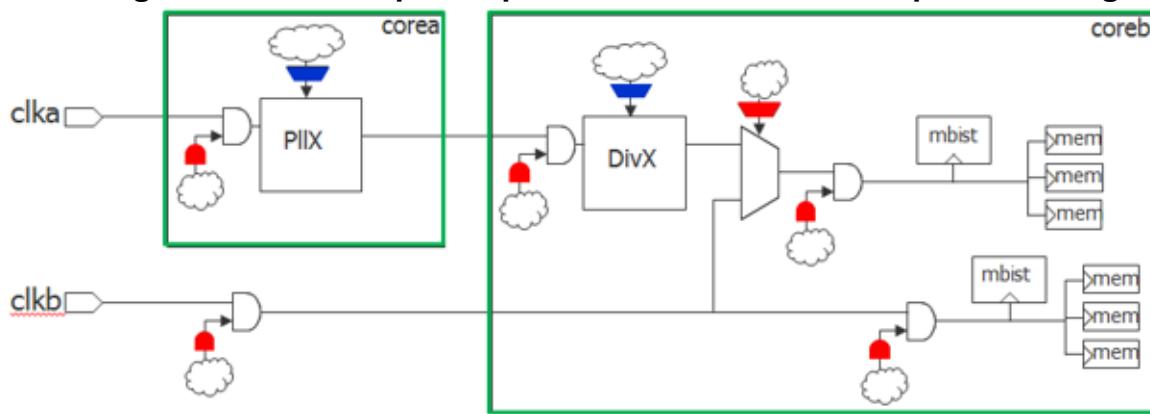

```
PatternsSpecification(mychip, gate, signoff) {
    Patterns(P1) {
        ProcedureStep(my_icall) {
            wait_time : 4ms ;
            iCall(core1_i1.instrumenta_i1.run) {           iProcArguments {
                mode : random ;
            }
        }
    }
}
```

Example 2

The following example shows how the Patterns wrapper was auto created by the [create_patterns_specification](#) command to perform signoff simulation for the memory BIST controller found inside coreb (See [Figure 10](#)). Notice how the content of the DftControlSettings, the SimulationOptions/LowerPhysicalBlockInstances and the ProcedureSteps wrappers were created. The command traces all the clocks of the MemoryBist controllers found in the TestStep/MemoryBist wrapper. For every physical block entered, it asserts the `dft_control_enable`, `nonscan_test`, and `all_test` dft control signals it finds in them. For more information about those signals, see the [add_dft_control_points](#), [add_dft_clock_enables](#), and [add_dft_clock_mux](#) command descriptions. Normally, the signoff simulation of a given physical block instance is done using the interface view for all other physical block instances. In this example, the clock traced through the corea_i1 instance so the full view of corea_i1 is requested when simulating coreb_i1 in order for it to get its clocks. Finally, notice how two ProcedureStep wrapper were auto inserted to initialize the PLL and clock divider seen when tracing the clocks. The clock divider is initialized after the PLL because it requires the output of the PLL to be running before it is initialized. This automatic inferring of the ProcedureStep only happens if you have defined the [tessent_default_procedure_name](#) attribute in the ToClockPort of the ICL model for the PLL and clock divider as described above in the Description section.

```
PatternsSpecification(chip,rtl,signoff) {
    Patterns(MemoryBist_P2) {
        tester_period : 100ns ;
        DftControlSettings {
            corea_i1.all_test : 1 ;
            corea_i1.nonscan_test : 1 ;
            coreb_i1.all_test : 1 ;
            coreb_i1.nonscan_test : 1 ;
            all_test : 1 ;
            nonscan_test : 1 ;
        }
        ClockPeriods {
            clka : 3.00ns;

EnableGroupInfo

Creates groups of Boundary Scan enable cells that can then be referenced using the BoundaryScan/RunTest/enable_group_info property.

Usage

```
PatternsSpecification(design_name ,design_id,pattern_id) {
    EnableGroupInfo(enable_group_info_id) {
        enable_cell_numbers : cell_number, ...;
    }
}
```

Description

The EnableGroupInfo wrapper is used to group enable cells together that will be tested simultaneously. The enable_group_info_id property can be used in the enable_group_info property to specify the enable groups to be tested separately and the sequence in which the enable groups are tested.

Arguments

- *enable_group_info_id*

A string that uniquely identifies the EnableGroupInfo wrapper such that it can be referenced using the BoundaryScan/enable_group_info property. All enable cells that are not part of the listed enable groups, whether they are part of a not listed enable group or part of a no enable group, are added to a new artificial group and all tested simultaneously.

- *enable_cell_numbers : cell_number, ...;*

A property used to list the enable Boundary Scan cell numbers in the design to be tested simultaneously. The cell number corresponds to the cell number listed in the BSDL description.

Examples

The following example defines two EnableGroupInfo wrappers with different enable cells listed in each. The BoundaryScan wrapper shows two BoundaryScan wrappers referencing each enable group.

```
PatternsSpecification(mychip,final,manufacturing) {
    Patterns(bscan) {
        TestStep(TS1) {
            BoundaryScan {
                enable_group_info : g1;
                RunTest(output) {
                }
            }
        }
        TestStep(TS2) {
            BoundaryScan {
                enable_group_info : g2;
                RunTest(output) {
                }
            }
        }
    }
    EnableGroupInfo(g1) {
        enable_cell_numbers : 3, 34, 78, 89;
    }
    EnableGroupInfo(g2) {
        enable_cell_numbers : 11, 37, 57, 101;
    }
}
```

SdfInfo

Defines SDF file usage scenarios that can be referenced by the Patterns/SimulationOptions/`sdf_info` properties.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    SdfInfo(sdf_info_id) {
        SdfFile(path_to_file) {
            instance_names      : instance_name, ... ;
            include_macro_name : macro_name ;
            exclude_macro_name : macro_name ;
        }
    }
}
```

Description

The SdfInfo wrapper is used to defined SDF file usage scenarios that can be referenced by the [Patterns/SimulationOptions](#)/`sdf_info` properties.

The various SDF files will be annotated on the specified instance path or the top-level module when the `instance_names` property is left empty. You can request the `sdf` annotation commands to only run or to not run when a given macro name is defined on the simulator command line.

Arguments

- `path_to_file`

A string that refers to an SDF file. Relative path are expressed relative to the current working directory; they are converted to an absolute path in the test bench such that the simulation can be performed in any directory.

- `instance_names : instance_name, ... ;`

A property that defines one or many Verilog instance paths that the SDF file applies to. When the property is specified as a null string (the default value), the SDF file is applied to the current design. The instance path names uses the period “.” because the hierarchy separator is used in a Verilog simulator.

- `include_macro_name : macro_name ;`

A property that defines a macro name that will be used to surround the `sdf_annotation` command with a ‘`ifdef macro_name`’ statement. When you specify this property, the `sdf` annotation only happens if you pass “`+define+macro_name`” on the simulator command line. The `sdf_annotation` command is not surrounded by a ‘`ifdef`’ statement unless this property is specified. This feature is very useful when you want to simulate with more than one version of an SDF for the same test benches as shown in the following example.

- `exclude_macro_name : macro_name ;`

A property used to define a macro name that will be used to surround the `sdf_annotation` command with a ‘`ifndef macro_name`’ statement. When you specify this property, the `sdf`

annotation can be suppressed by passing “+define+macro_name” on the simulator command line. The sdf_annotation command is not surrounded by a ‘ifndef statement unless this property is specified.

Examples

The following example defines an SdfInfo wrapper that loads an SDF file called “top.sdf_slow” for the current design and another SDF file called “corea.sdf_slow” for two instances of the physical block “corea” when the +define+sdf_slow macro is passed to the simulator. It loads an SDF file called “top.sdf_fast” for the current design and another SDF file called “corea.sdf_fast” for two instances of the physical block “corea” when the +define+sdf_fast macro is passed to the simulator.

```
SdfInfo(chip_corea) {
    SdfFile(..../SDFFiles/top.sdf_slow) {
        include_macro_name : sdf_slow ;
    }
    SdfFile(..../SDFFiles/corea.sdf_slow) {
        instance_names : tlb.corea_i1, tlb.corea_i2 ;
        include_macro_name : sdf_slow ;
    }
    SdfFile(..../SDFFiles/top.sdf_fast) {
        include_macro_name : sdf_fast ;
    }
    SdfFile(..../SDFFiles/corea.sdf_fast) {
        instance_names : tlb.corea_i1, tlb.corea_i2 ;
        include_macro_name : sdf_fast ;
    }
}
```

Below is the corresponding Verilog module that is created and simulated in parallel to the chip to load the SDF files.

```
module P1_sdf
initial begin
  `ifdef sdf_slow
    sdf_annotate(/home/ver_eng/SDFFiles/top.sdf_slow,
                TB.top_inst);
  `endif
  `ifdef sdf_slow
    $sdf_annotate(/home/ver_eng/SDFFiles/corea.sdf_slow,
                  TB.top_inst.tlb.corea_i1);
    $sdf_annotate(/home/ver_eng/SDFFiles/corea.sdf_slow,
                  TB.top_inst.tlb.corea_i2);
  `endif
  `ifdef sdf_fast
    sdf_annotate(/home/ver_eng/SDFFiles/top.sdf_fast,
                 TB.top_inst);
  `endif
  `ifdef sdf_fast
    $sdf_annotate(/home/ver_eng/SDFFiles/corea.sdf_fast,
                  TB.top_inst.tlb.corea_i1);
    $sdf_annotate(/home/ver_eng/SDFFiles/corea.sdf_fast,
                  TB.top_inst.tlb.corea_i2);
  `endif
end
endmodule
```

LoadBoardInfo

A wrapper used to define the different tester and load board capabilities.

Usage

```
PatternsSpecification(design_name,design_id,pattern_id) {
    LoadBoardInfo(load_board_info_id) {
        dot6_ttest : ttest_time ;           // default: auto
        TesterInterface {
        }
        Loopbacks {
        }
        ACLoopbacks {
        }
    }
}
```

Description

The LoadBoardInfo wrapper is used to define the different tester and load board capabilities and configurations. It can be referenced using the [PatternsSpecification/Patterns/load_board_info](#) property—see “[Patterns](#)” on page 3576.

You would need this wrapper specified and referenced when:

- Your tester supports applying a 'Z' pattern state (highZ) to an input-only pin, and you want to use that capability in your BoundaryScan/[RunTest](#) dot6_ac_input test pattern.
- Your load board features loopbacks between output and input ports used in patterns, including boundary scan tested ports for [BoundaryScan](#) patterns.
- On your load board, some of your tested ports:
 - Have pull resistors.
 - Are uncontrollable by the tester (input and bidirectional ports).
 - Are unobservable by the tester (output and bidirectional ports).

When no LoadBoardInfo is specified, Tesson Shell assumes:

- All input and bidirectional tested ports are controllable.
- The tester cannot disable the drive of an input-only port.
- All output and bidirectional ports can be observed for states 0, 1 and Z.

Arguments

- *load_board_info_id*

A string that uniquely identifies the LoadBoardInfo wrapper such that it can be referenced using the [PatternsSpecification/Patterns/load_board_info](#) property.

- `dot6_ttest : ttest_time ;`

An optional time value that specifies the minimum time required by the slowest coupling capacitor, among all AC Loopbacks, to fully discharge (under 1% of charge). The value of this property (also referred to as TTest in the IEEE 1149.6 standard) is used mainly by DC-related BoundaryScan tests such as `dot6_dc_input` and `dot6_dc_output`. They ensure that DC levels are systematically blocked by all coupling capacitors and therefore cannot be captured by the test receiver.

This property's value defaults to three times the slowest time constant along all AC pads that have an on-chip high-pass or low-pass filter as recommended by the IEEE 1149.6 standard. If no on-chip filter is present or if no BSDL file can be found, then the value defaults to three periods of TCK.

Examples

The following example will be described in the next sections.

```
LoadBoardInfo(tester1) {
    TesterInterface {
        Port (TRST) {
            control      : none;
            observation : none;
        }
        Port (IN1) {}
        Port (IN_DV1) {
            differential_inverse_of : IN_DV1_N; //only specify if no BSDL
        }
        Port (IN_AC1) {}
        Port (IN_AC1_DV) {
            differential_inverse_of : IN_AC1_DV_N; //only specify if no BSDL
        }
    }
    Loopbacks {
        IN1 : OUT1;
        IN_DV1 : OUT_DV1;
    }
    dot6_ttest : 15.0e-09s;
    ACLoopbacks {
        IN_AC1 : OUT_AC1;
        IN_AC1_DV : OUT_AC1_DV;
    }
}
```

TesterInterface

The TesterInterface wrapper enables you to specify which design ports are to be contacted to a tester channel

Usage

```
LoadBoardInfo(load_board_info_id) {
    TesterInterface {
        default_control      : auto | none | two_state_weak |
        two_state_strong |                               three_state | tied_high | tied_low ;
        default_observation : auto | none | two_state | three_state ;
        default_pull_resistor : from_bsdl | none | up | down ;
        Port(port_name) {
            control          : from_default | none | two_state_weak |
            two_state_strong | three_state | tied_high | tied_low ;
            observation       : from_default | none | two_state |
            three_state ;
            pull_resistor     : from_default | from_bsdl | none |
            up | down ;
            differential_inverse_of : port_name ;
        }
    }
}
```

Description

The TesterInterface wrapper enables you to specify which design ports are to be contacted to a tester channel during test pattern execution and their capabilities. Specifying this wrapper will apply the default_control, default_observation and default_pull_resistor values to all ports of the current design that are not specified in a Port wrapper.

Arguments

- default_control : auto | none | two_state_weak | two_state_strong | three_state | tied_high | tied_low ;

This property defines the control capabilities of the tester on ports that are not specified by a Port wrapper, or those that have a Port wrapper with the control : from_default value specified. The default value is “auto”, which resolves to “two_state_strong” for input ports, “none” for output ports and “three_state” for inout ports.

- default_observation : auto | none | two_state | three_state ;

This property defines the observation capabilities of the tester on ports that are not specified by a Port wrapper, or those that have a Port wrapper with the observation : from_default value specified. The default value is “auto”, which resolves to “three_state” for output and inout ports and to “none” for input ports.

- default_pull_resistor : from_bsdl | none | up | down ;

The property defines the polarity of the external weak pull resistor set by the tester on ports that are not specified by a Port wrapper, or those that have a Port wrapper with the

`pull_resistor` : `from_default` value specified. The default value is “`from_bsdl`”. For more details, see the property description of Port/`pull_resistor`.

- `Port(port_name)`

This identifier defines which port the following properties apply to. This must be an existing port of the current design.

When specifying a differential pair, you must only specify the positive leg’s name. If you have Tessent Boundary Scan DFT inserted, then the negative leg will be inferred from the BSDL file, if not, then you should use the `differential_inverse_of` property to specify the name of the negative leg of this differential port.

- `Port/control : from_default | none | two_state_weak | two_state_strong | three_state | tied_high | tied_low ;`

This property defines the control capabilities of the tester on the identified port. The default is “`from_default`”, which specifies the control capabilities will be defined by the `default_control` property. For an input-only port, setting the value “`none`” means the port is not contacted by the tester and will not be part of Tessent Boundary Scan patterns.

- `Port/observation : from_default | none | two_state | three_state ;`

This property defines the observation capabilities of the tester on the identified port. The default is “`from_default`”, which specifies the observation capabilities will be defined by the `default_observation` property. For an output-only port, setting the value “`none`” means the port is not contacted by the tester and will not be part of Tessent Boundary Scan patterns.

- `Port/pull_resistor : from_default | from_bsdl | none | up | down ;`

The property defines the polarity of the external weak pull resistor set by the tester on the port if any. The default value is “`from_default`”, which specifies the polarity will be defined by the `default_pull_resistor` property. When the value is “`from_bsdl`”, Tessent Shell will try to infer the value from the disable result value in the `BOUNDARY_REGISTER` section of the BSDL file if one can be found. A disable result value of “`weak0`” will infer this property’s value to “`down`” and a disable result value of “`weak1`” will infer this property’s value to “`up`”.

- `Port/differential_inverse_of : port_name ;`

This property is used to specify the negative leg of a differential port pair that complements this positive leg of the port. You should only use this property if you do not have Tessent BoundaryScan DFT.

Examples

In the example, the tester is not contacting the TRST TAP port and 4 inputs. IN_DV1 is a differential input so the control, observation and `pull_resistor` properties will be applied automatically to complimentary port IN_DV1_N.

Note: If a TAP TRST port is listed as uncontrollable, it will be specially treated. Tessent Shell will infer a CT1 constraint on that port.

```
LoadBoardInfo(tester1) {
    TesterInterface {
        Port (TRST) {
            control : none ;
            observation : none ;
        }
        Port (IN1) {}
        Port (IN_DV1) {
            differential_inverse_of : IN_DV1_N ; //only specify if no BSDL
        }
        Port (IN_AC1) {}
        Port (IN_AC1_DV) {
            differential_inverse_of : IN_AC1_DV_N ; //only specify if no BSDL
        }
    }
    [...]
}
```

Loopbacks

The Loopbacks wrapper specifies one or more connection loopbacks from source ports to destination ports.

Usage

```
LoadBoardInfo(load_board_info_id) {
    Loopbacks {
        destination_port : source_port ; // repeatable
    }
}
```

Description

The Loopbacks wrapper specifies one or more connection loopbacks from source ports to destination ports of the current design. Loopbacks specify direct connections, as opposed to ACLoopbacks, which connect source ports to destination ports through a coupling capacitor.

Usage Conditions

Note the following:

- *source_port* and *destination_port* must be output and input direction respectively. Inout ports are not allowed.
- An 1149.1 source must loop back to an 1149.1 destination and an 1149.6 source must loop back to an 1149.6 destination. Interconnecting 1149.1 and 1149.6 ports together is not allowed.
- To loop back differential pairs, you must only specify the positive leg's name. The negative leg will be inferred from the BSDL file or taken from the *differential_inverse_of* properties of the ports.

Arguments

- *destination_port : source_port* ;

This port pair describes a direct connection that is to be made in the simulation test bench and assumed by the test patterns.

Examples

In the example, OUT1 and OUT_DV1 are looping back to uncontacted ports IN1 and IN_DV1 respectively. Because IN_DV1 and OUT_DV1 are differential ports, their negative leg will also automatically be looped back.

```
LoadBoardInfo(tester1) {
    [...]
    Loopbacks {
        IN1 : OUT1 ;
        IN_DV1 : OUT_DV1 ;
    }
    [...]
}
```

ACLoopbacks

The ACLoopbacks wrapper specifies one or more connection loopbacks from AC source ports to AC destination ports.

Usage

```
LoadBoardInfo(load_board_info_id) {
    ACLoopbacks {
        destination_port : source_port ; // repeatable
    }
}
```

Description

The ACLoopbacks wrapper specifies one or more connection loopbacks from AC source ports to AC destination ports of the current design. ACLoopbacks specify port connections through a coupling capacitor, as opposed to Loopbacks, which connect directly source ports to destination ports.

Usage Conditions

Note the following:

- *source_port* and *destination_port* must be output and input direction respectively. Inout ports are not allowed.
- 1149.1 ports are not allowed.
- To loop back differential pairs, you must only specify the positive leg's name. The negative leg will be inferred from the BSDL file or taken from the *differential_inverse_of* properties of the ports.

Arguments

- *destination_port : source_port* ;

This port pair describes a connection through a coupling capacitor that is to be made in the simulation test bench and assumed by the test patterns.

Examples

In the example, OUT_AC1 and OUT_AC1_DV are looping back to uncontacted ports IN_AC1 and IN_AC1_DV respectively. Because IN_AC1_DV and OUT_AC1_DV are differential ports, their negative leg will also automatically be looped back. The resulting Verilog coupling capacitors will wait 15 ns before setting the loopback signal going into the inputs to Z.

```
LoadBoardInfo(tester1) {
    [...]
    dot6_ttest : 15.0e-09s ;
    ACLoopbacks {
        IN_AC1 : OUT_AC1 ;
        IN_AC1_DV : OUT_AC1_DV ;
    }
}
```

InSystemTest

Specifies the insertion of an IST controller inside the PatternsSpecification wrapper

Usage

```
PatternsSpecification (design_name, design_id, pattern_id) {
    InSystemTest {
        Controller(icl_instance_name) {
            TestProgram(index) {
                // TestProgram is a repeatable wrapper, where index starts at 0
                pattern: pattern_wrapper_name;
            }
        }
    }
}
```

Description

InSystemTest is an optional wrapper specified within the PatternsSpecification used to generate patterns for an IST controller. By default—that is, usage is set to simulation—the tool generates both a Verilog testbench and memory contents.

If you specify manufacturing_test as the usage, for the direct memory access architecture, the tool generates the memory contents file. For the CPU-based access architecture, it populates the mentor::in_system_test::PatternsSpecification dictionary.

The Controller wrapper is repeatable, depending on how many IST controllers you defined with the DftSpecification/InSystemTest wrapper.

The *icl_instance_name* is an existing ICL instance name. For details about Tessent MissionMode, refer to the [Tessent MissionMode User's Manual](#).

Arguments

- TestProgram (*index*) {
 pattern : *pattern_wrapper_name* ;
}

A repeatable wrapper that specifies a single test program to be executed by the IST controller. For the CPU-based access controller, you can specify any number of test programs. For the direct memory access controller, you can specify a maximum of max_test_program_count wrappers.

The *index* is an integer value starting at 0 that represents the test program number. For direct memory access, you can specify a range for the *index* from 0 to max_test_program_count 1. For CPU's, any number of test programs are allowed.

The pattern:*pattern_wrapper_name* property specifies the existing pattern wrapper name that is applied by the controller. Properties such as test_period, tck_ratio, constant port settings, and clock periods for the test program are sourced from the specified pattern.

Examples

The following example shows a dofile snippet for the In-System Test patterns specification after inserting three IST controllers.

```
...
PatternsSpecification(top, gate, ist) {
    Patterns(m8051_A_ist) {
        # test steps here ...
    }
    Patterns(m8051_B_ist) {
        # test steps here ...
    }
    Patterns(piccpu_ist) {
        # test steps here ...
    }
    InSystemTest {
        Controller(top_gate_tessent_in_system_test_m8051_A_inst) {
            TestProgram(0) {
                pattern: m8051_A_ist;
            }
        }
        Controller(top_gate_tessent_in_system_test_m8051_B_inst) {
            TestProgram(0) {
                pattern: m8051_B_ist;
            }
        }
        Controller(top_gate_tessent_in_system_test_piccpu_inst) {
            TestProgram(0) {
                pattern: piccpu_ist;
            }
        }
    }
}
process_patterns_specification
...
```

DefaultsSpecification Configuration Syntax

This section describes the configuration data syntax used inside Tessent Shell to specify default values used by the `create_dft_specification` command. Tessent Shell comes with built-in default values for all configuration properties. You can use the `DefaultsSpecification` wrapper to change many of those default values to match your preferences and requirements.

For complete information, see the “[DftSpecification](#)” on page 3179

DefaultsSpecification	3686
DefaultsSpecification/DftSpecification	3687
IjtagNetwork	3689
BoundaryScan	3693
MemoryBISR	3699
MemoryBIST	3703
DefaultsSpecification/PatternsSpecification	3714
SignOffOptions	3715
ManufacturingOptions	3717

DefaultsSpecification

Specifies changes to the built-in default values of all configuration properties

Usage

```
DefaultsSpecification(policy) { //Legal: company | group | user
    DftSpecification {
    }
    PatternsSpecification {
    }
}
```

Description

Specifies changes to the built-in default values of all configuration properties

You can use the DefaultsSpecification wrapper to change many of the built-in default values to match your preferences and requirements. The defaults setting mechanism also comes with a hierarchy of DefaultsSpecification wrappers that allow you to have company, group, and user-level defaults. You can load three configuration files in your .tesson_startup file: one containing a DefaultsSpecification(company) wrapper, one containing a DefaultsSpecification(group) wrapper, and one containing a DefaultsSpecification(user) wrapper. The final default value of a given property is taken from the DefaultsSpecification(user) wrapper if it is specified in that wrapper; it is taken from the DefaultsSpecification(group) wrapper if it is defined in that wrapper but not in the DefaultsSpecification(user) wrapper; and it is taken from the DefaultsSpecification(company) wrapper when it is defined there but not in the DefaultsSpecification(group) and DefaultsSpecification(user) wrappers. The final default value is the built-in default value if it is not specified in any of the three DefaultsSpecification wrappers.

You can refer to the [read_config_data](#) command to learn about loading in configuration data. You can refer to the [get_defaults_value](#) command to learn about accessing the specified defaults values from your dofile. If you prefer, you can also use the “[set_defaults_value -policy](#)” command to define your different policies instead of using configuration files.

Arguments

None

DefaultsSpecification/DftSpecification

A wrapper that specifies options that define the default values of the properties in the DFTSpecification wrapper.

Usage

```
DefaultsSpecification(policy) { //Legal: company | group | user
    DftSpecification {
        rtl_extension           : string ; // default: v
        gate_extension          : string ; // default: vg
        reuse_modules_when_possible : boolean ; // default: auto
        use_rtl_cells           : boolean ; // default: auto
        dft_cell_selection_name : string ;
        persistent_clock_cell_prefix : string ;
            //default: tesson_persistent_cell_
        persistent_cell_prefix   : string ;
            //default: tesson_persistent_cell_
        use_rtl_synchronizer_cell : on | off | auto ; // default: auto
        use_synchronizer_cell_with_reset : on | off ; // default: on
        IjtagNetwork {
        }
        BoundaryScan {
        }
        MemoryBist {
        }
        MemoryBisr {
        }
    }
}
```

Description

A wrapper that specifies options that define the default values of the properties in the DFTSpecification wrapper.

Arguments

- **rtl_extension : string ;**
A string that specifies the default value for the corresponding property found inside the **DftSpecification** wrapper.
- **gate_extension : string ;**
A string that specifies the default value for the corresponding property found inside the **DftSpecification** wrapper.
- **reuse_modules_when_possible : boolean ;**
A string that specifies the default value of the corresponding property found inside the **DftSpecification** wrapper.
- **use_rtl_cells : boolean ; // default: auto**
A property that sets the default value of the use_rtl_cells property found inside the **DftSpecification** wrapper when the **create_dft_specification** command is used.

- `dft_cell_selection_name : string ;`
A property that sets the default value of the `dft_cell_selection_name` property found inside the `DftSpecification` wrapper when the `create_dft_specification` command is used.
- `persistent_clock_cell_prefix : string ; // default: tesson_persistent_cell_`
A property that sets the default value of the `persistent_clock_cell_prefix` property found inside the `DftSpecification` wrapper when the `create_dft_specification` command is used.
- `persistent_cell_prefix : string ; // default: tesson_persistent_cell_`
A property that sets the default value of the `persistent_cell_prefix` property found inside the `DftSpecification` wrapper when the `create_dft_specification` command is used.
- `use_rtl_synchronizer_cell : on | off | auto ; //default: auto`
A property that sets the default value of the `use_rtl_synchronizer` property found inside the `DftSpecification` wrapper when the `create_dft_specification` command is used. This property is currently only used by the OCC and the MemoryBist wrappers.
- `use_synchronizer_cell_with_reset : on | off ; //default: on`
A property that sets the default value of the `use_synchronizer_cell_with_reset` property found inside the `DftSpecification` wrapper when the `create_dft_specification` command is used.

Examples

The following example shows a GlobalOptions wrapper that specifies the `rtl_extension` as “vb” and the `gate_extension` as ”v” inside the group defaults policy. Because it is not overridden by a user defaults policy wrapper, those default values are used by the `create_dft_specification` command.

```
> read_config_data -from_string {
  DefaultsSpecification(user) {
    DftSpecification {
      rtl_extension : vb ;
      gate_extension : v ;
    }
  }
}
> get_defaults_value DftSpecification/rtl_extension
vb
```

IjtagNetwork

A wrapper that is used to specify the default value of properties found in the DftSpecification/IjtagNetwork wrapper and define how the ijtag instances are to be handled during [create_dft_specification](#).

Usage

```
DefaultsSpecification(policy) { //Legal: company | group | user
    DftSpecification {
        IjtagNetwork {
            connect_data_signals_already_connected_to_ports : on | off ;
            ImplementationOptions {
                scan_path_retiming : latch | flop ;
            }
            HostScanInterface {
                Block {
                    tck           : port_name ; // default: ijtag_tck
                    reset         : port_name ; // default: ijtag_reset
                    select        : port_name ; // default: ijtag_sel
                    shift_en      : port_name ; // default: ijtag_se
                    capture_en   : port_name ; // default: ijtag_ce
                    update_en    : port_name ; // default: ijtag_ue
                    scan_in       : port_name ; // default: ijtag_si
                    scan_out      : port_name ; // default: ijtag_so
                }
                Chip {
                    tck           : port_name ; // default: tck
                    tdi           : port_name ; // default: tdi
                    tdo           : port_name ; // default: tdo
                    tms           : port_name ; // default: tms
                    trst          : port_name ; // default: trst
                }
            }
        }
    }
}
```

Description

A wrapper that is used to specify the default value of properties found in the DftSpecification/IjtagNetwork wrapper and define how the ijtag instances are to be handled during [create_dft_specification](#).

The properties found in the HostScanInterface/Block wrapper are used to define the Interface of the HostScanInterface when the design level is set to “physical_block” or “sub_block” using the [set_design_level](#) command. The properties found in the HostScanInterface/Chip wrapper are used to define the Interface of the HostScanInterface when the design level is set to “chip”.

Arguments

- connect_data_signals_already_connected_to_ports : on | off ;

A property that defines how the [create_dft_specification](#) command should deal with ijtag instances that have their

`set_ijtag_instance_options -connect_data_signals_already_connected_to_ports`
option set to auto.

- `ImplementationOptions/scan_path_retiming : latch | flop ;`
A property that specifies if the scan path retiming element is to be implemented using a latch or a flop.
- `HostScanInterface/Block/tck : port_name ;`
A property that sets the default value of the tck property found inside the [HostScanInterface/Interface](#) wrapper of the DftSpecification/[IjtagNetwork](#) wrapper. The default value is used during `create_dft_specification` when design level is `physical_block` or `sub_block`.
- `HostScanInterface/Block/reset : port_name ;`
A property that sets the default value of the reset property found inside the [HostScanInterface/Interface](#) wrapper of the DftSpecification/[IjtagNetwork](#) wrapper. The default value is used during `create_dft_specification` when design level is `physical_block` or `sub_block`.
- `HostScanInterface/Block/select : port_name ;`
A property that sets the default value of the select property found inside the [HostScanInterface/Interface](#) wrapper of the DftSpecification/[IjtagNetwork](#) wrapper. The default value is used during the `create_dft_specification` command when design level is `physical_block` or `sub_block`.
- `HostScanInterface/Block/shift_en : port_name ;`
A property that sets the default value of the shift_en property found inside the [HostScanInterface/Interface](#) wrapper of the DftSpecification/[IjtagNetwork](#) wrapper. The default value is used during the `create_dft_specification` command when the design level is `physical_block` or `sub_block`.
- `HostScanInterface/Block/capture_en : port_name ;`
A property that sets the default value of the capture_en property found inside the [HostScanInterface/Interface](#) wrapper of the DftSpecification/[IjtagNetwork](#) wrapper. The default value is used during the `create_dft_specification` command when the design level is `physical_block` or `sub_block`.
- `HostScanInterface/Block/update_en : port_name ;`
A property that sets the default value of the update_en property found inside the [HostScanInterface/Interface](#) wrapper of the DftSpecification/[IjtagNetwork](#) wrapper. The default value is used during the `create_dft_specification` command when the design level is `physical_block` or `sub_block`.
- `HostScanInterface/Block/scan_in : port_name ;`
A property that sets the default value of the scan_in property found inside the [HostScanInterface/Interface](#) wrapper of the DftSpecification/[IjtagNetwork](#) wrapper. The default value is used during the `create_dft_specification` command when the design level is `physical_block` or `sub_block`.

- HostScanInterface/Block/scan_out : *port_name* ;
A property that sets the default value of the scan_out property found inside the [HostScanInterface/Interface](#) wrapper of the DftSpecification/[IjtagNetwork](#) wrapper. The default value is used during the create_dft_specification command when the design level is physical_block or sub_block.
- HostScanInterface/Chip/tck : *port_name* ;
A property that sets the default value of the tck property found inside the [HostScanInterface/Interface](#) wrapper of the DftSpecification/[IjtagNetwork](#) wrapper. The default value is used during the create_dft_specification command when the design level is chip.
- HostScanInterface/Chip/trst : *port_name* ;
A property that sets the default value of the trst property found inside the [HostScanInterface/Interface](#) wrapper of the DftSpecification/[IjtagNetwork](#) wrapper. The default value is used during the create_dft_specification command when the design level is chip.
- HostScanInterface/Block/tms : *port_name* ;
A property that sets the default value of the tms property found inside the [HostScanInterface/Interface](#) wrapper of the DftSpecification/[IjtagNetwork](#) wrapper. The default value is used during the create_dft_specification command when the design level is chip.
- HostScanInterface/Block/tdi : *port_name* ;
A property that sets the default value of the tdi property found inside the [HostScanInterface/Interface](#) wrapper of the DftSpecification/[IjtagNetwork](#) wrapper. The default value is used during the create_dft_specification command when the design level is chip.
- HostScanInterface/Block/tdo : *port_name* ;
A property that sets the default value of the tdo property found inside the [HostScanInterface/Interface](#) wrapper of the DftSpecification/[IjtagNetwork](#) wrapper. The default value is used during the create_dft_specification command when the design level is chip.

Examples

The following wrappers define custom naming convention for the IJTAG ports that serves as the default for the entire company:

```
DefaultsSpecification(company) {
    DftSpecification {
        IjtagNetwork {
            HostScanInterface {
                Block {
                    tck           : my_tck ;
                    reset         : my_reset ;
                    select        : my_select ;
                    shift_en      : my_shift_en ;
                    capture_en   : my_capture_en ;
                    update_en    : my_update_en ;
                    scan_in       : my_scan_in ;
                    scan_out      : my_scan_out ;
                }
                Chip {
                    tck           : my_tck ;
                    tdi           : my_tdi ;
                    tdo           : my_tdo ;
                    tms           : my_tms ;
                    trst          : my_trst ;
                }
            }
        }
    }
}
```

BoundaryScan

Specifies certain default values for the boundary scan chain and embedded boundary scan chain to build and optionally insert into the design.

Usage

```
DefaultsSpecification(policy) { // legal: company | group | user
    DftSpecification {
        BoundaryScan {
            outputs_per_enable_cell      : int ; // default: 16
            max_segment_length_for_logictest : int | unlimited | auto ;
            tck_period                   : period ; // default 100ns
            Interface {
            }
            ImplementationOptions {
            }
        }
    }
}
```

Description

A wrapper that specifies certain default values for the both boundary scan and embedded boundary scan. All options apply to both, so is the [ImplementationOptions](#) wrapper. Only the [Interface](#) wrapper applies only to embedded boundary scan.

Arguments

- `outputs_per_enable_cell : int ;`
An optional property that instructs the tool to limit the number of output pins controlled by a given output enable cell. The default value of Tessent BoundaryScan is 16. Setting a value in the [DefaultsSpecification](#) implies new default values to be used for the respective property of both, the [DftSpecification/BoundaryScan](#) and [DftSpecification/EmbeddedBoundaryScan](#), respectively.
- `max_segment_length_for_logictest : int | unlimited | auto ;`
An optional property that instructs the tool to segment the boundary scan chains into smaller segments to be reused by scan-based logictest modes. The default value of Tessent BoundaryScan is auto. Setting a value in the [DefaultsSpecification](#) implies new default values to be used for the respective property of both, the [DftSpecification/BoundaryScan](#) and [DftSpecification/EmbeddedBoundaryScan](#), respectively.
- `tck_period : period ;`
An optional property that instructs the tool to use a different default period of the test clock. The default value of Tessent BoundaryScan period is 100ns. Setting a value in the [DefaultsSpecification](#) implies new default values to be used for the respective property of both, the [DftSpecification/BoundaryScan](#) and [DftSpecification/EmbeddedBoundaryScan](#), respectively.

Interface

Specifies certain default values for the embedded boundary scan interface only.

Usage

```
DefaultsSpecification(policy) { //Legal: company | group | user
    DftSpecification {
        BoundaryScan {
            Interface {
                select : port_naming ; //bscan_select
                reset : port_naming ; //bscan_reset
                force_disable : port_naming ; //bscan_force_disable
                select_jtag_input : port_naming ; //bscan_select_jtag_input
                select_jtag_output : port_naming ;
                                //bscan_select_jtag_output
                bscan_clock : port_naming ; //bscan_clock
                capture_en : port_naming ; //bscan_capture_en
                shift_en : port_naming ; //bscan_shift_en
                update_en : port_naming ; //bscan_update_en
                scan_in : port_naming ; //bscan_scan_in
                scan_out : port_naming ; //bscan_scan_out
                auxiliary_output : port_naming ; //bscan_%s_aux_out
                auxiliary_output_enable : port_naming ; //bscan_%s_aux_out_en
                auxiliary_input : port_naming ; //bscan_%s_aux_in
                auxiliary_input_enable : port_naming ; //bscan_%s_aux_in_en
                ac_init_clock0 : port_naming ; //bscan_ac_init_clk0
                ac_init_clock1 : port_naming ; //bscan_ac_init_clk1
                ac_signal : port_naming ; //bscan_ac_signal
                ac_mode_en : port_naming ; //bscan_ac_mode_en
            }
        }
    }
}
```

Description

A wrapper that specifies certain default values for the embedded boundary scan interface to be used. Using this wrapper you can override the default naming convention of the Tessent BoundaryScan tool's embedded boundary scan DFT specification DftSpecification/ EmbeddedBoundaryScan/Interface.

Arguments

- **select : *port_naming* ;**

An optional property that defines the name of the select signal. The select signal is used to enable or disable the embedded boundary scan interface of the core. When not specified, the port is named “bscan_select”. Setting this value in the **DefaultsSpecification** implies a new default value to be used for the respective property of DftSpecification/ EmbeddedBoundaryScan/Interface.

- **reset : *port_naming* ;**

An optional property used to provide the name for the port carrying the reset function. The reset function is active low. When not specified, the port is named “bscan_reset”. Setting

this value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.

- `force_disable : port_naming ;`

An optional property used to provide the name for the port carrying the `force_disable` function. When not specified, the port is named “bscan_force_disable”. Setting this value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.

- `select_jtag_input : port_naming ;`

An optional property used to provide the name for the port carrying the `select_jtag_input` function. When not specified, the port is named “bscan_select_jtag_input”. Setting this value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.

- `select_jtag_output : port_naming ;`

An optional property used to provide the name for the port carrying the `select_jtag_output` function. When not specified, the port is named “bscan_select_jtag_output”. Setting this value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.

- `bscan_clock : port_naming ;`

An optional property used to provide the name for the port carrying the `bscan_clock` function. When not specified, the port is named “bscan_clock”. Setting this value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.

- `capture_en : port_naming ;`

An optional property used to provide the name for the port carrying the `capture_en` function. When not specified, the port is named “bscan_capture_en”. Setting this value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.

- `shift_en : port_naming ;`

An optional property used to provide the name for the port carrying the `shift_en` function. When not specified, the port is named “bscan_shift_en”. Setting this value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.

- `update_en : port_naming ;`

An optional property used to provide the name for the port carrying the `update_en` function. When not specified, the port is named “bscan_update_en”. Setting this value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.

- `scan_in : port_naming ;`
An optional property used to provide the name for the port carrying the `scan_in` function. When not specified, the port is named “bscan_scan_in”. Setting this value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.
- `scan_out : port_naming ;`
An optional property used to provide the name for the port carrying the `scan_out` function. When not specified, the port is named “bscan_scan_out”. Setting this value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.
- `auxiliary_output : port_naming ;`
An optional property used to provide the name for the port carrying the `auxiliary_output` function. When not specified, the port is named “bscan_%s_aux_out”. The presence of the %s symbol somewhere in the string is required. The symbol %s is replaced by the `port_name` the auxiliary output is associated with. If the port is an element of a bus, the opening bracket is replaced by an underscore. For example, the default name for the auxiliary output port associated with port GPIO[4] is “bscan_GPIO_4_aux_out”. Setting this value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.
- `auxiliary_output_enable : port_naming ;`
An optional property used to provide the name for the port carrying the `auxiliary_output_enable` function. When not specified, the port is named “bscan_%s_aux_out_en”. The presence of the %s symbol somewhere in the string is required. The symbol %s is replaced by the `port_name` the auxiliary output enable is associated with. If the port is an element of a bus, the opening bracket is replaced by an underscore. For example, the default name for the auxiliary output enable port associated with port GPIO[4] is “bscan_GPIO_4_aux_out_en”. Setting this value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.
- `auxiliary_input : port_naming, ... ;`
An optional property used to provide the name for the port carrying the `auxiliary_input` function. When not specified, the port is named “bscan_%s_aux_in”. The presence of the %s symbol somewhere in the string is required. The symbol %s is replaced by the `port_name` the auxiliary input is associated with. If the port is an element of a bus, the opening bracket is replaced by an underscore. For example, the default name for the auxiliary input port associated with port GPIO[4] is “bscan_GPIO_4_aux_in”. Setting this value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.
- `auxiliary_input_enable : port_naming, ... ;`
An optional property used to provide the name for the port carrying the `auxiliary_input_enable` function. When not specified, the port is named

“bscan_%s_aux_in_en”. The presence of the %s symbol somewhere in the string is required. The symbol %s is replaced by the port_name the auxiliary output enable is associated with. If the port is an element of a bus, the opening bracket is replaced by an underscore. For example, the default name for the auxiliary input enable port associated with port GPIO[4] is “bscan_GPIO_4_aux_in_en”. Setting this value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.

- ac_init_clock0 : *port_naming* ;

An optional property used to provide the name for the port carrying the ac_init_clock0 function, which has a low “off” state. When not specified, the port is named “bscan_ac_init_clk0”. This port is only created when AC pads are present. Setting this value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.

- ac_init_clock1 : *port_naming* ;

An optional property used to provide the name for the port carrying the ac_init_clock1 function, which has a high “off” state. When not specified, the port is named “bscan_ac_init_clk1”. This port is only created when AC pads are present. Setting this value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.

- ac_signal : *port_naming* ;

An optional property used to provide the name for the port carrying the ac_signal function. When not specified, the port is named “bscan_ac_signal”. This port is only created when AC pads are present. Setting this value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.

- ac_mode_en : *port_naming* ;

An optional property used to provide the name for the port carrying the ac_mode_en function. When not specified, the port is named “bscan_ac_mode_en”. This port is only created when AC pads are present. Setting this value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/EmbeddedBoundaryScan/Interface.

ImplementationOptions

Specifies implementation options when building the boundary-scan cells.

Usage

```
DefaultsSpecification(policy) { // legal: company | group | user
    DftSpecification(module_name,id) {
        BoundaryScan {
            ImplementationOptions {
                clocking : tck | gated_tck | gated_tck_inv ; /*DefSpec
                update_stage : flop | latch ; /*DefSpec
                scan_path_retiming : flop | latch ; /*DefSpec
            }
        }
    }
}
```

Description

A wrapper that specifies implementation options when building the boundary-scan cells. The options consist of the clocking, and the use of latches or flip-flops as an update stage and for scan path retiming.

Arguments

- *clocking* : tck | gated_tck | gated_tck_inv ;
An optional property that specifies how the clocking of the boundary-scan cell should be constructed. The default value of Tessent BoundaryScan is gated_tck. Setting a value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/BoundaryScan/ImplementationOptions.
- *update_stage* : flop | latch ;
An optional property that specifies if the update stage is to be implemented using a latch or a flop. The default value of Tessent BoundaryScan is latch. Setting a value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/BoundaryScan/ImplementationOptions.
- *scan_path_retiming* : flop | latch ;
An optional property that specifies if the scan path retiming element is to be implemented using a latch. The default value of Tessent BoundaryScan is latch. Setting a value in the DefaultsSpecification implies a new default value to be used for the respective property of DftSpecification/BoundaryScan/ImplementationOptions.

MemoryBISR

Specifies certain default values for the memoryBISR to build and optionally insert into the design.

Usage

```
DefaultsSpecification(policy) { // legal: company | group | user
    DftSpecification {
        MemoryBISR {
            insert_fuse_box_controller_in_sub_block : boolean ; // default: off
            insert_fuse_box_controller_in_chip : boolean ; // default: on
            insert_fuse_box_controller_in_physical_block : boolean ;
                                            // default: off
            max_fuse_box_programming_sessions : int | unlimited ;
                                            // default: 1
            fuse_box_location : internal | external ;
            ChainInterface {
                scan_in : port_naming ; // Default : %s_bisr_si
                parallel_in : port_naming ;
                               // Default : %s_bisr_parallel_in
                scan_out : port_naming ; // Default : %s_bisr_so
                serial_repair_enable: port_naming ;
                               // Default : %s_bisr_serial_repair_enable
                capture_shift_clock : port_naming ; // Default : %s_bisr_clk
                shift_en : port_naming ; // Default : %s_bisr_shift_en
                reset : port_naming ; // Default : %s_bisr_reset
                memory_disable : port_naming ;
                               // Default : %s_bisr_mem_disable
                memory_chain_select : port_naming ;
                               // Default : %s_bisr_mem_chain_select
            }
        }
    }
}
```

Description

A wrapper that specifies certain default values for the memoryBISR to build and optionally insert into the design.

Arguments

- insert_fuse_box_controller_in_chip : on | off | when_fuse_box_present ;
 insert_fuse_box_controller_in_sub_block : on | off | when_fuse_box_present ;
 insert_fuse_box_controller_in_physical_block : on | off | when_fuse_box_present ;

Three optional properties that instructs the tool where to place the fuse box controller. The default is ON for the chip level and OFF for both, the sub block and physical block. The value of when_fuse_box_present allows the tool to add a controller at the same level of the fuse box, but only when there is actually a fuse box present at this level. If set, no controller will be added, if there is no fuse box.

There is no equivalent to these properties in the DftSpecification. If you want to change the fuse box controller location, you must use these properties in the DefaultsSpecification.

- `fuse_box_location : internal | external ;`

An optional property that specifies if the fuse box is to be instantiated inside the BISR controller, or if it already exists in the design and connections should be made to and from it. The default value of `fuse_box_location` is `internal`. Setting a value in the `DefaultsSpecification` implies a new default value to be used for the respective property of the `DftSpecification/MemoryBisr/Controller` wrapper.

- `max_fuse_box_programming_sessions : int | unlimited ;`

An optional property that specifies how many fuse box programming sessions are to be supported by the controller. The default value of `max_fuse_box_programming_sessions` is 1. The `unlimited` value disables the compression of repair information. Setting a value in the `DefaultsSpecification` implies a new default value to be used for the respective property of the `DftSpecification/MemoryBisr/Controller` wrapper. Refer to the description of this property in the `DftSpecification` for a more detailed description.

- `ChainInterface` wrapper

An optional wrapper that specifies the names of the ports created when connecting the BISR chains to ports of a module of type `sub_block` or `physical_block` as specified using the `set_design_level` command. A detailed description of the individual ports can be found at the `DftSpecification/MemoryBisr/Interface` wrapper.

- `scan_in : port_naming ;`

A string that specifies the naming to use for the `scan_in` port. When unspecified, it defaults to the value specified in the `MemoryBisr/Interface/scan_in` property inside the `DefaultsSpecification/DftSpecification` wrappers. See the `get_defaults_value` command description for more details about the company, group, and user defaults specifications.

The string must contain the “%s_” symbol. It is replaced by the power domain name followed by an underscore when the module contains more than one power domain name; otherwise, it is replaced by an empty string.

- `parallel_in : port_naming ;`

A string that specifies the naming to use for the BISR chain parallel input port. This property is only effective when `DftSpecification/MemoryBisr/memory_repair_loading_method: from_read_buffer` has been specified, otherwise it is ignored. When `parallel_in` is unspecified, it defaults to `%s_bisr_parallel_in`.

The string must contain the “%s_” symbol. It is replaced by the power domain name followed by the underscore when the module contains more than one power domain name; otherwise it is replaced by an empty string.

- `scan_out : port_naming ;`

A string that specifies the naming to use for the `scan_out` port. When unspecified, it defaults to the value specified in the `MemoryBisr/Interface/scan_out` property inside the `DefaultsSpecification/DftSpecification` wrappers. See the `get_defaults_value` command description for more details about the company, group, and user defaults specifications.

The string must contain the “%s_” symbol. It is replaced by the power domain name followed by an underscore when the module contains more than one power domain name; otherwise, it is replaced by an empty string.

- `serial_repair_enable : port_naming ;`

A string that specifies the naming to use for the fast BISR chain loading enable port. This property is only effective when DftSpecification/[MemoryBisr](#)/memory_repair_loading_method: from_read_buffer has been specified, otherwise it is ignored. This port will be connected to the “SerialRepairEnable” output port of the fuse box controller. When unspecified, it defaults to “%s_bisr_serial_repair_enable”.

The string must contain the “%s_” symbol. It is replaced by the power domain name followed by the underscore when the module contains more than one power domain name; otherwise it is replaced by an empty string.

- `capture_shift_clock : port_naming ;`

A string that specifies the naming to use for the capture_shift_clock port. When unspecified, it defaults to the value specified in the [MemoryBisr](#)/Interface/capture_shift_clock property inside the [DefaultsSpecification/DftSpecification](#) wrappers. See the [get_defaults_value](#) command description for more details about the company, group, and user defaults specifications.

The string must contain the “%s_” symbol. It is replaced by the power domain name followed by an underscore when the module contains more than one power domain name; otherwise, it is replaced by an empty string.

- `shift_en : port_naming ;`

A string that specifies the naming to use for the shift_en port. When unspecified, it defaults to the value specified in the [MemoryBisr](#)/Interface/shift_en property inside the [DefaultsSpecification/DftSpecification](#) wrappers. See the [get_defaults_value](#) command description for more details about the company, group and user defaults specifications.

The string must contain the “%s_” symbol. It is replaced by the power domain name followed by an underscore when the module contains more than one power domain name; otherwise, it is replaced by an empty string.

- `reset : port_naming ;`

A string that specifies the naming to use for the active low reset port. When unspecified, it defaults to the value specified in the [MemoryBisr](#)/Interface/reset property inside the [DefaultsSpecification/DftSpecification](#) wrappers. See the [get_defaults_value](#) command description for more details about the company, group and user defaults specifications.

The string must contain the “%s_” symbol. It is replaced by the power domain name followed by an underscore when the module contains more than one power domain name; otherwise, it is replaced by an empty string.

- `memory_disable : port_naming ;`

A string that specifies the naming to use for the memory_disable port. When unspecified, it defaults to the value specified in the [MemoryBisr](#)/Interface/memory_disable property inside

the [DefaultsSpecification/DftSpecification](#) wrappers. See the [get_defaults_value](#) command description for more details about the company, group and user defaults specifications.

The string must contain the “%s_” symbol. It is replaced by the power domain name followed by an underscore when the module contains more than one power domain name otherwise, it is replaced by an empty string.

This port is only created when at least one memory instance has a Memory wrapper (see “[Tessent Core Description](#)” on page 3755) with function “bisrSerialData” and a Memory with function “select” in its Memory library description or a child block with this port is present. Such ports are identified in the ICL module as [DataInPorts](#) with the Attribute “tessent_bisr_function” set to “memory_disable”.

- **memory_chain_select : *port_naming* ;**

A string that specifies the naming to use for the BISR register chain select MSEL port. This port will be connected to the “bisrSeIM” output port of the fuse box controller. When unspecified, it defaults to “%s_bisr_mem_chain_select”.

The string must contain the “%s_” symbol. It is replaced by the power domain name followed by the underscore when the module contains more than one power domain name; otherwise it is replaced by an empty string.

MemoryBist

Specifies the default values of properties found in the DftSpecification/MemoryBist wrapper.

Usage

```
DefaultsSpecification(policy) { // legal: company | group | user
    DftSpecification {
        MemoryBist {
            clock_partitioning      : per_clock_domain | per_sync_clock_group ;
            max_steps_per_controller : int | unlimited ;
            max_test_time_per_controller : time | 500ms ; // Default is 500ms
            max_memories_per_step    : int | unlimited ;
            max_power_per_step       : int | unlimited ; // Default is 500mW
            single_memory_dimension_per_step : on | off ;
            ControllerOptions {
            }
            RepairOptions {
            }
            DiagnosisOptions {
            }
            AlgorithmResourceOptions {
            }
            MemoryInterfaceOptions {
            }
            MemoryClusterOptions {
            }
        }
    }
}
```

Description

A wrapper that specifies the default values of properties found in the DftSpecification/
[MemoryBist](#) wrapper.

You can also provide test scheduling constraints to guide the creation of the DftSpecification using the [create_dft_specification](#) command.

Arguments

- clock_partitioning : per_clock_domain | per_sync_clock_group ;

A property that specifies how memories will be grouped by the [create_dft_specification](#) command according to their clock sources. When set to per_clock_domain, the memories on the same clock domain are allowed to be assigned to a controller. When set to per_sync_clock_group, controller sharing is allowed for memories belonging to synchronous clock sources and having the same clock frequency. Synchronous clock groupings are specified with the [add_synchronous_clock_group](#) command and current groupings can be reported with the [report_synchronous_clock_groups](#) command.

- max_steps_per_controller : int | unlimited ;

A property that constrains the number of test steps that will be allocated per controller. A controller step designates the group of memories that will be tested in parallel. The

[create_dft_specification](#) command will assign test steps to controllers such that the requirement is met.

When running the [process_dft_specification](#) command, the validation of the DftSpecification will issue a warning if the controller step count requirement is exceeded.

- max_test_time_per_controller : time | unlimited ;

A property that constrains the test time that a controller can use to complete the test. The [create_dft_specification](#) command will assign memories to controllers such that the requirement is met. The default value is 500ms.

The estimated test time of a controller is the sum of the execution time of its controller steps. The test time of a controller step depends on factors such as the chosen algorithm and the memory sizes.

When running the [process_dft_specification](#) command, the validation of the DftSpecification will issue a warning if the test time requirement is exceeded.

- max_memories_per_step : int | unlimited ;

A property that constrains the number of memories that will be tested in parallel within a controller step. The [create_dft_specification](#) command will assign memories to controller steps such that the requirement is met.

When running the [process_dft_specification](#) command, the validation of the DftSpecification will issue a warning if the memory count requirement is exceeded.

- max_power_per_step : int | unlimited ;

A property that constrains the power consumption per controller step. The [create_dft_specification](#) command will assign memories to controller steps such that the requirement is met. The specified value is assumed to be in milliwatts. The default value is 500mW.

The estimated power per step is the sum of the power consumed by memories tested in parallel. The memory power is calculated by multiplying the MilliWattsPerMegaHertz property in the memory library description by the frequency of the clock domain. It does not include the power consumed by the BIST circuitry.

When running the [process_dft_specification](#) command, the validation of the DftSpecification will issue a warning if the power consumption requirement is exceeded.

- single_memory_dimension_per_step : on | off ;

A property that specifies how memories of different dimensions will be grouped by the [create_dft_specification](#) command.

When set to on, only memories having the same number of columns, rows, and banks will be allowed to be tested in parallel within a controller step. When set to off, memories of different sizes will be allowed to be tested in parallel.

ControllerOptions

Specifies the default values of properties found in the Controller/AdvancedOptions and Controller/Step wrappers of the DftSpecification/MemoryBist wrapper.

Usage

```
DefaultsSpecification(policy) { // legal: company | group | user
    DftSpecification {
        MemoryBist {
            ControllerOptions {
                algorithm : algo_name ; // Default: // from library
                operation_set : opset_name ;// Default: // from library
                extra_algorithms : algo_name, ... ;
                extra_operation_sets : opset_name, ... ;
                functional_debug_mode : on | off ;
                comparator_location : shared_in_controller | per interface ;
                pipeline_controller_outputs : on | off ;
                selective_parallel_memory_test : on | off ;
                shared_comparators_per_go_id : int | all ; // Default: 1
                use_multicycle_paths : on | off ;
                gate_bist_clock_in_functional_mode : off | with_clock_gating_cell | with_clock_mux ;
                min_misr_segment_bits : 24 | 256 ;
            }
        }
    }
}
```

Description

A wrapper that specifies the default values of properties found in the [AdvancedOptions](#) and [Step](#) wrappers of the DftSpecification/MemoryBist wrapper.

Arguments

- `algorithm : algo_name ;`
A property that sets the default value of the algorithm property found inside the [AdvancedOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- `operation_set : opset_name ;`
A property that sets the default value of the operation_set property found inside the [AdvancedOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- `extra_algorithms : algo_name, ... ;`
A property that sets the default value of the extra_algorithms property found inside the [AdvancedOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.

- extra_operation_sets : *opset_name*, ... ;
A property that sets the default value of the extra_operation_sets property found inside the [AdvancedOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- functional_debug_mode : on | off ;
A property that sets the default value of the functional_debug_mode property found inside the [AdvancedOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper
- comparator_location : shared_in_controller | per_interface ;
A property that sets the default value of the comparator_location property found inside the [Step](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- pipeline_controller_outputs : on | off ;
A property that sets the default value of the pipeline_controller_outputs property found inside the [AdvancedOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- selective_parallel_memory_test : on | off ;
A property that sets the default value of the selective_parallel_memory_test property found inside the [AdvancedOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- shared_comparators_per_go_id : *int* | all ;
A property that sets the default value of the shared_comparators_per_go_id property found inside the [AdvancedOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper. The default is 1.
- use_multicycle_paths : on | off ;
A property that sets the default value of the use_multicycle_paths property found inside the [AdvancedOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- gate_bist_clock_in_functional_mode : off | with_clock_gating_cell | with_clock_mux ;
A property that sets the default value of the gate_bist_clock_in_functional_mode property found inside the [AdvancedOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- min_misr_segment_bits : 24 | 256 ;
A property that sets the default value of the min_misr_segment_bits property found inside the [AdvancedOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.

RepairOptions

Specifies the default values of properties found in the DftSpecification/MemoryBist/Controller/
RepairOptions wrapper.

Usage

```
DefaultsSpecification(policy) { // legal: company | group | user
    DftSpecification {
        MemoryBist {
            RepairOptions {
                fuse_set_extraction_sequence : address_before_fuse_map | fuse_map_before_address ;
                row_bira_location : controller | follow_comparators ;
                max_repair_group_size : unlimited | {int[kilobits | megabits]} ;
                repair_sharing : on | off ;
            }
        }
    }
}
```

Description

A wrapper that specifies the default values of properties found in the DftSpecification/
MemoryBist/[RepairOptions](#) wrapper.

Arguments

- **fuse_set_extraction_sequence : address_before_fuse_map | fuse_map_before_address ;**
A property that sets the default value of the fuse_set_extraction_sequence property found inside the [RepairOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- **row_bira_location : controller | follow_comparators ;**
A property that sets the default value of the row_bira_location property found inside the [RepairOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- **max_repair_group_size : unlimited | {int[kilobits | megabits]}**
A property that specifies the total memory size limit on a memory group. The default value of “unlimited” indicates that any number of compatible memories can be assigned to repair groups. The int[units] pair specifies the maximum size allowed for a repair group. Any memory that would cause this limit to be exceeded will be assigned to a different repair group.
- **repair_sharing on | off**
A property that will globally enable and disable repair sharing for memories that have “-repair_sharing auto” specified, which is the default. The “-repair_sharing” value can be changed from “auto” for a memory instance with the [set_memory_instance_options](#) command.

DiagnosisOptions

Specifies the default values of properties found in the DftSpecification/MemoryBist/Controller/
DiagnosisOptions wrapper.

Usage

```
DefaultsSpecification(policy) { // legal: company | group | user
    DftSpecification {
        MemoryBist {
            DiagnosisOptions {
                comparator_selection_mux      : on | off | auto ;
                go_status                      : auto | per_memory ;
                StopOnErrorOptions {
                    failure_limit             : int | off ; // Default: 4096
                }
            }
        }
    }
}
```

Description

A wrapper that specifies the default values of properties found in the DftSpecification/
MemoryBist/[DiagnosisOptions](#) wrapper.

Arguments

- **comparator_selection_mux** : on | off | auto;
A property that sets the default value of the comparator_selection_mux property found inside the [DiagnosisOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- **go_status** : auto | per_memory ;
A property that sets the default value of the go_status property found inside the [DiagnosisOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- **StopOnErrorOptions/failure_limit** : *int* | off ;
A property that sets the default value of the StopOnErrorOptions/failure_limit property found inside the [DiagnosisOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper. The default value becomes 4096 when the controller tests at least one memory of type SRAM or DRAM. It becomes “off” when the controller tests only memories of type ROM. The error counter is no longer used for ROM diagnosis as it was in the LV flow. Instead the functional debug mode is used to perform ROM diagnosis.

AlgorithmResourceOptions

Specifies the default values of properties found in the DftSpecification/MemoryBist/Controller/[AlgorithmResourceOptions](#) wrapper.

Usage

```
DefaultsSpecification(policy) { // legal: company | group | user
    DftSpecification {
        MemoryBist {
            AlgorithmResourceOptions {
                soft_instruction_count : int //Default: 0
                data_register_bits : int | auto ;
                counter_a_bits : int | auto ;
                delay_counter_bits : int | auto ;
                max_data_inversion_address_bit_index : int | max_index ;
                // Default: 0
                a_equals_b_command_allowed : on | off ;
                address_segment_x0_y0_allowed : on | off ;
                max_x0_segment_bits : 1 | auto ;
                max_y0_segment_bits : 1 | auto ;
            }
        }
    }
}
```

Description

A wrapper that specifies the default values of properties found in the DftSpecification/MemoryBist/[AlgorithmResourceOptions](#) wrapper.

Arguments

- `soft_instruction_count : int ;`
A property that sets the default value of the `soft_instruction_count` property found inside the [AlgorithmResourceOptions](#) wrapper of the DftSpecification/MemoryBist wrapper.
- `data_register_bits : int | auto ;`
A property that sets the default value of the `data_register_bits` property found inside the [AlgorithmResourceOptions](#) wrapper of the DftSpecification/MemoryBist wrapper.
- `counter_a_bits : int | auto ;`
A property that sets the default value of the `counter_a_bits` property found inside the [AlgorithmResourceOptions](#) wrapper of the DftSpecification/MemoryBist wrapper.
- `delay_counter_bits : int | auto ;`
A property that sets the default value of the `delay_counter_bits` property found inside the [AlgorithmResourceOptions](#) wrapper of the DftSpecification/MemoryBist wrapper.

- max_data_inversion_address_bit_index : int | max_index ;
A property that sets the default value of the max_data_inversion_address_bit_index property found inside the [AlgorithmResourceOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper. The default is 0.
- a_equals_b_command_allowed : on | off ;
A property that sets the default value of the a_equals_b_command_allowed property found inside the [AlgorithmResourceOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- address_segment_x0_y0_allowed : on | off ;
A property that sets the default value of the address_segment_x0_y0_allowed property found inside the [AlgorithmResourceOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- max_x0_segment_bits : 1 | auto ;
A property that sets the default value of the max_x0_segment_bits property found inside the [AlgorithmResourceOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- max_y0_segment_bits : 1 | auto ;
A property that sets the default value of the max_y0_segment_bits property found inside the [AlgorithmResourceOptions](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.

MemoryInterfaceOptions

Specifies the default values of properties found in the Controller/AdvancedOptions Controller/Step, and Controller/Step/MemoryInterface wrappers of the DftSpecification/MemoryBist wrapper.

Usage

```
DefaultsSpecification(policy) { // legal: company | group | user
    DftSpecification {
        MemoryBist {
            MemoryInterfaceOptions {
                bist_data_in_pipelining      : on | off | int ; // Default: off
                bist_data_out_pipelining     : on | off | per_port ;
                                            // Default: off
                local_comparators_per_go_id  : int | all ; // Default: 1
                observation_xor_size         : 1..8 | off ; // Default: 3
                repair_analysis_present      : off | auto ;
                scan_bypass_logic            : async_mux | none | sync_mux |
                                                from_library ;
                repair_group_scope           : physical_memory | controller ;
                                            // Default: controller
            }
        }
    }
}
```

Description

A wrapper that specifies the default values of properties found in the [AdvancedOptions](#), [Step](#) and Controller/Step/MemoryInterface wrappers of the DftSpecification/MemoryBist wrapper.

Arguments

- `bist_data_in_pipelining` : `on` | `off` | `int`;

A property that sets the default value of the of the `bist_data_in_pipelining` property found inside the [Step](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.

- `bist_data_out_pipelining` : `on` | `off` | `per_port`;

A property that sets the default value of the of the `bist_data_out_pipelining` property found inside the [Step](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.

- `local_comparators_per_go_id` : `int` | `all`;

A property that sets the default value of the `MemoryInterface/local_comparators_per_go_id` property found inside the [Step](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.

- `observation_xor_size` : `1..8` | `off`;

A property that sets the default value of the `observation_xor_size` property found inside the [AdvancedOptions](#) wrapper of the DftSpecification/MemoryBist/[Controller](#) wrapper.

- repair_analysis_present : off | auto;

A property that sets the default value of the MemoryInterface/repair_analysis_present property found inside the [Step](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.

- scan_bypass_logic : async_mux | none | sync_mux | [from_library](#) ;

A property that sets the default value of the MemoryInterface/scan_bypass_logic property found inside the [Step](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.

- repair_group_scope : physical_memory | [controller](#) ;

Memory instances that have repair sharing enabled, the selected value impacts repair grouping as follows:

- physical_memory — Specifies the repair group is restricted within a physical memory. Memories with multiple [RowSegment](#) and/or [ColumnSegment](#) wrappers will be considered as having a single RowSegment and/or ColumnSegment wrapper for redundancy analysis as long as the memory size does not exceed the size specified by the max_repair_group_size property in the [RepairOptions](#) wrapper.
- controller — Specifies the repair group is restricted to all memories tested by the controller. The repair group cannot contain memories tested by other controllers. Memories are automatically assigned to repair groups as long as the memory size does not exceed the size specified by the max_repair_group_size property in the [RepairOptions](#) wrapper.

Repair sharing can be enabled for memory instances with the [set_memory_instance_options](#) command if the DefaultsSpecification for repair_sharing is “off”.

MemoryClusterOptions

A wrapper that is used to specify default values of properties found in the DftSpecification/MemoryBist/Controller/MemoryCluster wrapper

Usage

```
DefaultsSpecification(policy) { // legal: company | group | user
    DftSpecification {
        MemoryBist {
            MemoryClusterOptions {
                pipeline_cluster_inputs      : on | off ;
                pipeline_cluster_outputs     : on | off ;
                memory_access_level         : physical | logical | auto ;
                repair_analysis_present     : auto | off ;
                repair_group_scope          : physical_memory | logical_memory | controller ;
                                            // Default: controller
            }
        }
    }
}
```

Description

A wrapper that specifies the default values of properties found in the DftSpecification/MemoryBist/[MemoryCluster](#) wrapper.

Arguments

- **pipeline_cluster_inputs** : on | off ;
A property that sets the default value of the `pipeline_cluster_inputs` property found inside the [MemoryCluster](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- **pipeline_cluster_outputs** : on | off ;
A property that sets the default value of the `pipeline_cluster_outputs` property found inside the [MemoryCluster](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- **memory_access_level** : physical | logical | auto ;
A property that sets the default value of the `memory_access_level` property found inside the [MemoryCluster](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- **repair_analysis_present** : auto | off ;
A property that sets the default value of the `repair_analysis_present` property found inside the [MemoryCluster](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.
- **repair_group_scope** : physical_memory | logical_memory | controller ;
A property that sets the default value of the `repair_group_scope` property found inside the [MemoryCluster](#) wrapper of the DftSpecification/[MemoryBist](#) wrapper.

DefaultsSpecification/PatternsSpecification

Specifies certain default values for the pattern generation process through the PatternsSpecification.

Usage

```
DefaultsSpecification(policy) { // legal: company | group | user
    PatternsSpecification {
        tester_period : 100ns ;
        AdvancedOptions {
            parameter_file   : file_path ;
            Parameters {
                parameter_name : parameter_value ; // repeatable
            }
        }
        SignOffOptions {
        }
        ManufacturingOptions {
        }
    }
}
```

Description

These wrappers are used to define how the patterns are to be created when running the `create_patterns_specification` command to create different pattern types.

Arguments

- `tester_period : period ;`
An optional property that defines the period of the tester clock. The default is 100ns. Setting a value in the DefaultsSpecification implies a new default value to be used for the respective property of PatternsSpecification/Patterns.
- `AdvancedOptions/parameter_file : file_path ;`
An optional that specifies the name of a file containing parameters used to configure the `write_patterns` command. Setting a value in the DefaultsSpecification implies a new default value to be used for the respective property of PatternsSpecification.
- `AdvancedOptions/Parameters/parameter_name : parameter_value ;`
An optional that specifies parameter-value pairs used to configure the `write_patterns` command. A parameter specified in this wrapper overrides the same parameter specified in the specified `parameter_file`. Setting a value in the DefaultsSpecification implies a new default value to be used for the respective property of PatternsSpecification

SignOffOptions

Defines how simulation signoff pattern wrappers are to be created when running the `create_patterns_specification` command.

Usage

```
DefaultsSpecification(policy) { // legal: company | group | user
    PatternsSpecification {
        SignOffOptions {
            simulate_instruments_in_lower_physical_instances : on | off ;
            testbench_module_name : format_string ;
        }
    }
}
```

Description

This wrapper is used to define how the simulation signoff patterns wrapper are to be created when running the `create_patterns_specification` command to create the signoff simulation patterns.

Arguments

- `simulate_instruments_in_lower_physical_instances : on | off ;`

A property that specifies to re-execute the lower physical instance simulations at higher levels when you are using a hierarchical flow. This property has no effect if your current design does not include any lower physical instances.

This property only affects the pattern specification creation when `create_patterns_specification` is called with usage “signoff”. It has no effect for usage “manufacturing”. When specified to “on”, the pattern specification will include `Patterns` wrapper to simulate all tests situated in the top-level module and below the child physical blocks. The `Patterns` wrapper will keep the simulation of the test in each physical block instance separated from the other such that the interface model of the other physical block instances can be used when simulating a given physical block instance in order to manage the simulation performance. If you have declared some modules as “sub_block” modules using the `set_design_level` command, their tests will always be simulated as part of their parent physical module, whether it is the top module or a child physical block. When the property is set to off, only the tests situated in the top module and its child sub_block modules are simulated. The tests situated below the child physical block are omitted.

- `testbench_module_name : format_string ;`

A property that specifies the top-level module name of the test bench in the `patternName.v` file. You can use this property to give a different test bench module name for each test bench so that more than one test bench can be compiled into a common work library for a Verilog simulator.

The default is TB. You can specify %d to mean the module name of the current design or %p to mean the pattern name. The advantage of using TB for all test benches is that you can use the same waveform file to analyze failing simulations in any test bench.

[DefaultsSpecification/PatternsSpecification](#)

ManufacturingOptions

Defines how simulation manufacturing pattern wrappers are to be created when running the create_patterns_specification command.

Usage

```
DefaultsSpecification(policy) { // legal: company group user
    PatternsSpecification {
        ManufacturingOptions {
            max_async_clock_sources      : integer | unlimited ;
            manufacturing_patterns_format : format ;
            compress_pattern_files       : on | off ;
            MemoryBist {
                max_controllers_per_test_step : integer | unlimited ;
            }
        }
    }
}
```

Description

The ManufacturingOptions wrapper is used in the Defaults/PatternsSpecification wrapper.

Arguments

- `max_async_clock_sources : integer | unlimited ;`

A property that specifies how many asynchronous clocks can be active within one Patterns wrapper. Modern testers can generate multiple asynchronous clocks. Use this property to control how many instruments, belonging to different asynchronous frequency groups, can be executed in parallel.

If you specify an integer, Tessent Shell creates memory BIST patterns that use no more than the specified number of asynchronous clocks. Valid integer values are 0 or greater. When you specify a value of 0, all clocks used in the pattern are synchronous. Use the value of 0 when the tester does not have any asynchronous clock generators.

If you specify unlimited, Tessent Shell groups all memory BIST controllers inside of a single pattern. Use this value when the tester is capable of driving an unlimited number of asynchronous clock channels.

- `manufacturing_patterns_format : format ;`

A property that specifies a format for the saved test patterns. Valid formats are wgl, stil, ctl, stil2005, titdl, fjtld, mitdl, or tstl. The default format is stil.

For a description of each format type, see the write_patterns command's format_switch in the *Tessent Shell Reference Manual*.

- `compress_pattern_files : on | off ;`

A property that enables pattern compression.

- MemoryBist/max.controllers_per_test_step : *integer* | unlimited ;

A property that partitions the memoryBIST controllers into many test steps. When an integer is specified, the memoryBIST controller will insert no more than the specified number memoryBIST controllers per test step during create_patterns_specification. This property only affects the memoryBIST pre-repair (if present) and Go/NoGo patterns.

When generating the ParallelRetentionTest patterns, all memoryBIST controllers are inserted inside the same test step, but the number of controllers with the same parallel_retention_group will not exceed the specified value.

If BIRA is present, the CheckRepairNeeded patterns are not affected by this property.

Metadata Configuration Syntax

The metadata syntax is used to define all of the available syntax documented in the DftSpecification and DefaultsSpecification/DftSpecification wrappers.

This section describes the configuration metadata syntax used inside Tesson Shell to define all valid configuration syntax. The metadata syntax is also used to create the configuration tree widgets in DFTVisualizer that are used to edit and view the configuration data in the Configuration Data window. For information about loading configuration data in the DFTVisualizer Configuration Data window, see the [add_config_tab](#) and [display_specification](#) commands. Finally, the metadata is used by the [report_config_syntax](#) command to report the available syntax in a human-readable format that is consistent with how the syntax is documented in this reference guide.

You typically do not need to define metadata because all configuration data is fully defined in the tool. You can, however, define your own metadata to define any configuration syntax needed to automate portions of your flows. Both DFTVisualizer and the [report_config_syntax](#) command, which are driven by the metadata, will completely support your syntax.

You can also augment the metadata of the [DftSpecification](#) for your custom needs. The added elements will be ignored by the [process_dft_specification](#) command. You can then add your own code to access the added properties and use it for your custom needs. For example, you may want to package a fully-specified DftSpecification file for an RTL core such that the user of the core can simply add the DFT hardware by running [process_dft_specification](#) with your packaged DftSpecification file. In this file, you may want to define extra information such as clock sources with their periods. After you have done this, you can use configuration data commands, such as the [get_config_value](#) command, to access the information and issue the [add_clocks](#) commands in your flow. You can also add extra information that is accessed by your [process_dft_specification.post_insertion Procedure](#) and have it automatically perform custom actions based on the captured information in the [DftSpecification](#) file.

If you create custom metadata and want it to be loaded into the tool, you must store the metadata file in the <plugin>/metadata directory, where <plugin> is a directory pointed to by the TESSENT_PLUGIN_PATH environment variable, and you must name the metadata file with the extension “.tesson_meta”. If you name the <plugin> directory “tesson_plugin” and place it one level above the bin directory that contains the Tesson Shell executable “tesson”, the tool automatically loads the metadata at invocation unless the TESSENT_PLUGIN_IGNORE_DEFAULT_PATH environment variable is defined.

Wrapper	3721
Property	3730
RepeatableProperty	3735
DataWrapper	3738
CsvWrapper	3741
Id	3743

Value	3747
RowIdElement	3751

Wrapper

A wrapper used in metadata to define the syntax of a wrapper that is usable in configuration data.

Usage

```
Partitions : partition_list ; // Only on first line of file
Wrapper(wrapper_name) {
    Repeatable      : On | Off | Single ;
    IgnoreUnknowns  : On | Off ;
    Usage           : normal | hidden | Env(EnvVar)
                      | AccessFeature(feature_name) ;
    ReferenceableOnly : On | Off ;
    InsertFirst;
    InsertLast; // default behavior
    InsertBefore     : meta_leaf_name ;
    InsertAfter      : meta_leaf_name ;
    MergeableContent : On | Off ;
    Options(Visualizer) {
        cdv_tab_prefix : string ;
        DisplayString   : string ;
    }
    //Everything below is repeatable and optional
    Id(name_id) {
    }
    Property(property_name) {
    }
    RepeatableProperty(property_name) {
    }
    DataWrapper(wrapper_name) {
    }
    CsvWrapper(wrapper_name) {
    }
    Reference = relative_or_absolute_meta_path ;
    ReferenceWithInheritedDefault = relative_or_absolute_meta_path ;
    ReferenceContents = relative_or_absolute_meta_path ;
}
```

Description

A wrapper used in metadata to define the syntax of a wrapper that is usable in configuration data.

The presence of the Partitions property is used to define the partition in which the wrapper, and all of the elements defined within it, are to exist.

Arguments

- Partitions : *partition_list* ;

An optional property that can only be specified on the first line of a file, and that controls in which partition the metadata is to be used when defining syntax. When unspecified, the wrappers and what is defined within them, are defined in the default partition.

The partition name can be specified as “default”, “tcd”, or “default, tcd”. The “default” partition is the one in which the [DftSpecification](#) and [DefaultsSpecification/DftSpecification](#) wrappers exist. The tcd partition is the one in which the files loaded with the [read_core_descriptions](#) command are loaded into. The tcd partition is read-only and configuration data found in it cannot be modified using configuration-editing commands such as the [add_config_element](#) command.

All existing syntax defined in the “tcd” partition within the tool is also defined in the default partition. If you absolutely need to edit a tcd file, you need to load it into the default partition using the [read_config_data](#) command, perform your edits using the editing commands, save it back to the file using [write_config_data](#), and then load it back into the tcd partition using the [read_core_descriptions](#) command. Even if it exists in the default partition, the content of this configuration data is not used by the tool because the tool only looks for tcd data in the tcd partition.

- *wrapper_name*

A required string that defines the name of the wrapper to create. The string must start with a letter and only include letters, numbers, and underscores. The *wrapper_name* must be unique across all *wrapper_names* for root-level wrappers inside a partition, and across all *wrapper_names* and *property_names* found within a common parent wrapper.

When you want to define extra syntax inside an already defined wrapper, you create a wrapper that contains your new elements and has a “/” as the first character. For example, if you wanted to add a new wrapper called MyCustomData inside DftSpecification/IjtagNetwork, you would do it this way:

```
Wrapper(/DftSpecification/IjtagNetwork) {
    Wrapper(MycustomData) {
        ...
    }
}
```

- Repeatable : On | Off | Single ;

A property used to define whether the wrapper is repeatable. Both the Off and Single options mean that the wrapper is not repeatable. The difference between Off and Single is that a wrapper identified as “Repeatable : Single” always exists whether or not it is specified in the configuration data. You can get the value of properties inside a Single wrapper without having to first check if the wrapper exists or not. A “Repeatable : Off” wrapper does not exist until it is specified.

- IgnoreUnknowns : On | Off ;

A property that specifies that wrappers and properties not declared in the metadata of this wrapper are to be tolerated in this wrapper. You should never set this On in wrappers that are not purely machine generated and consumed by a machine as any typos will go unnoticed and will be silently ignored. These unknown elements will not be viewable and editable in DftVisualizer and [report_config_syntax](#) will not report their syntax. It is much safer to define all allowed syntax within a wrapper even if you choose to keep some hidden using the “Usage : hidden;” property which documented next.

- Usage : normal | hidden | Env(EnvVar) | AccessFeature(*feature_name*) ;

A property that controls the visibility of a wrapper. When set to normal, the wrapper is reported by [report_config_syntax](#) and visible in DFTVisualizer. When set to hidden, the wrapper is not reported by [report_config_syntax](#) and is invisible in DFTVisualizer. Its value can still be fetched and edited using the configuration introspection and editing commands such as [get_config_value](#) if the name of the hidden element is known to the user. The “Usage : Env(EnvVar)” is treated as normal if the EnvVar environment variable is defined and set to 1; otherwise, it is treated as hidden. When the Usage value is AccessFeature(*feature_name*), the usage value is “normal”, if the *access_code* for the *feature_name* is enabled, otherwise the Usage value is “hidden”.

- ReferenceableOnly : On | Off ;

A property that controls the existence of the wrapper. When set to On, this wrapper definition does not exist when it is defined. It and its children only exist when referenced using the [Reference](#) property . This option is useful to create a wrapper that defines a library of elements to be referenced from other wrappers.

- *InsertFirst* ;

An implicit Boolean property that specifies that the wrapper is to be inserted before the already existing elements in the wrapper. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command. Also, it controls the order in which wrappers with “Repeatable : Single” gets displayed in the configuration tabs inside DFTVisualizer.

- *InsertLast* ;

An implicit Boolean property that specifies that the wrapper is to be inserted after the already existing elements in the wrapper. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command. Also, it controls the order in which wrappers with “Repeatable : Single” gets displayed in the configuration tabs inside DFTVisualizer.

- InsertBefore : *meta_leaf_name* ;

A property that specifies that the wrapper is to be inserted before an already existing element in the wrapper. You refer to the element using its leaf_name. For example, to insert a wrapper before Wrapper(IjtagNetwork), you would specify “InsertBefore : IjtagNetwork;”. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command. Also, it controls the order in which wrappers with “Repeatable : Single” are displayed in the configuration tabs inside DftVisualizer.

- InsertAfter : *meta_leaf_name* ;

A property that specifies that the wrapper is to be inserted after an already existing element in the wrapper. You refer to the element using its leaf_name. For example, to insert a

wrapper after Wrapper(IjtagNetwork), you would specify “InsertAfter : IjtagNetwork;”. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command. Also, it controls the order in which wrappers with “Repeatable : Single” are displayed in the configuration tabs inside DftVisualizer.

- MergeableContent : On | Off ;
A property that specifies that the content of the wrapper is merged with existing content. When this property is set to on, the content of the wrapper is merged with the existing content when reading in a new copy of the same parent wrapper. For example, if WprA was defined with MergeableContent set to On and a WprA already exist in memory with SubWrapper1. If you read a second copy of WprA which contains SubWrapper2, the content of the new WprA wrapper will be merged with the content of the one that already exists in memory such that both SubWrapper1 and SubWrapper2 will exist in WprA.
- Options(Visualizer)/cdv_tab_prefix : *string* ;
A property used to control the name of the Tab that is used by DFTVisualizer when the [add_config_tab](#) command is issued on this wrapper. The specified prefix is concatenated with an integer incremented from 1 for all added configuration tabs having a common prefix.
- Options(Visualizer)/DisplayString : *string* ;
A property used to control how the wrapper is labelled in the Configuration Data window. When unspecified, it default to wrapper_name. This option is useful when you want to create a GUI to display configuration data and you want to name the tree nodes using sentences as oppose to the strict wrapper names.
- Reference = *relative_or_absolute_meta_path* ;
A property used to define an element inside the wrapper using the same definition that was used inside another wrapper. This not only allows you to keep the metadata DRY, it also enables the element to be moved or copied from one location to the other using DFTVisualizer or the “[add_config_element](#) -copy_from” and the [move_config_element](#) commands. For an element to be copied or moved from one wrapper to the next, the metadata definition in both places must be created in one place by either having both of them reference a unique definition, or by having one definition reference the other. The path may be absolute or relative such as in these two examples:

```
Reference = ../Interface/scan_in;
Reference = /DftSpecification/IjtagNetwork/HostScanInterface/
Interface/scan_in;
```

- ReferenceWithInheritedDefault = *relative_meta_path* ;
A property used to define a property inside the wrapper using the same definition that was used inside another wrapper. Not only is the definition inherited, the value of the referenced property becomes the default value of the new property. To use this feature, the *relative_meta_path* can only come back down in wrappers specified with “Repeatable :

Single”; this is because to be able to inherit the default value from it, the referenced property must always exist whenever the referencing property exists. For example, the path `../../Interface/scan_in` is legal because Interface is defined with “Repeatable : Single” inside the IJtagNetwork/HostScanInterface wrapper. The above example could be used to create a property called “scan_in” in a wrapper found inside HostScanInterface that defaults to the value of the “`../../Interface/scan_in`” property when the “`./scan_in`” property is not specified.

- ReferenceContents = *relative_or_absolute_meta_path* ;

A property used to reference the elements inside of the wrapper that it points to and not the wrapper itself. See [Example 2](#) for an example usage of this property.

Examples

Example 1

The following example defines the metadata used by the Sib wrapper inside the DftSpecification/IJtagNetwork wrapper. Following is the constructed syntax reported by report_config_syntax on the same wrapper. Notice the recursive definition of the Sib node inside the Sib node achieved by referencing itself using “Reference = `../Sib;`”.

```
> report_config_data -partition meta \
    /dftspecification/ijtagnetwork/hostscaninterface/sib
```

```
Wrapper(Sib) {
    Repeatable : On;
    Id(id) {
        Type : String;
        Repeatable : Off;
        IgnoreCase : On;
        Options(Visualizer) {
            Counter : global;
            DefaultValueList : #;
        }
    }
    Wrapper(Interface) {
        Repeatable : single;
        Wrapper(Client) {
            Repeatable : single;
            Property(tck) {
                Value(port_name) {
                    Type : String;
                    DefaultValue : ijtag_tck;
                }
            }
            Property(reset) {
                Value(port_name) {
                    Type : String;
                    DefaultValue : ijtag_reset;
                }
            }
            Property(select) {
                Value(port_name) {
                    Type : String;
                    DefaultValue : ijtag_sel;
                }
            }
            Property(capture_en) {
                Value(port_name) {
                    Type : String;
                    DefaultValue : ijtag_ce;
                }
            }
            Property(shift_en) {
                Value(port_name) {
                    Type : String;
                    DefaultValue : ijtag_se;
                }
            }
            Property(update_en) {
                Value(port_name) {
                    Type : String;
                    DefaultValue : ijtag_ue;
                }
            }
            Property(scan_in) {
                Value(port_name) {
                    Type : String;
                    DefaultValue : ijtag_si;
                }
            }
            Property(scan_out) {
```

```
        Value(port_name) {
            Type : String;
            DefaultValue : ijtag_so;
        }
    }
    Property(reset_polarity) {

```

```
DftSpecification(<module_name>,<id>) {
    IJtagNetwork {
        HostScanInterface(<id>) {
            Sib(<id>) {
                Interface {
                    Client {
                        tck : <port_name> ; // default: ijtag_tck
                        reset : <port_name> ; // default: ijtag_reset
                        select : <port_name> ; // default: ijtag_sel
                        capture_en : <port_name> ; // default: ijtag_ce
                        shift_en : <port_name> ; // default: ijtag_se
                        update_en : <port_name> ; // default: ijtag_ue
                        scan_in : <port_name> ; // default: ijtag_si
                        scan_out : <port_name> ; // default: ijtag_so

                        reset_polarity : <active_polarity> ; // legal : active_high
(active_low)
                    }
                    Host {
                        select : <port_name> ; // default: ijtag_to_sel
                        scan_in : <port_name> ; // default: ijtag_from_so
                    }
                }
                Attributes {
                    <attribute> : <string> ; // repeatable
                }
                parent_instance : <instance_name> ;
                leaf_instance_name : <leaf_instance_name> ;
                keep_active_during_scan_test : <boolean> ; // default: auto
                capture_value : <enum> ; // legal : 1 (0) self
            }
            Sib(<id>) {
                // Same as /DftSpecification/IJtagNetwork/HostScanInterface/Sib
            }
            Tdr(<id>) {
                // Same as /DftSpecification/IJtagNetwork/HostScanInterface/Tdr
            }
            ScanMux(<id>) {
                // Same as /DftSpecification/IJtagNetwork/HostScanInterface/
            }
            ScanMux
        }
        DesignInstance(<instance_name>) {
            // Same as /DftSpecification/IJtagNetwork/HostScanInterface/
        }
        DesignInstance
    }
}
}
```

Example 2

In the following example, the two “Test” wrappers are equivalent. In the first case, the objects P and Q of the RefWrapper are both referenced explicitly. In the second case, the objects P and Q of the RefWrapper are referenced once using the new “ReferenceContents” property.

```
Wrapper(Test) {
    Reference = /RefWrapper/P;
    Reference = /RefWrapper/W;
}

Wrapper(Test) {
    ReferenceContents = /RefWrapper;
}

Wrapper(RefWrapper) {
    Property(P) {...}
    Wrapper(W) {...}
}
```

Property

A wrapper used in metadata to define a property that is usable in configuration data.

Usage

```
Wrapper(wrapper_name) {
    Property(property_name) {
        Usage      : normal | hidden | Env(EnvVar)
                    | AccessFeature(feature_name) ;
        InsertFirst ;
        InsertLast ;           // default
        InsertBefore : meta_leaf_name ;
        InsertAfter  : meta_leaf_name ;
        Options(Visualizer) {
            DisplayString   : string ;
            BlankSpaceAbove : on ;
        }
        Value(value_id) { // repeatable
        }
    }
}
```

Description

A wrapper used in metadata to define a property that is usable in configuration data.

A property exists as soon as its parent wrapper exists regardless of whether the property is specified or not.

Arguments

- Usage : normal | hidden | Env(EnvVar) | AccessFeature(*feature_name*) ;

A property that controls the visibility of the property. When set to normal, the property is reported by the [report_config_syntax](#) command and is visible in DFTVisualizer. When set to hidden, the wrapper is not reported by report_config_syntax and is invisible in DFTVisualizer. Its value can still be fetched and edited using the configuration introspection and editing commands, such as the [get_config_value](#) command, if the name of the hidden property is known by the user. The “Usage : Env(EnvVar)” is treated as normal if the EnvVar environment variable is defined and set to 1; otherwise, it is treated as hidden. When the Usage value is AccessFeature(*feature_name*), the usage value is “normal”, if the *access_code* for the *feature_name* is enabled, otherwise the Usage value is “hidden”.

- InsertFirst ;

An implicit Boolean property that specifies that the property is to be inserted before the already existing elements in the wrapper. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command; it also controls the order in which properties are displayed in the Configuration Option panel inside DftVisualizer.

- InsertLast ;

An implicit Boolean property that specifies that the property is to be inserted after the already existing elements in the wrapper. This is useful if you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command; it also controls the order in which properties are displayed in the Configuration Option panel in DftVisualizer.

- InsertBefore : *meta_leaf_name* ;

A property that specifies that the property is to be inserted before an already existing element in the wrapper. You refer to the element using its *leaf_name*. For example, to insert a property before Property(scan_in), you would specify “InsertBefore : scan_in;”. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command; it also controls the order in which properties are displayed in the Configuration Options panel in DftVisualizer.

- InsertAfter : *meta_leaf_name* ;

A property that specifies that the property is to be inserted after an already existing element in the wrapper. You refer to the element using its *leaf_name*. For example, to insert a property after Property(scan_in), you would specify “InsertAfter : scan_in;”. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command; it also controls the order in which properties are displayed in the Configuration Options panel in DFTVisualizer.

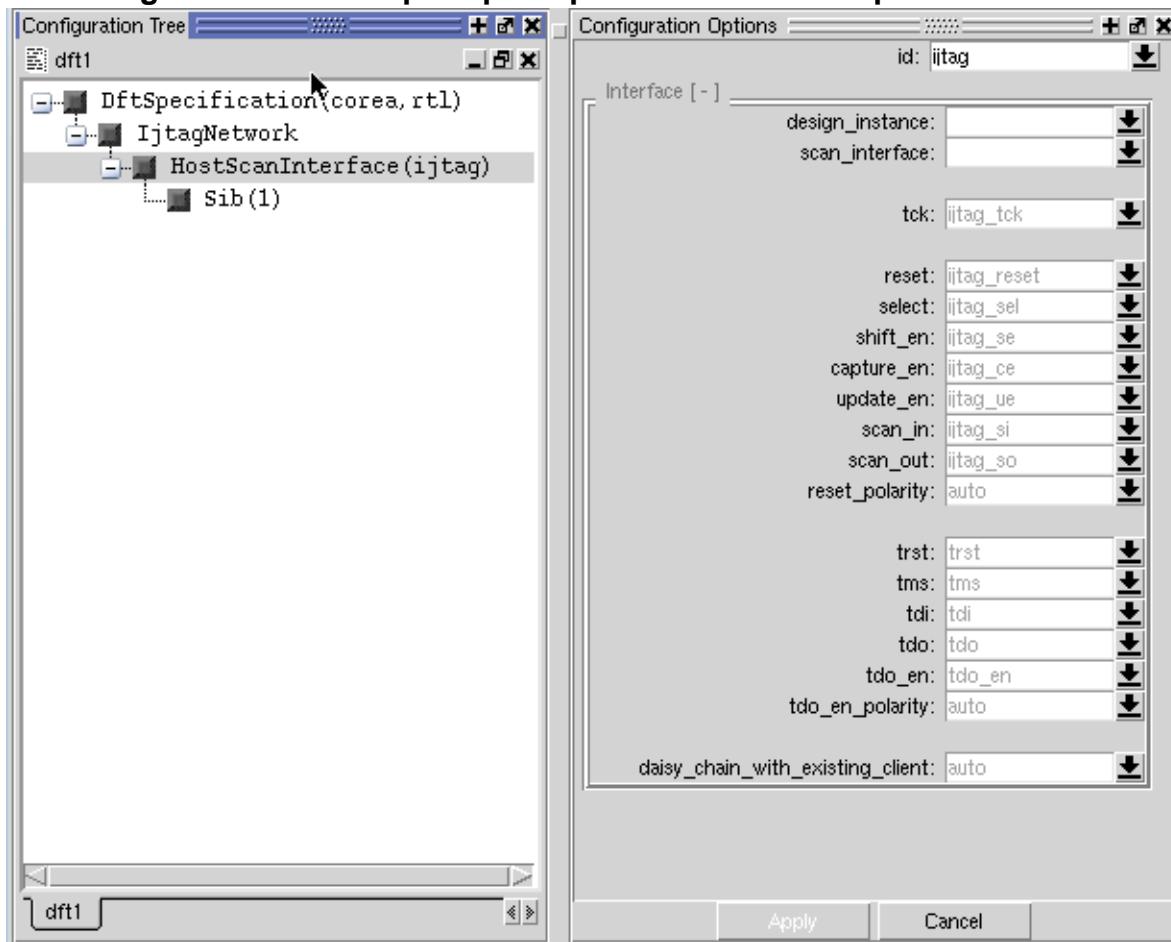

- Options(Visualizer)/DisplayString : *string* ;

A property used to control how the property is identified in the GUI. When unspecified, it defaults to *property_name*. This option is useful when you want to create a GUI to display configuration data and you want to name the properties using sentences as opposed to the strict property name.

- Options(Visualizer)/BlankSpaceAbove : On | Off ;

A property used to control the insertion of a blank space above the property when creating the Configuration Options panel. You can see its effect in the panel shown in [Figure 10-61](#) on page 3732. The option was specified inside the tck, reset, trst and daisy_chain_with_existing_client property wrappers.

Figure 10-61. Example Option panel where blank spaces were added

Examples

The following example defines properties of all types. It is used in the example of the `get_config_value` command to illustrate how to introspect them. You can use `report_config_data` DftSpecification -partition meta to see many more examples.

```
Wrapper(SingularWrapper) {
    Repeatable : single;
    Wrapper(WrapperWithRepeatableId) {
        id(name*) {
            type : string;
        }
        Reference = /SingularWrapper/WrapperWithRepeatableId;
        Property(time_property) {
            Value(time) {
                type : time;
                DefaultValue : 3.5ns;
            }
        }
        Property(integer_property) {
            Value(integer) {
                type : int;
                DefaultValue : 3;
            }
        }
        Property(binary_property) {
            Value(binary) {
                type : binary;
                DefaultValue : 3'b0;
            }
        }
        Property(string_property) {
            Value(string*) {
                type : string;
                DefaultValue : "";
            }
        }
    CSVWrapper(CsvWrapper) {
        Repeatable : on;
        id(module_name) {
            Type : String;
        }
        id(design_id) {
            Type : String;
            IgnoreCase : On;
        }
    }
    DataWrapper(DataWrapper_with_no_value) {
        RowIdElement(port) {
            Type : String;
            repeatable : on;
        }
    }
    DataWrapper(DataWrapper_value) {
        RowIdElement(port) {
            Type : String;
            repeatable : on;
        }
        Value(period) {
            Type : time;
        }
    }
}
}
```

RepeatableProperty

A wrapper used in metadata to define a repeatable property that is usable in configuration data.

Usage

```
Wrapper(wrapper_name) {
    RepeatableProperty(property_name) {
        Usage          : normal | hidden | Env(envVar)
                        | AccessFeature(feature_name) ;
        InsertFirst ;
        InsertLast ;           // default
        InsertBefore : meta_leaf_name ;
        InsertAfter  : meta_leaf_name ;
        Options(Visualizer) {
            DisplayString : string ;
        }
        Id(id) {             // repeatable and optional
        }
        Value(value_id) {   // repeatable, minimum one
        }
    }
}
```

Description

A wrapper used in metadata to define a repeatable property that is usable in configuration data.

As opposed to normal properties, a repeatable property has no default values and does not exist until it is specified.

Arguments

- Usage : normal | hidden | Env(EnvVar) | AccessFeature(*feature_name*) ;

A property that controls the visibility of a property. When set to normal, the property is reported by [report_config_syntax](#) and visible in DFTVisualizer. When set to hidden, the wrapper is not reported by [report_config_syntax](#) and invisible in DFTVisualizer. Its value can still be fetched and edited using the configuration introspection and editing commands such as the [get_config_value](#) command if the name of the hidden property is known to the user. The “Usage : Env(EnvVar)” is treated as normal if the EnvVar environment variable is defined and set to 1; otherwise it is treated as hidden. When the Usage value is AccessFeature(*feature_name*), the usage value is “normal”, if the *access_code* for the *feature_name* is enabled, otherwise the Usage value is “hidden”.

- InsertFirst ;

An implicit Boolean property that specifies that the property is to be inserted before the already existing elements in the wrapper. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command; it also controls the order in which folding regions associated with the properties are displayed in the Configuration Options panel in DFTVisualizer.

- InsertLast ;

An implicit Boolean property that specifies that the property is to be inserted after the already existing elements in the wrapper. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command; it also controls the order in which folding regions associated with the properties are displayed in the Configuration Options panel in DftVisualizer.

- InsertBefore : *meta_leaf_name* ;

A property that specifies that the property is to be inserted before an already existing element in the wrapper. You refer to the element using its *leaf_name*. For example, to insert a property before Property(scan_in), you would specify “InsertBefore : scan_in;”. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command; it also controls the order in which folding regions associated with the properties are displayed in the Configuration Options panel in DftVisualizer.

- InsertAfter : *meta_leaf_name* ;

A property that specifies that the property is to be inserted after an already existing element in the wrapper. You refer to the element using its *leaf_name*. For example, to insert a property after Property(scan_in), you would specify “InsertAfter : scan_in;”. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command; it also controls the order in which folding regions associated with the properties are displayed in the Configuration Options panel in DftVisualizer.

- Options(Visualizer)/DisplayString : *string* ;

A property used to control how the folding region associated with a repeatable property is identified in the Configuration Data window. When unspecified, it defaults to *property_name*. A convention of using lower case name with underscore is employed when naming normal and repeatable properties in the tool. The convention for the folding region name in DftVisualizer is to use Camel naming. This is achieved by using this option.

Examples

The following example shows how the connection property is defined inside the [Tdr](#) wrapper.

```
> report_config_data [get_config_value Tdr/DataOutPorts/Connection \
    -in_wrapper /DftSpecification/IjtagNetwork/HostScanInterface \
    -partition meta -object] RepeatableProperty(connection) {
Options(Visualizer) {
    DisplayString : Connections ;
}
Id(range) {
    Type : string ;
    Repeatable : On ;
}
Value(pin_name) {
    Type : string ;
    Repeatable : On ;
}
}
```

Related Topics

[DftSpecification](#)

[Property](#)

[DataWrapper](#)

[CsvWrapper](#)

[report_config_syntax](#)

DataWrapper

A wrapper used in metadata to define a data wrapper that is usable in configuration data.

Usage

```
Wrapper(wrapper_name) {
    DataWrapper(wrapper_name) {
        Usage           : normal | hidden | Env(envVar)
                           | AccessFeature(feature_name) ;
        InsertFirst ;
        InsertLast ; //default
        InsertBefore   : meta_leaf_name ;
        InsertAfter    : meta_leaf_name ;
        Options(Visualizer) {
            DisplayString : string ;
        }
        RowIdElement(element_id) { // not_repeatable, required
        }
        Value(value_id) {          // repeatable, optional
        }
    }
}
```

Description

A wrapper used in metadata to define a data wrapper that is usable in configuration data.

As opposed to a normal wrapper, a data wrapper contains only data rows composed of arbitrary row id element with optional values. This type of wrapper is useful to associate values to arbitrary elements such as ports:

```
ClockPeriods {
    clka : 4ns;
    clkb : 3ns;
}
```

A data wrapper is like a wrapper with “Repeatable : Single”. It is not repeatable and starts to exist as soon as its parent wrapper exists.

Arguments

- Usage : normal | hidden | Env(EnvVar) | AccessFeature(*feature_name*) ;

A property that controls the visibility of the data wrapper. When set to normal, the data wrapper is reported by [report_config_syntax](#) and visible in DFTVisualizer. When set to hidden, the data wrapper is not reported by report_config_syntax and invisible in DFTVisualizer. Its content can still be fetched and edited using the configuration introspection and editing commands such as the [get_config_value](#) command if the name of the hidden data wrapper is known to the user. The “Usage : Env(EnvVar)” is treated as normal if the EnvVar environment variable is defined and set to 1 otherwise it is treated as hidden. When the Usage value is AccessFeature(*feature_name*), the usage value is

“normal”, if the *access_code* for the *feature_name* is enabled, otherwise the Usage value is “hidden”.

- InsertFirst ;

An implicit Boolean property that specifies that the data wrapper is to be inserted before the already existing elements in the wrapper. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command; it also controls the order in which folding regions associated with the data wrappers are displayed in the Configuration Options panel inside DFTVisualizer.

- InsertLast ;

An implicit Boolean property that specifies that the data wrapper is to be inserted after all already existing elements in the wrapper. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command; it also controls the order in which folding regions associated with the data wrappers are displayed in the Configuration Options panel inside DFTVisualizer.

- InsertBefore : *meta_leaf_name* ;

A property that specifies that the data wrapper is to be inserted before an already existing element in the wrapper. You refer to the element using its *leaf_name*. For example, to insert a data wrapper before Property(scan_in), you would specify “InsertBefore : scan_in;”. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command. Also, it controls the order in which folding regions associated with the data wrappers are displayed in the Configuration Options panel inside DftVisualizer.

- InsertAfter : *meta_leaf_name* ;

A property that specifies that the data wrapper is to be inserted after an already existing element in the wrapper. You refer to the element using its *leaf_name*. For example, to insert a data wrapper after Property(scan_in), you would specify “InsertAfter : scan_in;”. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command. Also, it controls the order in which folding regions associated with the data wrappers are displayed in the Configuration Options panel inside DftVisualizer.

- Options(Visualizer)/DisplayString : *string* ;

A property used to control how the folding region associated with a data wrapper is identified in the Configuration Data window. When unspecified, it defaults to *wrapper_name*. This option is useful when you want to create a GUI to display configuration data and you want to name the folding regions as opposed to the strict data wrapper name.

Examples

The following example shows how the ClockPeriods data wrapper shown in the description section above is defined in metadata. Notice the value of type time with the extra allowed symbols sync and sync2x.

```
  DataWrapper(ClockPeriods) {
    RowIdElement(clock_port) {
      Repeatable : Off ;
      Type       : String ;
      IgnoreCase : Off ;
    }
    Value(period) {
      Type           : Time ;
      AllowedSymbols : sync, sync2x ;
    }
  }
```

Related Topics

[DftSpecification](#)

[Property](#)

[RepeatableProperty](#)

[CsvWrapper](#)

[report_config_syntax](#)

CsvWrapper

A wrapper used in metadata to define a CSV wrapper that is usable in configuration data.

Usage

```
Wrapper(wrapper_name) {
    CsvWrapper(wrapper_name) {
        Usage      : normal | hidden | Env(envVar)
                    | AccessFeature(feature_name) ;
        InsertFirst ;
        InsertLast ;      // default
        InsertBefore : meta_leaf_name ;
        InsertAfter  : meta_leaf_name ;
        Id(id) {         // repeatable and optional
            }
    }
}
```

Description

A wrapper used in metadata to define a CSV wrapper that is usable in configuration data.

As opposed to a normal wrapper, a CSV wrapper contains only rows composed of arbitrary comma separated values.

```
csv {
    v1,v2,"v3 with spaces or comma";
    v4,v5;
}
```

See the command description of [report_config_data](#) and [write_config_data](#) to see how the wrapper content can be imported from or exported to Excel. CSV wrappers are not visible nor editable inside DftVisualizer. They are meant to be manipulated graphically inside Excel.

Arguments

- Usage : normal | hidden | Env(EnvVar) | AccessFeature(*feature_name*) ;

A property that controls the visibility of the CSV wrapper. When set to normal, the wrapper is reported by the [report_config_syntax](#) command. When set to hidden, the wrapper is not reported by report_config_syntax. Its value can still be fetched and edited using the configuration introspection and editing commands such as [get_config_value](#) if the name of the hidden CSV wrapper is known to the user. The “Usage : Env(EnvVar)” is treated as normal if the EnvVar environment variable is defined and set to 1; otherwise it is treated as hidden. When the Usage value is AccessFeature(*feature_name*), the usage value is “normal”, if the *access_code* for the *feature_name* is enabled, otherwise the Usage value is “hidden”.

- InsertFirst ;

An implicit Boolean property that specifies that the CSV wrapper is to be inserted before the already existing elements in the wrapper. This is useful when you are trying to insert extra

metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command.

- **InsertLast ;**

An implicit Boolean property that specifies that the CSV wrapper is to be inserted after the already existing elements in the wrapper. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command.

- **InsertBefore : *meta_leaf_name* ;**

A property that specifies that the CSV wrapper is to be inserted before the already existing elements in the wrapper. You refer to the element using its *leaf_name*. For example, to insert a CSV wrapper before Wrapper(IjtagNetwork), you would specify “InsertBefore : IjtagNetwork;”. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command.

- **InsertAfter : *meta_leaf_name* ;**

A property that specifies that the CSV wrapper is to be inserted after an already existing element in the wrapper. You refer to the element using its *leaf_name*. For example, to insert a CSV wrapper after Wrapper(IjtagNetwork), you would specify “InsertAfter : IjtagNetwork;”. This is useful when you are trying to insert extra metadata into an already existing wrapper. The relative position of the elements in the metadata controls the order in which they are reported by the [report_config_syntax](#) command.

Examples

The following example shows how a generic scratch CSV wrapper is defined in the tool. You can use scratch CSV wrappers to import and introspect CSV data.

```
CsvWrapper(csv) {
    Repeatable : On ;
    Usage : hidden ;
    Id(name) {
        Type : string ;
    }
}
```

[report_config_syntax](#)

Id

A wrapper used in metadata to define an identifier for named wrappers, repeatable properties, and named CSV wrappers.

Syntax

```

Wrapper(wrapper_name) {
    Id (name_id) {
        Type : String | Boolean | Real | Int | Time | Binary ;
        LegalString : string_list ;           // For String
        LegalInt : integer_range_list ;      // For Int
        LegalReal : real_range_list ;        // For Real
        LegalSize : int | Unsigned ;         // For Binary
        AllowedSymbols : string_list ;       // For all but String
        IgnoreCase : On | Off ;
        Repeatable : On | Off ;
        Mandatory : On | Off ;
        Option(Visualiser) {
            Counter : local | global |
                        ParentWrapper(wrapper_name).var_name ;
            DefaultValueList : string_list ;
        }
    }
    RepeatableProperty(property_name) {
        Id (name_id) {
        }
    }
    CsvWrapper(wrapper_name) {
        Id (name_id) {
        }
    }
}

```

Description

A wrapper used in metadata to define an identifier for named wrappers, repeatable properties, and named CSV wrappers.

Parameters

- *name_id*

A string used to name the identifier. This name can later be referenced using the “[get_config_value -id name_id](#)” command.

The *name_id* must start with a letter, include only letters, numbers and underscores, and may be terminated by an asterisk “*”. If the *name_id* ends with an *, the Id is repeatable. If there is more than one Id wrapper, only the last one is allowed to have an * at the end. For example:

```

Wrapper(Step) {
    Id(instance*) {
    }
}

```

allows Step(u1,u2), where u1 and u2 are repeated instance Ids.

- **Type : value ;**

A property that defines the type of the Id. The allowed types are String, Boolean, Real, Int, Time, and Binary. Ids of type time are allowed to have a unit string: s, ms, us, ns, ps, or fs. Binary numbers can be expressed in binary or hexadecimal format using the Verilog syntax: <size>'b<binary_digits>, 'b<binary_digits>, <size>'h<hexadecimal_digits>, and 'h<hexadecimal_digits>. The default selection is of type String.

- **LegalString : string_list ;**

A property that can be used when Type is set to String to limit the string to an allowed list. The validation of the allowed symbols is case insensitive by default or based on the Id's IgnoreCase property.

- **LegalInt : integer_range_list ;**

A property that can be used when Type is set to Int to limit the integer to some allowed ranges. Use two periods in a row to denote a range. Use the comma to separate multiple ranges such as in “1..9, 20, 21”.

Instead of using only numerical values, integer_range_list can also use the keywords maxposint and maxnegint. The numerical equivalent of maxposint is max value of a 64-bit integer, which is 9223372036854775807. The numerical equivalent of maxnegint is the largest negative number of a 64-bit integer, which is -9223372036854775808.

- **LegalReal : real_range_list ;**

A property that can be used when Type is set to Real to limit the real to some allowed ranges. Use two periods in a row to denote a range. Use the comma to separate multiple ranges such as in “1.0..9.5, 20.0, 21.0”.

- **LegalSize : int | Unsized ;**

A property that can be used when Type is set to Binary to limit the binary number to a specific size.

- **AllowedSymbols : string_list ;**

A property that can be used when Type is set to anything but String to allow extra symbols along with the allowed Boolean, Real, Int, Time, and Binary values. The LegalSize property is an example of a property of type Int with an extra allowed symbol of “Unsized”. The validation of the allowed symbols is case insensitive by default or based on the Id's IgnoreCase property.

- **IgnoreCase : On | Off ;**

A property that can be used to make the LegalString and the AllowedSymbols case sensitive. By default, the LegalString and the AllowedSymbols are case insensitive.

- Repeatable : On | Off ;

A property that controls if a given name _id can be repeated or not. The validation of the repeatability will consider casing or not based on the IgnoreCase property documented above.

- Mandatory : On | Off ;

A property that specifies if the Id is required or not. This option can only be specified Off if you have more than one Id wrapper, the Id wrapper is not the first one and all Id wrappers below it also have this property set to Off.

- Option(Visualiser)/Counter : local | global | ParentWrapper(wrapper_name).var_name ;

A property used to define how the Id will be populated automatically when adding the wrapper graphically inside DftVisualizer. When the DefaultValueList reaches the element with a # character, the # character is replaced by an integer. The integer is a counter that is either local to the wrapper, global to the entire root wrapper, or local to a named variable attached to a parent wrapper. For example, Ids defined with a counter as ParentWrapper(controller).memory_interface will share a counter when found anywhere below a wrapper called “controller”. The specified parent wrapper leaf name must exist in the ancestry of the element defining the Id.

- Option(Visualiser)/DefaultValueList : string_list ;

A property used to define a list of strings that will be used for the first, second, and so on instances of the wrapper. The string elements may contain any number of letters, numbers and underscores. The last element of the list must include a # character and may be just a # character. For example, the IJtagNetwork/HostScanInterface/Id(id) is defined with a DefaultValueList of “ijtag, ijtag#”. If you add a first HostScanInterface, you will see its Id will be “ijtag”. Any other subsequent instances will be labelled ijtag0, ijtag1, and so on.

Examples

The following example defines a wrapper with two Ids, the second one is repeatable and optional.

```
Wrapper(EX1) {
    Id(name) {
        type : string;
    }
    Id(period*) {
        type : time;
        Mandatory : off;
    }
}
```

Value

report_config_data

Value

A wrapper used in metadata to define an identifier for values of properties, repeatable properties, and data wrappers.

Usage

```
Wrapper(wrapper_name) {
    Property(property_name) {
        Value (value_id) {
            Type           : String | Boolean | Real | Int | Time | Binary |
                               ImplicitBoolean ;
            LegalString   : string_list ;           // For String
            LegalInt      : integer_range_list ;  // For Int
            LegalReal     : real_range_list ;      // For Real
            LegalSize     : int | Unsigned ;       // For Binary
            DefaultValue   : default_value ;
            AllowedSymbols: string_list ;         // For all but String and
                                               // ImplicitBoolean
            IgnoreCase     : On | Off ;
            Mandatory     : On | Off ;
            SizedBinary   : On | Off ;
        }
    }
    RepeatableProperty(property_name) {
        Value (value_id) {
    }
}
DataWrapper(wrapper_name) {
    Value (value_id) {
}
}
```

Description

A wrapper used in metadata to define an identifier for values of properties, repeatable properties, and data wrappers.

Arguments

- *value_id*

A string used to name the value. You can reference this name later by using the “[get_config_value -value_id value_id](#)” command.

The *value_id* must start with a letter, include only letters, numbers and underscores and may be terminated by an asterisk “*”. If the *value_id* ends with an *, a comma separated list of values can be entered for that value. If there is more than one Value wrapper, only the last one is allowed to have an * at the end.

Example 1:

```
RepeatableProperty(instance) {
    Value(instance_path) {}
}
```

- instance is specified as: instance : chip/module/instance;
- Result: value_id “instance_path” will contain “chip/module/instance”.

Example 2:

```
RepeatableProperty(instance) {
    Value(power_domain) {}
    Value(instance_path) {}
}
```

- instance is specified as: instance : domain1, chip/module/instance;
- Result: value_id “power_domain” will contain “domain1”
 value_id “instance_path” will contain “chip/module/instance”

Example 3:

```
RepeatableProperty(instance) {
    Value(power_domain) {}
    Value(instance_paths*) {}
}
```

- Where instance is specified as:
 instance : domain1, instance1, instance2, “chip/module/\escaped_inst”;
- Result: value_id “power_domain” will contain “domain1”
 value_id “instance_paths” will be returned as a Tcl list containing
 ‘instance1, instance2, {chip/module/\escaped_inst }’ by [get_config_value](#).

- Type : *value* ;

A property that defines the type of the Value. The allowed types are String, Boolean, Real, Int, Time, Binary, and ImplicitBoolean. Values of type time are allowed to have a unit string: s, ms, us, ns, ps, or fs. Binary numbers can be expressed in binary or hexadecimal format using the Verilog syntax: <size>‘b<binary_digits>, ‘b<binary_digits>, <size>‘h<hexadecimal_digits>, and ‘h<hexadecimal_digits>. ImplicitBoolean values are implied true as soon as the property is specified with no value. The property InsertFirst in the [Property](#) wrapper is an example of a property with Type ImplicitBoolean. The default selection is of type String.

- LegalString : *string_list* ;

A property that can be used when Type is set to String to limit the string to an allowed list. The validation of the allowed list will consider casing or not based on the Value’s IgnoreCase property.

- LegalInt : *integer_range_list* ;

A property that can be used when Type is set to Int to limit the integer to some allowed ranges. Use two periods in a row to denote a range. Use the comma to separate multiple ranges such as in “1..9, 20, 21”.

Instead of using only numerical values, *integer_range_list* can also use the keywords maxposint and maxnegint. The numerical equivalent of maxposint is max value of a 64-bit

<p>integer, which is 9223372036854775807. The numerical equivalent of maxnegint is the largest negative number of a 64-bit integer, which is -9223372036854775808.</p> <ul style="list-style-type: none"> • LegalReal : <i>real_range_list</i> ; A property that can be used when Type is set to Real to limit the real to some allowed ranges. Use two periods in a row to denote a range. Use the comma to separate multiple ranges such as in “1.0..9.5, 20.0, 21.0”. • LegalSize : int Unsized ; A property that can be used when Type is set to Binary to limit the binary number to a specific size. • DefaultValue: <i>default_value</i> ; A property that is mandatory and only used when the Value wrapper is inside a Property wrapper. The specified <i>default_value</i> provide the value of the property when the property is not specified in the wrapper where it exist. • AllowedSymbols : <i>string_list</i> ; A property that can be used when Type is set to anything but String and ImplicitBoolean to allow extra symbols along with the allowed Boolean, Real, Int, Time, and Binary values. The LegalSize property for Value is an example of a property of type Int with an extra allowed symbol of “Unsized”. The validation of the allowed symbols will consider casing or not based on the Value’s IgnoreCase property. • IgnoreCase : <u>On</u> Off ; A property that can be used to make the LegalString and the AllowedSymbols case-insensitive. • Mandatory : On <u>Off</u> ; A property that specifies if the Value is required or not. This option can only be specified Off for second level or lower Value wrappers and if the Value wrappers below it are also Off. • SizedBinary : On <u>Off</u> ; A property that specifies that the binary value from the configuration data must be a sized binary. It must be a sized binary, hexadecimal, or decimal number using the <i>int'b</i>, <i>int'h</i>, or <i>int'd</i> prefix.

Examples

The following example defines a property with two values; the second one is repeatable and optional.

```
Property(EX1) {
    Value(name) {
        type : string ;
    }
    Value(period*) {
        type : time ;
        Mandatory : off ;
    }
}
```

[report_config_syntax](#)

RowIdElement

A wrapper used in metadata to define the syntax of the RowIdElements of a data wrapper.

Usage

```
  DataWrapper(wrapper_name) {
    RowIdElement(element_id) {
      Type : String | Boolean | Real | Int | Time | Binary ;
      LegalString : string_list ;           // For String
      LegalInt : integer_range_list ;      // For Int
      LegalReal : real_range_list ;        // For Real
      LegalSize : int | Unsigned ;         // For Binary
      AllowedSymbols : string_list ;       // For all but String
      IgnoreCase : On | Off ;
      Repeatable : On | Off ;
    }
  }
```

Description

A wrapper used in metadata to define the syntax of the RowIdElements of a data wrapper.

Arguments

- *element_id*

A string used to name the row id element.

The *element_id* must start with a letter, include only letters, numbers and underscores.

- Type : String | Boolean | Real | Int | Time | Binary ;

A property that defines the type of the RowIdElement. The allowed types are String, Boolean, Real, Int, Time, and Binary. RowIdElements of type time are allowed to have a unit string: s, ms, us, ns, ps, or fs. Binary numbers can be expressed in binary or hexadecimal format using the Verilog syntax: <size>'b<binary_digits>, 'b<binary_digits>, <size>'h<hexadecimal_digits>, and 'h<hexadecimal_digits>.

- LegalString : *string_list* ;

A property that can be used when Type is set to String to limit the string to an allowed list. The validation of the allowed list will consider casing or not based on the IgnoreCase property documented below.

- LegalInt : *integer_range_list* ;

A property that can be used when Type is set to Int to limit the integer to some allowed ranges. Use two periods in a row to denote a range. Use the comma to separate multiple ranges such as in “1..9, 20, 21”.

Instead of using only numerical values, *integer_range_list* can also use the keywords maxposint and maxnegint. The numerical equivalent of maxposint is max value of a 64-bit integer, which is 9223372036854775807. The numerical equivalent of maxnegint is the largest negative number of a 64-bit integer, which is -9223372036854775808.

- LegalReal : *real_range_list* ;
A property that can be used when Type is set to Real to limit the real to some allowed ranges. Use two periods in a row to denote a range. Use the comma to separate multiple ranges such as in “1.0..9.5, 20.0, 21.0”.
- LegalSize : *int* | Unsized ;
A property that can be used when Type is set to Binary to limit the binary number to a specific size.
- AllowedSymbols : *string_list* ;
A property that can be used when Type is set to anything but String to allow extra symbols along with the allowed Boolean, Real, Int, Time, and Binary values. The LegalSize property above is an example of a property of type Int with an extra allowed symbol of “Unsized”. The validation of the allowed symbols will consider casing or not based on the IgnoreCase property documented below.
- IgnoreCase : On | Off ;
A property that can be used to make the LegalString and the AllowedSymbols case-insensitive. This option also affects whether casing is ignored when performing the repeatability check described in the following Repeatable property.
- Repeatable : On | Off ;
A property that controls whether a given element_id can be repeated or not within the Data Wrapper. The validation of the repeatability will consider casing or not based on the preceding IgnoreCase property.

Examples

The following example defines a data wrapper with RowIdElement which is a arbitrary string meant to represent a clock port name. Each clock port name are only allowed once as specified by the fact that Repeatable is set to Off. Because IgnoreCase is also Off, port names Clk and clk will not be considered as repeated port names.

```
DataWrapper(ClockPeriods) {
    RowIdElement(clock_port) {
        Repeatable : Off ;
        Type       : String ;
        IgnoreCase : Off ;
    }
    Value(period) {
        Type           : Time ;
        AllowedSymbols : sync. sync2x ;
    }
}
```

Tessent Core Description

This section provides links to supporting documentation that describes the Tessent Core Description (TCD) configuration data syntax.

Refer to the links below for the primary documentation that describes the following TCD macro module types:

- **BoundaryScan Segments** — Refer to “[Tessent Core Description](#)” in the *Tessent BoundaryScan User’s Manual*.
- **FuseBoxInterface** — Refer to “[FuseBoxInterface](#)” in the *Tessent MemoryBIST User’s Manual*.
- **Memories** — Refer to “[Memory](#)” in the *Tessent MemoryBIST User’s Manual*.
- **Scan** — Refer to “[Scan](#)” on page 3756.
- **Shared Bus Memory Clusters** — Refer to “[MemoryCluster](#)” in the *Tessent MemoryBIST User’s Manual*.

[Scan](#).....[3756](#)

Scan

Describes the scan chains for the specific *module_name*.

Usage

```
Core(module_name) {
    Scan {
        module_type : normal | occ
        allow_scan_out_retiming : 1 | 0;
        is_hard_module : 1 | 0;
        exclude_from_concatenated_netlist : 1 | 0;
        pre_scan_drc_on_boundary_only : 1 | 0;
        internal_scan_only : 1 | 0;
        TestEn(port_name,...) {
            active_polarity : sized_binary | all_ones | all_zeros;
        }
        traceable : 1 | 0;
        ScanEn(scan_en_port_or_pin_name,...) {
            clock : port_name;
            active_polarity : sized_binary | all_ones | all_zeros;
        }
        Clock(clock_port_or_pin_name,...) {
            off_state : sized_binary | all_ones | all_zeros;
        }
        ClockOut(clock_out_port_or_pin_name,...) {
            slow_clock_input : port_name;
            fast_clock_input : port_name;
        }
        FastCaptureClockEn(pin_name_on_persistent_cell) {
            clock_input : port_name;
        }
        ShiftRegisterClockEn(pin_name_on_persistent_cell) {
            clock_input : port_name;
        }
        SetReset(set_reset_port_or_pin_name,...) {
            active_polarity : sized_binary | all_ones | all_zeros
        }
        ScanChain {
            length : int | auto;
            no_si_pipelineing : 1 | 0;
            scan_in_port : port_name,...;
            scan_out_port : port_name,...;
            scan_in_clock : port_name,...;
            scan_out_clock : port_name,...;
        }
        Iproc(proc_name) {
            parameter_value_list : parameter_value, ...;
        }
    }
}
```

Description

Describes the scan chains for the specific *module_name*. Such descriptions are automatically read during module matching. See the “[“set_design_sources -format tcd_scan” command](#)

description for information about where the tool searches for these items. See the [read_core_descriptions](#) command description for information on reading the descriptions explicitly. See the [set_module_matching_options](#) command description for information about the name matching process.

To see the content of a read-in Core(*module_name*)/Scan, use the following command syntax:

```
report_config_data Core(module_name)/Scan -partition tcd
```

To see the complete supported syntax, use the following command syntax:

```
report_config_syntax [get_config_value Core/Scan -partition meta:tcd -object]
```

Arguments

- **module_type** : [normal](#) | occ;

A property that defines the type of the module. Most module have type normal. The only special module is the OCC modules.

Identifying a module with type “occ” instructs the tool to infer a clock on the specified ClockOut location when entering the analysis mode in the dft -scan context if no clock exists. This ensures the scan insertion flow does not make clock connections for inserted retiming elements to a net that is not driven by the OCC. Also, the scan insertion uses this information to not align all the OCC chains, which may result in encoding conflicts when too many OCC care bits align.

- **allow_scan_out_retimings** : 1 | 0;

A Boolean property used to specify if the clock associated to scan chain is suitable for being used as the source for retiming elements or not. By default, when a segment needs retiming, the retiming element is added after the scan-out port using the clock port associated to the scan chain. In certain situations, this is not the best approach because the clock input is not balanced with the chain scan-out port. This situation happens in an OCC, for example, as can be seen in the [Schematic](#) diagram for the On-Chip Clock Controller in the *Tessent Scan and ATPG User's Manual*. When the property is set to 0, the retiming element is added at the scan-in port of the next scan element instead and the clock associated to the next scan element is used.

- **is_hard_module** : 1 | 0;

A property used to specify whether the module is hard or not. When set to 1, flip-flops not traced as part of the scan chains are assumed to be non-scannable. These scan chains are not collected by scan insertion and no DRC violation for those non scannable flops will be issued.

When set to 0, the module is assumed to be soft and the flip-flops not traced as part of the scan chains are assumed to be scannable unless explicitly declared non-scannable using the [add_nonscan_instances](#) command. The extra scannable flops may generate DRC violations, and if DRC clean, these flops are inserted in the newly-created scan chains.

- `exclude_from_concatenated_netlist : 1 | 0;`

A property used to specify that the module is a hard macro and should not be included in the concatenated netlist. A hard macro is a module that has its layout separate, but is too large to be a cell. You do not want to include these modules in the concatenated netlist because the synthesis and layout tool use the Liberty format instead of the netlist view. This property can only be set to 1 when the `is_hard_module` property is set to 1. Its value gets transferred to the `exclude_from_concatenated_netlist` module level attributes and affect the [write_design](#) command accordingly. See the documentation of the `-exclude_modules` switch of the [write_design](#) command description for more details.

- `pre_scan_drc_on_boundary_only : 1 | 0;`

A property used to specify that the module is to be treated as a black box. The scan chains are DRC'd from the external boundary of the module. They are not traced, and no DRC violation for the internals of the module are reported. This property is useful when the module requires a complex test_setup procedure to configure the module in scan mode.

For example, this feature is used to describe the chain going through the Tessent OCC controller. Because the scan chain length is configurable by the `max_capture_size` static signals, they would need to be configured to the maximum value for the tracing to work and max chain length considered during scan chain balancing. Instead of doing that, the maximum length of the chain is described using the `ScanChain/length` property. If the scan internals of the scan chain turned out to be have a design flaw, it would be detected right after scan insertion when performing DRC one scan mode at a time.

- `internal_scan_only : 1 | 0;`

A property used to identify that the scan chains of the module are allowed or not to be promoted to as being wrapper chains. See the [analyze_wrapper_cells](#) command description to understand how existing chain chains are handled by the analysis. When this property is set to 1, the scan chains are not allowed to be promoted to the shared wrapper chains and dedicated wrapper cells will be inferred to isolate them if the chain interacts with the outside.

- `TestEn(port_name,...)`

A wrapper used to define one or more TestEn ports on the module. See the description of the `ltest_en` DFT signal in [Table 3-10](#) on page 190 located in the [add_dft_signals](#) command description.

- `TestEn/active_polarity : sized_binary | all_ones | all_zeros;`

A property that defines the active polarity of the TestEn ports. The value must be a sized binary number where the width must match exactly the number of ports listed in the `TestEn` parenthesis. A “1” in the *n*th position means the *n*th TestEn port in the list is active high, and a “0” means it is active low. For example, the port list (`A, b[1:0]`), would require a 3-bit binary number where the left most bit corresponds to port `A` and the right most bit corresponds to bit `b[0]`. You can also use the symbols `all_ones` and `all_zeros` when they are all of the same active polarity.

- traceable : 1 | 0;

A property that is used to specify if the scan chain is traceable or not. When not traceable, the length, scan_in_clock and scan_out_clock properties inside the ScanChain wrapper must be specified as they cannot be extracted.

Note

Currently, it is not always possible to accurately identify the flops inside the OCC. Therefore, you are no longer allowed to change the traceable property.

- ScanEn(*scan_en_port_or_pin_name*,...)

A wrapper used to define one or more ports as having the function “ScanEn”. These ports are asserted active to place the scan chains in its shift configuration. At least one ScanEn port is required when there are one or more ScanChain wrappers.

- ScanEn/active_polarity : sized_binary | all_ones | all_zeros;

A property that defines the active polarity of the ScanEn ports. The value must be a sized binary number where the width must match exactly the number of ports listed in the ScanEn parenthesis. A “1” in the *n*th position means the *n*th ScanEn port in the list is active high, and a “0” means it is active low. For example, the port list (A, b[1:0]), would require a 3-bit binary number where the left most bit corresponds to port A and the right most bit corresponds to bit b[0]. You can also use the symbols all_ones and all_zeros when they are all of the same active polarity.

- Clock(*clock_port_or_pin_name*,...)

A wrapper used to define one or more ports as having the function “Clock”. All scan cells in the scan chain must be clocked by one of those defined Clock ports.

- Clock/off_state : sized_binary | all_ones | all_zeros;

A property that defines the offset of the clock ports when pulsing them to extract the scan chains. The value must be a sized binary number where the width must match exactly the number of ports listed in the ScanEn parenthesis. A “1” in the *n*th position means the *n*th ScanEn port in the list is active high, and a “0” means it is active low. For example, the port list (A, b[1:0]), would require a 3-bit binary number where the left most bit corresponds to port A and the right most bit corresponds to bit b[0].

The offstate is only relevant if your chains have a mixture of rising and falling edge flip-flops. Defining the off state incorrectly in that case may end up with the scan chain being extracted with a length that is not 100 percent accurate and may have a minor effect on chain balancing.

- ClockOut(*clock_out_port_or_pin_name*,...)

This wrapper defines one port or pin inside the module on which to add a clock when going to analysis mode in the dft -scan context. The ClockOut ports are only allowed and used when module_type is set to occ. See the description of the module_type property above for more information. The ClockOut port wrapper must include one slow_clock_port and/or fast_clock_port.

- ClockOut/slow_clock_input : *port_name*;

A string property use to provide the name of the input port through which the slow clock enters the module. This clock is used as the shift clock and optionally the capture when not operating in fast capture mode. If you have an OCC that only gates the clock and the shift clock is injected earlier in the clock tree, you will only have a fast_clock_port. The mini tck OCC present in the Sib(sti) only has a slow_clock_port.

- ClockOut/fast_clock_input : *port_name*;

A string property use to provide the name of the input port through which the fast clock enters the module. This clock is used as the capture clock when operating in fast capture mode. If you have an OCC that only gates the clock and the shift clock is injected earlier in the clock tree, you will only have a fast_clock_port.

- FastCaptureClockEn(*pin_name_on_persistent_cell*)

This wrapper is only used within the Core/Scan wrapper with a module_type equal to “occ”. The wrapper specifies the enable pin of the clock gating cell that gates the fast clock during logic test mode. This pin is forced off when running the DFT_C1, DFT_C2, DFT_C3, and DFT_C6 DRCs in order to check the functional clock source.

- FastCaptureClockEn/clock_input : *port_name*;

The property is currently unused.

- ShiftRegisterClockEn(*pin_name_on_persistent_cell*)

This wrapper is only used within the Core/Scan wrapper with module_type equal to “occ”. The wrapper specifies the enable pin of the clock gating cell that gates the clock of the shift register inside the OCC. This pin is forced off when running the DFT_C1, DFT_C2, DFT_C3, and DFT_C6 DRCs in order to check the functional clock source.

- ShiftRegisterClockEn/clock_input : *port_name*;

The property is currently unused.

- SetReset(*set_reset_port_name*,...)

A wrapper used to define one or more ports as having the function “SetReset”. These ports controls the Set and Reset pins of the scannable flip-flops found inside the module and are asserted inactive when tracing the scan chains.

- SetReset/active_polarity : sized_binary | all_ones | all_zeros;

A property that defines the active polarity of the SetReset ports. The value must be a sized binary number where the width must match exactly the number of ports listed in the ScanEn parenthesis. A “1” in the *n*th position means the *n*th SetReset port in the list is active high, and a “0” means it is active low. For example, the port list (A, b[1:0]), would requires a 3 bit binary number where the left most bit corresponds to port A and the right most bit corresponds to bit b[0]. You can also use the symbols all_ones and all_zeros when they are all of the same active polarity.

- ScanChain/length : int | auto;

A property used to define the length of the scan chain. The value auto is only allowed when the traceable property is 1. When the value is an integer and traceable is 1, a warning is generated if the traced length differs from the specified length and the traced length is used. The minimum scan chain length is one scan cell.

- ScanChain/no_si_pipelining : 1 | 0;

A Boolean property used to specify if the scan chain allows the insertion of a pipelining flip-flop in front of the scan_in_port. When set to 1, the no_si_pipelining property overrides any pipelining instructions set by the [set_scan_insertion_options -si_pipelining](#) command specified with “all_chains” or “wrapper_chains_only”.

Scan chains defined inside tcd_scan wrappers and having module_type equal to occ have no_si_pipelining inferred by the tool to 1. The tcd_scan data created by scan insertion automatically sets this property to 1 if the scan chain starts with a scan element having the no_si_pipelining property set or inferred to 1, or when a pipelining flip-flop is already inserted inside the core.

When set to 0, the tool does not prevent the insertion of a pipelining flip-flop on the scan chain in front of the scan_in_port and follows the direction set by the [set_scan_insertion_options -si_pipelining](#) command.

- ScanChain/*scan_in_port* : *port_name*, ...;

A property used to define the name of the scan-in port for the chain.

- ScanChain/*scan_out_port* : *port_name*, ...;

A property used to define the name of the scan-out port for the chain.

- ScanChain/*scan_in_clock* : *port_name*, ...;

A property used to defined the name of the clock used by the first scan flop of the chain. This property is optional when traceable is 1. A warning is generated if the clock of the first scan element of the chain is extracted and found to be different than the specified one. The extracted one is used when they differ.

- ScanChain/*scan_out_clock* : *port_name*, ...;

A property used to defined the name of the clock used by the last scan flop of the chain. This property is optional when traceable is 1. A warning is generated if the clock of the last scan element of the chain is extracted and found to be different than the specified one. The extracted one is used when they differ.

- Iproc(*proc_name*)

This wrapper defines the name of an iProc that must be used to activate the OCC. This iProc is automatically iCalled from the parent level when the OCC is still active in the external test modeof the child. If you are using the Tessent OCC, this is automatically populated with the name “setup”.

- `Iproc(proc_name)/parameter_value_list : parameter_value, ... ;`

This wrapper defines the parameters to used when calling the iProc mentioned in the parent wrapper. If you are using the Tessent OCC, this is automatically populated with this parameter value pair: “`fast_capture_mode, 1`”.

Chapter 12

Tessent Shell Data Base (TSDB)

This chapter describes the Tessent Shell Database which is a structured directory containing subdirectories and files. The subdirectory naming is designed to group related information for each specific view of each design block. The complete subdirectory is deleted and recreated cleanly when a step is repeated thereby ensuring that no stale files from a previous run can remain in the active TSDB directory.

The [root_directory](#) name can be anything and located anywhere, and is specified using the [set_tsdb_output_directory](#) command. You can use a single root directory as the output of all of your design blocks but you can use as many as you like. As long as you make the TSDB directories associated to child blocks visible (using the [open_tsdb](#) command) to the tool when processing a given block, it does not matter if you have everything consolidated into one directory or distributed into many.

root_directory	3763
instruments	3765
dft_inserted_designs	3768
patterns	3774
logic_test_cores	3776
<code><design_name>.lbist_mode[_<mode_name>]</code>	3777
<code><design_name>.atpg_mode[_<mode_name>]</code>	3778
<code><design_name>.atpg_retargeting_mode[_<mode_name>]</code>	3779

[root_directory](#)

A directory that groups up to four subdirectories containing related information.

Summary

Figure 12-1. Root Directory Structure

Description

A directory that groups up to four subdirectories containing related information. The **root_directory** is specified using the [set_tsdb_output_directory](#) command. The subdirectories are created by the first command that needs to create a subdirectories inside them.

- **instruments** — This directory is the first time you issue the [process_dft_specification](#) or the “[write_edt_files -tsdb](#)” command and switch.
- **dft_inserted_designs** — This directory is created when you do either of the following:
 - The first time you issue the [process_dft_specification](#) command without specifying the [-no_insertion](#) option.
 - The first time you issue the “[extract_icl -write_in_tsdb](#)” command and switch.
- **patterns** — This directory is created the first time you issue the [process_patterns_specification](#) command.
- **logic_test_cores** — This directory is created the first time you issue the [write_tsdb_data](#) command in the patterns -scan context (see “[Contexts and System Modes](#)” in the *Tessent Shell User’s Manual*). Currently, only the LogicBIST patterns are supported by the [write_tsdb_data](#) command.

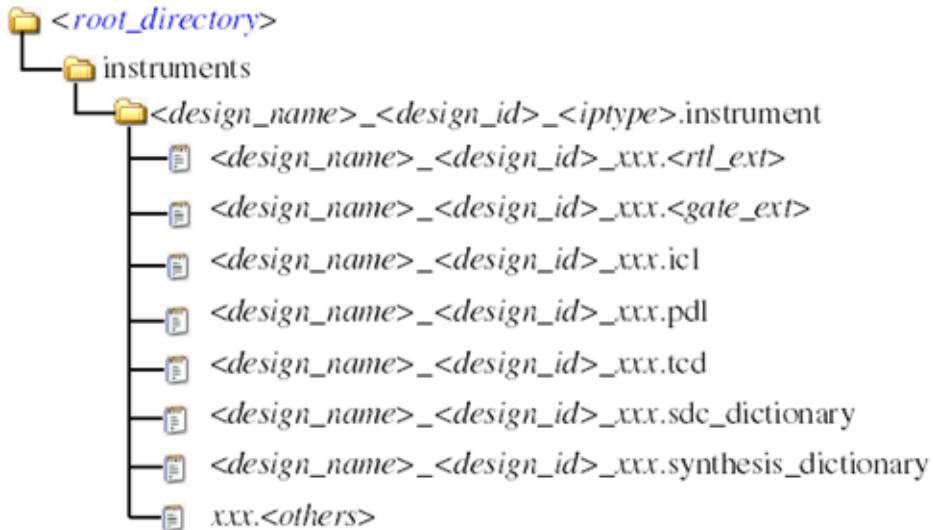

Components

The different subdirectories are documented in their respective sections in this chapter.

instruments

An instruments directory that contains a series of subdirectories that are referred to as “instrument containers”.

Summary

Description

The instruments directory contains a series of subdirectories that are referred to as “instrument containers”. The instrument container names are formed by concatenating the name of the design, the design identifier, and a unique string that is specific to the instrument or IP type. [Table 12-1](#) shows the string used for the various instrument types supported by the tool. See the “[set_context -design_identifier](#)” command to learn more about the design identifier string.

You can only have one instrument container per design_name/design_id/ ip_type combination visible in the opened TSDBs. If you have multiple TSDB directories containing the output of multiple runs on the same design with the same design id, and you try to open a second TSDB using the [open_tsdb](#) command, the tool will report an error if the new TSDB exposes a second copy of the same instrument container. If this occurs, you need to close the first TSDB before opening the second one. Also note that the current TSDB output directory, specified with the [set_tsdb_output_directory](#) command, is always open.

Table 12-1. Instrument Container Names

Instrument Type	Instrument container name
Boundary Scan	<design_name>_<design_id>_bscan.instrument
EDT	<design_name>_<design_id>_edt.instrument

Table 12-1. Instrument Container Names (cont.)

Instrument Type	Instrument container name
Hybrid EDT/LBIST	<design_name>_<design_id>_edt_lbist.instrument
IJTAG Network	<design_name>_<design_id>_ijtag.instrument
Logic Bist	<design_name>_<design_id>_lbist.instrument
LPCT	<design_name>_<design_id>_edt.instrument
Memory BISR	<design_name>_<design_id>_mbisr.instrument
Memory BIST	<design_name>_<design_id>_mbist.instrument
ncp_index_decoder	<design_name>_<design_id>_lbist_ncp_index_decoder.instrument
OCC	<design_name>_<design_id>_occ.instrument
RTL cells	<design_name>_<design_id>_cells.instrument

Components

- <design_name>_<design_id>_xxx.<rtl_ext>
One or many files containing the Verilog RTL description of the instrument. The extension defaults to “v” but is user-specified using the rtl_extension property in the DFTSpecification.
- <design_name>_<design_id>_xxx.<gate_ext>
One or many files containing the Verilog netlist description of the instrument. The extension defaults to “vg” but is user-specified using the gate_extension property in the DFTSpecification. This view of the instrument is only generated when synthesizing the instrument using the run_synthesis command which is only used when the -no_rtl insertion flow is used. In the -rtl insertion flow, the instruments are synthesized in context along with the rest of the functional logic.
- <design_name>_<design_id>_xxx.icl
One or many files containing the ICL descriptions of the instruments. The extension is always “icl”. These ICL descriptions are collected into a unified ICL file and stored in a [dft_inserted_designs](#) subdirectory when running ICL extraction.
- <design_name>_<design_id>_xxx.pdl
One or many files containing the PDL iProcs for the instruments. The extension is always “pdl”. The PDL files contain an iProcsForModule statement referring to an ICL module name followed by one or many iProcs. The PDL files are concatenated into a single file and stored beside the unified ICL file when running ICL extraction.
- <design_name>_<design_id>_xxx.tcd

One or many files containing extra information about the instrument. The “tcd” extension stands for “Tessent Core Description”. This file uses the configuration data format to encode extra information needed while using the instrument. For example, memory BIST uses this file to store the complete information about the memories tested by the controller such that precise diagnosis of failures can be done later. The TCD configuration file consists of a wrapper Core(<module_name>) with a sub-wrapper specific to the instrument type. Again, for example, memory BIST creates a “Core(<ctrl_mod_name>)/MemoryBistController” to store all of the information needed to diagnose failures on memories tested by a given controller.

- <design_name>_<design_id>_xxx.sdc_dictionary

One or many files containing a Tcl dictionary capturing timing exceptions associated with the instrument modules. The instance-specific information ends up in the extracted ICL file. The true SDC procs ends up being created in the *dft_inserted_designs* subdirectory when running ICL extraction (using the [extract_icl](#) or [set_system_mode](#) commands in analysis mode).

- <design_name>_<design_id>_xxx.synthesis_dictionary

One or many files containing a Tcl dictionary capturing tool-independent synthesis instructions. The information is used by the [run_synthesis](#) command to understand which modules need to be synthesized, which RTL files to read, and which netlist files to write out. This file is created systematically but is typically only created when using the -no_rtl insertion flow. When using the rtl insertion flow, the [run_synthesis](#) is not used and the instruments are synthesized in context along with the rest of the functional logic.

- xxx.<others>

Optional extra files having custom extensions specific to each instrument type that enable features that are specific to each of them. For example, the boundary scan instrument creates a BSDL file for the current design with the extension “.bsdl” to describe the boundary scan implementation.

dft_inserted_designs

A directory that contains one or many subdirectories that capture the information relative to a design in which some DFT has been inserted.

Summary

Description

The `dft_inserted_designs` directory contains one or many subdirectories capturing the information relative to a design in which some DFT has been inserted. The name of the subdirectory is formed by concatenating the name of the design with the design identifier followed by the “`.dft_inserted_design`” extension. See the [set_context -design_identifier](#) option description to read about the design identifier string value.

The directory is created and populated when the [process_dft_specification](#) command runs unless the `-no_insertion` option is specified. The directory can also be created by the

“[write_edt_files -tsdb](#)” commands. Finally, if it was not already created by the [process_dft_specification](#) or the [write_edt_files](#) commands, the directory can be created by the [extract_icl](#) command. The creating step is stored in the *.tsdb_info* file such that the tool knows to delete the directory completely before recreating it using the step that originally created it. This ensures there can never be any stale information in the *.dft_inserted_design* directory as you repeat the process.

You can only have one *.dft_inserted_design* directory per *design_name/design_id* combination visible in the opened TSDBs. If you have multiple TSDB directories containing the output of multiple runs on the same design with the same design id, and you try to open a second TSDB using the [open_tsdb](#) command, the tool will issue an error if the new TSDB exposes a second copy of the same *.dft_inserted_design* directory. If this occurs, you need to close the first TSDB before opening the second one. Also note that the current TSDB output directory, specified with the [set_tsdb_output_directory](#) command, is always open.

Components

- *<design_name>.tsdb_info*

A file that is created when the *.dft_inserted_design* directory is created to store information about the design view and the creation step. The format of this file is shown below.

```
TsdbInfo(module_name,design_id) {
    creation_date      : date;
    creation_user      : user_id;
    creation_step      : process_dft_specification | extract_icl |
                         write_edt_files;
    level              : chip | physical_block | sub_block;
    icl_extraction_needed : on | off;
    library_name       : logical_library_name;
    OpenedTsdbDirectories {
        path_to_tsdb_directory ; // repeatable
    }
    ChildBlockModules {
        module_name : design_id;
    }
}
```

You can read this file into memory using the [read_config_data](#) and introspect its content using the [get_config_value](#) command.

This file may grow over time as more information may be needed to automate new flows.

This file is created when the [process_dft_specification](#) runs unless the *-no_insertion* option is specified. It can also be created by the “[write_edt_files -tsdb](#)” commands. Finally, the file can be created by the [extract_icl](#) command, if it was not already created by the [process_dft_specification](#) or the [write_edt_files](#) commands.

- *<design_name>.<gate_ext>_no_instruments*

A Verilog netlist file, created when you use the “[set_context -no_rtl](#)” flow, that contains all of the design files forming the current physical block. The netlist of sub-blocks are included in this netlist but the netlist from child physical blocks is not included. See the [set_design_level](#) command for more information about the block types.

Note, this concatenated netlist does not include the netlist of the instruments inserted in the current insertion pass because they need to be synthesized prior to being included in the netlist.

This file is created by `process_dft_specification` when the `-no_insertion` option is not used, or by the “[write_edt_files -tsdb](#)” command.

- **modified_rtl_files**

A directory, created when using the “[set_context -rtl](#)” flow, that contains the RTL files that were edited during the current insertion pass. In the RTL flow, the file structure of the original RTL must be preserved. Because RTL supports five Verilog formats and four VHDL formats, they cannot be mixed into a common file because each file needs to be read with a unique [read_verilog](#) -format or [read_vhdl](#) -format command. Also, because of compiler directives that persist from one file to another, the file compilation order must be preserved to ensure that the proper design view is loaded. The list of modified files is taken and their common ancestor directory is computed. The relative path between every file and the common ancestor directory is preserved in the `modified_rtl_files` directory. For example, assume the following three files were modified: /a/b/c/f1, /a/b/c/f2, and /a/b/d/f3. The common ancestor is “/a/b”. The subdirectory “c” will be created in the `modified_rtl_files` directory to store f1 and f2, and the subdirectory “d” will be created in the `modified_rtl_files` directory to store f3. If included files are edited, their file names are uniquely modified and stored in the subdirectory called “INCLUDE”.

This directory is created by the `process_dft_specification` command when the `-no_insertion` option is not used

- **<design_name>.design_source_dictionary**

A file that contains a Tcl dictionary describing precisely how to load the current design. The directory consists of a series of ordered Read# entries containing the complete information to reproduce it. The information is general enough to be translated into read commands for any tool. The [run_testbench_simulations](#) command uses that information to create the compilation script for the supported simulators.

This file is created by the `process_dft_specification` command when the `-no_insertion` option is not used, or by `extract_icl` if not already created by the `process_dft_specification` command.

The format of the Read# entries is shown below:

```

read# { // read1 for the first read, read2 for the second, etc.
    format { // See read\_verilog/read\_vhdl -format option
        "verilog_1995" | "verilog_2001" | "verilog_sv31a" |
        "verilog_sv2005" | "verilog_sv2009" | "vhdl_1987" |
        "vhdl_1993" | "vhdl_2002" | "vhdl_2008"
    }
    work_library { //See read\_verilog/read\_vhdl -in_library option
        "<library_name>"
    }
    files {
        "<relative_file_name>"
        ...
    }
    libraries { // See set\_design\_sources command
        {directory | file <relative_directory_or_file_name>}
    }
    extensions { // See set\_design\_sources command
        <extension list used for searching in directory libraries>
    }
    defines { // See set\_design\_macros command
        "<macro_name>[=<value>]
        ...
    }
    incdirs { // See set\_design\_include\_directories command
        <relative_directory_name>
        ...
    }
    options { // See allowed options in read\_verilog and read\_vhdl
        // commands
        <option_used_in_read_command>
        ...
    }
}

```

This file is not generated when a design is assembled in -no_rtl context.

- <*design_name*>.<*format*>_interface

A file that contains only the port and parameter declarations of the current design. The format of the file is encoded in the extension such that the right format can be used to load it back. The table below shows the mapping between the extension and the format.

This file is created by the [process_dft_specification](#) command when the -no_insertion option is not used, or by [extract_icl](#) if it is not already created by [process_dft_specification](#) command.

Table 12-2. Format to extension mapping for the interface view

Format	extension
verilog 1995	v95_interface
verilog 2001	v_interface

Table 12-2. Format to extension mapping for the interface view (cont.)

Format	extension
verilog sv31a	sv31a_interface
verilog sv2005	sv05_interface
verilog sv2009	sv09_interface
vhdl 1987	vhd87_interface
vhdl 1993	vhd_interface
vhdl 2002	vhd02_interface
vhdl 2008	vhd08_interface

- *<design_name>.scandef*

A file that is created by [insert_test_logic](#) -write_in_tsdb on. It contains the scandef description of the scan chains so that you can perform scan chain reordering and re-partitioning during layout.

- *<design_name>.tcd*

A file that is created by the [process_dft_specification](#), [insert_test_logic](#) -write_in_tsdb on, and [write_design](#) -tsdb commands. It contains the DesignInfo and optionally the Scan wrappers within the Core(*design_name*) wrapper. The DesignInfo includes lots of data specified or created in an insertion pass so that it can be restored at the beginning of a future insertion pass. The file is always read-in when using the [read_design](#) command no matter which view is loaded ensuring that the DesignInfo is imported. The Scan wrapper describes the scan chains that were created by the [insert_test_logic](#) command and is reused in a hierarchical scan insertion process.

The information stored in the Scan wrapper is also used by the [import_scan_mode](#) command to import the clock, chain, and load_unload definitions of the scan mode such that it can be used to create ATPG modes.

- *<design_name>.tcd_bscan*

A file that is created by the [process_dft_specification](#) command when inserting a Boundary Scan chain into a sub or physical block and the block contains a Core(<module_name>)/BoundaryScan wrapper. This file is reused at the next level up to stitch the boundary scan chain in the parent module and eventually generate the BSDL file once the chip level is reached. See the [set_design_level](#) command for a description of the design levels.

- *<design_name>.icl*

A file that contains the concatenated ICL representation of the current design. It is generated when running the [extract_icl](#) command.

- *<design_name>.pdl*

A file that contains the content of all PDL files that were seen beside the input ICL and tcd_memory_lib files when running the [extract_icl](#) command. For every read-in ICL or tcd_memory_lib file, a PDL file having the same name and location but with the .pdl extension are loaded and concatenated into the merged PDL file. These PDL files must only contain a series of iProcsForModules and iProcs statements. The automatic collection of PDL files makes it easy to place a PDL file beside any ICL file and have it automatically collected during ICL extraction and automatically loaded after ICL elaboration so that it can be used in a [ProcedureStep](#) wrapper or with the [set_test_setup_icall](#) command.

The source of each imported file is marked with a comment specifying where it was taken from. Because ICL extraction is done hierarchically, a merged PDL file may be merged into a higher level PDL file. You will notice that the markers get extra # as they get included into a parent file as shown here:

```
# Imported from ../corea_rtl.dft_inserted_design/corea.pdl
## Imported from ../../../../../my_instrument/counter.pdl

The path "../../../../../my_instrument/counter.pdl" is relative to its
original file location "../corea_rtl.dft_inserted_design".
```

- <design_name>.sdc

A file that is created during ICL extraction or explicitly created using the [extract_sdc](#) command. The file combines the module-level timing information found in the .sdc_dictionary files with the instance-level information found in the ICL file. Refer to the “[Timing Constraints SDC](#)” in the *Tessent Shell User’s Manual* for complete information.

- <design_name>.<gate_ext>

A file that is typically created by the [run_synthesis](#) command after you have run the [process_dft_specification](#) command in the -no_rtl context. The [run_synthesis](#) command concatenates the <design_name>.<gate_ext>_no_instruments netlist with the newly-synthesized instruments found in the files at:

[instruments](#)/`<design_name>_<design_id>_xxx.<gate_ext>`

When using the [write_design](#) -tsdb command in the -no_rtl context, this file is directly created with the content of the current design found in memory. When using the [write_design](#) -tsdb -softlink_netlist command, the <design_name>.<gate_ext> entry is created as softlink to point to the location of the file containing the current design module in memory.

- <design_name>.dft_info_dictionary

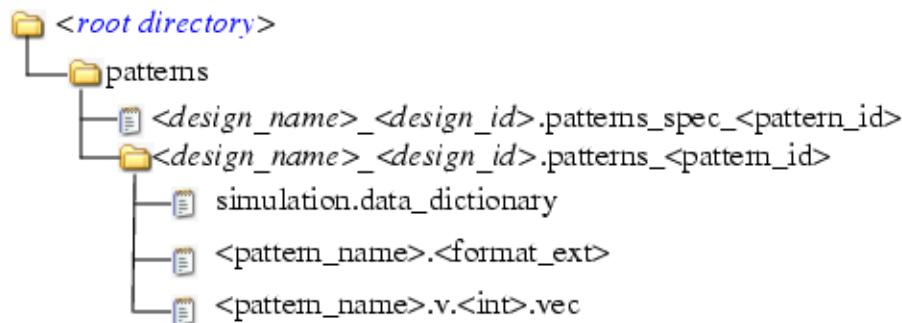

A file that is created during ICL extraction when using the [extract_icl](#) command with the -write_in_tsdb switch not set to off. The file is a Tcl dictionary containing the information about the DFT inserted in the design that must be considered during scan

insertion when using a third-party tool. See the [get_dft_info_dictionary](#) command for more information.

patterns

A directory that stores the patterns and pattern specifications associated with each design, design id, and pattern id.

Summary

Description

A directory used to store the patterns and patterns specifications associated with each design, design id, and pattern id. The patterns specification file is always updated upon each successful validation of the specification using the `process_patterns_specification` where is the TSDB output directory as specified using the [set_tsdb_output_directory](#) command.

Components

- <*design_name*>_<*design_id*>.patterns_spec_<*pattern_id*>
A file that contains the patterns specification that was just created using the [create_patterns_specification](#), and successfully validated using the [process_patterns_specification](#) command. The <*design_name*>, <*design_id*>, and <*pattern_id*> values correspond exactly to the matching elements in the PatternsSpecification(<*design_name*>, <*design_id*>, <*pattern_id*>) wrapper.
- <*design_name*>_<*design_id*>.patterns_<*pattern_id*>
A directory that is created the first time a given PatternsSpecification(<*design_name*>, <*design_id*>, <*pattern_id*>) wrapper is processed using the [process_patterns_specification](#) command. The <*design_name*>, <*design_id*> and <*pattern_id*> values correspond exactly to the matching elements in the PatternsSpecification(<*design_name*>, <*design_id*>, <*pattern_id*>) wrapper.

- simulation.data_dictionary

A file that contains a Tcl dictionary that is used by the [run_testbench_simulations](#) command to know the patterns list with their associated information as well as the design source dictionary explaining how to load the complete design downward. The format of the dictionary is illustrated below. Notice that the list of entries found in the Patterns entry is always the full list of patterns found in the PatternsSpecification wrapper independent of the -select or the -exclude option used in the last invocation of the process_patterns_specification command.

```
set simulation_dict {
    top_design_logical_library <library_name>
    patterns {
        <pattern_name> {
            testbench_module_name <module_name>
            top_design_instance_name <instance_name>
            extra_simulation_file_list <file_list>
            top_module_name_list <module_name_list>
            simulation_macro_list {<macro_definition_list>}
            lower_instances {
                <instance_name> {
                    view full | interface
                    logical_library <library_name>
                }
            }
            file_list {<testbench_and_sidefiles_list>}
            icl_time "<datetime>"
            sim_data_files <status>
        }
        design_source_dictionary {
            read# {
            }
        }
    }
}
```

- <pattern_name>.<format_ext>

A file that contains the top-level test bench or the patterns file expressed in the requested format. The extension of the file is “v” for Verilog test benches, or the exact format specified using the “manufacturing_patterns_format” property in the PatternsSpecification wrapper. If the “compress_pattern_files” option also found in the PatternsSpecification wrapper is specified to “on”, the patterns file are compressed and the .gz string is appended to the <format_ext> string.

Not all patterns found in the PatternsSpecification wrapper will be updated or created when running the process_patterns_specification command with the -select or the -exclude options. Stale pattern files left over in the <design_name>_<design_id>.patterns_<pattern_id> directories from a previous run of the process_patterns_specification command will be automatically deleted from the directory if they are no longer found in the current PatternsSpecification wrapper.

- <pattern_name>.v.<int>.vec

A set of files that is only created for Verilog test benches that contain the vector data for the associated pattern.

- <pattern_name>_<others>.v

A set of files that is only created for Verilog test benches that contain side modules to be compiled in parallel with the Verilog test bench. Such modules may include clock monitoring behavioral code. They may also contain bisr emulation code for sub-physical instances using the interface view. See the “emulate_bisr_chains_in_lower_physical_blocks” property inside the SimulationOptions wrapper for more information about those files.

logic_test_cores

A directory that stores the information generated when a test mode on a logic core was successfully design rule checked, and for which ATPG or LogicBIST patterns may have to be created.

Summary

Description

A directory used to store the information generated when a test mode on a logic core was successfully design rule checked, and for which ATPG or LogicBIST patterns may have been created.

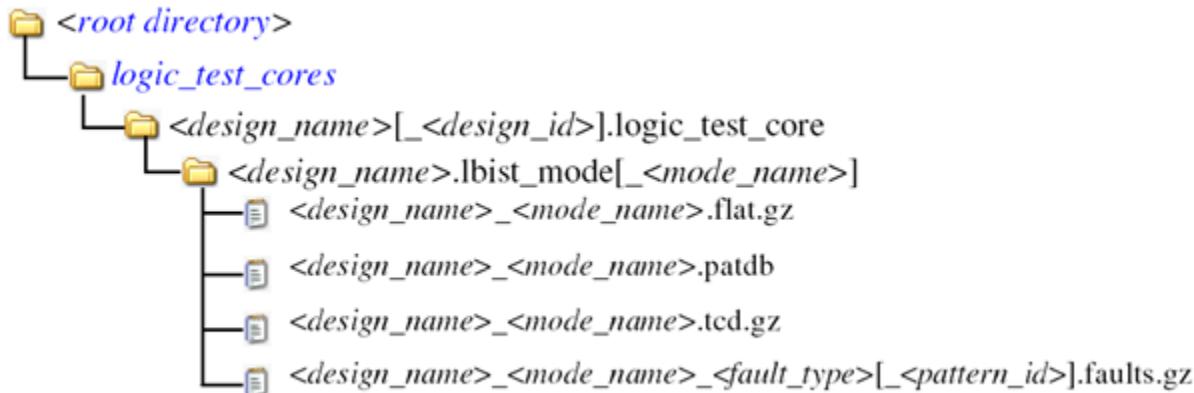

Components

- **<design_name>[_<design_id>].logic_test_core**
A directory used to hold all logic_bist, atpg, and atpg_retargeting containers. The directory uses the design name as its name with an optional design_id suffix that you can use to differentiate various views of the same design such as the pre-layout and post-layout versions.

<design_name>.lbist_mode[<mode_name>]

A directory used to store the information generated when a LogicBIST test mode on a logic core was successfully design rule checked and for which LogicBIST patterns were created.

Summary

Description

A directory used to store the information generated when a LogicBIST test mode on a logic core was successfully design rule checked and for which LogicBIST patterns were created.

Components

- **<design_name>.lbist_mode[<mode_name>]**
A directory used to store the information for a given LogicBIST test mode associated to a given design. The design is uniquely identified using its name and an optional design id as specified using the [set_context](#) command. The mode name is specified using the [set_current_mode](#) command.

The directory is created clean each time the [write_tsdb_data](#) command is issued in analysis mode and patterns -scan context. The mode is identified as a LogicBIST mode when there was at least one [add_lfsrs](#) command specified in setup mode prior to going to

analysis mode. You can use the “[get_context](#) -logic_bist” command to verify that it is a LogicBIST mode.

- <design_name>_<mode_name>.flat.gz

A file containing the flat model representing the DRCed LogicBIST test mode. This file is used to fault simulate other fault models at a later time without having to redo DRC. Its main utility is, however, to perform diagnosis when the design is in production. See the [Tessent Diagnosis User's Manual](#) for further information about how to run diagnosis and how it uses the flat model.

- <design_name>_<mode_name>.patdb

A file containing the LogicBIST pattern information. It contains all PRPG seeds, all MISR signatures, and the flop expect data for a specified amount of patterns.

- <design_name>_<mode_name>.tcd.gz

A file containing a Core/LbistMode wrapper describing different aspect of the logictest test mode. The stored information is mainly used to map diagnostic data back to flip-flop names.

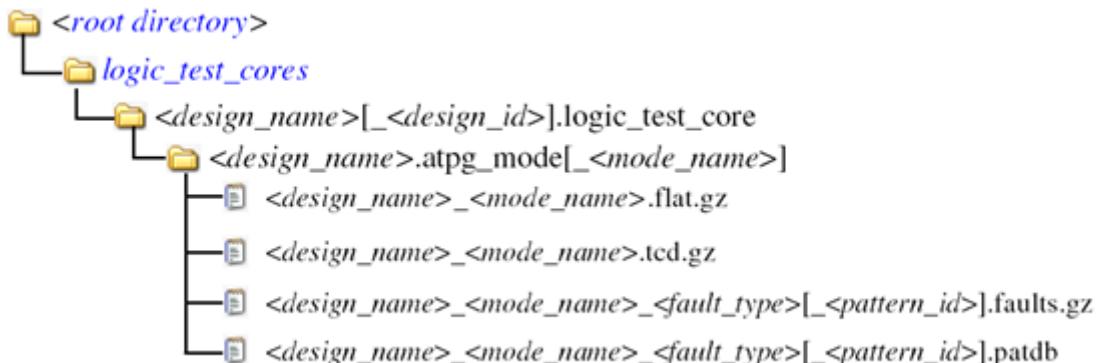

- <design_name>_<mode_name>_<fault_type>[_<pattern_id>].faults.gz

A file containing the fault classification for a given fault type and a specific pattern id that will later be used to create a consolidated fault coverage report per fault model. The pattern_id is specified using the -pattern_id option when invoking the [write_tsdb_data](#) command.

<design_name>.atpg_mode[_<mode_name>]

A directory used to store the information related to a logic core that has been configured for ATPG, passed design rule checks, and for which ATPG patterns were created.

Summary

Description

A directory used to store the information related to a logic core that has been configured for ATPG, passed design rule checks, and for which ATPG patterns were created. One typical usage is to store the ATPG results after generating retargetable patterns for a wrapped core. See also the [write_tsdb_data](#) command.

Components

- <*design_name*>.atpg_mode[<*mode_name*>]

A directory used to store the information for a given ATPG test mode associated to a given design. The design is uniquely identified using its name and an optional design id as specified using the [set_context](#) command. The mode name is specified using the [set_current_mode](#) command.

- <*design_name*>_<*mode_name*>.flat.gz

A file containing the flat model representing the DRCed ATPG test mode. The primary purpose of this file is for diagnosis. This file is also used to fault simulate other fault models at a later time without having to redo DRC.

- <*design_name*>_<*mode_name*>.tcd.gz

A file containing a Core wrapper describing different aspect of the ATPG test mode. The TCD file for the ATPG mode is used for pattern retargeting. Similarly, for top-level ATPG, it can be used for the core mapping flow. See “[Scan Pattern Retargeting](#)” and “[Core Mapping for ATPG Process Overview](#)” in the *Tessent Scan and ATPG User's Manual*.

- <*design_name*>_<*mode_name*>_<*fault_type*>[_<*pattern_id*>].faults.gz

A file containing the fault classification for a given fault type and a specific pattern id that will later be used to create a consolidated fault coverage report per fault model. The *pattern_id* is specified using the -pattern_id option when invoking the [write_tsdb_data](#) command.

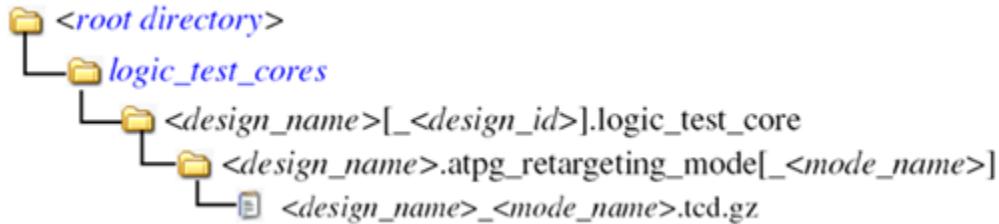

- <*design_name*>_<*mode_name*>_<*fault_type*>[_<*pattern_id*>].patdb

A file containing the ATPG pattern information.

<design_name>.atpg_retargeting_mode[<mode_name>]

A directory used to store the information related to a logic core that has been configured for retargeted ATPG, passed design rule checks, and for which retargeted ATPG patterns were created.

Summary

Description

A directory used to store the information related to a logic core that has been configured for retargeted ATPG, passed design rule checks, and for which retargeted ATPG patterns were created. See also the [write_tsdb_data](#) command and “Scan Pattern Retargeting” in the *Tessent Scan and ATPG User’s Manual*.

Components

- **<design_name>.atpg_retargeting_mode[_<mode_name>]**

A directory used to store the information for a given ATPG retargeting test mode associated to a given design. The design is uniquely identified using its name and an optional design id as specified using the [set_context](#) command. The mode name is specified using the [set_current_mode](#) command. The ATPG retargeting mode does not require that you have done pattern retargeting first. You need to have done at least done core extraction for pattern retargeting; see “[Core-in-Core Pattern Retargeting](#)” in the *Tessent Scan and ATPG User’s Manual* for more information.

- **<design_name>_<mode_name>.tcd**

A file containing a Core wrapper describing different aspect of the ATPG retargeting test mode. The TCD for the retargeting mode can be used for the following: pattern retargeting in a subsequent step to core extraction without requiring extraction or even a design; and/or for reverse mapping of tester failures for core-level diagnosis.

Chapter 13

Instrument Connectivity Language (ICL)

This chapter specifies the syntax of the Instrument Connectivity Language (ICL) of the IEEE 1687-2014 (IJTAG) standard as implemented by Tessent IJTAG.

For more information about Tessent IJTAG, refer to the *Tessent IJTAG User's Manual*.

ICL Overview

The syntax described in this chapter is not based on the formal grammar used in the IJTAG standard, but rather through a hierarchical description of an ICL Module and its elements.

Examples and suggestions for usage are provided for each language element. These elements are divided into language statements; that is, all the elements in the direct body of the ICL **Module** definition (plus a few more), and parameters. Parameters to an ICL language statement further define the properties of the statement. For example, the ICL language statement **ScanRegister** has the parameter **ResetValue**, which defines which value the scan register will assume if the reset signal turns active.

Common Features of the ICL Language.....	3784
Numbers	3784
Strings	3785
Identifiers	3785
Limited Identifier Mathematics	3786
Concatenations	3786

Unsupported ICL Language Elements

Most of the language elements of the IEEE 1687 standard are supported. Currently unsupported ICL language elements or language elements with limited support are clearly marked.

For example:

Note
 The DefaultLoadValue parameter is currently not supported within the ScanInterface.

Common Features of the ICL Language

The following sections introduce common features of the language.

Numbers	3784
Strings	3785
Identifiers	3785
Limited Identifier Mathematics	3786
Concatenations	3786

Numbers

ICL recognizes unsigned integer numbers in any of the following three number base formats: decimal, hexadecimal, and binary.

Unsized decimal numbers may be composed of a sequence of the digits 0 to 9. If needed, their size will be determined based on context.

Sized numbers are composed of a size constant, followed by an optional white space and a base token (d or D for decimal, h or H for hexadecimal, and b or B for binary), and the digits of the number, expressed in the respective number base. The size constant always expresses the number of binary digits of the sized number, independent of the used base format. For example, the sized numbers 4'b1011, 4'hb and 4'd11 are identical and exactly 4 binary digits wide.

Binary, decimal, and hexadecimal numbers may use their respective common digit symbols (0 and 1 for binary, 0 to 9 for decimal, 0 to 9 and a to f for hexadecimal). These digit symbols are case insensitive. In addition, binary and hexadecimal numbers may use x or X to denote the unknown digit value.

Padding is applied automatically as necessary if the number of digits of the sized number is less than the size constant requires. For example, assume this comparison:

```
LogicSignal test { dataIn[7:0] == 8'b10 ; }
```

The “==” operator compares two 8-bit (that is, 8 binary digit wide sized numbers). However, only 2 digits “10” are given. Padding is executed based on the following rules: If the left most digit is non-x, then the padding adds as many 0 to the left as necessary. If however the leftmost digit is x, then padding adds as many x to the left as necessary. The above example will therefore be padded to the following:

```
LogicSignal test { dataIn[7:0] == 8'b00000010 ; }
```

The opposite of padding is truncation. Truncation happens if the number of digits of the sized number is larger than the size constant requires. Consequently, excessive digits are removed

from the left until the size requirement is matched. However, only occurrences of 0 or x may be removed. Removing any other digit symbol results in an error.

Strings

Escaping in ICL strings is not compliant with the IEEE 1687-2014 standard. This has been done to maintain backward compatibility with existing ICL files generated by Mentor Graphics tools.

Backslashes in ICL strings are interpreted as escaping indicators only if the next character is a backslash or double quotes. If the next character is something else, the backslash is interpreted as an ordinary character of the string.

Identifiers

IJTAG differentiates between four identifiers: The scalar identifier, the parameter identifier, the vector identifier, and the pin identifier.

The scalar identifier is used to denote the elements of the ICL netlist such as the ports of a module, a module name or an instance name. The scalar identifier is case sensitive and must start with a letter. Thereafter, the scalar identifier may use letters, numbers, and the underscore symbol. It may not contain any white spaces nor the "[" or "]" symbols (these are used for vector identifiers).

The parameter identifier is used to reference a [Parameter](#) or [LocalParameter](#) definition. The parameter reference is composed of the "\$" symbol and the scalar identifier name of the referenced (local) parameter. For example, if the parameter scalar identifier is `userValue`, the parameter reference will be `$userValue`.

There are two types of vector identifiers: The single index and the range vector identifier. There is no length limit for these identifiers.

A single index vector identifier is composed of a scalar identifier, followed by the "[" symbol, an unsigned decimal number, followed by the "]" symbol. Its width is considered to be 1. An example is `bus[4]`, denoting the 4th bit of the scalar identifier `bus`.

A ranged vector identifier is composed of a scalar identifier, followed by the "[" symbol, a first unsigned decimal number, the ":" symbol, a second unsigned decimal number, and followed by the "]" symbol. An example is:

```
bus [0 : 4]
```

denoting 5 bits of the scalar identifier `bus`. Note that the range can either be increasing, for example `[0:4]`, or decreasing, for example `[4:0]`.

Pin identifiers refer to a port name, optionally including an instance path name. The port name is either a scalar, a single index or range index vector identifier. The instance names are all

scalar identifiers, and the instance path is composed of these scalar identifiers, separated by the “.” symbol. An example is:

```
top.myInstA.myInstB.dataIn[7:0]
```

In this example the identifiers “top”, “myInstA” and “myInstB” are all denoting names of instances, whereas dataIn[7:0] is a ranged vector identifier of a port scalar named dataIn.

Limited Identifier Mathematics

Parameter identifiers, single indexes and ranged indexes may use limited mathematical operations: + (addition), - (subtraction), * (multiplication), / (division), and % (modulo). For parameter identifiers, a parameter value can be computed using these operations; for vector identifiers any used unsigned decimal number can be expressed using these operations. In addition, parameter reference may be used.

Examples are:

```
Parameter ten = 10 ;
Parameter twenty = 2*$ten ;
bus[$twenty:$ten]
bus[$twenty%2]
bus[$ten-1:0]
```

Concatenations

Under certain conditions, identifiers might be concatenated with other identifiers and/or sized and unsized numbers. The concatenation operator is the “,” symbol.

A first example is the following:

```
Parameter topBit 1'b1 ;
LogicSignal test { dataInA[3:0], dataInB[3:0] == $topBit, 0, 4'b1111 ; }
```

Observe that the left hand side of the comparator (==) is 8 bits wide. The right hand side has 2 sized numbers of a total width of 5 bits. Therefore the unsized number 0 in the middle will be auto-expanded into 3'b000. It is obvious that such a comparison construct may contain at most one unsigned number. This example shows also the usage of parameter references in lieu of a number.

A concatenation may also include the “~” symbol, denoting a sized, bit-wise, binary inversion. For example: ~4' ha is equivalent to 4'h5.

Interestingly, the “~”symbol can also be used within the concatenation:

```
LogicSignal test { dataInA[3:0], dataInB[3:0] == $topBit, ~0, 4'b1111 ; }
```

Here, the unsized, but inverted 0 is auto-expanded into 4'b1111.

ICL Statement Descriptions

The following describes each ICL statement available in Tessent IJTAG.

Syntax Conventions	3789
Module	3790
Attribute	3792

Syntax Conventions

This chapter uses these syntax conventions when documenting ICL syntax properties.

Table 13-1. SyntaxConventions for ICL Files

Convention	Example	Usage
<i>Upright</i>	<code>ScanInPort port_name ;</code>	An upright font indicates an ICL language element, either a statement or a parameter.
<i>Italic</i>	<code>scan_in : port_pin_name;</code>	An italic font indicates a user-supplied value.
<u>Underline</u>	<code>wgl_type : generic lsi;</code>	An underlined item indicates the default value.
	<code>logic_level : both high low;</code>	The vertical bar separates a list of values from which you must choose one. Do not include the bar in the configuration file.
...	<code>port_naming : port_naming, ...;</code>	Ellipses indicate a repeatable value. The comment “// repeatable” also indicates a repeatable value.
//	<code>// default: ijtag_so</code>	The double slash indicates the text immediately following is a comment and tells the tool to ignore the text.

Module

Defines the name of an ICL module.

Usage

```
Module module_name {
    Attribute att_name = att_value;
    Parameter param_name = param_value;
    LocalParameter param_name = param_value;
    ScanInterface interface_name { ... }

    //---- Port Functions
    ScanInPort port_name { ... }
    ShiftEnPort port_name { ... }
    CaptureEnPort port_name { ... }
    UpdateEnPort port_name { ... }
    DataInPort port_name { ... }
    DataOutPort port_name { ... }
    SelectPort port_name { ... }
    ResetPort port_name { ... }
    TMSPort port_name { ... }
    TCKPort port_name { ... }
    ClockPort port_name { ... }
    TRSTPort port_name { ... }

    ToTCKPort port_name { ... }
    ToTMSPort port_name { ... }
    ToTRSTPort port_name { ... }
    ToIRSelectPort port_name { ... }

    Instance instance_name Of another_module_name { ... }
    LogicSignal signal_name { ... }
    ScanRegister register_name { ... }
    DataRegister register_name { ... }
    ScanMux mux_name SelectedBy selector { ... }
    DataMux mux_name SelectedBy selector { ... }
    ClockMux mux_name SelectedBy selector { ... }
    OneHotDataGroup name { ... }
    OneHotScanGroup name { ... }
    Enum enum_name { ... }
    Alias alias_name = element_list { ... }
    AccessLink instance_name Of link_type { ... }
}
```

Description

The syntax above lists the complete contents (statements) of an ICL module. Not all statements may be used at the same time.

Each ICL statement is explained in detail in the following pages. All statements are hyperlinked from here to the respective statement description, as well as back to this module description.

Arguments

- `module_name`

The `Module` statement defines the name of an ICL module. The name of the module must be unique among all loaded modules. To build an ICL design, you use the [Instance](#) statement.

Related Topics

[NameSpace](#)

[Instance](#)

[UseNameSpace](#)

Attribute

Specifies a user attribute name and value.

Usage

```
Module module_name {  
    Attribute att_name = att_value ;  
}
```

Description

The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool.

Tessent understands several [port attributes](#) and [pin attributes](#) as defined in this manual.

Note that most Tessent attributes are read-only and are automatically generated by the Tessent tool, which also assigns a value to the attribute.

The Attribute statement is not only allowed in [Module](#), but in most ICL objects documented in this chapter.

Note

 In its usage within ICL objects, like modules, ports, scan or data mux, and so on, the Attribute statement is always optional.

Arguments

- *att_name = att_value*

An required string and optional “=”symbol and value combination, where *att_name* defines the name of the Attribute, and *att_value*, if present, defines the value of the attribute.

Within an ICL object where multiple Attribute statements are used, each *att_name* must be unique.

Examples

Example 1

The first example shows a very simple usage of assigning a string “true” to an attribute name “is_top”:

```
Module top {  
    Attribute is_top = "true" ;  
    [...]  
}
```

Example 2

The second example shows a Tessent attribute connection_rule_option that influences ICL Network Extraction. Please see [Performing ICL Extraction](#) in the *Tessent IJTAG User's Manual* for the details of the attribute.

```
DataInPort din {Attribute connection_rule_option = "allowed_tied_high";}
```

ScanInterface

Defines a set of ports of the module that together perform a scan operation.

Usage

```
Module module_name {
    ScanInterface interface_name {
        Attribute att_name = att_value ;
        Port port_name ;
        DefaultLoadValue load_value ;
        Chain chain_name { ... }
    }
}
```

Description

Defines a set of ports of the module that together perform a scan operation.

The ScanInterface defines a set of ports of the module that together perform a scan operation. A typical example of ports include the shift enable, capture, and update enable ports, together with at least a pair of scan-in and scan-out ports. However, the ScanInterface is applied also to the TAP, since a shift-based interface to or from a module is also defined; that is, a scan interface. See the discussion on *port_names* below, which defines the sets of ports of the four recognized use models of the ScanInterface — the client interface, the host interface, the client TAP interface, and the host TAP interface. A module may have more than one scan interface, in particular several client interfaces or interfaces for different use models. However, only one scan interface may be active at the same time. This means, for example, that a set of scan chains that are supposed to be operated together must all be in the same ScanInterface definition.

For a handoff module, with more than one portfunction of type [ScanInPort](#) or [ScanOutPort](#), there must be as many ScanInterface statements as there are scan interfaces in the module. This does not mean, for example, that the number of scan-in and scan-out port pairs defines the number of ScanInterface statements. Since several pairs of scan-in and scan-out ports may belong to the same scan interface, which means they are supposed to be operated simultaneously, the number of ScanInterface statements may be smaller.

The examples below are for simple ScanInterface definitions. Additional examples, especially those for multiple parallel scan chains, are provided in the ScanInterface/[Chain](#) section.

Arguments

- *interface_name*
A required string that defines the name of the scan interface of the module.
- Attribute *att_name = att_value* ;
A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool.

- Port *port_name* ;

A repeatable, optional keyword-string pair that references the name of an existing port of the module. Four use models of a ScanInterface can be distinguished. The port_names for a given ScanInterface must all belong to the same use model.

- The client interface — Through a client scan interface a module receives all signals necessary to operate a defined set of scan chains. Ports of the following port functions form a client scan interface: at least one pair of [ScanInPort](#) and [ScanOutPort](#), one [ShiftEnPort](#) and/or at least one [SelectPort](#), and [CaptureEnPort](#), [UpdateEnPort](#), [ResetPort](#), or [TCKPort](#). There can be more than one CaptureEnPort or more than one UpdateEnPort in one client interface, as long as all ports with the same port function have distinct function_modifier attributes. If the shift enable, capture enable, or update enable ports are not stated and the module has exactly one of each, these ports are implied for the scan interface using the modules set of port functions, or for non-handoff modules, the set or implied set of port functions. If more than one pair of scan-in and scan-out ports belong to the same scan interface, the [Chain](#) object must be used. In this case, no port name should reference a scan-in and scan-out port, nor should the DefaultLoadValue be used.

If a non-handoff module has exactly one client interface, than the ScanInterface statement is not required. The tool assumes a “default” client interface.

- The host interface — Through a host scan interface a module defines shift operating control signals for another module. Ports of the following port functions form a host scan interface: one [ScanInPort](#) and/or one [ScanOutPort](#), one [ToShiftEnPort](#) and/or at least one [ToSelectPort](#), and [ToCaptureEnPort](#), [ToUpdateEnPort](#), [ToResetPort](#), or [ToTCKPort](#). There can be more than one ToCaptureEnPort or more than one ToUpdateEnPort in one host interface, as long as all ports with the same port function have distinct function_modifier attributes. Similar to the client interface, if the module has exactly one [ToShiftEnPort](#), [ToCaptureEnPort](#), or [ToUpdateEnPort](#), these ports are assumed for each host scan interface, for which they have not been stated already.
- The client TAP interface — Through a client TAP interface, the module receives all signals necessary to operate a TAP controller: One of each [ScanInPort](#), [ScanOutPort](#), and [TMSPort](#), and at most one of [TRSTPort](#) and [TCKPort](#).
- The host TAP interface — Through a host TAP interface, the module defines signals for another module’s client TAP interface: One [ScanInPort](#) and/or one [ScanOutPort](#), one [ToTMSPort](#), and at least one of [ToTRSTPort](#) and [ToTCKPort](#).

Note

 ScanInterfaces with multiple CaptureEnPorts, UpdateEnPorts, ToCaptureEnPorts or ToUpdateEnPorts are not standard-compliant. Third-party IJTAG tools might reject the processing of ICL files with such ScanInterface specifications.

- DefaultLoadValue *load_value* ;
An optional keyword-string pair that defines the value to be loaded into the single scan chain defined by a pair port names of portfunction type ScanInPort and ScanOutPort of a black-box module. The DefaultLoadValue property affects the behavior of the iScan command only. The iScan command is currently not supported.
- Chain *chain_name* ;
A repeatable, optional keyword-string pair that declares the name of a scan chain of the module. All chain names must be unique within a ScanInterface. If the ScanInterface has only one [ScanInPort/ScanOutPort](#) pair, than [Chain](#) object is not required.

Examples

Example 1

The following example shows three equivalent description of an ICL module with a single scan-in / scan-out client scan interface. This is not a complete list, other variations are possible. Note that for the module tdr4_1, no ScanInterface statement is given. It is not necessary, since the module has exactly one client scan interface. However, you may provide a ScanInterface as shown for modules tdr4_2, and tdr4_3.

```

Module tdr4_1 {
    ScanInPort      si;
    ScanOutPort     so      { Source R[0]; }
    ShiftEnPort     se;
    SelectPort      en;
    CaptureEnPort   ce;
    UpdateEnPort    ue;
    TCKPort         tck;
    ScanRegister R[7:0] {
        ScanInSource  si;
        ResetValue    8'b0 ;
    }
}
Module tdr4_2 {
    ScanInPort      si;
    ScanOutPort     so      { Source R[0]; }
    ShiftEnPort     se;
    SelectPort      en;
    CaptureEnPort   ce;
    UpdateEnPort    ue;
    TCKPort         tck;
    ScanInterface interface1 {
        Port en ;
        Port si; Port so;
    }
    ScanRegister R[7:0] {
        ScanInSource  si;
        ResetValue    8'b0 ;
    }
}
Module tdr4_3 {
    ScanInPort      si;
    ScanOutPort     so      { Source R[0]; }
    ShiftEnPort     se;
    SelectPort      en;
    CaptureEnPort   ce;
    UpdateEnPort    ue;
    TCKPort         tck;
    ScanInterface interface2 {
        Port se ;
        Chain chain1 {
            Port si; Port so;
        }
    }
    ScanRegister R[7:0] {
        ScanInSource  si;
        ResetValue    8'b0 ;
    }
}

```

Example 2

The next example shows the port functions and both the client and host TAP interfaces of a typical TAP controller module.

```

Module tap {
    TCKPort      tck;
    ScanInPort   tdi;
    ScanOutPort  tdo      {  Source IRMux;  }
    TMSPort      tms;
    TRSTPort     trst;
    ToSelectPort tdrEn     {  Source sel;   }
    ScanInPort   fromTdr;
    ToSelectPort tapEn     {  Source IR[2];  }
    ToCaptureEnPort tce;
    ToShiftEnPort tse;
    ToUpdateEnPort tue;
    ScanInterface clientTAP {
        Port tdi; Port tdo;
        Port tms; Port trst;
    }
    ScanInterface hostTAP  {
        Port fromTdr1; Port tdrEn1;
        Port tce; Port tse; Port tue;
    }
    [...]
}

```

Example 3

The next example shows an example implementation of a SIB (Segment Insertion Bit) module. This module implements a scan chain switch by selecting either of two scan input ports. The module also generates an outgoing enable signal that is correlated to the second scan-in port.

```

Module sib {
    ScanInPort      si;
    ScanOutPort     so  {  Source SIB;  }
    ShiftEnPort    se;
    CaptureEnPort  ce;
    UpdateEnPort   ue;
    SelectPort     en;
    TCKPort        tck;
    ScanInPort     fso;
    ToSelectPort   ten {  Source And;  }
    ScanInterface client {
        Port si; Port so;
        Port se; Port ce; Port ue; Port en;
    }
    ScanInterface host  {
        Port fso; Port ten;
    }
    ScanRegister SIB {
        ResetValue    1'b0;
        ScanInSource Mux;
    }
    ScanMux Mux SelectedBy SIB {
        1'b0 : si;
        1'b1 : fso;
    }
    LogicSignal And { en,SIB == 2'b11;  }
}

```

Chain

Defines the name of a scan chain within a ScanInterface.

Usage

```
ScanInterface interface_name {
    Chain chain_name {
        Attribute att_name = att_value ;
        Port port_name ;
        DefaultLoadValue load_value ;
    }
}
```

Description

The Chain statement defines the name of a scan chain within a [ScanInterface](#).

This statement does not create a scan register in the sense of the [ScanRegister](#) statement. Here it is only a declaration which [ScanInPort](#) and [ScanOutPort](#) of the module will be operated together with the control signals of the [ScanInterface](#). There can be more than one Chain statement in a [ScanInterface](#). In this case, each scan chain name must be unique.

Arguments

- Chain *chain_name* ;
A repeatable, required keyword-string pair that defines the name of a scan chain within a given ScanInterface. There can be more than one scan chain in any given ScanInterface. However, the names of the scan chains within a ScanInterface must all be unique.
- Attribute *att_name = att_value* ;
A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent does not have any built-in attributes for the ScanInterface/Chain statement.
- Port *port_name* ;
A required keyword-string pair, with the *port_name* referencing a [ScanInPort](#) or [ScanOutPort](#) port of the module. Within each Chain statement, there are exactly two Port statements, one referencing the scan-in port, and the other referencing the scan-out port.
- DefaultLoadValue *load_value* ;
An optional keyword-string pair that defines the value to be loaded into the single scan chain defined by a pair port names of portfunction type ScanInPort and ScanOutPort of a black-box module. The DefaultLoadValue property affects the behavior of the iScan command only. The iScan command is currently not supported.

Examples

Example 1

The following example shows a module with two client ScanInterfaces, each operating two scan chains.

```
Module chip1 {
    ScanInPort siA1 ;
    ScanInPort siA2 ;
    ScanOutPort soA1 { Source blockA.so1 ; }
    ScanOutPort soA2 { Source blockA.so2 ; }
    ScanInPort siB1 ;
    ScanInPort siB2 ;
    ScanOutPort soB1 { Source blockB.so1 ; }
    ScanOutPort soB2 { Source blockB.so2 ; }
    ShiftEnPort sel1 ;
    CaptureEnPort cel1 ;
    UpdateEnPort uel ;     ShiftEnPort se2 ;
    CaptureEnPort ce2 ;
    UpdateEnPort ue2 ;     TCKPort tck ;
    ScanInterface cA12 {
        Port sel1; Port cel1; Port uel;
        Chain c1 { Port siA1; Port soA1 ; }
        Chain c2 { Port siA2; Port soA2 ; }
    }
    ScanInterface cB12 {
        Port se2; Port ce2; Port ue2;
        Chain c1 { Port siB1; Port soB1 ; }
        Chain c2 { Port siB2; Port soB2 ; }
    }
}
[...]
```

Example 2

In this variation of Example 1 above, the [ShiftEnPort](#), [CaptureEnPort](#), and [UpdateEnPort](#) ports are shared among both [ScanInterface](#). The selection between the two interfaces is accomplished through the two [SelectPort](#) sel1 and sel2, respectively.

```
Module chip2 {
    ScanInPort siA1 ;
    ScanInPort siA2 ;
    ScanOutPort soA1 { Source blockA.so1 ; }
    ScanOutPort soA2 { Source blockA.so2 ; }
    ScanInPort siB1 ;
    ScanInPort siB2 ;
    ScanOutPort soB1 { Source blockB.so1 ; }
    ScanOutPort soB2 { Source blockB.so2 ; }
    SelectPort selA ;
    SelectPort selB ;    ShiftEnPort se ;
    CaptureEnPort ce ;
    UpdateEnPort ue ;    TCKPort tck ;    ScanInterface cA12 {
        Port selA;
        Chain c1 { Port siA1; Port soA1 ; }
        Chain c2 { Port siA2; Port soA2 ; }
    }           ScanInterface cB12 {
        Port selB;
        Chain c1 { Port siB1; Port soB1 ; }
        Chain c2 { Port siB2; Port soB2 ; }
    }
    [...]
}
```

Example 3

This example is another variation of Example 1. The difference is that all ports are busses and not individual ports as in Example 1. The operation of the modules is identical.

```
Module chip3 {
    ScanInPort si[3:0] ;
    ScanOutPort so[3:0] { Source blockA.so1, blockA.so2,
                         blockB.so1, blockB.so2 ;
                         }    ShiftEnPort se[1:0] ;
    CaptureEnPort ce[1:0] ;
    UpdateEnPort ue[1:0] ;    TCKPort tck ;    ScanInterface cA12 {
        Port se[0]; Port ce[0]; Port ue[0];
        Chain c1 { Port si[0]; Port so[0] ; }
        Chain c2 { Port si[1]; Port so[1] ; }
    }           ScanInterface cB12 {
        Port se[1] ; Port ce[1]; Port ue[1];
        Chain c1 { Port si[2]; Port so[2] ; }
        Chain c2 { Port si[3]; Port so[3] ; }
    }
    [...]
}
```

[ScanInterface](#)

[ScanRegister](#)

ScanInPort

Declares the name of a scan input port of a Module.

Usage

```
Module module_name {
    ScanInPort port_name {
        Attribute att_name = att_value ;
    }
}
```

Description

A port function that declares the name of a scan input port of a [Module](#).

A module may have zero or more scan-in ports. However, if a module has at least one [ScanOutPort](#) defined, then there must be at least one ScanInPort.

If a module has exactly one ScanInPort, than the module may also have a [ScanInterface](#) defined. However, if a module has more than one ScanInPort, than there must be at least one [ScanInterface](#) definition.

The scan-in port is used to execute a serial write (that is, not a parallel write operation). If a parallel write is to be done, use the [DataInPort](#) port function instead.

Arguments

- *port_name*

A required string that identifies the name of a scan-in port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL ScanInPort of the module that is also used for the respective ports of the design module.

- Attribute *att_name = att_value ;*

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [port attributes](#) and [pin attributes](#) as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Examples

The following example shows an ICL module definition with a single scan-in / scan-out chain, therefore, no [ScanInterface](#) is required. The scan-in port is named “si”. Observe that the port name is reused in the body of the [ScanRegister](#) R[7:0] declaration. There, it declares that the

scan register will receive its scan data from the object named “si”, which happens to be the ScanInPort of the Module.

```
Module tdr2 {
    ScanInPort      si;
    ScanOutPort     so { Source R[0]; }
    ShiftEnPort     se;
    SelectPort      en;
    CaptureEnPort   ce;
    UpdateEnPort    ue;
    TCKPort         tck;
    ScanRegister R[7:0] {
        ScanInSource   si;
        ResetValue     8'b0 ;
        DefaultLoadValue 8'b0 ;
    }
}
```

ShiftEnPort

Declares the name of the shift enable port of a Module's client ScanInterface.

Usage

```
Module module_name {
    ShiftEnPort port_name {
        Attribute att_name = att_value ;
    }
}
```

Description

A port function that declares the name of the shift enable port of a [Module](#)'s client [ScanInterface](#).

This port is used to enable the shift operation into a module's [ScanRegister](#) elements. A module may have zero or more shift enable ports. For an internal module; that is, not a hand-off module, a single shift enable port is implied if there are scan in/out ports in the module. In this case, a ShiftEnPort need not be declared. The ShiftEnPort must be declared if:

- The module is a hand-off module.
- There is more than one shift enable port in the ICL module definition. This may happen if there are multiple scan in/out ports defined that are operated independently.

The shift enable signal is an active high signal. A ShiftEnPort of an instance is sourced by a ToShiftEnPort. A [ScanRegister](#) object is expected to hold its scan data, as long as the shift enable port is low, independently on the number of clock cycles.

Arguments

- *port_name*

A required string that identifies the name of a shift enable port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL ShiftEnPort of the module that is also used for the respective ports of the design module.

- Attribute *att_name = att_value ;*

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [port attributes](#) and [pin_attributes](#) as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Examples

The following example shows an ICL module definition with a single scan-in / scan-out chain, therefore, no client [ScanInterface](#) is required. The shift enable port is named “se”. Observe that the body of the Module does not further use the shift enable port name, nor is its active-high value used or stated anywhere. Its connection to the scan chain is done implicitly. Please see the examples of the [ScanInterface](#) to learn how you can use multiple scan chains, potentially with multiple shift enable signals.

```
Module tdr2 {
    ScanInPort      si;
    ScanOutPort     so { Source R[0]; }
    ShiftEnPort     se;
    SelectPort      en;
    CaptureEnPort   ce;
    UpdateEnPort    ue;
    TCKPort         tck;
    ScanRegister R[7:0] {
        ScanInSource   si;
        ResetValue     8'b0 ;
        DefaultLoadValue 8'b0 ;
    }
}
```

CaptureEnPort

Declares the name of the capture enable port of a Module's client ScanInterface.

Usage

```
Module module_name {  
    CaptureEnPort port_name {  
        Attribute att_name = att_value ;  
    }  
}
```

Description

A port function that declares the name of the capture enable port of a [Module](#)'s client [ScanInterface](#).

This port is used to control the capture operation of a module's [ScanRegister](#) elements. A module may have zero or more capture enable ports. For an internal module; that is, not a hand-off module, a single capture enable port is implied if there are scan in/out ports in the module. In this case, a CaptureEnPort need not be declared. The CaputureEnPort must be declared if:

- The module is a hand-off module.
- There is more than one capture enable port in the ICL module definition. This may happen if there are multiple scan in/out ports defined that are operated independently.

The capture enable signal is an active high signal. A CaptureEnPort of an instance is sourced by a CaptureEnPort of the parent module, a [ToCaptureEnPort](#) of another instance or a DataMux which has a capture signal at one of its inputs and the constant value 1'b0 at the other input. If the DataMux is configured such that it selects the constant value 1'b0, the capture enable pulse is assumed to be suppressed.

Note

 The suppressing of the enable signal described above is currently not supported in Tessent.

Arguments

- *port_name*

A required string that identifies the name of a capture enable port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL CaptureEnPort of the module that is also used for the respective ports of the module in the design.

- Attribute *att_name = att_value* ;

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the

language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [port attributes](#) and [pin attributes](#) as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Examples

The following example shows an ICL module definition with a single scan-in / scan-out chain, therefore, no client [ScanInterface](#) is required. The capture enable port is named “ce”. Observe that the body of the Module does not further use the capture enable port name, nor is its active-high value used or stated anywhere. Its connection to the scan chain is done implicitly. Please see the examples of the [ScanInterface](#) to learn how you can use multiple scan chains, potentially with multiple capture enable signals.

```
Module tdr2 {
    ScanInPort      si;
    ScanOutPort     so { Source R[0]; }
    ShiftEnPort     se;
    SelectPort      en;
    CaptureEnPort   ce;
    UpdateEnPort    ue;
    TCKPort         tck;
    ScanRegister R[7:0] {
        ScanInSource   si;
        ResetValue     8'b0 ;
        DefaultLoadValue 8'b0 ;
    }
}
```

UpdateEnPort

Declares the name of the update enable port of a Module's client ScanInterface.

Usage

```
Module module_name {
    UpdateEnPort port_name {
        Attribute att_name = att_value ;
    }
}
```

Description

A port function that declares the name of the update enable port of a [Module](#)'s client [ScanInterface](#).

This port is used to control the update operation of a module's [ScanRegister](#) elements. A module may have zero or more capture enable ports. A module may have zero or more update enable ports. For an internal module; that is, not a hand-off module, a single update enable port is implied if there are scan in/out ports in the module. In this case, an UpdateEnPort need not be declared. The UpdateEnPort must be declared if:

- The module is a hand-off module.
- There is more than one update enable port in the ICL module definition. This may happen if there are multiple scan in/out ports defined that are operated independently.

The update enable signal is an active high signal. An UpdateEnPort of an instance is sourced by an UpdateEnPort of the parent module, a ToUpdateEnPort of another instance or a DataMux which has an update signal at one of its inputs and the constant value 1'b0 at the other input. If the DataMux is configured such that it selects the constant value 1'b0, the update enable pulse is assumed to be suppressed. An UpdateEnPort of an instance is sourced by an UpdateEnPort of the parent module, a ToUpdateEnPort of another instance or a DataMux which has an update signal at one of its inputs and the constant value 1'b0 at the other input. If the DataMux is configured such that it selects the constant value 1'b0, the update enable pulse is assumed to be suppressed.

Note

 The suppressing of the enable signal described above is currently not supported in Tessent.

Arguments

- *port_name*

A required string that identifies the name of an update enable port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL UpdateEnPort of the module that is also used for the respective ports of the module in the design.

- Attribute *att_name* = *att_value* ;

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [port attributes](#) and [pin attributes](#) as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Examples

The following example shows an ICL module definition with a single scan-in / scan-out chain, therefore, no client [ScanInterface](#) is required. The update enable port is named “ue”. Observe that the body of the Module does not further use the update enable port name, nor is its active-high value used or stated anywhere. Its connection to the scan chain is done implicitly. Please see the examples of the [ScanInterface](#) to learn how you can use multiple scan chains, potentially with multiple update enable signals.

```
Module tdr2 {
    ScanInPort      si;
    ScanOutPort     so { Source R[0]; }
    ShiftEnPort     se;
    SelectPort      en;
    CaptureEnPort   ce;
    UpdateEnPort    ue;
    TCKPort         tck;
    ScanRegister R[7:0] {
        ScanInSource  si;
        ResetValue    8'b0 ;
        DefaultLoadValue 8'b0 ;
    }
}
```

DataInPort

Declares the name of the data in port of a Module.

Usage

```
Module module_name {
    DataInPort port_name {
        RefEnum enum_name ;
        DefaultLoadValue default_load_value ;
        Attribute att_name = att_value ;
    }
}
```

Description

A port function that declares the name of the data in port of a [Module](#).

A module may have zero or more data in ports. The number and bus-width of all declared data in ports is not correlated to the number and bus-width of any [DataOutPort](#).

A data in port is used to execute a parallel write (that is, not a scan operation), to ports of the module. For a scan operation, use the [ScanInPort](#) port function instead. If parallel writes to ports of the module are allowed, the DataInPort function(s) must be declared for the module. If a module does not have DataInPort port functions, no parallel data write is allowed. Certain additional restrictions apply as explained next.

There should be at most one RefEnum per DataInPort, and the widths of the data within the referenced enumeration table should match the width of the data in port.

If a data in port is used to select a scan path, for example, as the select of a [ScanMux](#), it may not be target of a write operation. This ensures that the scan selection remains under control of the software application.

If a data in port is connected to an [Instance](#) or [DataRegister](#) with an AddressValue statement, all data in ports are concatenated in the order of declaration until the required data width is achieved. See the discussion of AddressValue for further explanation and an example.

Arguments

- *port_name*

A required string that identifies the name of a data in port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL DataInPort of the module that is also used for the respective ports of the module in the design.

- RefEnum *enum_name* ;

An optional keyword-string pair that references the name of an Enum table. Using the enumeration table, the writing to the data in port can use synonyms listed in the table, instead of bit strings. It must be understood that the enumeration table is not necessarily a complete list. It is still allowed to write to the data in ports any value, including those not listed in the enumeration table. A DataInPort may have at most one RefEnum statement.

- DefaultLoadValue *default_load_value* ;

An optional keyword-string pair that identifies the value that each DataIn port will assume if no user-defined value had been written to it beforehand and other bits of the Ports needs to be written to. If used, the width of *default_load_value* must match the width of the port.

For DataInPorts on the current design, the tool will automatically force those DataInPorts to the specified *default_load_value* at the beginning of the pattern. There is one exception to this behavior. If the DataInPort is declared as an inout port in the design module having the same name as the top level ICL module, the port is driven to Z at the beginning of the pattern and will remain Z until the port is the target of an explicit iWrite command or its value is needed to justify other iRead or iWrite commands.

- Attribute *att_name* = *att_value* ;

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessonst understands several [port attributes](#) and [pin attributes](#) as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Examples

Example 1

The following example shows an ICL module definition with only DataInPort, [DataOutPort](#), and a [ClockPort](#) port functions. This module does not include any scan interface. Its only way of data IO is through the parallel data port in[7:0] and out[7:0]. Observe that the body of the module is empty, not containing any other ICL objects, like [DataRegister](#), or [LogicSignal](#).

```
Module instrument {
    DataInPort  in[7:0];
    DataOutPort out[7:0];
    ClockPort   clk;
}
```

Example 2

The following example shows an ICL module definition with both a parallel data input/output and a scan interface (implicitly defined, since there is only one scan-in / scan-out pair). Observe how the data in port is used inside the [ScanRegister](#). It is declared as the source of the capture values of the scan register, which means that the scan register will capture the value from the data in ports fq on the positive edge of the [CaptureEnPort](#) ce, under the condition that the [SelectPort](#) en is also high. Finally, observe the usage of the RefEnum and [Enum](#) statements.

```

Module tdr_ref {
    ScanInPort      si;
    ScanOutPort     so      {  Source R[0];   }
    ShiftEnPort     se;
    SelectPort      en;
    CaptureEnPort   ce;
    UpdateEnPort    ue;
    TCKPort         tck;
    DataInPort      fq[7:0]  {  RefEnum OptionalValues;  }
    DataOutPort     td[7:0]  {  Source R[7:0]; RefEnum OptionalValues;  }
    ScanRegister R[7:0] {
        CaptureSource fq[7:0];
        ScanInSource  si;
        RefEnum       OptionalValues ;
    }   Enum OptionalValues {
        reset = 8'b0 ;
        set   = 8'b11111111 ;
        chain = 8'b11001100 ;
        green = 8'hee ;
        blue  = 8'd198 ;
    }
}

```

Example 3

The following example shows how a data input port can be used to select a scan path. In such a case, the data input port falls under the control of the Tessent, which will determine the necessary data in values to fulfill any read or write requests to the scan chains.

```

Module msel {
    ScanOutPort so {  Source smux;  }
    DataInPort  dataSel;
    ScanMux smux SelectedBy dataSel {
        1'b0 : tdr0[0];
        1'b1 : tdr1[0];
    }
    [...]
}

```

SelectPort

Declares the name of the select input port of a Module's client ScanInterface.

Usage

```
Module module_name {
    SelectPort port_name {
        Attribute att_name = att_value ;
    }
}
```

Description

A port function that declares the name of the select input port of a [Module](#)'s client [ScanInterface](#).

A module may have zero or more select ports. It is used to enable a scan interface of a module. When the select port is active (high), the scan interface is active. However, if the select port is inactive (low), the scan interface will not respond to any other control signal defined for this scan interface. The SelectPort statement for a non-handoff module is optional and implied if the module has a scan interface. The SelectPort is only required if the port is part of the [ScanInterface](#) statement. A SelectPort which is not part of a scan interface and which is not part of the scan network configuration logic is equivalent to a DataInPort.

Arguments

- *port_name*

A required string that identifies the name of a select port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL SelectPort of the module that is also used for the respective port of the module in the design.

- Attribute *att_name = att_value* ;

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [port attributes](#) and [pin attributes](#) as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Examples

In this example, the [ShiftEnPort](#), [CaptureEnPort](#), and [UpdateEnPort](#) ports are shared among both [ScanInterface](#). The selection between the two interfaces is accomplished through the two [SelectPort](#) sel1 and sel2, respectively.

```
Module chip2 {
    ScanInPort siA1 ;
    ScanInPort siA2 ;
    ScanOutPort soA1 { Source blockA.so1 ; }
    ScanOutPort soA2 { Source blockA.so2 ; }
    ScanInPort siB1 ;
    ScanInPort siB2 ;
    ScanOutPort soB1 { Source blockB.so1 ; }
    ScanOutPort soB2 { Source blockB.so2 ; }
    SelectPort selA ;
    SelectPort selB ;
    ShiftEnPort se ;
    CaptureEnPort ce ;
    UpdateEnPort ue ;
    TCKPort tck ;
    ScanInterface cA12 {
        Port selA;
        Chain c1 { Port siA1; Port soA1 ; }
        Chain c2 { Port siA2; Port soA2 ; }
    }
    ScanInterface cB12 {
        Port selB;
        Chain c1 { Port siB1; Port soB1 ; }
        Chain c2 { Port siB2; Port soB2 ; }
    }
    [...]
}
```

ResetPort

Declares the name of the reset input port of a Module's client ScanInterface.

Usage

```
Module module_name {
    ResetPort port_name {
        Attribute att_name = att_value ;
        ActivePolarity 0 | 1 ;
    }
}
```

Description

A port function that declares the name of the reset input port of a [Module](#)'s client [ScanInterface](#).

You have the option to chose the active polarity of the port.

A ResetPort can be explicitly connected to various sorts of drivers by means of the InputPort binding in the instantiation of the module, causing the ResetPort to become active under different conditions (synchronous reset, asynchronous reset, enforced local reset and so on). If the driver has not been specified explicitly, then the ResetPort may be implicitly connected to a reset signal in the parent module. See the chapter "[How to Model Global Reset, Local Reset and Embedded TAPs](#)" in the *Tessent IJTAG User's Manual* for the details on the reset functionality and the different ways of connecting a ResetPort.

Arguments

- *port_name*

A required string that identifies the name of a reset port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL ResetPort of the module that is also used for the respective port of the module in the design.

- Attribute *att_name* = *att_value* ;

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [port attributes](#) and [pin attributes](#) as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

- ActivePolarity 0 | 1

An optional keyword-value pair, that defines if the reset port of the module is considered active low (value = 0), or active high (value =1). If the ActivePolarity statement is not given, the active polarity of the reset port is assumed to be high.

[ScanInterface](#)

TMSPort

Declares the name of the TMS input port of a Module's client TAP ScanInterface.

Usage

```
Module module_name {
    TMSPort port_name {
        Attribute att_name = att_value ;
    }
}
```

Description

A port function that declares the name of the TMS input port of a [Module](#)'s client TAP ScanInterface.

If a module has a client TAP interface, the TMSPort declaration may not be omitted. If the module has a [ToIRSelectPort](#), the module must also have exactly one TMSPort.

IJTAG supports top-level TAPs, as well as any number of embedded TAP controllers.

A TMSPort can be explicitly connected to various sorts of drivers by means of the InputPort binding in the instantiation of the module, causing the TMSPort either to be in its normal mode of operation or to be continuously driven with the value '1' (which causes the associated TAP controller to be held in "reset" state) or to be continuously driven with the value '0' (which causes the associated TAP controller to be held in "idle" state). If the driver has not been specified explicitly, then the TMSPort may be implicitly connected to a tms signal in the parent module. See chapter "[How to Model Global Reset, Local Reset and Embedded TAPs](#)" in the *Tessent IJTAG User's Manual* for the details on embedded TAPs and the different ways of connecting a TMSPort.

Arguments

- *port_name*

A required string that identifies the name of the TMS port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#)

It is recommended to use a port name for the ICL TMSPort of the module that is also used for the respective port of the module in the design.

- Attribute *att_name = att_value* ;

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [icl_port](#) attributes and [icl_pin](#)

attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Examples

The following shows a complete example ICL module definition of a TAP controller. Observe that the state machine is not described, there is only a generic module that defines the instruction register select signal. IJTAG has built-in the knowledge of a TAP's state machine.

```
Module tap {
    TCKPort      tck;
    ScanInPort   tdi;
    ScanOutPort  tdo      {  Source IRMux;  }
    TMSPort      tms;
    TRSTPort     trst;
    ToSelectPort tdrEn1   {  Source sel1;   }
    ScanInPort   fromTdr1;
    ToSelectPort tapEn1   {  Source IR[2];  }
    ToCaptureEnPort tce;
    ToShiftEnPort tse;
    ToUpdateEnPort tue;
    ScanInterface clientTAP {
        Port tdi; Port tdo;
        Port tms; Port trst;
    }
    ScanInterface hostTAP  {
        Port fromTdr1; Port tdrEn1;
        Port tce; Port tse; Port tue;
    }
    Instance fsm_i Of fsm  {
        InputPort tck = tck;
        InputPort tms = tms;
        InputPort trst = trst;
    }
    ScanRegister IR[2:0] {
        CaptureSource 3'b001;
        ResetValue     3'b000;
        ScanInSource   tdi;
    }

    ScanRegister bypass {
        CaptureSource 1'b0;
        ScanInSource   tdi;
    } ScanMux IRMux SelectedBy fsm_i.irSel {
        1'b0 : DRMux;
        1'b1 : IR[0];
    } ScanMux DRMux SelectedBy IR[2:0] {
        3'bx00 : bypass;
        3'bx01 : fromTdr1;
    } LogicSignal sel1 {  IR[2:0] == 3'bx01; }
}Module fsm {
    TCKPort      tck;
    TMSPort      tms;
    TRSTPort     trst;
    ToIRSelectPort irSel;
    ToResetPort  tlr;
}
```

[ToIRSelectPort](#)

TCKPort

Declares the name of the test clock (TCK) input port of a Module.

Usage

```
Module module_name {
    TCKPort port_name {
        Attribute att_name = att_value ;
    }
}
```

Description

A port function that declares the name of the test clock (TCK) input port of a [Module](#).

The declaration of the TCKPort is optional for an internal module (that is, not for a hand-off module), even if the module contains scan registers. In this case, the test clock is implicitly assumed.

A module may have more than one TCKPort statement. In this case, all declared test clocks will be considered equivalent and with the same polarity.

Non test clock ports are defined through the [ClockPort](#) statement.

Note that IJTAG has no means of defining the actual speed of a test clock. This is left to the software implementing the standard. In Tessent, you can use the [add_clocks](#) command to define clock properties, like the period or the off-value.

Arguments

- *port_name*

A required string that identifies the name of the test clock port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotScanGroup](#), [OneHotDataGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL TCKPort of the module that is also used for the respective port of the module in the design.

- Attribute *att_name = att_value* ;

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [port attributes](#) and [pin attributes](#) as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Related Topics

[ScanInterface](#)

[ScanRegister](#)

[ClockPort](#)

ClockPort

Declares the name of a functional clock input port of a Module.

Usage

```
Module module_name {
    ClockPort port_name {
        Attribute att_name = att_value ;
        DifferentialInvOf other_clock_port_name ;
    }
}
```

Description

A port function that declares the name of a functional clock input port of a [Module](#) (that is, a clock that is not a test clock).

A test clock is defined through the [TCKPort](#) statement. A module may have zero or more clock ports.

Note that IJTAG has no means of defining the actual speed of a functional clock. This is left to the software implementing the standard. In Tessent, you can use the [add_clocks](#) command to define clock properties, like the period, or if the clock is synchronous or asynchronous to the test clock. Inside of ICL, only the [ToClockPort](#) statement can be used to model an oscillator-like behavior.

Arguments

- *port_name*

A required string that identifies the name of a clock port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL ClockPort of the module that is also used for the respective ports of the module in the design.

- DifferentialInvOf *other_clock_port_name* ;

An optional keyword-string pair. Differential functional clocks are declared through the DifferentialInvOf keyword. The *other_clock_port_name* string references another ClockPort *port_name* of the same module.

- Attribute *att_name* = *att_value* ;

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [port attributes](#) and [pin attributes](#) as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Examples

The following example declares one test clock and two functional, non-test clocks, an ordinary one and a differential one, the latter of which consists of two clock pins “pdifff” and “ndiff”.

```
Module top {
    TCKPort tck;
    ClockPort sclk;
    ClockPort pdifff;
    ClockPort ndiff { DifferentialInvOf pdifff ; }
```

Related Topics

[TCKPort](#)

TRSTPort

Declares the name of a TAP reset input port of a Module's client TAP ScanInterface.

Usage

```
Module module_name {  
    TRSTPort port_name {  
        Attribute att_name = att_value ;  
    }  
}
```

Description

A port function that declares the name of a TAP reset input port of a [Module](#)'s client TAP [ScanInterface](#). The active polarity of the port is low.

A TRSTPort can be explicitly connected to various sorts of drivers by means of the InputPort binding in the instantiation of the module, causing the TRSTPort to become active under different conditions (asynchronous global reset, enforced local reset and so on). If the driver has not been specified explicitly, then the TRSTPort may be implicitly connected to a trst signal in the parent module. See chapter "[How to Model Global Reset, Local Reset and Embedded TAPs](#)" in the *Tessent IJTAG User's Manual* for the details on the reset functionality and the different ways of connecting a TRSTPort.

Arguments

- *port_name*

A required string that identifies the name of the TRST port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL TRSTPort of the module that is also used for the respective port of the module in the design.

- Attribute *att_name = att_value* ;

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [icl_port](#) attributes and [icl_pin](#) attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Related Topics

[TMSPort](#)

[ScanInterface](#)

AddressPort

Declares the name of an address input port of a Module.

Usage

```
Module module_name {
    AddressPort port_name {
        Attribute att_name = att_value ;
    }
}
```

Description

A port function that declares the name of an address input port of a [Module](#). It is used if the module contains addressable instances or data registers.

This port serves as the address of the addressable instances and data registers.

Arguments

- *port_name*

A required string that identifies the name of an address port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL AddressPort of the module that is also used for the respective ports of the module in the design.

The source of the address port name signal may only be an address port of the parent module, or scan register bits of a [ScanRegister](#) statement. In both cases, this connection must be direct, and may not include any logic signals.

If a module has more than one AddressPort, the address comparison with logic signals of the module implicitly concatenates all address port signals in order of declaration (top to bottom).

- Attribute *att_name = att_value ;*

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [port attributes](#) and [pin attributes](#) as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Related Topics

[DataRegister](#)

WriteEnPort

Declares the name of the write enable input port of a Module.

Usage

```
Module module_name {
    WriteEnPort port_name {
        Attribute att_name = att_value ;
    }
}
```

Description

A port function that declares the name of the write enable input port of a [Module](#). It is used if the module contains addressable instances or data registers.

This port serves as the write enable to the addressable instance and data registers.

Arguments

- *port_name*

A required string that identifies the name of a write enable port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL ScanInPort of the module that is also used for the respective ports of the module in the design.

The source of the write enable port name signal may only be a write enable port of the parent module, or scan register bits of a [ScanRegister](#) statement. In both cases, this connection must be direct, and may not include any logic signals.

A module may have at most one WriteEnPort statement. A module must have a WriteEnPort statement, if the module contains writable, addressable data registers or writable, addressable instances.

- Attribute *att_name = att_value* ;

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [icl_port](#) attributes and [icl_pin](#) attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Related Topics

[Instance](#)

[ReadEnPort](#)

DataRegister

ReadEnPort

Declares the name of the read enable input port of a Module.

Usage

```
Module module_name {
    ReadEnPort port_name {
        Attribute att_name = att_value ;
    }
}
```

Description

A port function that declares the name of the read enable input port of a [Module](#). It is used if the module contains addressable instances or data registers.

This port serves as the read enable to the addressable instance and data registers.

A read operation is executed in two steps. At first the ReadEnPort must be activated (high) and the address must be supplied ([AddressPort](#)). In the second step, the capture is executed and the data is being read. During this second step the ReadEnPort is automatically deactivated (low) by means of an automatic iApplyEndState property (see the [Alias](#) statement).

Arguments

- *port_name*

A required string that identifies the name of a read enable port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL ScanInPort of the module that is also used for the respective ports of the module in the design.

The source of the read enable port name signal may only be a read enable port of the parent module, or scan register bits of a [ScanRegister](#) statement. In both cases, this connection must be direct, and may not include any logic signals.

A module may have at most one ReadEnPort statement. A module must have a ReadEnPort statement, if the module contains readable, addressable data registers or readable, addressable instances.

A read enable port is assumed to have an automatic iApplyEndState property. See the [Alias](#) statement to learn more about iApplyEndState.

- Attribute *att_name = att_value* ;

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [icl_port](#) attributes and [icl_pin](#)

attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

ScanOutPort

Declares the name of a scan-out port of a Module.

Usage

Syntax 1

```
Module module_name {  
    ScanOutPort port_name ;  
}
```

Syntax 2

```
Module module_name {  
    ScanOutPort port_name {  
        Source source_name ;  
        Enable enable_name ;  
        Attribute att_name = att_value ;  
    }  
}
```

Description

A port function that declares the name of a scan-out port of a [Module](#).

A module may have zero or more scan-out ports. However, if a module has at least one [ScanInPort](#) defined, then there must be at least one ScanOutPort.

The scan-out port is used to execute a serial read (that is, not a parallel read operation). For a parallel read, use the [DataOutPort](#) port function instead.

If none of the parameters Source, Enable, or Attribute are used, you must use Syntax 1. However, in this case, the scan chain is broken at the ScanOutPort. Retargeting cannot use this port, and if no other solution can be found, reading and writing from the broken scan segment will result in an error during PDL command retargeting.

Arguments

- *port_name*

A required string that identifies the name of a scan-out port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL ScanOutPort of the module that is also used for the respective ports of the design module.

- *Source source_name ;*

A keyword-string pair that identifies the source of the scan-out data, like a [ScanRegister](#) or a ScanOutPort of another module instance. A ScanOutPort may have at most one Source statement. The Source statement is not needed for black box modules, which are currently

not supported by Tesson. If the source _name references a [ScanRegister](#), it should reference the right most bit of the register. Further, the width of the Source must match the width of the ScanOutPort.

- Enable *enable_name* ;

A keyword-string pair that identifies the enable signal of the scan-out port. The enable signal must become active in order to connect the scan-out port with the scan source. The activation and deactivation of the enable signal is taken care of by Tesson. Please see the [OneHotScanGroup](#) to learn more about the usage of the enable signal. A ScanOutPort may have at most one Enable statement.

- Attribute *att_name = att_value* ;

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tesson understands several [port attributes](#) and pin_attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Examples

The following example shows the usage of the ScanOutPort and its Source statement. Observe that the width of the scan-out port is 2, hence the concatenation of the right most bits of both scan registers. Please see the discussion and examples of the [OneHotScanGroup](#) to learn more about the usage of the ScanOutPort's enable signal.

```
Module tdr2x {
    ScanInPort      si[1:0];
    ScanOutPort     so[1:0] { Source R0[0],R1[0]; }
    ShiftEnPort    se;
    SelectPort      en;
    CaptureEnPort  ce;
    UpdateEnPort   ue;
    TCKPort         tck;
    ScanInterface chain2x {
        Port se;
        Chain c0 { Port si[0]; Port so[0]; }
        Chain c1 { Port si[1]; Port so[1]; }
    }

    ScanRegister R0[9:0] {
        ScanInSource    si[0];
        ResetValue      10'b0 ;
    }
    ScanRegister R1[4:0] {
        ScanInSource    si[1];
        ResetValue      5'b0 ;
    }
}
```

DataOutPort

Declares the name of the data out port of a Module.

Usage

Syntax 1

```
Module module_name {  
    DataOutPort port_name ;  
}
```

Syntax 2

```
Module module_name {  
    DataOutPort port_name {  
        Source source_name ;  
        Enable enable_name ;  
        RefEnum enum_name ;  
        Attribute att_name = att_value ;  
    }  
}
```

Description

A port function that declares the name of the data out port of a [Module](#).

A module may have zero or more data out ports. The number and bus-width of all declared data out ports is not correlated to the number and bus-width of any [DataInPort](#).

A data out port is used to execute a parallel read (that is, not a scan operation) to ports of the module or to readable objects inside the module, like [DataRegister](#). If data is to be scanned-out, use the [ScanOutPort](#) port function instead. If a parallel read from ports or objects of the module is to be allowed, the DataOutPort function(s) must be declared for the module. If a module does not have DataOutPort port functions, no parallel data read is allowed. Certain additional restrictions apply as explained next.

If the data output port signal has [SelectPort](#) or [ToSelectPort](#), which is part of an [ScanInterface](#) in its fanin, then it may not be target of an [iWrite](#) or [iRead](#) operation. This ensures that the scan selection remains under control of the software application.

If a data out port is connected to an [Instance](#) or [DataRegister](#) with an [AddressValue](#) statement, all data out ports are concatenated in the order of declaration until the required data width is achieved. See the discussion of [AddressValue](#) for further explanation and an example.

If none of the parameters [Source](#), [Enable](#), [Attribute](#), or [RefEnum](#) are used, you must use Syntax 1. However, in this case, the data connection is broken at the DataOutPort. Retargeting cannot use this port, and if no other solution can be found, reading and writing from the broken data connection will result in an error during PDL command retargeting.

Arguments

- *port_name*

A required string that identifies the name of a data out port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL DataOutPort of the module that is also used for the respective ports of the module in the design.

- Source *source_name* ;

An optional keyword-string pair that identifies the source of the parallel output data, like a [DataRegister](#) or a [DataOutPort](#) of another module instance. A DataOutPort may have at most one Source statement. Further, the width of the Source must match the width of the DataOutPort.

- Enable *enable_name* ;

An optional keyword-string pair that identifies the enable signal of the data out port. The enable signal must become active in order to connect the data output port with the data source. The activation and deactivation of the enable signal is taken care of by Tessent. Please see the [to learn more about the usage of the enable signal](#). A DataOutPort may have at most one Enable statement.

- RefEnum *enum_name* ;

An optional keyword-string pair that references the name of a Related Topics table. Using the enumeration table, the writing to the data in port can use synonyms listed in the table, instead of bit strings. It must be understood that the enumeration table is not necessarily a complete list. It is still allowed to write to the data in ports any value, including those not listed in the enumeration table. A DataOutPort may have at most one RefEnum statement.

- Attribute *att_name* = *att_value* ;

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [port attributes](#) and [icl_pin](#) as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Examples

The following example shows an ICL module definition with both a parallel data input/output and a scan interface (implicitly defined, since there is only one scan-in / scan-out pair). Observe how the data in port is used inside the [ScanRegister](#). It is declared as the source of the capture values of the scan register, which means that the scan register will capture the value from the data in ports fq on the positive edge of the [CaptureEnPort](#) ce, under the condition that the [SelectPort](#) en is also high. Finally, observe the usage of the RefEnum and Related Topics statements.

```
Module tdr_ref {
    ScanInPort      si;
    ScanOutPort     so      {  Source R[0];   }
    ShiftEnPort     se;
    SelectPort      en;
    CaptureEnPort   ce;
    UpdateEnPort    ue;
    TCKPort         tck;
    DataInPort      fq[7:0]  {  RefEnum OptionalValues;  }
    DataOutPort     td[7:0]  {  Source R[7:0]; RefEnum OptionalValues;  }
    ScanRegister R[7:0] {
        CaptureSource fq[7:0];
        ScanInSource  si;
        RefEnum       OptionalValues ;
    }   Enum OptionalValues {
        reset = 8'b0 ;
        set   = 8'b11111111 ;
        chain = 8'b11001100 ;
        green = 8'hee ;
        blue  = 8'd198 ;
    }
}
```

[Enum](#)

ToShiftEnPort

Declares the name of the to-shift enable port of a Module's host ScanInterface.

Usage

Syntax 1

```
Module module_name {  
    ToShiftEnPort port_name ;  
}
```

Syntax 2

```
Module module_name {  
    ToShiftEnPort port_name {  
        Source source_name ;  
        Attribute att_name = att_value ;  
    }  
}
```

Description

A port function that declares the name of the to-shift enable port of a [Module](#)'s host [ScanInterface](#).

This port is used to enable the shift operation of another module's [ScanRegister](#) elements. It is an active high output signal. A module may have zero or more to-shift enable ports.

If neither of the parameters Source or Attribute are used, you must use Syntax 1.

Arguments

- *port_name*

A required string that identifies the name of a shift enable port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL ToShiftEnPort of the module that is also used for the respective ports of the design module.

- Source *source_name* ;

An optional keyword-string pair that identifies the source of the to-shift enable signal. A ToShiftEnPort may have at most one Source statement. Further, the width of the Source must match the width of the ToShiftEnPort.

A to-shift enable signal pointing to a shift enable signal may evaluate to a constant 0 or a constant 1. If it evaluates to a constant 0, the scan network controlled by the to-shift enable signal is considered disabled. No read or write operation into this scan chain segment may occur. If it evaluates to a constant 1, it is considered an error.

Note

 The features associated with the Source specification are currently not supported.
Tessent currently ignores the Source specification..

- Attribute *att_name* = *att_value* ;

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several **icl_port** attributes and **icl_pin** attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Examples

The following shows a complete example ICL module definition of a TAP controller. Observe that the state machine is not described, there is only a generic module that defines the instruction register select signal. IJTAG has built-in the knowledge of a TAP's state machine. Also observe the usage of the various To*EnPort statements.

```
Module tap {
    TCKPort      tck;
    ScanInPort   tdi;
    ScanOutPort  tdo      {  Source IRMux; }
    TMSPort      tms;
    TRSTPort     trst;
    ToSelectPort tdrEn1   {  Source sel1;  }
    ScanInPort   fromTdr1;
    ToSelectPort tapEn1   {  Source IR[2];  }
    ToCaptureEnPort tce;
    ToShiftEnPort tse;
    ToUpdateEnPort tue;   ScanInterface clientTAP {
        Port tdi; Port tdo;
        Port tms; Port trst;
    }   ScanInterface hostTAP {
        Port fromTdr1; Port tdrEn1;
        Port tce; Port tse; Port tue;
    }   Instance fsm_i Of fsm  {
        InputPort tck = tck;
        InputPort tms = tms;
        InputPort trst = trst;
    }   ScanRegister IR[2:0] {
        CaptureSource 3'b001;
        ResetValue    3'b000;
        ScanInSource  tdi;
    }

    ScanRegister bypass {
        CaptureSource 1'b0;
        ScanInSource  tdi;
    }   ScanMux IRMux SelectedBy fsm_i.irSel {
        1'b0 : DRMux;
        1'b1 : IR[0];
    }   ScanMux DRMux SelectedBy IR[2:0] {
        3'bx00 : bypass;
        3'bx01 : fromTdr1;
    }   LogicSignal sel1 {  IR[2:0] == 3'bx01;  }
}Module fsm {
    TCKPort      tck;
    TMSPort      tms;
    TRSTPort     trst;
    ToIRSelectPort irSel;
    ToResetPort  tlr;
}
```

ToCaptureEnPort

Declares the name of the to-capture enable output port of a Module's host ScanInterface.

Usage

Syntax 1

```
Module module_name {
    ToCaptureEnPort port_name ;
}
```

Syntax 2

```
Module module_name {
    ToCaptureEnPort port_name {
        Source source_name ;
        Attribute att_name = att_value ;
    }
}
```

Description

A port function that declares the name of the to-capture enable output port of a [Module](#)'s host [ScanInterface](#).

This port is used to trigger the capture operation of another module's [ScanRegister](#) elements. It is an active high output signal. A module may have zero or more to-update enable ports.

If neither of the parameters Source or Attribute are used, you must use Syntax 1.

Arguments

- *port_name*

A required string that identifies the name of a shift enable port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL ToCaptureEnPort of the module that is also used for the respective ports of the design module.

- Source *source_name* ;

An optional keyword-string pair that identifies the source of the to-capture enable signal. A ToCaptureEnPort may have at most one Source statement. Further, the width of the Source must match the width of the ToCaptureEnPort.

The Source may point to a CaptureEnPort of the same module, a ToCaptureEnPort of an instance or a DataMux which has a capture signal at one of its inputs and the constant value 1'b0 at the other input. If the DataMux is configured such that it selects the constant value 1'b0, the capture enable pulse is assumed to be suppressed.

Note

The suppressing of the enable signal described above is currently not supported in Tesson.

- Attribute *att_name* = *att_value* ;

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tesson understands several **icl_port** attributes and **icl_pin** attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Examples

The following shows a complete example ICL module definition of a TAP controller. Observe that the state machine is not described, there is only a generic module that defines the instruction register select signal. IJTAG has built-in knowledge of a TAP's state machine. Also observe the usage of the various To*EnPort statements.

```

ToUpdateEnPort

Declares the name of the to-update enable port of a Module's host ScanInterface.

Usage

Syntax 1

```
Module module_name {  
    ToUpdateEnPort port_name ;  
}
```

Syntax 2

```
Module module_name {  
    ToUpdateEnPort port_name {  
        Source source_name ;  
        Attribute att_name = att_value ;  
    }  
}
```

Description

A port function that declares the name of the to-update enable port of a [Module](#)'s host [ScanInterface](#).

This port is used to trigger the update operation of another module's [ScanRegister](#) elements. It is an active high output signal. A module may have zero or more to-update enable ports.

If neither of the parameters Source or Attribute are used, you must use Syntax 1.

Arguments

- *port_name*

A required string that identifies the name of a shift enable port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL ToUpdateEnPort of the module that is also used for the respective ports of the design module.

- Source *source_name* ;

An optional keyword-string pair that identifies the source of the to-update enable signal. A ToUpdateEnPort may have at most one Source statement. Further, the width of the Source must match the width of the ToUpdateEnPort.

The Source may point to an UpdateEnPort of the same module, a ToUpdateEnPort of an instance or a DataMux which has an update signal at one of its inputs and the constant value 1'b0 at the other input. If the DataMux is configured such that it selects the constant value 1'b0, the update enable pulse is assumed to be suppressed.

Note

The suppressing of the enable signal described above is currently not supported in Tesson.

- Attribute *att_name* = *att_value* ;

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tesson understands several **icl_port** attributes and **icl_pin** attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Examples

The following shows a complete example ICL module definition of a TAP controller. Observe that the state machine is not described, there is only a generic module that defines the instruction register select signal. IJTAG has built-in the knowledge of a TAP's state machine. Also observe the usage of the various To*EnPort statements.

ToResetPort

Declares the name of the to-reset output port of a Module's host ScanInterface.

Usage

Syntax 1

```
Module module_name {  
    ToResetPort port_name ;  
}
```

Syntax 2

```
Module module_name {  
    ToResetPort port_name {  
        Attribute att_name = att_value ;  
        Source source_name ;  
        ActivePolarity 0 | 1;  
    }  
}
```

Description

A port function that declares the name of the to-reset output port of a [Module](#)'s host [ScanInterface](#).

The to-reset port is used as the source of the [ResetPort](#) of another module. You have the option to chose the active polarity of the to-reset port.

It is important to differentiate between the active polarity, 0 or 1, and when a to-reset signal becomes active / inactive. For example, it is possible that the to-reset signal's active polarity is 0, but it is enabled if the module's input reset port turns active high (1).

If none of the parameters Source, Attribute, or ActivePolarity are used, you must use Syntax 1.

Arguments

- *port_name*

A required string that identifies the name of a to-reset port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotScanGroup](#), [OneHotDataGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL ToResetPort of the module that is also used for the respective port of the module in the design.

- Attribute *att_name = att_value*

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [icl_port](#)attributes and [icl_pin](#)

attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

- ActivePolarity 0 | 1

An optional keyword-value pair, that defines if the to-reset port of the module is considered active low (value = 0), or active high (value =1). A module may have at most one ActivePolarity statement. If the ActivePolarity statement is not given, the active polarity of the to-reset port is assumed to be the 1 (high).

The activity/inactivity of the to-reset signal is given through the single [ResetPort](#) statement of the module, or, if the module does not have a [ResetPort](#) or more than one, through the global reset signal. In other words, if the reset signal is active, the to-reset signal is active as well, however, the ActivePolarity may be different.

- Source source_name

An optional keyword-string pair that identifies the source of the to-reset signal. A ToResetPort may have at most one Source statement. However, if the module has more than one [ResetPort](#) statement, then the Source must be specified. Further, the width of the Source must match the width of the ToResetPort.

The Source property can point to various sorts of drivers within the module, causing the ToResetPort to become active under different conditions (synchronous reset, asynchronous reset, enforced local reset and so on). If the Source has not been specified, then the ToResetPort may be implicitly connected to a reset signal in the current module. See chapter “[How to Model Global Reset, Local Reset and Embedded TAPs](#)” in the *Tessent IJTAG User's Manual* for the details on the reset functionality and the different ways of connecting a ToResetPort.

Examples

The following shows an example ICL netlist that switches the active polarity of the reset signal between instances. Observe that the outgoing active polarity of res.trp is low, so is the incoming polarity of the module instance inst_inst.re. It is an error to connect a ToResetPort to a ResetPort with different polarities.

```
Module chip_reset {
    ScanInPort si ;
    ScanOutPort so { Source inst_inst.so ; } ShiftEnPort se ;
    CaptureEnPort ce ;
    UpdateEnPort ue ;
    SelectPort selC ; ResetPort re { ActivePolarity 1 ; }
    TCKPort tck ; Instance res_inst Of res {
        InputPort re = re ;
    } Instance inst_inst Of inst {
        InputPort si = si ;
        InputPort se = se;
        InputPort ce = ce ;
        InputPort ue = ue ;
        InputPort sel = selC ;
        InputPort re = res_inst.trp ;
    }
}
Module res {
    ResetPort re ;
    ToResetPort trp { ActivePolarity 0 ; }
}
Module inst {
    ScanInPort si ;
    ScanOutPort so { Source R[0] ; }
    ShiftEnPort se ;
    CaptureEnPort ce ;
    UpdateEnPort ue ;
    SelectPort sel ;
    TCKPort tck ;

    ResetPort re { ActivePolarity 0; }
    ScanRegister R[7:0] {
        ScanInSource si ;
        ResetValue 8'b0 ;
    }
}
```

ToSelectPort

Declares the name of the to-select port of a Module's host ScanInterface.

Usage

Syntax 1

```
Module module_name {  
    ToSelectPort port_name ;  
}
```

Syntax 2

```
Module module_name {  
    ToSelectPort port_name {  
        Source source_name ;  
        Attribute att_name = att_value ;  
    }  
}
```

Description

A port function that declares the name of the to-select port of a [Module](#)'s host [ScanInterface](#).

This port is typically used to enable the scan operation in another module. It is an active high output signal. A module may have none, one, or several to-select ports.

Arguments

- *port_name*

A required string that identifies the name of a to-select port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL ToSelectPort of the module that is also used for the respective ports of the design module.

- Source *source_name*

An optional keyword-string pair that identifies the source of the to-select signal. The width of the Source must match the width of the ToUpdateEnPort.

An optional keyword-string pair that identifies the source of the to-select signal. The width of the Source must match the width of the ToUpdateEnPort. If the to-select diagonal fans out into a ScanInterface, which is referenced by an *AllowBroadcastingOnScanInterface* property, anywhere in the hierarchy, then the Source statement is required.

Note

Currently Tessent does not support any broadcasting.

- Attribute *att_name* = *att_value*

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several **icl_port** attributes and **icl_pin** attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Examples

The following shows an example ICL netlist that switches the active polarity of the reset signal between instances. Observe that the outgoing active polarity of res.trp is low, so is the incoming polarity of the module instance inst_inst.re. Further, the SelectPort signal for the instance inst_inst is computed based on the top level DataIn signal din.

```

Module chip {
    ScanInPort si ;
    ScanOutPort so { Source inst_inst.so ; }
    ShiftEnPort se ;
    CaptureEnPort ce ;
    UpdateEnPort ue ;
    DataInPort din ;
    ResetPort re { ActivePolarity 1 ; }
    TCKPort tck ;
    Instance res_inst Of res {
        InputPort gres = din ;
        InputPort re = re ;
    } Instance inst_inst Of inst {
        InputPort si = si ;
        InputPort se = se;
        InputPort ce = ce ;
        InputPort ue = ue ;
        InputPort sel = res_inst.tsel ;
        InputPort re = res_inst.trp ;
    }
}
Module res {
    ResetPort re ;
    DataInPort gres ;
    ToResetPort trp { ActivePolarity 0 ; }
    ToSelectPort tsel { Source gres; }
}
Module inst {
    ScanInPort si ;
    ScanOutPort so { Source R[0] ; }
    ShiftEnPort se ;
    CaptureEnPort ce ;
    UpdateEnPort ue ;
    SelectPort sel ;
    TCKPort tck ;

    ResetPort re { ActivePolarity 0; }
    ScanRegister R[7:0] {
        ScanInSource si ;
        ResetValue 8'b0 ;
    }
}

```

ToClockPort

Declares the name of a functional to-clock output port of a Module

Usage

Syntax 1

```
Module module_name {  
    ToClockPort port_name ;  
}
```

Syntax 2

```
Module module_name {  
    ToClockPort port_name {  
        Source source_name ;  
        FreqMultiplier pos_int ;  
        FreqDivider pos_int ;  
        DifferentialInvOf other_clock_port_name ;  
        Period pos_int unit ;  
        Attribute att_name = att_value ;  
    }  
}
```

Description

A port function that declares the name of a functional to-clock output port of a [Module](#) (that is, a clock that is not a test clock).

The test clock is defined through the [ToTCKPort](#) statement. A module may have zero or more to-clock ports.

A ToClockPort serves as the source of a functional clock to another module. It has three principal features:

- Modify an existing incoming functional clock with respect to its frequency by multiplication and division of the period
- Serve as an oscillator clock generation with a defined outgoing clock frequency
- Convert from differential to single-ended clock signals and vice versa.

If none of the parameters are used, you must use Syntax 1.

Arguments

- *port_name*

A required string that identifies the name of a to-clock port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL ToClockPort of the module that is also used for the respective ports of the module in the design.

- Source *source_name*

An optional keyword-string pair that identifies the source of the to-clock signal. A ToClockPort may have at most one Source statement. The width of the Source must match the width of the ToClockPort. The usage of Source is mutually exclusive with the usage of Period as well as with the usage of DifferentialInvOf within the same ToClockPort statement.

- FreqMultiplier *pos_int*

An optional keyword-positive integer number pair that identifies the multiplication factor of the to-clock outgoing clock signal with respect to an incoming clock signal of the module, referenced by Source. A ToClockPort may have at most one FreqMultiplier statement. The usage of FreqMultiplier is mutually exclusive with the usage of Period as well as with the usage of DifferentialInvOf within the same ToClockPort statement.

- FreqDivider *pos_int*

An optional keyword-positive integer number pair that identifies the division factor of the to-clock outgoing clock signal with respect to an incoming clock signal of the module, referenced by Source. A ToClockPort may have at most one FreqDivider statement. The usage of FreqDivider is mutually exclusive with the usage of Period as well as with the usage of DifferentialInvOf within the same ToClockPort statement.

- DifferentialInvOf *other_clock_port_name*

An optional keyword-string pair. Differential functional clocks are declared through the DifferentialInvOf keyword. The *other_clock_port_name* string references another ClockPort *port_name* of the same module. The usage of DifferentialInvOf is mutually exclusive from the usage of Source, FreqMultiplier, FreqDivider, and Period, leaving the DifferentialInvOf the only parameter other than the Attribute within a ToClockPort statement.

- Period *pos_int unit*

An optional keyword-positive integer number pair, followed by an optional unit string. If used, the unit string is exactly one of these time units: s, ms, us, ns, ps. If unit is not used, the default is “ns”.

Using the Period parameter, you can create a module that does not require an incoming clock signal to generate an outgoing clock signal of a specified period. This module is like an oscillator.

The usage of Period is mutually exclusive from the usage of Source, FreqMultiplier, FreqDivider, and DifferentialInvOf, leaving the Period as the only parameter other than the Attribute within a ToClockPort statement.

- Attribute *att_name = att_value*

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the

language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [icl_port](#) attributes and [icl_pin](#) attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Examples

The following example represents a programmable clock generation logic that selectively uses one of two incoming reference clocks and manipulates either with a selectable set of modifiers.

```

Module chip_clock {
    ScanInPort      si ;
    ScanOutPort     so { Source clockGen_inst.so ; }
    ShiftEnPort     se ;
    CaptureEnPort   ce ;
    UpdateEnPort    ue ;
    TCKPort         tck ;
    ClockPort       refClkA ;
    ClockPort       refClkB ;
    DataInPort      din[7:0] ;
    DataOutPort     dout[7:0] { Source inst_inst.out ; }
    Instance clockGen_inst Of clockGen {
        InputPort si = si ;
        InputPort refClkA = refClkA ;
        InputPort refClkB = refClkB ;
        Parameter sclkMult = 1 ;
        Parameter sclkDiv = 3 ;
    }   Instance inst_inst Of instrument {
        InputPort clk = clockGen_inst.sclk ;
        InputPort in = din ;
    }
}
Module clockGen {
    ScanInPort      si ;
    ScanOutPort     so { Source clkSelReg[0] ; }
    ClockPort       refClkA ;
    ClockPort       refClkB ;
    Parameter sclkMult = 1 ;
    Parameter sclkDiv = 1 ;
    ToClockPort sclk {
        FreqMultiplier $sclkMult ;
        FreqDivider $sclkDiv ;
        Source refSelM ;
    }
    ScanRegister clkSelReg[2:0] {
        ScanInSource si ;
        ResetValue 3'b100 ;
    }   ClockMux refSelM SelectedBy clkSelReg[2] {
        1'b1 : refClkA ;
        1'b0 : refClkB ;
    }
}
Module instrument {
    DataInPort      in[7:0];
    DataOutPort     out[7:0];
    ClockPort       clk;

    Alias enable      = in[7]           { RefEnum YesNo;      }
    Alias mode[3:0]   = in[6:5],in[3:2] { RefEnum Modes;     }
    Alias p1[2:0]     = in[4],in[1:0];
    Alias go          = out[0]          { RefEnum PassFail; }
    Alias done         = out[1]          { RefEnum YesNo;      }
    Alias count[5:0]  = out[7:2];    Enum PassFail {
        Pass = 1'b1;
        Fail = 1'b0;
    }
    Enum YesNo {
        Yes = 1'b1;
    }
}

```

```
    No      = 1'b0;
}
Enum Modes {
    red    = 4'b0011;
    blue   = 4'b1000;
    green  = 4'b0100;
}
}
```

Related Topics

[ClockPort](#)

[TCKPort](#)

[ToTCKPort](#)

ToTCKPort

Declares the name of a test to-test clock output port of a Module.

Usage

Syntax 1

```
Module module_name {  
    ToTCKPort port_name ;  
}
```

Syntax

```
Module module_name {  
    ToTCKPort port_name {  
        Attribute att_name = att_value ;  
    }  
}
```

Description

A port function that declares the name of a test to-test clock output port of a [Module](#) (that is, a clock that is not a functional clock).

The test clock is defined through the [ToClockPort](#) statement. A module may have zero or more to-test clock ports. If a module has several to-test clock outputs, all clocks are considered equivalent in period and polarity.

Unlike the [ToClockPort](#) statement, there are no modifiers in the ToTCKPort statement. The outgoing to-test clock signal is just a pass-through of the incoming test clock.

If no parameter is used, you must use Syntax 1.

Arguments

- *port_name*

A required string that identifies the name of a to-clock port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL ToClockPort of the module that is also used for the respective ports of the module in the design.

- Attribute *att_name = att_value*

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [icl_port](#) attributes and [icl_pin](#) attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Examples

The following example modifies the example given in [ToClockPort](#). Here, a [TCKPort](#) and a [ToTCKPort](#) port was added to the module. Observe that ToTCKPort is just passing through the test clock. No manipulation of the test clock signal can happen.

```
Module clockGen {
    ScanInPort      si ;
    ScanOutPort     so { Source clkSelReg[0] ; }
    TCKPort         tck ;
    ClockPort       refClkA ;
    ClockPort       refClkB ;
    Parameter sclkMult = 1 ;
    Parameter sclkDiv = 1 ;
    ToTCKPort       ttck ;
    ToClockPort     sclk {
        FreqMultiplier $sclkMult ;
        FreqDivider   $sclkDiv ;
        Source refSelM ;
    }
    ScanRegister clkSelReg[2:0] {
        ScanInSource si ;
        ResetValue 3'b100 ;
    }   ClockMux refSelM SelectedBy clkSelReg[2] {
        1'b1 : refClkA ;
        1'b0 : refClkB ;
    }
}
```

[ClockPort](#)

[TCKPort](#)

[ToClockPort](#)

ToTMSPort

Declares the name of the to-TMS port of a Module's host TAP ScanInterface.

Usage

Syntax 1

```
Module module_name {  
    ToTMSPort port_name ;  
}
```

Syntax 2

```
Module module_name {  
    ToTMSPort port_name {  
        Source source_name ;  
        Attribute att_name = att_value ;  
    }  
}
```

Description

A port function that declares the name of the to-TMS port of a [Module](#)'s host TAP [ScanInterface](#). This port is typically used to provide a TMS signal to an embedded TAP controller module or to module that contains an embedded TAP controller.

If Source is used, the outgoing to-TMS signal is considered gated.

If neither of the parameters Source or Attribute are used, you must use Syntax 1.

Arguments

- *port_name*

A required string that identifies the name of a to-TMS port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL ToTMSPort of the module that is also used for the respective ports of the design module.

Any module that has a ToTMSPort must also have at least one [TMSPort](#).

- Source *source_name*

An optional keyword-string pair that identifies the logic signal that is considered gating the to-TMS signal of the module. A ToTMSPort may have at most one Source statement. Source is required if the module has more than one [TMSPort](#). If the module has only one [TMSPort](#), Source is optional and if not provided, ToTMSPort then refers to the [TMSPort](#).

The Source property can point to various sorts of drivers within the module, causing the ToTMSPort either to be in its normal mode of operation or to be continuously driven with

the value '1' (which causes the downstream embedded TAP controllers to be held in "reset" state) or to be continuously driven with the value '0' (which causes the downstream embedded TAP controller to be held in "idle" state). If the Source has not been specified explicitly, then the ToTMSPort may be implicitly connected to a tms signal in the current module. See chapter "[How to Model Global Reset, Local Reset and Embedded TAPs](#)" in the *Tessent IJTAG User's Manual* for the details on embedded TAPs and the different ways of connecting a ToTMSPort.

- Attribute *att_name* = *att_value*

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [icl_port](#) attributes and [icl_pin](#) attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

Related Topics

[TMSPort](#)

[ToTCKPort](#)

[ToTRSTPort](#)

ToTRSTPort

Declares the name of the to-TRST port of a Module's host TAP ScanInterface.

Usage

Syntax 1

```
Module module_name {  
    ToTRSTPort port_name ;  
}
```

Syntax 2

```
Module module_name {  
    ToTRSTPort port_name {  
        Source source_name ;  
        Attribute att_name = att_value ;  
    }  
}
```

Description

A port function that declares the name of the to-TRST port of a [Module](#)'s host TAP [ScanInterface](#). This port is used to distribute the TRST signal throughout the design. The to-TRST outgoing signal is always active low (0).

A module may have zero or more to-TRST ports. If a module has several to-TRST outputs, all to-TRST signals are considered equivalent.

If Source is used, the outgoing to-TRST signal is considered gated.

If neither of the parameters Source or Attribute are used, you must use Syntax 1.

Arguments

- *port_name*

A required string that identifies the name of a to-TMS port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL ToTRSTPort of the module that is also used for the respective ports of the design module.

- Source *source_name*

An optional keyword-string pair that identifies the logic signal that is considered gating the to-TRST signal of the module. A ToTRSTPort may have at most one Source statement, and the width of the Source must match the width of the ToTRSTPort. Source is required if the module has more than one [TRSTPort](#). If the module has only one [TRSTPort](#), Source is optional and if not provided, ToTRSTPort then refers to the [TRSTPort](#). Further, if the module does not have a [TRSTPort](#), the ToTRSTPort refers to the global TRST signal.

The Source property can point to various sorts of drivers within the module, causing the ToTRSTPort to become active under different conditions (asynchronous global reset, enforced local reset and so on). If the Source has not been specified, then the ToTRSTPort may be implicitly connected to a trst signal in the current module. See chapter “[How to Model Global Reset, Local Reset and Embedded TAPs](#)” in the *Tessent IJTAG User's Manual* for the details on the reset functionality and the different ways of connecting a ToTRSTPort.

- Attribute *att_name* = *att_value*

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [icl_port](#) attributes and [icl_pin](#) as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

ToIRSelectPort

Declares the name of the to-IR Select port of a Module.

Usage

Syntax 1

```
Module module_name {  
    ToIRSelectPort port_name ;  
}
```

Syntax 2

```
Module module_name {  
    ToIRSelectPort port_name {  
        Attribute att_name = att_value ;  
    }  
}
```

Description

A port function that declares the name of the to-IR Select port of a [Module](#).

This signal is used to select between the instruction register of a TAP controller and another scan register, usually a data register. The to-IR Select signal is always associated with the TMS signal, and if present, with the TRST signal.

If the parameter Attribute is not used, you must use Syntax 1.

Arguments

- *port_name*

A required string that identifies the name of a to-IR Select port of the module. The port names for all ports of a module must be unique. In addition, the port name may not be used for any of the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

It is recommended to use a port name for the ICL ToIRSelectPort of the module that is also used for the respective ports of the design module.

- Attribute *att_name = att_value*

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [icl_port](#) attributes and [icl_pin](#) attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

[TMSPort](#)

[TRSTPort](#)

Instance

Names an instance of an ICL module.

Usage

Syntax 1

```
Module module_name {
    Instance instance_name Of module_name {
        Attribute att_name = att_value ;
        InputPort moduleinputport_name = concat_signal ;
        Parameter parameter_name = parameter_value ;
        AddressValue number ;
    }
}
```

Syntax 2

```
Module module_name {
    Instance instance_name Of module_name ;
}
```

Description

The Instance statement names an instance of an ICL module. It also declares the address and/or all input connections of the instance to source signals of other instances or the top level module. Note that in ICL no output connections are listed in the Instance statement.

In addition to the input port connections, [Parameters](#) defined within the module definition may be overwritten. [LocalParameter](#) cannot be overwritten though.

Syntax 2 must be used if the module has no input ports and none of the other parameters is used.

Arguments

- *instance_name Of module_name*

A required string-string pair, connected with the case-sensitive keyword ‘Of’, defining the name of the instance and referencing an existing module name of which an instance is to be created. Within a module, all instance names must be unique. Also, no module may contain an instance of itself anywhere through its hierarchy.

- Attribute *att_name = att_value*

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value are defined by you, and may be ignored by any IJTAG software tool. Tessent understands several [port attributes](#) and pin_attributes as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

- InputPort *moduleinputport_name* = *concat_signal*

A repeatable, required keyword and string-value pair, connected with the ‘=’ symbol. For each input port defined in the module there must be exactly one such line in the Instance statement, however exceptions apply as explained below. *moduleinputport_name* must refer to an input port name of the referenced module. For modules without any input ports the InputPort parameter may not be used. The order of the input port declaration in the referenced module and the order of the InputPort parameters can be different.

concat_signal may reference a single signal or a concatenation of signals of the same or compatible type. The type of *concat_signal* must match the type of the input port definition in the module, or must be a compatible type. *concat_signal* may only be one of these signals: reset, scan, data, read enable, write enable, clock, TCK, shift enable, capture enable, update enable, TMS, or TRST. The width of the module’s port definition and *concat_signal* must match. For an indexed input port of the module, the InputPort parameter may be used as often as necessary to cover the entire index range in any order. However, overlapping indices or ranges are not allowed. For instances without the AddressValue parameter, the InputPort parameter may connect the module’s WriteEnPort, ReadEnPort, AddressPort, or SelectPort to data signals; that is, a data signal is a compatible source for those port functions.

Note that not all input ports of a module must be connected explicitly. For a non-handoff module; that is, for a module that is not the top level module you hand over to a third party, several connections are automatically implied, if their source in the parent module can be determined unambiguously. It is legal to list these connections through the InputPort parameter, but it is not necessary. The following connections are automatically implied for non-hand-off module instances that do not have the AddressValue statement: TCK, shift enable, capture enable, update enable.

- Parameter *parameter_name* = *parameter_value*

A repeatable, optional keyword and string-value pair, connected with the “=” symbol. The referenced *parameter_name* must have been defined in the module referenced by *module_name*; also the type of *parameter_value* must match the type used in the module for the parameter.

Using the [Parameter](#) statement again within Instance overwrites the respective parameter value set in the module definition, but only for the current instance. Another instance of the module may use another overwrite value, or may use the original value defined in the module. Through this construct, ICL can define parameterized modules, where the final parameter is defined during each instantiation of the module.

- AddressValue *number*

A required keyword and number pair, if this instance is part of the [OneHotDataGroup](#). The AddressValue parameter may not be used if the instance is not part of a [OneHotDataGroup](#). Within the [OneHotDataGroup](#), the *number* declares a part of the address that is associated with the instance. The final address of a [DataRegister](#) is determined by the sum of all addresses along the hierarchical instance path leading to the data register. In this sense

number is only one element of the sum, comprising the address of a data register of the [OneHotDataGroup](#).

The following connections are automatically implied for non-hand-off module instances that do have the AddressValue statement: TCK, the instance's AddressPort is assumed to be connected to the logical address signal of the parent module, the instance's WriteEnPort is assumed to be connected to the WriteEnPort of the parent module, the instance's ReadEnPort is assumed to be connected to the ReadEnPort of the parent module, and the instance's DataInPort is assumed to be connected to the logical data in signals of the parent module.

Note

In IJTAG, the Instance statement describes the “AllowBroadcastingOnScanInterface” parameter. This parameter is currently not supported in Tessent.

Examples

Example 1

The following example demonstrates the usage of automatic default connections in the common case of a scan interface. Observe that the instance declaration for tdr_inst of module tdr only declares the scan input port connection. TCK and all the enable signals are connected fully automatically to the respective signals of the parent module. Explicit connections are only necessary, if there are multiple signals of the same type in the parent module, for example two select ports.

```
Module chip_tdr {
    ScanInPort      si;
    ScanOutPort     so      { Source tdr_inst.so; }
    ShiftEnPort     se;
    SelectPort      en;
    CaptureEnPort   ce;
    UpdateEnPort    ue;
    TCKPort         tck;
    Instance tdr_inst Of tdr {
        InputPort si = si ;
    }
}
Module tdr {
    ScanInPort      si;
    ScanOutPort     so      { Source R[0]; }
    ShiftEnPort     se;
    SelectPort      en;
    CaptureEnPort   ce;
    UpdateEnPort    ue;
    TCKPort         tck;
    ScanRegister R[7:0] {
        ScanInSource  si;
        ResetValue    8'b0 ;
    }
}
```

Example 2

The following example demonstrates not only the usage of the [OneHotDataGroup](#), but also the usage of the [InputPort](#) parameter and some of the compatible signal connections. Observe that module “top” does have neither a [ReadEnPort](#), nor a [WriteEnPort](#). Instead it has 2 [DataInPort](#) statements that are connected to the respective input ports of the instances of module “phy”. Since the connection of the data signals of the parent module (that is, top) to the instances is done implicitly, by the order of declaration, it is important that the 16 data input bits of [DataIn](#) are declared before the 2 bits of the write and read enable. Also note that the module top defines just one [AddressPort](#) of 8 bits, which is implicitly mapped to the two 4-bit [AddressPorts](#) of phy in their order of declaration. Further, observe that the [AddressPort](#) of “bank” only 2-bits wide, since only two bits are required for this module’s operation.

```

Module top {
    AddressPort address[7:0] ;
    DataInPort dataIn[15:0] ;
    DataInPort write_enable ;
    DataInPort read_enable ;
    DataOutPort dataOut[15:0] {
        Source outMux[15:0] ;
        Enable read_enable ;
    }
    OneHotDataGroup outMux[15:0] {
        Instance phy1 Of phy {
            AddressValue 2'b01, 6'b000000 ;
            InputPort we = write_enable ;
            InputPort re = read_enable ;
        }
        Instance phy2 Of phy {
            AddressValue 2'b10, 6'b000000 ;
            InputPort we = write_enable ;
            InputPort re = read_enable ;
        }
    }
}
Module phy {
    WriteEnPort 7 we ;
    ReadEnPort re ;
    AddressPort address1[3:0] ;
    AddressPort address2[3:0] ;
    DataInPort dataIn1[7:0] ;
    DataInPort dataIn2[7:0] ;
    DataOutPort dataOut[15:0] { Source outMux[15:0] ;
}
OneHotDataGroup outMux[15:0] {
    Instance bank1 Of bank {
        AddressValue 4'b0001,2'b00 ;
    }
    Instance bank2 Of bank {
        AddressValue 4'b0010,2'b00 ;
    }
}
Module bank {
    WriteEnPort we ;
    ReadEnPort re ;
    AddressPort address[1:0] ;
    DataInPort dataIn[15:0] ;
    DataOutPort dataOut[15:0] { Source outMux[15:0] ;
}
OneHotDataGroup outMux[15:0] {
//    AddressValue 2'bx,4'bx,2'b<num>
    DataRegister D0[15:0] { AddressValue 2'b00 ; }
    DataRegister D1[15:0] { AddressValue 2'b01 ; }
    DataRegister D2[15:0] { AddressValue 2'b10 ; }
    DataRegister D3[15:0] { AddressValue 2'b11 ; }
}
}

```

Parameter

Define a named variable and assigns a default value.

Usage

Syntax 1 : Defining a parameter

```
Module module_name {  
    Parameter parameter_name = parameter_value ;  
}
```

Syntax 2 : Optionally overwriting a parameter in an Instance statement

```
Module module_name {  
    Instance instance_name of other_module_name {  
        Parameter parameter_name = parameter_value ;  
    }  
}
```

Description

With the help of the Parameter statement you can define a named variable and assign a default value.

The default value is specified in the module that declares the Parameter. The value can be overwritten with every instance of the Module. Through this, ICL allows you to create parameterized modules.

You build a reference to the Parameter by using the ‘\$’ symbol in front of the parameter_name.

The parameter reference can be used in many locations, for example in an Enum statement. The reference will be resolved to the current value before the statement the Parameter is evaluated.

Arguments

- Parameter *parameter_name* = *parameter_value*

A required string-value pair, connected with the ‘=’ symbol. The parameter name must be unique across all Parameter and LocalParameter statements within the module. The parameter value may be exactly one of the following: an unsized number, a sized number, or a string. A parameter reference representing an unsized number may only be used where an unsized number is expected. Similarly for the sized number. A parameter reference representing a string may only be used in an attribute within any statement in the module, or within a Callback function. Places where a parameter reference is allowed include an attribute value, the index value for a vector identifier, or where a size or unsized number is allowed. For example, you cannot use a parameter to substitute any arbitrary number, such as creating object names, like an Instance name “inst\$size”, where “size” is a parameter

Although parameters can be used to define other parameters, a circular definition is not allowed.

Note

 Currently Tessent does not support the Callback functionality.

Examples

Example 1

The following example shows several usages of Parameter. In particular observe that the Parameter ‘Width’ is used to parameterize the values in the enumeration table.

```
Module inst {
    ScanInPort      si;
    ScanOutPort     so      { Source R[0]; }
    TCKPort         tck;
    Parameter Width = 8 ;
    Parameter Regmax = $Width - 1 ;
    Parameter userValue = 8'hff ;
    Parameter Val_A = 4'b1001, $userValue, 4'b1111 ;
    Parameter RegName = "R" ;
    LocalParameter Regmin = 0 ;

    ScanRegister R[$Regmax:$Regmin] {
        Attribute Register = "$RegName($RegMax:$RegMin)" ;
        ScanInSource si;
        ResetValue   Reset ;
        RefEnum      SomeValues ;
    }   Enum SomeValues {
        Reset = $Width'b0 ;
        User1 = $userValue ;
    }
}
```

Example 2

The following example uses the module defined above. In its instantiation, the parameters ‘Width’ and ‘userValue’ will be overwritten. This allows ICL to create parameterized modules, where the size of registers will be fixed during the instantiation of the module and not during the declaration of the module.

```
Module top {
    ScanInPort      si;
    ScanOutPort     so      {  Source inst2.so;    }
    ShiftEnPort     se;
    SelectPort       en;
    CaptureEnPort   ce;
    UpdateEnPort    ue;
    TCKPort         tck;

    Instance inst1 Of inst {
        InputPort si = si ;
        Parameter Width = 16 ;
        Parameter userValue = 16'hffff ;
    }
    Instance inst2 Of inst {
        InputPort si = inst1.so ;
        Parameter Width = 4 ;
        Parameter userValue = 4'ha ;
    }
}
```

[LocalParameter](#)

[Instance](#)

[Alias](#)

[Enum](#)

LocalParameter

Has the same semantic and use model as the Parameter statement but cannot be overwritten in the Instance statement.

Usage

```
Module module_name {  
    LocalParameter parameter_name = parameter_value ;  
}
```

Description

A LocalParameter has the same semantic and use model as the [Parameter](#) statement. The only difference is that a LocalParameter cannot be overwritten in the [Instance](#) statement.

Arguments

- *parameter_name = parameter_value*

A required string-value pair, connected with the ‘=’ symbol. The parameter name must be unique across all [Parameter](#) and LocalParameter statements within the module. The parameter value may be exactly one of the following: an unsized number, a sized number, or a string. A parameter reference representing an unsized number may only be used where an unsized number is expected. Similarly for the sized number. A parameter reference representing a string may only be used in an attribute within any statement in the module, or within a Callback function. Places where a parameter reference is allowed include an attribute value, the index value for a vector identifier, or where a size or unsized number is allowed. For example, you cannot use a parameter to substitute any arbitrary number, such as creating object names, like an [Instance](#) name “inst\$size”, where “size” is a parameter

Although parameters can be used to define other parameters, a circular definition is not allowed.

[Parameter](#)

[Instance](#)

[Alias](#)

[Enum](#)

Enum

Adds an entry to an enumeration table that links a mnemonic string to an arbitrary value.

Usage

```
Module module_name {
    Enum enum_name {
        name = value ;
    }
}
```

Description

With the **Enum** statement, ICL introduces an enumeration table that links a mnemonic string to an arbitrary value. This string can then be used in lieu of the value at places like [DataInPort](#), [DataOutPort](#), and [LogicSignal](#). For the [ScanRegister](#) and the [DataRegister](#) the string can be used for the DefaultLoadValue, ResetValue, and CaptureSource ([ScanRegister](#) only).

Further, PDL commands like [iWrite](#) or [iRead](#) can also use the name instead of the value. Choosing meaningful mnemonics can make both, ICL and PDL, much more human readable.

In no usage of the enumeration table are you limited to only the names listed in the table. You are free to continue using any legal value, and in particular values not listed in the table. The example below shows such a case.

Arguments

- *enum_name*

A required string that identifies the name of the enumeration table. Using this name the RefEnum parameter inside the [ScanRegister](#) statement, for example, can reference the enumeration table. The *enum_name* must be unique among all **Enum** statements within the module.

- *name = value*

A required, repeatable string-value pair, connected with the '=' symbol. These pairs make up the enumeration table. All values must be of the same width, and the names must be unique within the same **Enum**. An enumeration table must contain at least one name-value pair.

Examples

The following enumeration table shows several examples of value definitions. The width of the value depends on the usage of the table entries in other objects, like [ScanRegister](#) or [DataInPort](#), referenced by RefEnum. within these statements. The number type is not relevant as shown. Also observe that two [Parameter](#) were defined, which are used in the enumeration table 'Modes'. As usual, these parameters could be overwritten differently in each instance of the module.

```
Module instrument {
    DataInPort  in[7:0];
    DataOutPort out[7:0];
    ClockPort   clk;

    Alias enable      = in[7]           { RefEnum YesNo;      }
    Alias mode[3:0]   = in[6:5],in[3:2] { RefEnum Modes;     }
    Alias p1[2:0]     = in[4],in[1:0];
    Alias go         = out[0]          { RefEnum PassFail;  }
    Alias done        = out[1]          { RefEnum YesNo;      }
    Alias count[5:0]  = out[7:2];
    Parameter userEnum1val = 4'b1111 ;
    Parameter userEnum2val = 4'h22 ;
    Enum PassFail {
        Pass = 1'b1;
        Fail = 1'b0;
    }
    Enum YesNo {
        Yes = 1'b1;
        No = 1'b0;
    }
    Enum Modes {
        none   = 4'b0 ;
        red    = 4'b0011 ;
        blue   = 4'haa ;
        green  = 4'd9 ;
        userEnum1 = $userEnum1val ;
        userEnum2 = $userEnum2val ;
    }
}
```

Next, here is a snippet of a dofile, writing to the ‘mode’ [Alias](#) of the module, using the names defined in the ‘Mode’ enumeration table which is associated with the alias through the [RefEnum](#) parameter. The done [Alias](#) is then read from ‘out’.

```
open_pattern_set enumTest
iWrite mode red
iApply
iWrite mode 0b1010
iApply
iRead done Yes
iApply
close_pattern_set
write_patterns enumTest.pdl -pdl
```

The following lists the contents of the saved PDL file enumTest.pdl:

```
iProcsForModule instrument
iProc enumTest {} {
    iWrite in[6] 0b0
    iWrite in[5] 0b0
    iWrite in[3] 0b1
    iWrite in[2] 0b1
    iApply
    iWrite in[6] 0b1
    iWrite in[5] 0b0
    iWrite in[3] 0b1
    iWrite in[2] 0b0
    iApply
    iRead out[1] 0b1
    iApply
}
```

Alias

Collects signals from different origins to form a named, new, virtual signal.

Usage

Syntax 1

```
Module module_name {
    Alias alias_name = concat_signal ;
}
```

Syntax 2

```
Module module_name {
    Alias alias_name = concat_signal {
        RefEnum enum_name ;
        AccessTogether ;
        iApplyEndState value ;
    }
}
```

Description

The Alias statement collects signals from different origins to form a named, new, virtual signal.

The name of the alias can be used in any operation or construct where the original signals would have been allowed. For example, PDL commands like [iWrite](#) or [iRead](#) can use the alias name. Choosing meaningful alias names can make both ICL and PDL, much more human readable.

A second usage of the Alias statement is to instruct Tesson to automatically return to a specified value for the selected signals. Typically this feature is used to return a write-enable signal to the inactive value assignment automatically, once the write operation has been completed.

If none of the parameters RefEnum, AccessTogether, or iApplyEndState are used, you must use Syntax 1.

The name of the Alias must be unique among all port names, and among all the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#).

Arguments

- `alias_name = concat_signal`

A required string-string pair, connected with the '=' symbol. The `alias_name` defines the name of the alias, whereas `concat_signal` refers to one signal, or a concatenation of signals. Such a concatenation of signals is created by a signal name followed by a comma (','), followed by another signal name and so on. The concatenated signals can only be from [DataInPort](#), [ScanInPort](#), [DataOutPort](#), or [ScanOutPort](#). The width of the alias name should match the width of the concatenated signal.

An alias name can become part of another Alias statement, however circular definitions are not allowed. Further, if any of the signals in the concatenation has more than one level of hierarchy; that is, the hierarchical instance-port path name contains the dot (“.”), the Alias may not be used in any other ICL statements, but only in PDL.

- RefEnum *enum_name*

An optional keyword-string pair that references the name of a Related Topics table. Using the enumeration table, the writing to the aliased signal can use synonyms listed in the table, instead of bit strings. Understand that the enumeration table is not necessarily a complete list. You are still allowed to read or write any value, including those not listed in the enumeration table. An Alias statement may have at most one RefEnum parameter.

- AccessTogether

An optional keyword that requests Tessent to operate all signals listed in *concat_signal* at the same time. If this turns out to be not possible, for example, based on mutually exclusive hardware requirements, an error will be returned. Without this keyword, Tessent is allowed to find a solution where some of the signals are operated first, followed by operating another set of signals in the *concat_signal* Alias.

Note

Currently Tessent does not support the AccessTogether parameter.

- iApplyEndState *value*

An optional keyword-string pair that identifies the value to which the signals listed *concat_signal* will return to automatically, if ever changed by an [iWrite](#) command. The value will return with the next [iApply](#) PDL command. Typically this feature is used to return the write-enable signal to the inactive value assignment automatically, once the write operation has been completed.

There are additional conditions to the signals and value used in the Alias and iApplyEndState statement and parameter: All resolved signals must be legal targets of the [iWrite](#) command; *value* may not contain unknown values; if a signal is part of multiple iApplyEndState parameters, all specified values must be the same; if the signals resolve to register bits, either [ScanRegister](#) or [DataRegister](#), the register must have a ResetValue parameter defined and the reset value should match the iApplyEndState-value for these signals; if a signal does not resolve to register bits, it must resolve to primary inputs, no other resolved signal source is allowed for the *concat_signal*, if the iApplyEndState parameter is used; further, there may not be a [DataOutPort](#) with an Enable parameter between the resolved signal source and the signal specified in *concat_signal of the Alias statement*.

Examples

The following example shows several usages of the Alias statement.

```
Module instrument {
    DataInPort  in[8:0];
    DataOutPort out[7:0];
    ClockPort   clk;

    Alias write_en      = in[8]{ RefEnum YesNo; iApplyEndState 1'b0; }
    Alias enable        = in[7]           { RefEnum YesNo;          }
    Alias mode[3:0]     = in[6:5],in[3:2] { RefEnum Modes;         }
    Alias p1[2:0]       = in[4],in[1:0];
    Alias go            = out[0]          { RefEnum PassFail;      }
    Alias done           = out[1]          { RefEnum YesNo;         }
    Alias count[5:0]    = out[7:2];
    Enum PassFail {
        Pass = 1'b1;
        Fail = 1'b0;
    }
    Enum YesNo {
        Yes = 1'b1;
        No = 1'b0;
    }
    Enum Modes {
        none = 4'b0 ;
        red  = 4'b0011 ;
        blue = 4'haa ;
        green = 4'd9 ;
    }
}
```

[DataRegister](#)

LogicSignal

Creates a new signal that can then be referenced in other ICL statements.

Usage

```
Module module_name {
    LogicSignal signal_name {
        expression ;
    }
}
```

Description

The LogicSignal statement creates a new signal named *signal_name*, which itself can then be referenced in other ICL statements, and in particular other LogicSignal statements.

Using the LogicSignal statement, logical operations between signals like AND or EXOR can be implemented.

Arguments

- *signal_name*

A required string that identifies the newly created signal name. The value it assumes depends on the result of the evaluation of *expression*.

The name of the LogicSignal must be unique among all port names, and among all the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [Alias](#).

In any case, the width of *signal_name* is always 1. In particular, comparisons and Boolean logic operations return 1'b1, if the expression evaluates to true, and 1'b0, if the expression evaluates to false.

- *expression*

A required string that defines a Boolean expression that evaluates to a single-bit result, based on the signals and their value used in the expression.

The common Boolean and Logical operators are supported. In decreasing order of preference, these are: Boolean not (!), Bitwise not (~), logical AND (&&) and logical OR(||), bitwise AND (&), bitwise OR (), and bitwise XOR (^), logical equality (==) and inequality (!=).

All operators are left-to-right associative, and operators with equal precedence are evaluated left-to-right. Associativity and precedence may be expressly specified with parentheses () .

Valid operands are registers, ports, sized and unsized numbers, logical signals, as well as parameters and aliases that resolve into those. In addition, signals can be concatenated.

For expressions containing unsized numbers, it must be possible to determine the required width of the unsized number unambiguously. If the width must be extended, the additional

bits will either be filled with 0, if the most significant bit is either 0 or 1, or the bits will be filled with unknown (x).

For the logical equality and inequality operation, the width of the operands on either side of the operator must be the same.

Any parameter reference will be resolved before the expression is evaluated.

Enumeration table entries can be used for operands which are used in their entirety in the expression, and not just a part of the operand. The operand must have declared its binding to this enumeration by means of the RefEnum statement. Enumeration values are allowed only in combination with equality (==) and inequality (!=) operators. See the example below.

Examples

The following example shows several usages of the LogicSignal statement. sig1 demonstrates the usage of an enumeration table value entry. Note that ‘mode[3:0]’ is the entire operand for which the Enum ‘Modes’ applies. Therefore, any table entry may be used for this operand. sig2 shows the usage of concatenation, the expansion of an unsigned number and the usage of a parameter reference. Observe that the width of the right operand is 5, whereas the width of the sized elements of the left operand is 3. Therefore, the unsigned number ‘0’ will be expanded to width 2, matching the width of the right operand. Lastly, sig3 shows an example of bit-operations.

```
Module instrument {
    [ ... ]
    DataInPort  in[7:0];
    [ ... ]

}
```

ScanRegister

Defines and names a scan register of a certain width and with certain properties.

Usage

```
Module module_name {
    ScanRegister register_name {
        Attribute att_name = att_value;
        ScanInSource scan_in_source;
        CaptureSource capture_source;
        DefaultLoadValue default_load_value;
        ResetValue reset_value;
        RefEnum enum_name;
    }
}
```

Description

The statement ScanRegister defines and names a scan register of a certain width and with certain properties. These properties, like the reset value, are described through parameters of the scan register.

Arguments

- *register_name*

A required string that identifies the name of a the scan register of the module. The name of the ScanRegister must be unique among all port names, and among all the following objects: [DataRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

- Attribute *att_name = att_value*

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you and may be ignored by any IJTAG software tool. Tessonnt understands several [port attributes](#) and [pin attributes](#)as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

- ScanInSource *scan_in_source*

A required keyword-string pair that identifies the signal that is providing the scan data to the left most bit of the scan chain. If *scan_in_source* references another scan register, it must reference the right-most bit of that scan register (that is, the ‘scan out bit’).

For ranged scan registers; that is, scan registers that have a width > 1, the scan register always shifts from left to right, independently if the left most index is larger than the right most index, or vice-versa.

- CaptureSource *capture_source*

An optional keyword-string pair that identifies the signal from which the ScanRegister captures data in response to the [CaptureEnPort](#) and [TCKPort](#) signal. If used, the width of *capture_source* must match the width of the register.

- DefaultLoadValue *default_load_value*

An optional keyword-string pair that identifies the value that each scan register cell will assume if no user-defined value had been written to it beforehand and if no reset had been triggered. If used, the width of *default_load_value* must match the width of the register.

When both the DefaultLoadValue parameter and the ResetValue parameter exist in the same Scan Register statement, the non-x bit values of *reset_value* must match those of *default_load_value*.

- ResetValue *reset_value*

An optional keyword-string pair that identifies the value that each scan register cell will assume as a response to an active reset signal of the module. In more detail, it is the update stage of the scan register that assumes the declared reset value. If used, the width of *reset_value* must match the width of the register. If the ResetValue parameter is not used, the scan register does not respond to the module's incoming reset signal. However, if the module contains scan registers with a ResetValue parameter, the module must have only one ResetPort statement.

When both the DefaultLoadValue parameter the ResetValue parameter exist in the same Scan Register statement, the non-x bit values of *reset_value* must match those of *default_load_value*.

- RefEnum *enum_name*

An optional keyword-string pair that references the name of an table. Using the enumeration table, reading and writing to the scan register can use synonyms listed in the table, instead of bit strings. Understand that the enumeration table is not necessarily a complete list. It is still allowed to read or write any value, including those not listed in the enumeration table. A ScanRegister statement may have at most one RefEnum parameter. In addition, the width of the elements in the enumeration table must match the width of the scan register.

Additional Rules

A ScanRegister is considered to be in the active scan path if it responds to the [ShiftEnPort](#) signal associated to the ScanInterface through an active ScanInterface. It holds its data as long as the ShiftEnPort remains inactive (low) between the capture- and the update-cycle.

Any scan register bit that controls parts of a scan network (that is, the select line of a ScanMux, a SelectPort or ToSelectPort), or is part of a ScanInterface, anywhere in the hierarchy of the design, will have a non-x reset value (that is, a reset value of 0 or 1).

If a scan register bit is the source of a data signal, the scan register must have an update stage that (or an equivalent implementation) which changes only in response to an active UpdateEnPort signal.

It is important to understand the rules which determine what value gets loaded into the scan register bits. Assume no user-defined care bits have ever been written to any scan register bits. Now an iApply block accesses the ScanRegister. The scan register bits will assume a value in this order of preference: The specified values required to satisfy the operations in the iApply block; the value DefaultLoadValue specifies, if is a 0 or 1; the value ResetValue specifies, if it is a 0 or 1; any scan register bits still unassigned a 0 or 1, will be loaded with a 0.

If a scan register receives a reset signal, all scan register bits assume the value specified in *reset_value*. For the remaining x-values apply the sequence of events outlined in the paragraph above.

If a ScanRegister is on the active scan path (that is, a shift operation may happen), any scan register bits that are not required to satisfy the operations in the current iApply block will remain unchanged from their current value.

Examples

Example 1

The following shows a complete example ICL module definition of a TAP controller. Observe that the two different ScanRegisters: ‘IR’ has a width of 3, whereas ‘bypass’ has a width of 1. ‘IR’ must have as ResetValue parameter defined, since it controls the [ScanMux](#) DRMux. Further, observe the usage of the name of the scan register in the expression of the LogicSignal ‘sel1’.

```

Module tap {
    TCKPort      tck;
    ScanInPort   tdi;
    ScanOutPort  tdo      {  Source IRMux; }
    TMSPort      tms;
    TRSTPort     trst;
    ToSelectPort tdrEn1   {  Source sel1;  }
    ScanInPort   fromTdr1;
    ToSelectPort tapEn1   {  Source IR[2];  }
    ToCaptureEnPort tce;
    ToShiftEnPort tse;
    ToUpdateEnPort tue;
    ScanInterface clientTAP {
        Port tdi; Port tdo;
        Port tms; Port trst;
    }
    ScanInterface hostTAP  {
        Port fromTdr1; Port tdrEn1;
        Port tce; Port tse; Port tue;
    }
    Instance fsm_i Of fsm  {
        InputPort tck = tck;
        InputPort tms = tms;
        InputPort trst = trst;
    }
    ScanRegister IR[2:0] {
        CaptureSource 3'b001;
        ResetValue     3'b000;
        ScanInSource   tdi;
    }
    ScanRegister bypass {
        CaptureSource 1'b0;
        ScanInSource   tdi;
    }
    ScanMux IRMux SelectedBy fsm_i.irSel {
        1'b0 : DRMux;
        1'b1 : IR[0];
    }
    ScanMux DRMux SelectedBy IR[2:0] {
        3'bx00 : bypass;
        3'bx01 : fromTdr1;
    }
    LogicSignal sel1 {  IR[2:0] == 3'bx01; }
}
Module fsm {
    TCKPort      tck;
    TMSPort      tms;
    TRSTPort     trst;
    ToIRSelectPort irSel;
    ToResetPort   tlr;
}

```

Example 2

The following example shows an ICL module definition of a sensor where CaptureSource can be used to combine multiple DataInPorts to form the width of the ScanRegister.

```
Module sensor {
    TCKPort      tck;
    TRSTPort     rst;
    ScanInPort   si;
    ScanOutPort  so;      {  Source  S_reg[0]; }
    CaptureEnPort capture_en;
    ShiftEnPort  shift_en;
    UpdateEnPort update_en;
    SelectPort   sel_en;
    DataInPort   sdata_in [2:0];
    DataInPort   sens_from;
    DataInPort   cntrl [1:0];
    ScanRegister S_reg [5:0] {
        ResetValue  6'b000000;
        CaptureSource sdata_in, sens_from, cntrl ;
        ScanInSource si;
    }
}
```

DataRegister

Defines and names a data register of a certain width and with certain properties.

Usage

Syntax 1

```
Module module_name {
    DataRegister register_name {
        WriteDataSource concat_signal ;
        WriteEnSource enable_source ;
        ResetValue reset_value ;
        DefaultLoadValue load_value ;
        RefEnum enum_name ;
        Attribute att_name = att_value;
    }
}
```

Syntax 2

```
Module module_name {
    DataRegister register_name {
        AddressValue address_value ;

        ResetValue reset_value ;
        DefaultLoadValue load_value ;
        RefEnum enum_name ;
        Attribute att_name = att_value;
    }
}
```

Description

The statement DataRegister defines and names a data register of a certain width and with certain properties. These properties, like the reset value, are described through parameters of the data register. The DataRegister is used for parallel reading and writing as opposed to a [ScanRegister](#), which offers a scan-based access.

There are three, mutually exclusive types of DataRegisters: A Selectable DataRegister, for which a signal must be defined from which the DataRegister captures data; an Addressable DataRegister, for which an AddressValue must be specified; and a CallBack DataRegister. You should use Syntax 1 if you have a Selectable DataRegister. You should use Syntax 2 if you have an Addressable DataRegister.

Further, the Addressable DataRegister can only be used inside a [OneHotDataGroup](#), and inside a [OneHotDataGroup](#) there can only be Addressable DataRegisters.

Note

Currently Tessent does not support the Callback functionality.

Arguments

- *register_name*

A required string that identifies the name of a data register of the module. The name of the DataRegister must be unique among all port names, and among all the following objects: [ScanRegister](#), [ScanMux](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

- *ResetValue reset_value*

An optional keyword-string pair that identifies the value that each data register cell will assume as a response to an active reset signal of the module. In more detail, it is the update stage of the scan register that assumes the declared reset value. If used, the width of *reset_value* must match the width of the register. If the ResetValue parameter is not used, the data register does not respond to the module's incoming reset signal. However, if the module contains data registers with a ResetValue parameter, the module must have only one ResetPort statement.

When both the DefaultLoadValue parameter and the ResetValue parameter exist in the same DataRegister statement, the non-x bit values of *reset_value* must match those of *default_load_value*.

- *DefaultLoadValue default_load_value*

An optional keyword-string pair that identifies the value that each data register cell will assume if no user-defined value had been written to it beforehand and if no reset had been triggered. If used, the width of *default_load_value* must match the width of the register.

When both the DefaultLoadValue parameter and the ResetValue parameter exist in the same DataRegister statement, the non-x bit values of *reset_value* must match those of *default_load_value*.

- *RefEnum enum_name*

An optional keyword-string pair that references the name of an [Enum](#) table. Using the enumeration table, reading and writing to the data register can use synonyms listed in the table, instead of bit strings. Understand that the enumeration table is not necessarily a complete list. It is still allowed to read or write any value, including those not listed in the enumeration table. A DataRegister statement may have at most one RefEnum parameter. In addition, the width of the elements in the enumeration table must match the width of the data register.

- Attribute *att_name = att_value*

A repeatable, optional keyword, string and value combination. The standard does not have any built-in attributes, only the structure of the Attribute parameter is defined by the language. The attribute name and the attribute value is defined by you and may be ignored by any IJTAG software tool. Tessent understands several [port attributes](#) and [pin_attributes](#) as defined in this manual. Note that most attributes are read-only and are automatically generated by the tool.

- WriteDataSource *concat_signal*

A keyword and string pair required for a selectable DataRegister. *concat_signal* references a single signal or a concatenation of signals from where the DataRegister will capture data in response to a write request when WriteEnSource turns active (high). *concat_signal* must refer either to the module's [DataInPorts](#), another DataRegister, or to a [ScanRegister](#).

- WriteEnSource *enable_source*

A keyword and string pair required for a selectable DataRegister. *enable_source* references a 1-bit wide signal which determines when the DataRegister can capture data from WriteDataSource. The DataRegister will capture data in response to a write request when WriteEnSource turns active (high).

- AddressValue *address_value*

A keyword and number pair required if an Addressable DataRegister; that is, the DataRegister is part of the [OneHotDataGroup](#). The AddressValue parameter may not be used if the DataRegister if not part of a [OneHotDataGroup](#). Within the [OneHotDataGroup](#), the *number* declares a part of the address that is associated with the DataRegister. The final address of a [DataRegister](#) is determined by the sum of all addresses along the hierarchical instance path leading to the data register. In this sense *number* is only one element of the sum, comprising the address of a data register of the [OneHotDataGroup](#).

The DataRegister will be loaded from the logical data-in signal with the right most indices first, when the DataRegister's address has been applied and the module's WriteEnPort is active (high). The address of a DataRegister is computed by adding all address_values of all [Instances](#) leading to the DataRegister.

Similarly, reading from the Addressable DataRegister requires the module's ReadEnPort being active (high), and the address of the DataRegister being applied.

Examples

The following example shows a selectable data register. An example of addressable data registers can be found with the [OneHotDataGroup](#) statement, as well as with the [Instance](#) statement.

Observe the usage of the [Parameter](#) statement as well as Parameter overwrites. Further observe how the write enable signal is computed for the data registers in module bank using a [LogicSignal](#) statement and concatenation of the parameterized signals of the comparisons.

All together, this example shows how a selectable DataRegister can be used very much in a way of an addressable DataRegister, but without any of the constraints that come with an addressable DataRegister. In this particular implementation, the read and write enable signal of bank are explicitly managed (see for example, the usage of [Dx_Mux](#)). Depending on your DataRegister implementation, you may be able to relax this and allow reading from and writing to a data register simultaneously. Tesson sets up constraints for the IJTAG software such that no race conditions can occur.

```

Module chip_selectable_dataregister {
    DataInPort write_enable ;
    DataInPort read_enable ;
    DataInPort address[7:0] ;
    DataInPort dataIn[15:0] ;
    DataOutPort dataOut[15:0] { Source outMux[15:0] ; }
    Parameter bank1Address = 4'b0011 ;
    Parameter bank2Address = 4'b1100 ;
    DataMux outMux[15:0] SelectedBy address[7:4] {
        $bank1Address : bank1.dataOut[15:0] ;
        $bank2Address : bank2.dataOut[15:0] ;
    }
    Instance bank1 Of bank {
        InputPort we = write_enable ;
        InputPort re = read_enable ;
        InputPort dataIn[15:0] = dataIn[15:0] ;
        InputPort address[3:0] = address[3:0] ;
    }
    Instance bank2 Of bank {
        InputPort we = write_enable ;
        InputPort re = read_enable ;
        InputPort dataIn[15:0] = dataIn[15:0] ;
        InputPort address[3:0] = address[3:0] ;
        Parameter D0_Address = 4'b1000 ;
        Parameter D1_Address = 4'b1100 ;
    }
}
Module bank {
    DataInPort we ; Alias weR = we { iApplyEndState 1'b0 ; }
    DataInPort re ;
    DataInPort address[3:0] ;
    DataInPort dataIn[15:0] ;
    DataOutPort dataOut[15:0] { Source Dx_Mux[15:0] ;
Enable re; } Parameter D0_Address = 4'b0000 ;
    Parameter D1_Address = 4'b0001 ;
    DataMux Dx_Mux[15:0] SelectedBy we,address[3:0] {
        1'b0, $D0_Address : D0[15:0] ;
        1'b0, $D1_Address : D1[15:0] ;
    }
    LogicSignal D0_wen { re,we,address[3:0] == 2'b01, $D0_Address ; }
    DataRegister D0[15:0] {
        ResetValue 16'b0 ;
        WriteEnSource D0_wen ;
        WriteDataSource dataIn[15:0] ;
    }
    LogicSignal D1_wen { re,we,address[3:0] == 2'b01, $D1_Address ; }
    DataRegister D1[15:0] {
        ResetValue 16'b0 ;
        WriteEnSource D1_wen ;
        WriteDataSource dataIn[15:0] ;
    }
}

[ScanRegister](#)

[OneHotDataGroup](#)

ScanMux

Creates and names a scan multiplexer.

Usage

```
Module module_name {
    ScanMux mux_name SelectedBy mux_select_signal {
        mux_select_value : scan_source_name ;
    }
}
```

Description

The ScanMux statement creates and names a scan multiplexer.

IJTAG differentiates between a scan multiplexer, a data multiplexer, and a clock multiplexer. All three share the same syntax (other than the keyword), but their semantics differ. The scan multiplexer only switches between scan signals, the data multiplexer only switches between data signals, and the clock multiplexer only switches between clock signals. No signal types may be mixed for any of the multiplexers. The select signal of the multiplexers may be sourced only by data signals. Note that the parallel output of a scan register is also a data signal.

A common design structure is to have a ScanMux, with a 1-bit TDR at the output of the ScanMux, and the parallel output of the TDR connected to the select input of the mux. In this configuration, the TDR behind the mux is always on the scan path, independent of which scan input ports of the mux have been selected. Through this TDR, Tesson can select either of the scan input ports of the mux as needed.

Arguments

- *mux_name*

A string that identifies the name of a scan multiplexer of the module. The name of the ScanMux must be unique among all port names, and among all the following objects: [ScanRegister](#), [DataRegister](#), [DataMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

Using this name, the outgoing signal of the multiplexer can be referenced. The width of *mux_name* must match the width of the *scan_source_name*.

- *mux_select_value : scan_source_name*

A repeatable string-string pair, connected by a colon symbol ‘:’. A ScanMux must have at least one *mux_select_value - scan_source_name* pair. The width of the *mux_select_value* must match the width of the *mux_select_signal*.

The *mux_select_value* describes the value the select signal (*mux_select_signal*) of the mux must assume for the *mux_name* signal to connect to the *scan_source_name* signal. The *mux_select_value* may contain x-values. The collection of all specified *mux_select_value* parameters need not cover the entire number space. Any select value not listed causes the *mux_name* signal to assume x-values of the correct width.

Examples

The following shows usages of all the multiplexer types.

```
Module chip2 {
    ScanInPort siA ;
    ScanInPort siB ;
    ScanOutPort so      { Source scanM ; }
    ShiftEnPort sel ;
    CaptureEnPort cel ;
    UpdateEnPort uel ;
    ShiftEnPort se2 ;
    CaptureEnPort ce2 ;
    UpdateEnPort ue2 ;
    TCKPort tck ;
    ClockPort clkA ;
    ClockPort clkB ;
    ToClockPort clk { Source clockM ; }
    DataInPort dselA ;
    DataInPort dselB[2:0] ;
    DataOutPort do[3:0] { Source dataM[3:0] ; }
    ScanInterface cA12 {
        Port sel; Port cel; Port uel;
        Chain c1 { Port siA; Port so ; }
    }
    ScanInterface cB12 {
        Port se2; Port ce2; Port ue2;
        Chain c1 { Port siB; Port so ; }
    }
    ScanRegister regA[7:0] {
        ScanInSource siA ;
        ResetValue 8'b0 ;
    }
    ScanRegister regB[7:0] {
        ScanInSource siB ;
        ResetValue 8'b0 ;
    }
    ScanMux scanM SelectedBy dselA {
        1'b0 : regA[0] ;
        1'b1 : regB[0] ;
    }
    ClockMux clockM SelectedBy dselA {
        1'b0 : clkA ;
        1'b1 : clkB ;
    }
    DataMux dataM[3:0] SelectedBy dselB[2:0] {
        3'bx00 : regA[7:4] ;
        3'bx01 : regA[3:0] ;
        3'bx1x : regB[5:2] ;
    }
}
```

[DataMux](#)

[ClockMux](#)

DataMux

Creates and names a data multiplexer.

Usage

```
Module module_name {
    DataMux mux_name SelectedBy mux_select_signal {
        mux_select_value : data_source_name ;
    }
}
```

Description

The DataMux statement creates and names a data multiplexer.

IJTAG differentiates between a scan multiplexer, a data multiplexer, and a clock multiplexer. All three share the same syntax (other than the keyword), but their semantics differ. The scan multiplexer only switches between scan signals, the data multiplexer only switches between data signals, and the clock multiplexer only switches between clock signals. No signal types may be mixed for any of the multiplexers. The select signal of the multiplexers may be sourced only by data signals.

A DataMux can also be used for the gating of reset signals, tms signals and trst signals. See chapter “[How to Model Global Reset, Local Reset and Embedded TAPs](#)” in the *Tessent IJTAG User's Manual* for the details about the reset, trst and tms gating.

Arguments

- *mux_name*

A string that identifies the name of a data multiplexer of the module. The name of the ScanMux must be unique among all port names, and among all the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [ClockMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

Using this name, the outgoing signal of the multiplexer can be referenced. The width of *mux_name* must match the width of the *data_source_name*.

- *mux_select_value : data_source_name*

A repeatable string-string pair, connected by a colon symbol ‘:’. A DataMux must have at least one *mux_select_value* - *data_source_name* pair. The width of the *mux_select_value* must match the width of the *mux_select_signal*.

The *mux_select_value* describes the value the select signal (*mux_select_signal*) of the mux must assume for the *mux_name* signal to connect to the *data_source_name* signal. The *mux_select_value* may contain x-values. The collection of all specified *mux_select_value* parameters need not cover the entire number space. Any select value not listed causes the *mux_name* signal to assume x-values of the correct width.

Examples

The following shows usages of all the multiplexer types.

```
Module chip2 {
    ScanInPort siA ;
    ScanInPort siB ;
    ScanOutPort so      { Source scanM ; }
    ShiftEnPort sel ;
    CaptureEnPort cel ;
    UpdateEnPort uel ;
    ShiftEnPort se2 ;
    CaptureEnPort ce2 ;
    UpdateEnPort ue2 ;
    TCKPort tck ;
    ClockPort clkA ;
    ClockPort clkB ;
    ToClockPort clk { Source clockM ; }
    DataInPort dselA ;
    DataInPort dselB[2:0] ;
    DataOutPort do[3:0] { Source dataM[3:0] ; }
    ScanInterface cA12 {
        Port sel; Port cel; Port uel;
        Chain c1 { Port siA; Port so ; }
    }
    ScanInterface cB12 {
        Port se2; Port ce2; Port ue2;
        Chain c1 { Port siB; Port so ; }
    }
    ScanRegister regA[7:0] {
        ScanInSource siA ;
        ResetValue 8'b0 ;
    }
    ScanRegister regB[7:0] {
        ScanInSource siB ;
        ResetValue 8'b0 ;
    }
    ScanMux scanM SelectedBy dselA {
        1'b0 : regA[0] ;
        1'b1 : regB[0] ;
    }
    ClockMux clockM SelectedBy dselA {
        1'b0 : clkA ;
        1'b1 : clkB ;
    }
    DataMux dataM[3:0] SelectedBy dselB[2:0] {
        3'bx00 : regA[7:4] ;
        3'bx01 : regA[3:0] ;
        3'bx1x : regB[5:2] ;
    }
}
```

[ScanMux](#)

[ClockMux](#)

ClockMux

Creates and names a clock multiplexer.

Usage

```
Module module_name {
    ClockMux mux_name SelectedBy mux_select_signal {
        mux_select_value : clock_source_name ;
    }
}
```

Description

The ClockMux statement creates and names a clock multiplexer.

IJTAG differentiates between a scan multiplexer, a data multiplexer, and a clock multiplexer. All three share the same syntax (other than the keyword), but their semantics differ. The scan multiplexer only switches between scan signals, the data multiplexer only switches between data signals, and the clock multiplexer only switches between clock signals. No signal types may be mixed for any of the multiplexers. The select signal of the multiplexers may be sourced only by data signals.

Arguments

- *mux_name*

A string that identifies the name of a data multiplexer of the module. The name of the ScanMux must be unique among all port names, and among all the following objects: [ScanRegister](#), [DataRegister](#), [ScanMux](#), [DataMux](#), [OneHotDataGroup](#), [OneHotScanGroup](#), [LogicSignal](#), [Alias](#).

Using this name, the outgoing signal of the multiplexer can be referenced. The width of *mux_name* must match the width of the *clock_source_name*.

- *mux_select_value : clock_source_name*

A repeatable string-string pair, connected by a colon symbol ‘:’. A DataMux must have at least one *mux_select_value - clock_source_name* pair. The width of the *mux_select_value* must match the width of the *mux_select_signal*.

The *mux_select_value* describes the value the select signal (*mux_select_signal*) of the mux must assume for the *mux_name* signal to connect to the *clock_source_name* signal. The *mux_select_value* may contain x-values. The collection of all specified *mux_select_value* parameters need not cover the entire number space. Any select value not listed causes the *mux_name* signal to assume x-values of the correct width.

Examples

The following shows usages of all the multiplexer types.

```
Module chip2 {
    ScanInPort siA ;
    ScanInPort siB ;
    ScanOutPort so      { Source scanM ; }
    ShiftEnPort sel ;
    CaptureEnPort ce1 ;
    UpdateEnPort ue1 ;
    ShiftEnPort se2 ;
    CaptureEnPort ce2 ;
    UpdateEnPort ue2 ;
    TCKPort tck ;
    ClockPort clkA ;
    ClockPort clkB ;
    ToClockPort clk { Source clockM ; }
    DataInPort dselA ;
    DataInPort dselB[2:0] ;
    DataOutPort do[3:0] { Source dataM[3:0] ; }
    ScanInterface cA12 {
        Port sel; Port ce1; Port ue1;
        Chain c1 { Port siA; Port so ; }
    }
    ScanInterface cB12 {
        Port se2; Port ce2; Port ue2;
        Chain c1 { Port siB; Port so ; }
    }
    ScanRegister regA[7:0] {
        ScanInSource siA ;
        ResetValue 8'b0 ;
    }
    ScanRegister regB[7:0] {
        ScanInSource siB ;
        ResetValue 8'b0 ;
    }
    ScanMux scanM SelectedBy dselA {
        1'b0 : regA[0] ;
        1'b1 : regB[0] ;
    }
    ClockMux clockM SelectedBy dselA {
        1'b0 : clkA ;
        1'b1 : clkB ;
    }
    DataMux dataM[3:0] SelectedBy dselB[2:0] {
        3'bx00 : regA[7:4] ;
        3'bx01 : regA[3:0] ;
        3'bx1x : regB[5:2] ;
    }
}
```

OneHotDataGroup

Implements a convenient way of declaring a named, hierarchically distributed data multiplexer.

Usage

```
Module module_name {
    OneHotDataGroup onehotdatagroup_name {
        Instance ;
        DataRegister ;
        Port concat_signal ;
    }
}
```

Description

The OneHotDataGroup statement implements a convenient way of declaring a named, hierarchically distributed data multiplexer. You would use a OneHotDataGroup if various inputs to the multiplexer are sourced by data registers distributed across multiple instances. This statement simplifies the declaration of such a data multiplexer by automatically making the correct data input and data output connections, including read, write, and address connections.

A OneHotDataGroup may use any combination of the three options declaring the source input signal of the multiplexer. The order of the declarations is not relevant, since each source should have an enable signal defined in such a way that at most one source is selected at a time. The OneHotDataGroup then assumes the value of this selected, unique source, or the x-value, if none of the sources is selected, or if multiple data sources are selected simultaneously.

Arguments

- *onehotdatagroup_name*

A required string, declaring the name of the OneHotDataGroup. This name can be considered as the name of the distributed multiplexer. As usual, *onehotdatagroup_name* can be used to refer to the output signal of this multiplexer, for example as a source of a **DataOutPort** statement. The width of *onehotdatagroup_name* must be larger or equal to the width of the connected output ports of the referenced **Instance** or **DataRegister**.
onehotdatagroup_name assumes the value of the one selected source, or the x-value, if none of its sources are enabled.

- Instance

An optional, repeatable **Instance** statement. This instance must use the **AddressValue** parameter.

- DataRegister

An optional, repeatable **DataRegister** statement. This **DataRegister** must use the **AddressValue** parameter.

- *Port concat_signal*

An optional, repeatable keyword-string pair. *concat_signal* may reference a data output single signal or a concatenation of such signals. *concat_signal* may also be a hierarchical instance pathname ending at a data source signal. The referenced signal will be considered an input port of the multiplexer represented by the OneHotDataGroup statement. For the enable signal required for each source of the OneHotDataGroup's source signal, one of the following rules will apply:

- For a referenced DataOutPort, the Enable statement is included in the DataOutPort declaration.
- For a referenced DataOutPort, the Source parameter references another data signal, which has an enabling condition.
- The instance referenced in the instance pathname in a hierarchical *concat_signal* has an AddressValue parameter.
- A primary input port of the top level module is assumed to have an enabling condition from the outside.

Examples

The following shows an example of a OneHotDataGroup. Observe how the address of a **DataRegister** is determined. For example the **DataRegister** with the hierarchical name phy1.bank1.D1 has the address of $8'b01\ 000000 + 6'b0001\ 00 + 2'b01 = 8'b01\ 0001\ 01$. Similarly, the **DataRegister** phy2.R has the address $8'b10\ 000000 + 6'b0010\ 00 = 8'b10\ 0010\ 00$.

The Example 2 of the **Instance** statement shows a variation of this example.

```

Module top {
    AddressPort address[7:0] ;
    DataInPort dataIn[15:0] ;
    WriteEnPort write_enable ;
    ReadEnPort read_enable ;
    DataOutPort dataOut[15:0] { Source outMux[15:0] ; }
    OneHotDataGroup outMux[15:0] {
        Instance phy1 Of phy {
            AddressValue 2'b01, 6'b000000 ;
        }
        Instance phy2 Of phy {
            AddressValue 2'b10, 6'b000000 ;
        }
    }
}
Module phy {
    DataInPort dataIn1[7:0] ;
    DataInPort dataIn2[7:0] ;
    WriteEnPort we ;
    ReadEnPort re ;
    AddressPort address1[3:0] ;
    AddressPort address2[3:0] ;

[OneHotScanGroup](#)

[DataRegister](#)

OneHotScanGroup

Implements a convenient way of declaring a named, hierarchically distributed scan multiplexer.

Usage

```
Module module_name {
    OneHotScanGroup onehotscangroup_name {
        Port source_name ;
    }
}
```

Description

The OneHotScanGroup statement implements a convenient way of declaring a named, hierarchically distributed scan multiplexer. You would use a OneHotScanGroup if various inputs to the multiplexer are sourced by scan-out ports distributed across multiple instances. This statement simplifies the declaration of such a scan multiplexer by automatically making the correct scan input and scan output connections.

Arguments

- *onehotscangroup_name*

A required string, declaring the name of the OneHotScanGroup. This name can be considered as the name of the distributed multiplexer. As usual, *onehotscangroup_name* can be used to refer to the output signal of this multiplexer, for example as a source of a [ScanOutPort](#) statement. The width of *source_name* must be equal to the width of *onehotdatagroup_name*. Each scan source must have an enable signal defined in such a way that at most one source is selected at a time when the OneHotScanGroup is in the active scan path. This enable signal is not necessarily directly at the ScanOutPort of *source_name*, but might be located deeper in the hierarchy, for example, through cascaded OneHotScanGroups. When selected, the *onehotdatagroup_name* then assumes the value of this selected source, or the x-value, if none of the sources is selected, or multiple sources would have been selected.

- *Port source_name*

A required, repeatable keyword-string pair. *source_name* may reference a scan output port single signal or a concatenation of such signals. *source_name* may also be a hierarchical instance pathname ending at a scan output port signal. The referenced scan output port signals will be considered an input port of the multiplexer represented by the OneHotScanGroup statement.

Examples

The following shows an example of a OneHotScanGroup. Observe how easy it is to declare the hierarchically distributed scan multiplexer “outScanMux” and the usage of the OneHotScanGroup’s name in the Source statement of the top level scan-out port.

```

Module chip_onehotscangroup {
    ScanInPort      si;
    ScanOutPort     so      { Source outScanMux; }
    ShiftEnPort     se;
    SelectPort      en[3:0];
    CaptureEnPort   ce;
    UpdateEnPort    ue;
    TCKPort         tck;
    OneHotScanGroup outScanMux {
        Port tdr_0.so ;
        Port tdr_1.so ;
        Port tdr_2.so ;
        Port tdr_3.so ;
    }
    Instance tdr_0 Of tdr {
        InputPort si = si ;
        InputPort en = en[0];
    }
    Instance tdr_1 Of tdr {
        InputPort si = si ;
        InputPort en = en[1];
    }
    Instance tdr_2 Of tdr {
        InputPort si = si ;
        InputPort en = en[2];
    }
    Instance tdr_3 Of tdr {
        InputPort si = si ;
        InputPort en = en[3];
    }
}
Module tdr {   ScanInPort      si;
    ScanOutPort     so      { Source R[0]; Enable en; }
    ShiftEnPort     se;
    SelectPort      en;
    CaptureEnPort   ce;
    UpdateEnPort    ue;
    TCKPort         tck;
    ScanRegister R[7:0] {
        ScanInSource   si;
        ResetValue     8'b0 ;
    }
}

```

AccessLink

Links an ICL network to an 1149.1 TAP controller that is described in a BSDL file.

Usage

```
Module module_name {
    AccessLink instance_name Of STD_1149_1_2001 {
        BSDLEntity entity_name;
        instruction_name {
            ScanInterface { scan_interface_name; ... } // required
            ActiveSignals { signal_name; ... } // optional
        }
    }
}
```

Description

A wrapper that can be used inside the top level ICL Module to link an ICL network to an 1149.1 TAP controller that is described in a BSDL file. The tool currently only supports the BSDL format that is part of IEEE1149.1-2001.

When reading an ICL file which contains an ICL module with an AccessLink Of STD_1149_1_2001, the [read_icl](#) command must be used with the [-bsdl_file](#) option to provide the path to the referenced BSDLEntity. An error is generated if the specified BSDLEntity is not found in the specified BSDL file.

Arguments

- *instance_name*

A string used to define the instance name of the AccessLink. The string must start with a letter and only contain letters, numbers and underscores. As shown below, the *instance_name* is used when referring to the defined *signal_name* in an ICL connection. When the AccessLink is read in the tool, a TAP ICL module is created from the BSDL and instantiated in the top level ICL module in place of the AccessLink using the same *instance_name*. This is also illustrated below.

- *BSDLEntity entity_name;*

A required keyword-string pair which defines the name of the BSDL entity that is referenced by the AccessLink wrapper. The file pointed to by the “[read_icl -bsdl_file](#)” option must contain an “Entity *entity_name* is” clause.

- **instruction_name**

A required string that references one of the instruction names defined in the INSTRUCTION_OPCODE attribute of the BSDL file. When the specified *instruction_name* is loaded in the INSTRUCTION register, the *scan_interface_names* listed in the ScanInterface wrapper are placed along the active DR scan path between the TAP_SCAN_IN and TAP_SCAN_OUT ports.

- *scan_interface_name*

A repeatable string that references the ScanInterface of ICL module instances. The format of the string is a leaf_instance_name followed by an optional “.scan_interface_name” string. The “.scan_interface_name” string is optional when the ICL module associated with the leaf_instance_name only has one ScanInterface. If the ICL module associated to the leaf_instance_name has more than one ScanInterface wrapper, the “.scan_interface_name” string is required to identify one of them.

The scan_interface_name are serially daisy chained with the first one closer to TDI and the last one closer to TDO.

- *signal_name*

A repeatable string that defines signal_names that are high when the instruction_name is loaded into the INSTRUCTION register. When a signal_name is not specified inside a given instruction_name wrapper, the signal is low when the instruction_name is loaded into the INSTRUCTION register. The signal_names are identified as “instance_name.signal_name” when referenced to make connections in the ICL. This is illustrated below.

Examples

Below is an example of a top level ICL module containing an AccessLink. It references a BSDL file which contains the element shown below. After the elaboration which is triggered by the `set_current_design` command, you can see that a TAP controller was extracted from the BSDL file and instantiated into the top level ICL module. The TAP ports were also extracted and added to the ICL module. The original AccessLink wrapper is commented out. The ClockPorts and their original connections are left unaffected.

Note

 If an ICL module with an AccessLink statement has been loaded into memory by means of `read_icl`, then the commands `write_icl` and `report_icl_modules` do not result in usable ICL of this module before it has been subject to `set_current_design`.

Following is the content of mydesign.icl with an AccessLink wrapper. Notice how the ActiveSignal long_setup is referenced as “bsdl_tap.long_setup” when used to connect the “selectWIR” input port of the “core” instance.

```

Module mydesign {
    ClockPort CLK;
    AccessLink bsdl_tap Of STD_1149_1_2001 {
        BSDLEntity acme4523;
        BP0_LONG_SETUP {
            ScanInterface {core.ijtag0;}
            ActiveSignals {long_setup;}
        }
        BP0_SHORT_SETUP {
            ScanInterface {core.ijtag0;}
        }
        BP1_LONG_SETUP {
            ScanInterface {core.ijtag1;}
            ActiveSignals {long_setup;}
        }
        BP1_SHORT_SETUP {
            ScanInterface {core.ijtag1;}
        }
    }
}

Instance core Of core {
    InputPort selectWIR = bsdl_tap.long_setup;
    InputPort clk = CLK;
}
}

```

Following is the section from the BSDL file “acme4523.bsd1” that is used to extract the TAP controller.

```

entity acme4523 is
    attribute TAP_SCAN_RESET of TRST : signal is true;
    attribute TAP_SCAN_IN of TDI : signal is true;
    attribute TAP_SCAN_MODE of TMS : signal is true;
    attribute TAP_SCAN_OUT of TDO : signal is true;
    attribute TAP_SCAN_CLOCK of TCK : signal is (1.0e+07, BOTH);

    attribute INSTRUCTION_OPCODE of acme4523: entity is
        "IDCODE      (1111111111111110), " &
        "BYPASS      (1111111111111111), " &
        "EXTEST      (11111111111101000), " &
        "SAMPLE      (11111111111111000), " &
        "PRELOAD     (11111111111111000), " &
        "CLAMP       (1111111111111101111) " &
        "BP0_LONG_SETUP (XXXXXXXX000111XXX010), " &
        "BP1_LONG_SETUP (XXXXXXXX001101XXX010), " &
        "BP2_LONG_SETUP (XXXXXXXX001001XXX010), " &
        "BP3_LONG_SETUP (XXXXXXXX000101XXX010), " &
        "BP4_LONG_SETUP (XXXXXXXX000001XXX010), " &
        "BP0_SHORT_SETUP (XXXXXXXX110110XXX010), " &
        "BP1_SHORT_SETUP (XXXXXXXX111100XXX010), " &
        "BP2_SHORT_SETUP (XXXXXXXX111000XXX010), " &
        "BP3_SHORT_SETUP (XXXXXXXX110100XXX010), " &
        "BP4_SHORT_SETUP (XXXXXXXX110000XXX010) " ;

end acme4523;

```

Below is a dofile that loads the ICL modules in memory and elaborates them. The modified top level ICL module as well as the created TAP ICL modules are then reported. Notice how the TAP ICL module is called <bsdl_entity_name>_bsdl_tap. Its leaf instance name reused the one that was used by the AccessLink.

Chapter 14

Adding Custom Plugin Functionality

This chapter describes how you can augment the functionality of Tessent Shell with your own Tcl packages, commands and metadata definitions. It explains the concept of a plugin directory that you populate and how to get it auto loaded when Tessent Shell boots up.

The chapter also describes the best practice method to minimize the amount of code that is actually parsed at boot time and shows you how to have your code loaded on demand the first time your custom commands are used.

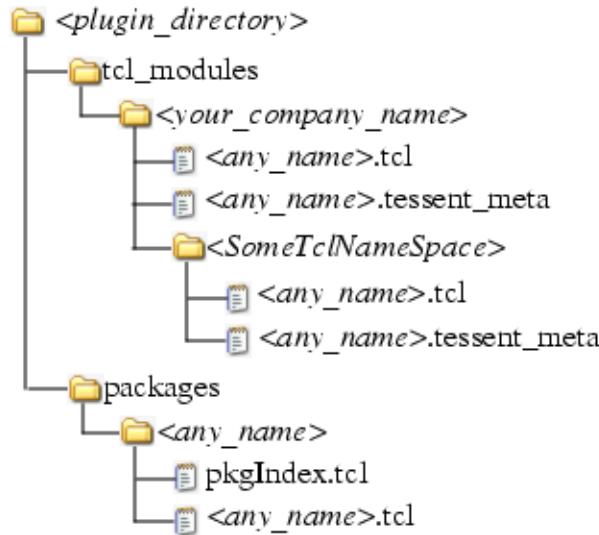

Finally, it describes how to create a proc called “u” to enable you to quickly reload the content of your plugin while you are developing and debugging it. The “u” proc is illustrated in [Example 1](#) for tcl_modules and in [Example 2](#) for packages.

plugin directory [3921](#)

plugin directory

A directory that contains special sub directories with tcl and metadata files to be auto loaded when Tessent Shell boots up.

Summary

Description

A directory that groups two subdirectories containing tcl code and metadata to load into Tesson Shell at boot time in order to augment its feature set with your custom Tcl code. The <plugin_directory> can be named anything you like. You point to your <plugin_directory> using the TESSENT_PLUGIN_PATH environment variable. Just like the PATH environment variable, you can specify more than one search location by separating multiple directory names with a colon.

You can also name your <plugin_directory> “tesson_plugin” and place it one level above the bin directory of Tesson Shell. By doing so, the directory will be automatically loaded without requiring the end user to set their TESSENT_PLUGIN_PATH environment variable. A user must define the environment variable TESSENT_PLUGIN_IGNORE_DEFAULT_PATH to suppress the auto loading of this plugin directory.

The file *tesson_plugin/tcl_module/<your_company>/defaults.tcl* is the best place to include the definition of your company defaults as it will be automatically be seen by all users of the Tesson Shell tool. The Tcl file simply needs to include a this command:

```
read_config_data -from_string {
    DefaultsSpecification(company) {
        <your defaults here>
    }
}
```

The content and purpose of each sub directory and file is explained in the next section.

Components

- *tcl_modules/<your_company_name>*

The directory “tcl_modules” is where you define new commands and new metadata. The name “tcl_modules” cannot be changed. Inside this directory, you use an arbitrary sub-directory name which is typically the name of your company. If you are part of a large company with many divisions and you don’t want to have to coordinate with them the names of your tcl modules, you can also append your division name to your company name.

- <any_name>.tcl

All the tcl files specified at this level are loaded when Tesson Shell starts. You want to limit the amount of Tcl code those files contains so as not to slow down the Tesson Shell boot time. Those files should only include attribute and command registrations and the registration must be declared within a “namespace eval <SomeNameSpace>” block as shown in the [Example 1](#) below. In the same example, notice how the “create_wrapper_proc” command is used around the proc name of the “[register_tcl_command -tcl_proc](#)” argument to add special code that knows to load the body of the proc from files named <SomeTclNameSpace>/*.tcl when the command is called for the first time. The wrapper proc also disables tool command

transcribing while running your proc and restores it to its original setting after your command is done. You can always use the “[set_transcript_style full](#)” command in your procs if you want them to still transcript or enable transcripting on demand based on an option like it is done with the “[process_dft_specification - transcript_insertion_commands](#)” option. The wrapper proc provides handling of the Ctrl-C interrupt such that it terminates your command with the appropriate error message and error code. Finally, if your proc has a bug which results in a tcl command to fail, it will echo the detailed error message with the calling stack so that you can quickly identify the location of the problem. See [Example 1](#) below on how to create a proc called “u” to quickly reload the body of your procs after you have corrected issues.

- <any_name>.tessent_meta

All the files having an extension “.tessent_meta” are read in the tool at boot time. The files are sorted alphabetically before being read. See the section about the “[Metadata Configuration Syntax](#)” on page 3719 for an explanation of the syntax and when you may want to use it. Realize that the metadata loading order is important when you are using the “reference” property as documented in the [Wrapper](#) section because the referenced elements must have been read before they are referenced.

The alphabetical ordering of the files provides you the ability to control read ordering. Also note that metadata files contained in the <SomeTclNameSpace> sub-directories are always loaded after the one at the current level.

- <SomeTclNameSpace>/<any_name>.tcl

The directory name <SomeTclNameSpace> must match the namespace name used in the <any_name>.tcl files above it. The [create_wrapper_proc](#) command uses the leaf namespace from where it is called to know which files to auto load the first time it is run. For example, if the [create_wrapper_proc](#) command is invoked within the “[namespace eval ABC {}](#)” block, it will automatically source any file matching “./ABC/*.tcl”. The tcl code found inside the “ABC/*.tcl” do not need to be inside a “[namespace eval ABC {}](#)” block as the wrapper proc will automatically add them to the namespace.

- <SomeTclNameSpace>/<any_name>.tessent_meta

Those files are loaded at boot time. They are loaded after the file found one level above. See the discussion in the “<any_name>.tessent_meta” section to find out when that may be important. It is best to place your “.tessent_meta” file at this lower level to avoid cluttering the “[tcl_modules/<your_company_name>](#)” directory.

- packages

This directory contains sub directories which are automatically added to the Tcl autopath search when the “[package require](#)” command is invoked. Each sub-directory must each contains a file called [pkgIndex.tcl](#) and *.tcl files which get loaded when the given “[package require](#)” command is issued.

- <any_name>/pkgIndex.tcl

This file has a very specific format. The format is shown below and is used to load a series of Tcl files when the associated package is requested. It is recommended to define <my_package> and <my_namespace> identically and using this format ::<my_company>::<my_feature>. With this convention, you can easily request the package and import its exposed commands to your local namespace as shown in [Example 2](#). The <file_name> strings are the name of the Tcl file implementing features of the package and they must exist in the same directory.

```
package ifneeded <my_package> 1.0 \
    [string map [list @ $dir ! <my_namespace>] {
        no_transcript { read_tcl [file join {@} <file_name>.tcl] \
            -namespace {!} }
        no_transcript { read_tcl [file join {@} <file_name>.tcl] \
            -namespace {!} }
        package provide <my_package> 1.0
    }]
}
```

- <any_name>/<any_name>.tcl

Those Tcl files contain procs which are to be made available to the user when he requests the package. You include a “namespace export <proc_name>” on top of each proc you want to be exportable to the end user. Leave out the “namespace export” command for any internal proc not intended for the end user. See [Example 2](#) below for an example of such files.

Example 1

This example shows you how to create a plugin that defines a tcl_module implementing commands used to manage stacks.

Following the directory structure described above, these two files are created:

```
my_plugin/tcl_modules/my_company/stack_commands.tcl
my_plugin/tcl_modules/my_company/stack_commands/command_body.tcl
```

As you can see below, the file “stack_command.tcl” contains only register_tcl_command invocations inside a “namespace eval stack_commands” Tcl block as well as a variable definition. When any of those registered Tcl commands are called, it will call the wrapper proc that was created by the “create_wrapper_proc” command. This wrapper proc will load the file “stack_commands/command_body.tcl” the first time it is called and then call the proc it has just loaded.

The example uses a namespace variable called stack to hold an array of stacks. Each sub-command which operates on the stacks has access to common data through this variable.

To have this plugin automatically loaded into Tessent Shell, you simply need to set the environment variable TESSENT_PLUGIN_PATH to point to it. In this example, the variable points to my_plugin and his_plugin:

```
setenv TESSENT_PLUGIN_PATH ~/my_plugin:~him/his_plugin
```

In the example below, imagine the new_stack proc had a typo and the second to last line was using the undefined variable \$idd instead of \$id as it should. You would get an error when you tried to use it as shown in the transcript below. Notice how the error message provides the full context of the error including the calling stack. This information is essential for locating errors especially as the code becomes complex.

These kinds of mistakes are very common as you develop code and below is a useful method to fix them easily. Define a tcl proc called “u” which you can use to reload the *.tcl files found in the sub directory. That way, you can edit the source file, save the update, type the u command and test the updated files without having to restart Tessent Shell. An example definition of a “u” proc is shown below. Once the “u” command was run and it reloaded the corrected file, you can see the proper operation of the stack commands in the transcript below.

```
> proc u {} {
    namespace eval ::tcl_modules::my_company::stack_commands {
        foreach file_name \
            [glob ../my_plugin/tcl_modules/my_company/stack_commands/*.tcl] {
            puts "updating $file_name"
            source $file_name
        }
    }
}
set s [new_stack]
can't read "idd": no such variable
    while executing
"set stack($idd) [list]"
    (procedure "new_stack" line 8)
    invoked from within
"new_stack {*}$args"
=====
TCL calling stack
    ::tcl_modules::my_company::stack_commands::new_stack.wrapper --
namespace :::

        -system_mode_list {setup analysis insertion} \
        -string_value {<stack_id> stack_id} \
        -syntax_bnf {<stack_id>} \
        -tcl_proc [create_wrapper_proc top_of]
    register_tcl_command new_stack \
        -context_list {all} \
        -system_mode_list {setup analysis insertion} \
        -syntax_bnf {} \
        -tcl_proc [create_wrapper_proc new_stack]
}
```

Content of the stack_commands/command_body.tcl file:

```
proc pop {args} {
    variable stack
    array set ARGS $args
    set stack_id $ARGS(stack_id)
    check_id $stack_id
    if {[llength $stack($stack_id)] > 0} {
        set res [lindex $stack($stack_id) end]
        set stack($stack_id) [lreplace $stack($stack_id) end end]
    } else {
        set res ""
    }
    return $res
}
proc push {args} {
    variable stack
    array set ARGS $args
    set stack_id $ARGS(stack_id)
    set value $ARGS(value)
    check_id $stack_id
    lappend stack($stack_id) $value
}
```

```
proc top_of {args} {
    variable stack
    array set ARGS $args
    set stack_id $ARGS(stack_id)
    check_id $stack_id
    if {[llength $stack($stack_id)] > 0} {
        set res [lindex $stack($stack_id) end]
    } else {
        set res ""
    }
    return $res
}
proc new_stack {args} {
    variable stack
    if {[array exists stack]} {
        set id [expr {[:tcl::mathfunc::max {*} [array names stack]] + 1}]
    } else {
        set id 0
    }
    set stack($id) [list]
    return $id
}
# local utility proc proc check_id {stack_id} {
variable stack
if {! [info exists stack($stack_id)]} {
    display_message "The stack id '$stack_id' is not active."
    return -code error
}
}
```

Example 2

This example shows you how to define a package which, when requested by the user, loads and exposes a series of debug utility procs. The files for this package are the following:

```
my_plugin/packages/debug_utilities/pkgIndex.tcl
my_plugin/packages/debug_utilities/timer_procs.tcl
my_plugin/packages/debug_utilities/conversion_procs.tcl
```

As you can see below, the user simply needs to issue the “package require” command to request the loading of the package. One can use the loaded command by specifying the complete namespace path to the commands such as

“`::my_company::debug_utilities::set_timer_start_point A`” but it is more convenient to import the commands into the local namespace using the “namespace import” command as shown below. After that, the procs becomes available locally as if they were defined in the local namespace.

Notice also the “u” proc in the example below. It is very useful again to enable debugging the source code of the procs without having to restart Tessian Shell. The “u” proc is slightly different than the one shown in [Example 1](#) as the pkgIndex.tcl file must be excluded from the reload.

```

> package require ::my_company::debug_utilities
1.0
> namespace import ::my_company::debug_utilities::*
> puts [join [info procs *timer*] \n]
report_timer_names
get_time_from_timer_start_point
set_timer_start_point
> puts [join [info procs *convert*] \n]
convert_to_wdhms
>
> proc u {} {
    namespace eval ::my_company::debug_utilities {
        set file_list [glob ../my_plugin/packages/debug_utilities/*.tcl]
        set pkgIndex_location [lsearch -glob $file_list */pkgIndex.tcl]
        foreach file_name [lreplace $file_list $pkgIndex_location \
                           $pkgIndex_location] {
            puts "updating $file_name"
            source $file_name
        }
    }
}
>
> set_timer_start_point A
Setting timer 'A' start time at '15:01:21'
> set_timer_start_point B
Setting timer 'B' start time at '15:01:21'
> get_time_from_timer_start_point A
weeks 0 days 0 hours 0 minutes 0 seconds 2
> get_time_from_timer_start_point B
weeks 0 days 0 hours 0 minutes 0 seconds 7

```

Content of the debug_utilities/pkgIndex.tcl file:

```

package ifneeded ::my_company::debug_utilities 1.0 \
    [string map [list @ $dir ! ::my_company::debug_utilities] {
        no_transcript { read_tcl [file join {@} timer_procs.tcl] \
                        -namespace {!} }
        no_transcript { read_tcl [file join {@} conversion_procs.tcl] \
                        -namespace {!} }
    }]
    package provide ::my_company::debug_utilities 1.0
}]
```

Content of the debug_utilities/timer_procs.tcl file:

```
variable timer_start_point_dict [dict create]

Chapter 15

Generation of ScanDEF

This chapter provides detailed information about ScanDEF.

ScanDEF File Generation	3931
ScanDEF File Format	3932

ScanDEF File Generation

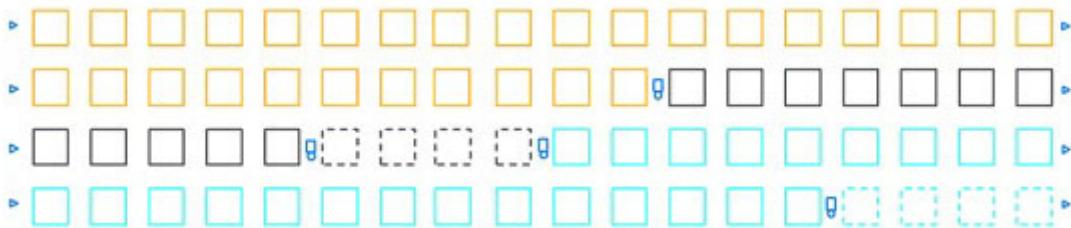

You use the command `write_scan_order` to generate the ScanDEF file.

In the legacy Tessent Shell scan insertion flow (which is equivalent to a single scan mode environment), every scan chain's make is unique and therefore can be written out into a scanDEF file using a simple structure. However, the same scan elements can be stitched into different scan chains in the Hierarchical Scan Insertion flow using a multi scan mode environment. Furthermore, since a single scanDEF file written out in the new flow would have to contain all scan elements regardless of the scan mode, it uses the unique scan segments rather than the unique scan chains to create the scan element groupings used by the layout tools for the scan chains optimization.

Each scan segment will comprise a set of scan path cells of a scan chain between the so called persistent components, which are buffer, mux, and/or (NOTE: only 2x1 actual MUXs are used; so, when there are more than 2 inputs, the AND/OR muxing is being used), and retiming cells. These persistent components will be written out into the START/STOP sections of each scanDEF segment corresponding to the scan segment, while the scan path cells of a scan segment will be written out into the ORDERED and/or FLOATING lists in the body section of a scanDEF segment.

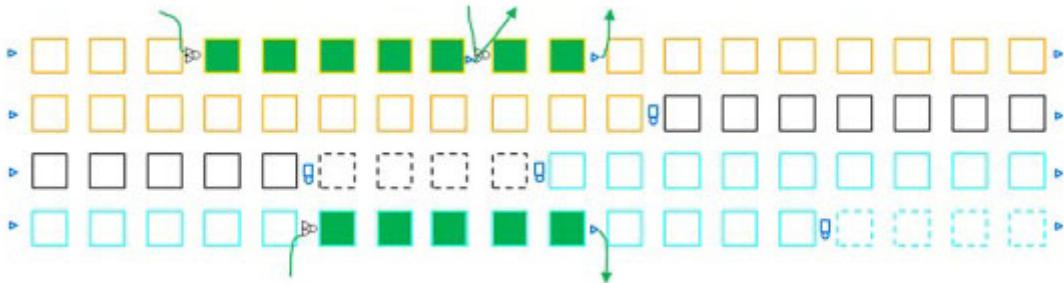

In the simplest case of scan chains in the single scan mode environment (see [Figure 15-1](#)), with four scan chains and three clock domains, each scan chain will be sub divided into the scan segments based on the clock/edge domain information, where the persistent components will consist of a buffer at the beginning and end of each scan chain and a retiming cell at the clock/edge domain transition points.

Figure 15-1. Single Scan Mode Environment

In the case of multi mode environment (see [Figure 15-2](#)), having InTest and ExTest scan modes, with four scan chains in the InTest mode, three wrapper chains in the ExTest mode, and three clock domains, each scan chain will be subdivided into the scan segments based on the clock/edge domain information plus the scan modes scan chains information. The persistent components in this case will consist of a buffer or mux (and/or) at the beginning of each scan chain, a buffer at the end of each scan chain, and a retiming cell at the clock/edge domain transition points.

Figure 15-2. Multi Scan Mode Environment

In general, the scan insertion tool always ensures that persistent gates exist at the beginning and end of scan chains, and when transitioning between constraint sets that need it. In addition, for power domain island transitions, persistent gates get inserted at the boundary of each power domain islands in order to simplify the insertion of level shifters.

Modules which have the “`exclude_from_concatenated_netlist`” attribute specified are considered as hard macros and are not included in the concatenated netlist. Moreover, when writing the scanDEF file, any traced scan elements from existing segments on these modules are omitted between the `scanIn` and `scanOut` sections of these segments, and stop at the SI/SO boundary, as is done for a cell library.

ScanDEF File Format

The new scanDEF file will contain all unique scan segments contributing to all scan chains in all scan modes.

The following is an example of a typical scanDEF segment:

```
- scan_segment_0
+ START tessent_persistent_cell_mux_stm1s1_intsi17_intsi13_i Y
+ ORDERED
    uWA/uA/f1 ( IN SI ) ( OUT Q )
    uWA/uA/bb/f2 ( IN SI ) ( OUT so )
    uWA/uA/f3 ( IN SI ) ( OUT Q )
+ FLOATING
    uWA/uA/f21 ( IN SI ) ( OUT Q )
+ STOP uWA/tessent_persistent_cell_buf_extso6_i A
# Partition constraints - clock domain: clk(+); chain type: core; scan
mode(s): InTest ExTest
+ PARTITION partition_1 MAXBITS 4 ;
```

Each scanDEF segment will start with unique segment name with following format:

scan_segment_%d

The START section will reference an output pin of a persistent component, which will be either a buffer, mux, or a retiming cell.

The STOP section will reference an input pin of a persistent component, which will be either a buffer or a retiming cell.

The body of a scanDEF segment will typically contain one or more FLOATING and/or ORDERED lists. Currently, an ORDERED list will be created for the cells on the known sub chain scan path (unless sub chain contains only 1 element) and the cells in a shift register. All other cells will be written out into the FLOATING lists.

In addition, a scanDEF segment will contain a PARTITION name. The PARTITION statement allows reordering tools to determine inter-segment compatibility for element swapping (both FLOATING elements and ORDERED elements): i.e. partition names determine the segments compatibility for repartitioning by swapping elements between them. Thus, segments with matching PARTITION names constitute a swap-compatible group. The length of the segments included in the same partition is specified by the MAXBITS constraint, which will be typically set to the number of elements in the segment's body. NOTE: if a PARTITION name is not provided, the segment is assumed to be in its own single partition and reordering can be performed only within this segment.

PARTITION name is generated based on the following criteria for a given scan segment: clock/edge domain, clusters this segment's scan chains belong to, power domains this segment's scan chains belong to, chain type (core, input_wrapper, output_wrapper), scan modes this segment's scan chains belong to. The mentioned criteria will be listed in the "Partition constraints" comment line.

scanDEF File Example

For the following scan chains configuration:
two scan modes, four scan chains in InTest, four scan chains in ExTest, four sub chains.

```
// command: report_scan_cells -scan_mode InTest
Scan mode 'InTest' scan cells:
-----
CellNo ChainName      GroupName Pathname   CellName ScanOut Clock ClockPolarity
-----
0  InTest_chain1 (schc1) grp1  /uWA/uA/f21 sff  Q    clk  (+)
1  InTest_chain1 (schi1) grp1  /uWA/uA/f1  sff  Q    clk  (+)
2  InTest_chain1 (schi1) grp1  /uWA/uA/bb/f2 sff  Q    clk  (+)
3  InTest_chain1 (schi1) grp1  /uWA/uA/f3  sff  Q    clk  (+)
0  InTest_chain2  grp1  /f1    sff  Q    clk2 (+)
0  InTest_chain3 (scho1) grp1  /uWA/uA/f31 sff  Q    clk  (+)
0  InTest_chain4 (schi2) grp1  /uB/f1    sff  Q    clk2 (+)
1  InTest_chain4 (schi2) grp1  /uB/f2    sff  Q    clk2 (+)
2  InTest_chain4 (schi2) grp1  /uB/f3    sff  Q    clk2 (+)
-----
// command: report scan cells -scan_mode ExTest
Scan mode 'ExTest' scan cells:
-----
CellNo ChainName      GroupName Pathname   CellName ScanOut Clock ClockPolarity
-----
0  ExTest_chain1 (schc1) grp1  /uWA/uA/f21 sff  Q    clk  (+)
1  ExTest_chain1 (schi1) grp1  /uWA/uA/f1  sff  Q    clk  (+)
2  ExTest_chain1 (schi1) grp1  /uWA/uA/bb/f2 sff  Q    clk  (+)
3  ExTest_chain1 (schi1) grp1  /uWA/uA/f3  sff  Q    clk  (+)
0  ExTest_chain2  grp1  /f1    sff  Q    clk2 (+)
0  ExTest_chain3 (scho1) grp1  /uWA/uA/f31 sff  Q    clk  (+)
0  ExTest_chain4 (schi2) grp1  /uB/f1    sff  Q    clk2 (+)
1  ExTest_chain4 (schi2) grp1  /uB/f2    sff  Q    clk2 (+)
2  ExTest_chain4 (schi2) grp1  /uB/f3    sff  Q    clk2 (+)
```

The scanDEF output will look as follows:

```
#  
VERSION 5.7 ;  
DIVIDERCHAR "/" ;  
BUSBITCHARS "[]" ;  
DESIGN A ;  
UNITS DISTANCE MICRONS 1000 ;  
  
SCANCHAINS 2 ;

What is a Parameter File?

The parameter file specifies field names and values for use in certain Vector Interfaces output formats.

The tool uses this file when you specify with the “[write_patterns](#) -Parameter” command.

The tool adds a section at the beginning of STIL, WGL, and Verilog output files that captures the environment data and the switches specified with the `write_patterns` command.

- In the STIL format, this information is added to the HEADER {} block as an annotation.
- In the WGL format, this information is added to the header block as a series of annotation statements.
- In the Verilog format, this information is added to the beginning of the Verilog test bench as a comment.

Parameter File Syntax

The parameter file is a text file containing a series of parameter statements.

Each statement uses the following format:

```
KEYWORD arguments;
```

Where:

- **UPPERCASE** — Indicates a keyword and must be entered exactly as shown.
- ***Italic*** — Indicates a user-supplied argument.
- {} — Indicates a multi-option argument. Include only one option and do not enter the braces.
- **Underline** — Indicates the default setting for a multi-option argument.

The parameter file has the following rules:

- All parameter statements must end with a semicolon.
- Comments are marked with double slashes “//” at the beginning of a line. The tool ignores everything between the slashes and the end of line character.
- You can use each parameter only once per file. If you use a parameter more than once, the latter entry overrides the previous one.

- Each parameter statement must occupy a single line. You cannot embed carriage returns within a parameter statement.
- Each parameter statement line cannot exceed 2048 characters. There are no restrictions on the parameter file size.

Note

 All parameters are optional, so you can include or exclude as needed. When you omit a parameter, the tool uses the default setting. Refer to each parameter description for the default behavior.

Parameter File Keywords

This is a list of the available parameter statements.

A Note about the ALL_* Parameter File Keywords

All of the ALL_* parameter file keywords affect all pattern formats except for binary and ASCII.

ALL_EDT_INTERNAL_USE_NUMBER_SHIFTS

This keyword applies the set_number_shifts specification to edt_internal patterns.

Usage

```
ALL_EDT_INTERNAL_USE_NUMBER_SHIFTS {0 | 1};
```

By default, when you use the `set_number_shifts` command with EDT on (compressed scan), the command specifies the number of external shifts used for loading the EDT channels (`write_patterns -edt_external`). However, when writing patterns using `-edt_internal`, the `set_number_shifts` specification does not apply. Setting `ALL_EDT_INTERNAL_USE_NUMBER_SHIFTS` to 1 applies the `set_number_shifts` specification to any `edt_internal` patterns that are written. This applies to serial Verilog test benches and the other tester formats.

ALL_EXCLUDE_POWER_GROUND

This keyword excludes any port with a “function” value of “power” or “ground” from the written pattern.

Usage

```
ALL_EXCLUDE_POWER_GROUND {AUTO | 1 | 0};
```

By default, the keyword excludes such ports in tester formats, such as WGL and STIL, and does not exclude such ports for Verilog or VHDL. Setting this keyword to 1 excludes power and ground ports from all formats (except binary and ASCII); setting this keyword to 0 prevents exclusion of power and ground ports.

Note that binary and ASCII patterns are not affected by this keyword.

This parameter keyword is affected by the `include_all_power_pins` property in the Patterns/
[AdvancedOptions](#) wrapper of the [PatternsSpecification](#).

ALL_EXCLUDE_UNUSED

Removes certain pins from patterns.

Usage

```
ALL_EXCLUDE_UNUSED {0 | 1};
```

The default is 1 or true. The keyword removes the following pins from patterns:

- All output pins that are masked.
- All input pins that are constrained to CX and are not used in any test procedures.
- All bidi pins that are constrained to CX or CZ and are either not used in any test procedures or are only forced to Z and masked in the test procedures.

Note that this keyword does not remove pins from a multi-bit bus unless it can remove the entire bus.

Setting this keyword to 0 or false disables the pin removal.

This keyword is affected by the include_all_power_pins property in the Patterns/
AdvancedOptions wrapper of the [PatternsSpecification](#).

Keyword Usage with IJTAG Patterns

For IJTAG patterns, a primary port is not considered unused if one of the following applies:

- The port is an IJTAG test clock (TCKPort or CaptureEnPort with Attribute function_modifier = “CaptureShiftClock” or function_modifier = “CaptureShiftClockInv”).
- The port has been added as a clock by means of the [add_clocks](#) command.
- The port is relevant for the application of the retargeted PDL as follows:
 - ScanInterface ports
 - DataInPorts and DataOutPorts required for the retargeting of [iRead](#) and [iWrite](#) commands
 - All ports that have been subject to [iComparePort](#) or [iForcePort](#)
 - If [import_patterns_from_svf](#) has been used; all ports that are in the SVF PIOMAP
 - All BSDL compliance ports (ICL ports with attribute compliance_value)

ALL_FIXED_CYCLES

Issuing a 2 with this keyword causes the tool to compute the largest number of cycles between scan loads by looking at all patterns in the pattern list, not just those being saved.

Usage

```
ALL_FIXED_CYCLES {2 | 1 | 0};
```

Issuing a 2 with this keyword causes the tool to compute the largest number of cycles between scan loads by looking at all patterns in the pattern list, not just those being saved. Issuing a 1 with this keyword specifies that the patterns will contain an equal number of non-scan cycles between each scan chain loading. This non-scan cycle is applied before the first shift cycle. The default is 0.

This will add “Shift” cycles before the regular apply shift of the load_unload procedure. It adds these additional cycles before the scan chain load to make all patterns have the same total

number of cycles per pattern, taking into account the differences in the number of capture cycles. The number of capture cycles can still vary depending on what ATPG needed or was directed with the Named Capture Procedures. However, no additional “Capture” cycles are added. The new cycles will use the timeplate that the “Shift” procedure uses.

ALL_FLATTEN_TIMING

Issuing a 1 with this keyword causes all outputs to compute existing timing equations and use only the resulting numeric values in the output files.

Usage

```
ALL_FLATTEN_TIMING {1 | 0};
```

Issuing a 1 with this keyword causes all outputs to compute existing timing equations and use only the resulting numeric values in the output files. The default of 0 will result in any output format which can support equation-based timing using the equations as they are specified.

This keyword is intended for having pattern output files not contain equation-based timing that has been added to the procedure file and preserved in the tool. Test data languages such as Verilog, WGL, and STIL have the ability to express time values in the timing blocks, as numerical values or as equations based on variables. Using equation-based timing allows one value to be specified for a global attribute, such as the test cycle period, while other values are derived from this using equations.

ALL_FULL_TIMEPLATES

When this keyword is set to 1 or true, all of the timeplates that have been defined and stored in the tool will be written to the resulting pattern file or test bench.

Usage

```
ALL_FULL_TIMEPLATES {0 | 1};
```

Without this, only timeplates that are marked as used by the patterns in the pattern range being written are used. Similar to **SIM_NAME_FILE**, this should be used when writing out a Verilog test bench that can be used with one design but multiple pattern sets. Turning on **ALL_FULL_TIMEPLATES** will ensure that all timeplates that could be referenced in the *.vec* files in different pattern sets are enumerated in the test bench.

ALL_HEADER_COMMENT

Specifies comment lines to add to the header of the pattern file.

Usage

```
ALL_HEADER_COMMENT string;
```

The string specified is added as a comment line to the header of the pattern file. Use an embedded newline ‘\n’ character for the comment string to span multiple lines.

Suppose you want to add comments to the header of a verilog pattern file. Do this with the following command:

```
write_patterns results/pat.v -replace -profile -ext -verilog -parameter_list \
{ALL_HEADER_COMMENT "Header Line 1\nHeader Line 2"}
```

These lines are added to the pattern file header:

```
// Header Line 1
// Header Line 2
```

ALL_IDDQ_TESTER_CYCLE

Issuing a 1 with this keyword forces the IDDQ file to contain tester cycle counts and serial simulation times even if the pattern file being saved is a parallel load pattern file.

Usage

```
ALL_IDDQ_TESTER_CYCLE {1 | 0};
```

Issuing a 1 with this keyword forces the IDDQ file to contain tester cycle counts and serial simulation times even if the pattern file being saved is a parallel load pattern file. Not using the keyword, or using it with a 0 argument invokes the default behavior where the IDDQ file uses tester cycle counts for serial pattern formats, and vector counts and parallel load times for parallel formats.

In the example, saving a parallel load pattern file for a particular design and using the -iddq_file, the IDDQ file has the following content:

```
/* Pattern # Cycle # Time */
0 71 7100
1 76 7600
...
```

Saving the same parallel load pattern file and using -iddq_file, but also using ALL_IDDQ_TESTER_CYCLE 1; produces an IDDQ file with the following content:

```
/* Pattern # Cycle # Time */
0 195 19500
1 324 32400
...
...
```

The cycle counts and times given now correspond to serially loaded tester cycle counts and simulation time stamps

ALL_MAX_LOOP

Sets a maximum loop count to use for a single loop. Any run loops that are larger than this value are split into multiple smaller loops, with most being the size specified by ALL_MAX_LOOP and the last loop giving the remainder.

Note

 This keyword only affects loops that are run loops generated by the IJTAG solver either in an [iCall](#) within test_setup or test_end, or for the context pattern -ijtag for retargeted patterns. See also the [iRunLoop](#) command.

Usage

```
ALL_MAX_LOOP N
```

N is a long integer value specifying the maximum loop count. The minimum value is 4, and the maximum is 2^{40} . The default for most pattern formats is off, but for the Verilog testbench the default is 2^{30} .

If you specify an incorrect value, the tool issues a warning stating that the value is illegal, and that the keyword is being ignored.

```
// Warning: Parameter Keyword ALL_MAX_LOOP has an illegal value, being
// ignored.
```

This keyword does not affect repeats or loops that come from repeated sub_procedures or loop statements within the test procedure file. As with all other parameter keywords, this only affects the STI pattern formats, such as the Verilog testbench, STIL, or WGL.

Related Topics

[iRunLoop](#)

ALL_MIN_SCAN_LOAD

Setting this keyword to 1 allows a scan load to specify only scan-in or scan out when appropriate.

Usage

```
ALL_MIN_SCAN_LOAD {1 | 0};
```

By default, all pattern outputs contain scan-in and scan out data for each scan load. Setting this keyword to 1 allows a scan load to specify only scan-in or scan out when appropriate (first scan in). The default is 0.

ALL_NO_CYCLE_OPT

This keyword specifies for all outputs to turn off cycle optimizations in non-scan areas of patterns and leave all cycles in the patterns.

Usage

```
ALL_NO_CYCLE_OPT {1 | 0};
```

When set to 1 (or omitting this keyword as it is the default), this keyword specifies that cycle optimization is not applied to remove duplicate cycles from clock_sequential and capture procedures. When set to 0, this keyword allows the following optimization in cycles that are part of the Capture or Clock procedures: If any two identical cycles are generated and do not measure any outputs, the duplicate cycles will be removed.

ALL_NO_LOOP

Disables the use of “loops” or “repeat” statements to represent sub_procedures.

Usage

```
ALL_NO_LOOP {1 | 0};
```

Disables the use of “loops” or “repeat” statements to represent sub_procedures. The default is off (0). For more information, refer to “[Disabling Sub_procedure Looping](#)” in the *Tessent Shell User’s Manual*.

ALL_NO_PATTERN_TYPE

If set to 1, this keyword eliminates the pattern type annotation.

Usage

```
ALL_NO_PATTERN_TYPE {1 | 0};
```

If set to 1, this keyword eliminates the pattern type annotation. This keyword applies to all Vector Interface formats. The default is 0.

Caution

 This keyword should only be used if the pattern type annotations are causing problems. If you set this keyword to 1, you will not be able to load the generated patterns back into the Tesson tools.

The keyword should not be used with any STIL or WGL pattern file to be read back in as it removes the pattern type annotation at the start of each pattern that identifies a pattern as something other than a basic scan pattern. With the clock_po pattern type annotation removed, the code to extract the ASCII pattern data from the STIL pattern file does not identify this as a clock_po pattern and incorrectly puts the pulse clock statement in and the unload scan chain statement. All STI patterns always have overlapped scan load and unload, so the unload is always present in the pattern data.

ALL_NONSCAN_CONSTANT

Setting this keyword to 1 forces all non-scan pins, excluding control and clock pins, to the constant value of the pad state for all scan patterns.

Usage

```
ALL_NONSCAN_CONSTANT {1 | 0};
```

Setting this keyword to 1 forces all non-scan pins, excluding control and clock pins, to the constant value of the pad state for all scan patterns. This keyword may be useful, as an alternative to procedure force statements, for testers that require constant pin values. The default is 0.

ALL_ORIGINAL_INDEX

When set to 1, saved pattern files use the original pattern index (from before filtering) for the annotations and comments prior to each pattern.

Usage

```
ALL_ORIGINAL_INDEX {1 | 0};
```

When set to 1, saved pattern files use the original pattern index (from before filtering) for the annotations and comments prior to each pattern. When set to 0 (the default), the pattern numbering in the comments and annotations is numbered in order starting at 0 from the first pattern as if the filtered patterns are a new pattern set. Note that this affects all types of pattern outputs other than Verilog because the Verilog test bench uses a built-in pattern count mechanism.

ALL_PRESERVE_FORCE_X

This keyword retains or removes explicitly forced X values on ports in the pattern file.

Usage

```
ALL_PRESERVE_FORCE_X {1 | 0};
```

If X values are present on input pins in a vector, then previous force values for this vector are copied from previous vectors in place of this X value.

Setting this keyword to 0 or false (the default) means that the tool ignores the explicitly forced X values on ports in the pattern file.

Setting this keyword to 1 or true instructs the tool to retain explicitly forced X values on ports in the pattern file.

ALL_TIME_RESOLUTION

This keyword is used to specify the number of significant bits for floating point time numbers.

Usage

```
ALL_TIME_RESOLUTION integer;
```

This keyword is used to specify the number of significant bits for floating point time numbers. The maximum is 4, and the default is 3.

ALL_USE_CYCLE_LOOP

Uses updated terminology in the generated pattern files to prevent confusion with Tessent Diagnosis terms.

Usage

```
ALL_USE_CYCLE_LOOP {1 | 0};
```

Uses updated terminology in the generated pattern files to prevent confusion with Tessent Diagnosis terms. The previous “cycle” and “loop” terms in the pattern files are replaced with “simulation cycle” or “vector” and “tester cycle”. Set this keyword to 1 to revert back to the “cycle” and “loop” terminology.

CTL_ONE_PAT

This keyword, if set to 1, causes all pattern data to be grouped into a single STIL pattern block, instead of one pattern block per ATPG pattern. The default is 0.

Usage

```
CTL_ONE_PAT {1 | 0};
```

This keyword, if set to 1, causes all pattern data to be grouped into a single STIL pattern block, instead of one pattern block per ATPG pattern. The default is 0.

CTL_NO_PROTO

This keyword, if set to 1, disallows protocol-level macros.

Usage

```
CTL_NO_PROTO {1 | 0};
```

This keyword, if set to 1, disallows protocol-level macros. The default of 0 allows protocol-level macros.

Note

 In addition to the three CTL parameter file keywords listed above, all parameter file keywords for STIL output also work with CTL output. The tool-generated CTL output can be customized using the above three parameters to be a more structural STIL output.

CTL_STIL_0

This keyword, if set to 1, causes the output to be backward compatible with the IEEE 1450.6 standard.

Usage

```
CTL_STIL_0 {1 | 0};
```

This keyword, if set to 1, causes the output to be backward compatible with the IEEE 1450.6 standard. The Environment block will be dropped and the STIL header will not mention the CTL extension. The default is 0.

Note

 CTL (IEEE 1450.6) is an extension of STIL that creates a standard format to describe IP core and SOC test information.

CTL_STIL_1

This keyword, if set to 1, causes the output to eliminate all 1450.6 syntax, but leaves the IEEE 1450.1 syntax.

Usage

```
CTL_STIL_1 {1 | 0};
```

This keyword, if set to 1, causes the output to eliminate all 1450.6 syntax, but leaves the IEEE 1450.1 syntax. The default is 0, which produces the full 1450.6 and 1450.1 syntax used in the CTL output.

The CTL_STIL_0 parameter file keyword can be used in the CTL output to eliminate the 1450.1 features along with all of the 1450.6 syntax.

For more information, refer to the “[write_patterns -CTL](#)” command description in the *Tessent Shell Reference Manual*.

FTDL_DESIGNER

Specifies an informational string to be used as the designer name in the DESIGNER statement at the top of the FTDL file.

Usage

```
FTDL_DESIGNER string;
```

Specifies an informational string to be used as the designer name in the DESIGNER statement at the top of the FTDL file. If not specified, the default is “ATPG”.

FTDL_MAX_PAT_BLOCK

Specifies the maximum number of vector statements allowed in a single TEST block, including all shifted values and repeated vectors.

Usage

```
FTDL_MAX_PAT_BLOCK integer;
```

Specifies the maximum number of vector statements allowed in a single TEST block, including all shifted values and repeated vectors. If not specified, the default is 5 million.

FTDL_REVISION

Specifies an informational string to be used as the revision string in the REVISION statement at the top of the FTDL file.

Usage

```
FTDL_REVISION string;
```

Specifies an informational string to be used as the revision string in the REVISION statement at the top of the FTDL file. If not specified, the default is “0001”.

FTDL_TCOMMENT

Setting this keyword to a string allows the user to override the default TCOMMENT field in the FTDL pattern with a custom entry.

Usage

```
FTDL_TCOMMENT string;
```

FTDL_TEST_NAME

Specifies the root name to be used for the test block(s) within the FTDL file. If not specified, the default root name is “FN”.

Usage

```
FTDL_TEST_NAME string;
```

Specifies the root name to be used for the test block(s) within the FTDL file. If not specified, the default root name is “FN”. The root name is combined with a test number to create each test block name.

FTDL_TEST_NUM

Specifies the starting test block number, to be appended to the root test block name.

Usage

```
FTDL_TEST_NUM integer;
```

Specifies the starting test block number, to be appended to the root test block name. For each additional test block needed in the FTDL file, the test number is incremented. If not specified, the starting test block number is 1.

FTDL_TEST_SUFFIX

Specifies a string to add as a suffix to the test block name.

Usage

```
FTDL_TEST_SUFFIX string;
```

Specifies a string to add as a suffix to the test block name. The total test block name is constructed from FTDL_TEST_NAME, FTDL_TEST_NUM, and optionally, FTDL_TEST_SUFFIX. The required argument *string* is the suffix that will be added after the test block number. The default is to have no suffix.

FTDL_ZMODE_MES

Controls whether the FTDL file allows for Z values to be measured on output pins and output sides of bidi pins.

Usage

```
FTDL_ZMODE_MES {1 | 0};
```

Controls whether the FTDL file allows for Z values to be measured on output pins and output sides of bidi pins. If set to 0, then the “ZMODE = NOMES” statement will be placed in all TEST blocks within the FTDL file, and no Z values will be used on output pins. If set to 1, then the “ZMODE = MES” statement are placed in all TEST blocks, and Z values are allowed on output pins. The default is 0, NOMES.

Keywords FTDL_TEST_NAME and FTDL_TEST_NUM are used together to create the name(s) of the TEST block(s) within the FTDL file.

Keyword FTDL_MAX_VEC_BLOCK is used to set the maximum number of vector statements allowed in a single TEST block within the FTLD file.

Keywords FTDL_REVISION and FTDL_DESIGNER simply supply informational strings to be used within the FTDL file.

Keyword FTDL_ZMODE_MES controls whether ZMODE = MES, or ZMODE = NOMES, and is used in the FTDL file.

The following is an example parameter file for FTDL.

```
FTDL_TEST_NAME "MyTest";
FTDL_REVISION "001.1";
FTDL_DESIGNER "Smith";
FTDL_ZMODE_MES 1;
```

SIM_ANNOTATE QUIET

When set to 1, this keyword suppresses the Verilog test bench from displaying the annotations during simulation.

Usage

```
SIM_ANNOTATE QUIET {1 | 0};
```

When set to 1, this keyword suppresses the Verilog test bench from displaying the annotations during simulation. The default behavior is to display the annotations.

SIM_CHAIN_ERROR

Setting this parameter to 1 adds a register/signal per scan chain to the Verilog test bench.

Usage

```
SIM_CHAIN_ERROR {1 | 0};
```

Setting this parameter to 1 adds a register/signal per scan chain to the Verilog test bench. This signal may be monitored during simulation and goes to 1 when a mismatch is detected on the scan chain. The name of the register/signal is mgcdft_chainname_error where *chainname* is the chain name specified on the add_scan_chains command line. The default is 0.

SIM_CHANGE_PATH

Setting this parameter to 1 inserts code into the test bench that allows you to change the path to the files during simulation.

Usage

```
SIM_CHANGE_PATH {1 | 0};
```

Setting this parameter to 1 inserts code into the test bench that allows you to change the path to the files during simulation. Use the VERILOG PlusArgs keyword “`NEWPATH=`” to pass a new file path to test bench. The tool adds a path separator after the string from the `+NEWPATH` plusarg before the filename. For example:

```
vsim top_CngP_v_ctl +NEWPATH=./results -c -voptargs=+acc=npr \
-do "run -all"
```

Note

 SIM_CHANGE_PATH and **SIM_KEEP_PATH** are mutually exclusive.
SIM_CHANGE_PATH is ignored if SIM_KEEP_PATH is present.

SIM_COMPARE_SUMMARY

Writes a summary of compares in the test bench at the end of simulation.

Usage

```
SIM_COMPARE_SUMMARY {1 | 0};
```

Using this keyword causes the following statements to be displayed by the test bench at the end of simulation:

- Simulation finished at time *sim_time*
- Number of miscomparisons = *num*
- Number of 0/1 compares = *num*
- Number of Z compares = *num*

SIM_COMPARE_X

When set to 1, this parameter adds code to the test bench to not mask X states, but to compare for differences.

Usage

```
SIM_COMPARE_X {1 | 0};
```

When set to 1, this parameter adds code to the test bench to not mask X states, but to compare for differences. This functionality is available in both Serial and Parallel test benches. Issuing a 0, the default behavior, causes the test bench to not include these capabilities.

Note

 While issuing a mismatch if we expect X is not required for ATPG, it is necessary for LibComp verification to identify cases where the translation is pessimistic; otherwise, modeling a state such as a Tie-X will not look like a problem since you won't get mismatches.

SIM_DELAY_SCAN_RELEASE

This keyword and positive integer pair delays the scan release in the parallel test bench by the specified number.

Usage

```
SIM_DELAY_SCAN_RELEASE integer;
```

This keyword and positive integer pair delays the scan release in the parallel test bench by the specified number. The unit of the specified *integer* is the same as the timescale units. If there are multiple chains, each release is delayed by the specified *integer*.

By default, the parallel test bench uses the timing from the shift procedure to produce the force, release, and shift clock events. The release occurs at the end of the shift procedure. Since the parallel test bench forces the clock events at the device boundary, but the force and release events happen at the cell boundaries, clock propagation delay can cause the clock edges to arrive after the release. If the period of the shift procedure is not large enough to prevent the late arrival of the clock edges, you can specify an additional delay to the release using the **SIM_DELAY_SCAN_RELEASE** keyword, which adds to the period of the shift procedure for the parallel test bench only.

The **SIM_DELAY_SCAN_RELEASE** keyword cannot be specified with the **SIM_STRETCH_SCAN_RELEASE** keyword as the two keywords will cause two different mechanisms for delaying the scan release event to be used together. In the event both keywords are specified, the tool issues a warning that the keywords are mutually exclusive. In this case, the **SIM_STRETCH_SCAN_RELEASE** keyword will override the **SIM_DELAY_SCAN_RELEASE** keyword.

SIM_DIAG_FILE

Controls the generation of the failure file in the test bench.

Usage

```
SIM_DIAG_FILE {2 | 1 | 0};
```

Controls the generation of the failure file in the test bench. The failure file name is generated by appending the test bench file name with “.fail”. For example, a test bench file named *testbench.v* would generate a failure file named *testbench.v.fail*.

For uncompressed ATPG, this keyword works for both serial and parallel Verilog test benches. For compressed ATPG, the keyword only works for the serial Verilog test benches and has no impact on the parallel test bench.

For “patterns -scan” context, the default setting is 1. For all other contexts, the default is 0. The options for this parameter are as follows:

- **0** — No Verilog code for generating the failure file is included in the test bench. This setting maintains backward compatibility with previous test bench versions.
- **1** — Verilog code for generating the failure file is included in the test bench, but the file is not automatically generated. To activate generation of the failure file, you must edit the test bench, setting the “_write_DIAG_file” parameter to 1.
- **2** — Verilog code for generating the failure file is included and activated in the test bench. You can explicitly disable failure file generation by setting the “_write_DIAG_file” parameter to 0 in the test bench.

SIM_DISTRIBUTED_PAT

Turns off the enhanced Verilog test bench that allows you to choose which patterns to simulate.

Usage

```
SIM_DISTRIBUTED_PAT {1 | 0};
```

Turns off the enhanced Verilog test bench that allows you to choose which patterns to simulate. When set to 0, all saved patterns are simulated. When set to 1 (the default), this statement allows you to choose which patterns to simulate.

SIM_DUMPFILE_PATH

You can then use the STARTPAT and ENDPAT PlusArgs keywords to specify the starting and ending patterns. For example, the following runs the simulation using pattern files 2 through 10:

```
vsim simple_testbench_v_ctl -c -do vsim.do +STARTPAT=2 +ENDPAT=10
```

If you specify only the ENDPAT keyword, the simulation begins with the first pattern or file and end at the specified pattern or file. For example, the following runs the simulation for the first four patterns:

```
vsim simple_testbench_v_ctl -c -do vsim.do +ENDPAT=4
```

If you specify only the STARTPAT keyword, the simulation starts with the specified pattern or file and end at the last pattern or file. For example, the following runs the simulation for pattern files 3 through 20, where 20 is the last pattern file:

```
vsim simple_testbench_v_ctl -c -do vsim.do +STARTPAT=3
```

To simulate a single pattern, specify the same value both the start and end keywords. For example, the following runs the simulation for only pattern 8:

```
vsim simple_testbench_v_ctl -c -do vsim.do +STARTPAT=8 +ENDPAT=8
```

SIM_DUMPFILE_PATH

Specifies the path of all dump files during Verilog simulation.

Usage

```
SIM_DUMPFILE_PATH pathname;
```

Specifies the path of all dump files during Verilog simulation.

SIM_EARLY_RELEASE

Designates the Verilog test bench to put the “release” statement immediately after the trailing edge of the first clock pulse in the shift procedure.

Usage

```
SIM_EARLY_RELEASE {1 | 0};
```

Designates the Verilog test bench to put the “release” statement immediately after the trailing edge of the first clock pulse in the shift procedure. Issuing a 0, the default behavior, will place the “release” statement at the end of the cycle.

SIM_EARLY_RELEASE_LAST

Used in conjunction with the SIM_EARLY_RELEASE_TIME keyword.

Usage

```
SIM_EARLY_RELEASE_LAST {1 | 0};
```

When multi-cycle shift procedures are present, by default **SIM_EARLY_RELEASE** causes the scan release to happen in the cycle that has the force_sci statement at the time specified. When the SIM_EARLY_RELEASE_LAST keyword is specified, the time specified by **SIM_EARLY_RELEASE_TIME** is applied to the last cycle in the multi-cycle shift procedure.

SIM_EARLY_RELEASE_TIME

Specifies exactly what time you want the Verilog test bench “release” statement to happen using the time scale specified in the procedure file.

Usage

```
SIM_EARLY_RELEASE_TIME integer;
```

Specifies exactly what time you want the Verilog test bench “release” statement to happen using the time scale specified in the procedure file. The integer value is a time value that is required to be in the same time scale as that used in the timeplate for the shift procedure. The time specified must be later than the time of the force_sci event, but not greater than the time of the end of the cycle that the force_sci event occurs in. The time is relative to the start of the cycle.

This keyword does not replace the SIM_EARLY_RELEASE keyword, but can be used as an alternative. If both the SIM_EARLY_RELEASE and the SIM_EARLY_RELEASE_TIME keywords are specified in the parameter file, then the SIM_EARLY_RELEASE_TIME keyword takes precedence. If neither keyword is used, then the default behavior of putting the “release” statement at the end of the cycle is still used.

Note

 The SIM_EARLY_RELEASE and SIM_EARLY_RELEASE_TIME statements are helpful when complex scan cells that use multiple clocks need the release to happen at a certain time prior to the end of the shift procedure, in order for the parallel load test bench to load the correct values. That is, if the forced value is held too long, a second clock pulse will latch in the wrong value.

SIM_FILL_BIDISCAN

Setting this keyword to 1 sets the bidirectional scan_input pins to the scan-in value of the first cell.

Usage

```
SIM_FILL_BIDISCAN {1 | 0};
```

By default, the bidirectional scan_input pins are set to “X” during parallel scan loading in the Verilog test bench. Setting this keyword to 1 sets the bidirectional scan_input pins to the scan-in value of the first cell.

SIM_FORCE_Z_AT_CYCLE

Controls when a bidi pin switches to a Z state in the Verilog test bench.

Usage

```
SIM_FORCE_Z_AT_CYCLE {1 | 0};
```

Controls when a bidi pin switches to a Z state in the Verilog test bench. The default behavior is that when a bidi pin is going to change to a Z value during a given simulation vector, then the Z is forced at time 0 for that vector. However, when you set the keyword value to 0, the Z value applies to the bidi pin at the force time specified in the timeplate rather than at time 0. Note that if the force time happens after the internal driver for the bidi pin turns on, bus contention is possible.

SIM_INCLUDE

Adds an include statement into the Verilog test bench after the comments and before the first module.

Usage

```
SIM_INCLUDE filename;
```

Adds an include statement into the Verilog test bench after the comments and before the first module. The contents of the filename specified must contain legal Verilog statements and syntax. This statement is used only in the Verilog outputs. The Default behavior is to not add any include statements.

SIM_INSTANCE_NAME

Specifies the instance name for your design, to be used within the test bench.

Usage

```
SIM_INSTANCE_NAME string;
```

Specifies the instance name for your design, to be used within the test bench.

For example, if your current design is simple_chain2 and you want to specify the instance name presy, this is the entry in the parameter file:

```
SIM_INSTANCE_NAME presy ;
```

And this is the test bench:

```
// top_module_name = simple_chain2_pat_par_v_ctl
module simple_chain2_pat_par_v_ctl;

simple_chain2 presy (.reset(reset), .clk(clk), .in1(in1),
    .scan_in1(scan_in1), .scan_en(scan_en), .out0(out0),
    .out1(out1), .out2(out2), .out3(out3), .all0(all0),
    .all1(all1), .wlout(wlout), .scan_out1(scan_out1));
```

SIM_KEEP_PATH

Causes the Verilog test bench to use the complete pathname entered on the command line to specify the pattern data file.

Usage

```
SIM_KEEP_PATH {1 | 0};
```

Causes the Verilog test bench to use the complete pathname entered on the command line to specify the pattern data file. Issuing a 0, the default behavior, causes the Verilog test bench to specify the pattern data file without any path information.

Note

SIM_CHANGE_PATH and **SIM_KEEP_PATH** are mutually exclusive.
SIM_CHANGE_PATH is ignored when **SIM_KEEP_PATH** is present.

SIM_MASK_FILE

Controls the generation of the mask file, which captures simulation mismatches, in the test bench.

Usage

```
SIM_MASK_FILE {2 | 1 | 0};
```

Controls the generation of the mask file, which captures simulation mismatches, in the test bench. The mask file name is generated by appending the test bench file name with “.mask”. For example, a test bench file named *testbench.v* would generate a mask file named *testbench.v.mask*.

For “patterns -scan” context, the default setting is 1. For all other contexts, the default is 0.

- **0** — No Verilog code for generating the mask file is included in the test bench. This setting maintains backward compatibility with previous test bench versions.
- **1** — Verilog code for generating the mask file is included in the test bench, but the file is not automatically generated. To activate generation of the mask file, you must edit the test bench, setting the “_write_MASK_file” parameter to 1.
- **2** — Verilog code for generating the mask file is included and activated in the test bench. You can explicitly disable mask file generation by setting the “_write_MASK_file” parameter to 0 in the test bench.

Note

 The simulation mismatches for the ChainTest patterns are recorded in the SIM_MASK_FILE, but they are commented out.

SIM_MIN_NAME_FILE

Controls the number of *.name* output files generated when saving patterns as a Verilog test bench.

Usage

```
SIM_MIN_NAME_FILE {1 | 0};
```

Controls the number of *.name* output files generated when saving patterns as a Verilog test bench. Setting this keyword to 0 causes the tool to generate a separate set of *.name* files for each test bench file. When using the -maxloads switch for large designs with many scan chains and patterns, this generates a very large number of files. Setting this keyword to 1 reduces the

number of output files by generating only one set of *.name* files for a design. The same *.name* files can be used for all generated Verilog test benches for that design.

This parameter file keyword is on by default when you use the [write_patterns](#) command with the -maxloads switch. It is off by default otherwise.

SIM_MISCOMPARE_LIMIT

Sets a limit in the Verilog test bench for the number of miscompares to allow before the simulation terminates.

Usage

```
SIM_MISCOMPARE_LIMIT integer;
```

Sets a limit in the Verilog test bench for the number of miscompares to allow before the simulation terminates. By default, the test bench runs the simulation until all saved patterns are simulated, regardless of how many miscompares happen. This keyword causes the simulation to abort upon reaching the miscompare limit.

SIM_MODULE_INCLUDE

Similar to the SIM_INCLUDE parameter, except it adds the include statement within the module definition for the test bench instead of after the comments and before the first module.

Usage

```
SIM_MODULE_INCLUDE filename;
```

Similar to the SIM_INCLUDE parameter, except it adds the include statement within the module definition for the test bench instead of after the comments and before the first module. The *filename* can be any valid file path. The contents of the specified file must contain legal Verilog statements and syntax. This statement is used only in the Verilog outputs. The default behavior is to not add any include statements.

SIM_MODULE_NAME

Specifies a string that overrides the module name of the DUT in the Verilog simulation test bench.

Usage

```
SIM_MODULE_NAME string;
```

SIM_NAME_FILE

Specifies a string that overrides the module name of the DUT in the Verilog simulation test bench.

SIM_NAME_FILE

Allow multiple test benches to use the same name files regardless of the name of the test bench.

Usage

```
SIM_NAME_FILE {1 | 0};
```

When writing out multiple test benches where only one is meant to be compiled and used, and the other data sets will be used (.cfg and .vec files) to simulate patterns using the one common test bench, this keyword should be used so that only one set of name files is written (*.po.name* and *.chain.name*) to save on disk space.

SIM_NO_CHAINNAME_FILE

This keyword controls the creation of chain name files. Setting this keyword to 1 prevents the generation of chain name files.

Usage

```
SIM_NO_CHAINNAME_FILE {1 | 0};
```

When saving a Verilog test bench, the tool, by default, generates a single chain name file with all the scan cell names. The names are loaded into one register in the test bench so that when mismatches occur during simulation, the test bench reports the mismatches by cell name, rather than by scan chain name and cell number. To avoid exceeding the limit of the register size, if there are more than two million scan cells, the tool default changes to automatically create one chain name file per scan chain.

When the chain name files are created, there is an increase in the number of files written, the disk space used, and the memory footprint of the Verilog test bench. This impacts simulation time when the design is large and when, due to memory constraints, the Verilog simulator needs to swap memory while running. The performance impact of chain name file creation is due to increased memory use rather than extra processing within the test bench during simulation, and influenced by design size and amount of memory available.

Setting this keyword to 1 prevents the tool from generating the chain name files. It also reduces the Verilog test bench memory footprint, the number of files written, and amount of data stored on the disk, and potentially speeds up simulation.

SIM_NO_INTERNAL_COMPARE

Enables or disables internal compares for the internal expect statements in the Verilog testbench.

Usage

```
SIM_NO_INTERNAL_COMPARE {1 | 0};
```

If there are expect statement in the procedure file on internal registers, then these expect statements will generate internal compares in the generated Verilog test bench. When this parameter is set to 1 or true, the generated Verilog testbench will not have internal compares for the internal “expect” statements.

The default is 0 or false.

SIM_NO_MEASURE_IN

In the Verilog test bench, when a value is being forced on a bidirectional pin (as in input mode), the test bench also tries to measure the same value on the bidirectional pin when a measure happens.

Usage

```
SIM_NO_MEASURE_IN {1 | 0};
```

In the Verilog test bench, when a value is being forced on a bidirectional pin (as in input mode), the test bench also tries to measure the same value on the bidirectional pin when a measure happens. Setting this keyword to 1 causes the test bench to not measure input values on the output side of bidirectional pins. The default is 0.

When you issue a “[write_patterns](#) -Verilog -mode LSI” command, the tool automatically sets SIM_NO_MEASURE_IN to 1.

SIM_PARALLEL_DELAY_SHIFT_CLOCKS

Delays the leading edge of all shift clocks in all shift procedures by the specified number of timescale units.

Usage

```
SIM_PARALLEL_DELAY_SHIFT_CLOCKS {integer};
```

Delays the leading edge of all shift clocks in all shift procedures by the specified number of timescale units. Any events occurring after the leading edge of the first shift clock is also

delayed to maintain the event order. The specified number must be a positive integer. If the specified delay causes any event to occur beyond the period of the timeplate, the tool ignores this keyword.

This keyword is valid only for Verilog parallel test bench generation.

SIM_PARALLEL_EARLY_FORCE_AND_MEASURE

Setting this keyword to 1 or true moves the measure_sco event to time 0 and the force_sci event to time 1.

Usage

```
SIM_PARALLEL_EARLY_FORCE_AND_MEASURE {1 | 0 | true | false};
```

Setting this keyword to 1 or true moves the measure_sco event to time 0 and the force_sci event to time 1. By default (0 or false), the measure_sco event occurs at the measure_po time specified in the timeplate for the shift procedure. The force_sci event then occurs one timescale unit later, regardless of the force_pi time specified in the timeplate.

This keyword is valid only for Verilog parallel test bench generation.

SIM_POST_SHIFT

Specifies the absolute number of independent post shifts to use during simulation.

Usage

```
SIM_POST_SHIFT integer;
```

Specifies the absolute number of independent post shifts to use during simulation. That is, if the load_unload procedure already has one post shift, setting this keyword to “2” causes two post shifts to be used rather than three.

If you specify a negative number or zero, the tool ignores this keyword. If you specify a number larger than the total number of shifts, the tool sets the number of post shifts to the total number of shifts minus one.

You can use this keyword to generate a parallel simulation test bench that applies a parallel load followed by N number of serial shift cycles. When used in the “patterns -scan” context, SIM_POST_SHIFT serial shift cycles are applied by forcing the scan-in values onto the scan pin of the design. You can also use this keyword to generate an EDT parallel simulation test bench; in this case, the serial shifts are performed on the EDT internal scan chains and the test bench forces values onto the scan ports driven by the decompressor.

However, you cannot use this keyword to generate an EDT parallel simulation test bench in which the serial inputs are shifted in through the EDT channels because serial simulation through the decompressor and other EDT logic is not supported by parallel test bench.

SIM_PRE_SHIFT

Specifies the absolute number of independent pre shifts to the load_unload procedure (prior to main shift) to use during simulation.

Usage

```
SIM_PRE_SHIFT integer;
```

Specifies the absolute number of independent pre shifts to the load_unload procedure (prior to main shift) to use during simulation. That is, if the load_unload procedure already has one pre shift, setting this keyword to “2” causes two pre shifts to be used rather than three.

If you specify a negative number or zero, the tool ignores this keyword. If you specify a number larger than the total number of shifts, the tool sets the number of pre shifts to the total number of shifts minus one.

SIM_PRECISION

Specifies the timescale precision.

Usage

```
SIM_PRECISION string;
```

Specifies the timescale precision. The string is a number and a unit, for example:

```
SIM_PRECISION 1ns;  
SIM_PRECISION 10ms;
```

The units supported are ms, us, ns, ps, and fs.

The tool checks this value to verify that it is less than or equal to the Timescale unit from the procedure file and outputs this value in the test benches.

SIM_SERIAL_CHAIN

Creates a test bench that applies chain test patterns in serial mode and all other patterns in parallel mode (when set to 1).

Usage

```
SIM_SERIAL_CHAIN {1 | 0};
```

Creates a test bench that applies chain test patterns in serial mode and all other patterns in parallel mode (when set to 1). The keyword is set to 0 by default.

SIM_SHIFT_DEBUG

Specifies for the serial Verilog test bench to use special test patterns that contain a parallel observe of the entire scan chain for every shift, while serially shifting the patterns.

Usage

```
SIM_SHIFT_DEBUG integer;
```

Specifies for the serial Verilog test bench to use special test patterns that contain a parallel observe of the entire scan chain for every shift, while serially shifting the patterns.

For debugging purposes only, this format makes it easier to pinpoint precisely which scan cell in a chain is causing a problem. Issuing a 0, which is the default behavior, causes the serial Verilog test bench to use test patterns that do not contain a parallel observe of the entire scan chain for every shift.

An integer value of 1 causes the test bench to shift serially and do a parallel compare for all shifts. An integer value of 2 or greater causes the test bench to shift serially and do parallel compares on the first 2 or greater shifts. This is done to reduce the amount of data in the pattern files.

The Verilog patterns you create using the keyword SIM_SHIFT_DEBUG typically take more time for the tool to create than other kinds of patterns and contain large amounts of data (so file sizes tend to be huge). Also, because they simulate serially, the patterns take more time to simulate. Be sure these are acceptable trade-offs before trying to use these patterns.

The tool ignores the SIM_SHIFT_DEBUG keyword unless you include the “[write_patterns -Serial](#)” switch. Also, if you do not include the -End or “-pattern_sets chain” options, the tool defaults to “-End 0”, saving chain test patterns and the first scan pattern. To save chain test patterns and a different set of scan patterns, use the -Begin and/or -End switches to specify the range of scan test patterns to save. To save only chain test patterns, include the “-pattern_sets chain” option.

Note that this functionality is available only for patterns created in the “patterns -scan” context and EDT bypass patterns (uncompressed).

SIM_SIGNAL_SPY

Specifies to use the SignalSpy functions \$signal_force, \$signal_release, and \$init_signal_spy (for observing the scan outs) to do a parallel load of the scan chain (when set to 1).

Usage

```
SIM_SIGNAL_SPY {1 | 0};
```

Specifies to use the SignalSpy functions \$signal_force, \$signal_release, and \$init_signal_spy (for observing the scan outs) to do a parallel load of the scan chain (when set to 1). There are three integer variables in the test bench that you can change from “0” to “1” to get verbose messaging from the SignalSpy functions. The variables are _ssi_verbose for \$init_signal_spy, _ssf_verbose for \$signal_force, and _ssr_verbose for \$signal_release. The default is 0, which specifies to use the standard Verilog force and release to do a parallel load of the scan chain.

These functions work only with the ModelSim Verilog simulator. The SignalSpyPathSeparator in the modelsim.ini file must not be set or be set to the default of “/”.

SIM_STATUS_MSG

Specifies the frequency of status messages output from the Verilog simulation test benches.

Usage

```
SIM_STATUS_MSG integer;
```

Specifies the frequency of status messages output from the Verilog simulation test benches. This keyword accepts an integer that specifies the interval (number of patterns) to wait before outputting a message. The simulation message is “Simulated *n* patterns.”

SIM_STRETCH_SCAN_RELEASE

Delays the release scan event in the parallel Verilog testbench by stretching the end of the shift cycle.

Usage

```
SIM_STRETCH_SCAN_RELEASE integer;
```

This keyword and positive integer pair delays the release scan event in the parallel Verilog testbench by stretching the end of the shift cycle by the amount specified by the *integer* argument to the keyword. The unit of the specified *integer* is the same as the timescale units. If there are multiple chains, each release scan event is delayed by the specified *integer*.

The SIM_STRETCH_SCAN_RELEASE keyword cannot be used at the same time as SIM_DELAY_SCAN_RELEASE as the two keywords will cause two different mechanisms for delaying the scan release event. In the event both keywords are specified, the tool issues a warning that the keywords are mutually exclusive, and, in this case, the SIM_STRETCH_SCAN_RELEASE keyword will override the SIM_DELAY_SCAN_RELEASE keyword.

SIM_TIMEPLATE_COMM

Turns on timeplate comments in the vector file.

Usage

```
SIM_TIMEPLATE_COMM {1 | 0};
```

Turns on timeplate comments in the vector file. The default is off (0). When you set this parameter to 1, the tool adds comments for the timeplate to the vector file. The format of the timeplate comment is:

```
// Timeplate: <timeplate_name>
```

SIM_TMP_REG_LENGTH

Changes the default length of the NEWPATH variable used in the generated testbench.

Usage

```
SIM_TMP_REG_LENGTH integer;
```

Overrides the default (512) limit for the NEWPATH variable used for filenames in the testbench.

If you specify a value less than the path of the generated testbench, the tool ignores this value and issues a warning similar to the following:

```
// Warning: Ignored SIM_TMP_REG_LENGTH of 12, because its value cannot be
// less than 54, the length of the file name
// 'results/user_specified_path_length_that_is_too_short.v'.
```

SIM_TOP_NAME

Specifies a new top level module name for the Verilog test bench.

Usage

```
SIM_TOP_NAME string;
```

Specifies a new top level module name for the Verilog test bench. The default behavior is to generate a default top level module name based on the design name and the name of the pattern file.

SIM_VECTOR_COMM

Set this keyword to 1 to turn on vector type comments in the vector file, the default is off.

Usage

```
SIM_VECTOR_COMM {1 | 0};
```

Set this keyword to 1 to turn on vector type comments in the vector file, the default is off. The format of the vector type comment is:

```
// Vector type: vector_type_string
```

Where *vector_type_string* is one of the vector types listed in [Table A-1](#).

Table A-1. Vector Types

Vector Type	Definition
TEST_SETUP	Vector from test_setup procedure.
TEST_END	Vector from test_end procedure.
SEQ_TRANSPARENT	Vector from seq_transparent procedure.
CLOCK PROCEDURE	Vector from clock procedure.
CLOCK PROCEDURE RESTORE	Vector from clock procedure that uses restore_bidi event.
LOAD_UNLOAD	Vector from load_unload procedure.
SHIFT	Vector from shift procedure.
SINGLE_SHIFT	Single shift vector applied in load_unload procedure.
SHIFT_EXTRA	Vector from multicycle shift procedure that does not contain the force_sci and measure_sco events.
SHADOW_CONTROL	Vector from shadow_control procedure.
MASTER_OBSERVE	Vector from master_observe procedure.
SHADOW_OBSERVE	Vector from shadow_observe procedure.
SKEW_LOAD	Vector from skew_load procedure.

Table A-1. Vector Types (cont.)

Vector Type	Definition
PRIMARY ¹	Vector from a non-scan procedure such as capture, named capture, clock_sequential, or ram_sequential.
PRIMARY_MEASURE ¹	Vector from a non-scan procedure that measures primary outputs.
PRIMARY_CLOCKPO ¹	Vector from a clock_po procedure.

1. In addition to the above, the “PRIMARY” vector types can have “_IDQ” appended to the end to indicate an idq measure point.

SIM_VECTYPE_SIGNAL

When set to 0, specifies that all vector types in the currently active procedure be represented in the pattern file as a signal, and that these signals be “1” when that vector type is active.

Usage

```
SIM_VECTYPE_SIGNAL {1 | 0 | 2};
```

When set to 0, specifies that all vector types in the currently active procedure be represented in the pattern file as a signal, and that these signals be “1” when that vector type is active. This allows you to specify the patterns for tracing and viewing so you can see what type of vector is currently active at any specified moment within a simulation. For an example of using this keyword, refer to “[Simulation Data Analysis](#)” in the *Tessent Scan and ATPG User's Manual*.

When set to 1, this keyword adds an encoded vector type to the Verilog or VHDL test bench in the bus MGCDFT_VECTYP[0-3]. [Table A-2](#), lists the signal or variable names added to the test bench that map to the bus encoding. Setting the keyword to 0 causes the test bench to not include these capabilities.

Table A-2. Translation Table

MGCDFT_VECTYP[0-3] Encoding	Signal/Variable
0001	mgcdft_test_setup
0010	mgcdft_load_unload
0011	mgcdft_shift
0100	mgcdft_single_shift
0101	mgcdft_shift_extra
0110	mgcdft_shadow_control
0111	mgcdft_master_observe
1000	mgcdft_shadow_observe

Table A-2. Translation Table (cont.)

MGCDFT_VECTYP[0-3] Encoding	Signal/Variable
1001	mgcdft_skew_load
1010	mgcdft_seq_transparent
1011	mgcdft_launch_capture
1100	mgcdft_shift
1101	mgcdft_clock_proc
1110	mgcdft_clock_proc_restore
1111	mgcdft_test_end
0000	mgcdft_unknown

Note

 Adding signals indicating vector type to the Verilog test bench enables you to see what type of vector is currently active at any specified moment within a simulation and can simplify simulation mismatch debugging.

Setting this keyword to 2 (the default), which is available only with a Verilog test bench, also adds the encoded vector types (default behavior). Additionally, the test bench will have the following _procedure_strings, which can be added to your WAVE display to show the currently active Procedure Type.

CLOCK_PROC	SEQ_TRANSPARENT	SINGLE_SHIFT
CLOCK_PROC_RES	SHADOW_CONTROL	SKEW_LOAD
LAUNCH_CAPTURE	SHADOW_OBSERVE	TEST_SETUP
LOAD	SHIFT	TEST_END
MASTER_OBSERVE	SHIFT_EXTRA	UNKNOWN

STIL_2005_SCAN

Issuing a 1 with this keyword is similar to the STIL_STRUCTURAL keyword except it also uses the IEEE 1450.1 ScanStructures block.

Usage

```
STIL_2005_SCAN {1 | 0};
```

Issuing a 1 with this keyword is similar to the STIL_STRUCTURAL keyword except it also uses the IEEE 1450.1 ScanStructures block. The default is 0, which produces the existing IEEE 1450.0 ScanStructures block.

With the STIL_2005_SCAN keyword, the CTL output uses the 1450.1 ScanStructures block by default. You can use the CTL_STIL_0 parameter file keyword in the CTL output to eliminate the new 1450.1 features along with all of the 1450.6 syntax. The parameter file keyword CTL_STIL_1 can be used to eliminate all 1450.6 syntax but leave the 1450.1 syntax.

Note that the ScanStructures in your STIL structure must match the compressed structure.

In order to use this output, you must use the “[write_patterns -STIL1999](#)” command.

STIL_CHAIN_CELLS

Setting this keyword to 0 removes the ScanCells list from the ScanChain definition in the ScanStructures block when saving non-compressed scan patterns that use scan chains.

Usage

```
STIL_CHAIN_CELLS {1 | 0};
```

Setting this keyword to 0 removes the ScanCells list from the ScanChain definition in the ScanStructures block when saving non-compressed scan patterns that use scan chains. The following example shows a ScanStructures block without the ScanCells list:

```
ScanStructures {
    ScanChain chain1 {
        ScanLength 100;
        ScanInversion 0;
        ScanIn "sci";
        ScanOut "sco";
    }
}
```

By default (1), the scan cell names are listed following the ScanLength statement.

For compressed patterns, see the STIL_CHANNEL_CELLS keyword.

STIL_CHANNEL_CELLS

Enables the listing of dummy scan cell names in the ScanStructures block when saving compressed patterns that use EDT channels.

Usage

```
STIL_CHANNEL_CELLS {1 | 0};
```

Enables the listing of dummy scan cell names in the ScanStructures block when saving compressed patterns that use EDT channels. By default (0), the dummy scan cell names are not listed.

For non-compressed patterns, see the STIL_CHAIN_CELLS keyword.

STIL_CLOCK_WFC_PULSE

This parameter, used with the write_patterns command, controls the waveform characters of a clock signal in the generated STIL pattern file.

Usage

```
STIL_CLOCK_WFC_PULSE {TRUE | FALSE};
```

When STIL_CLOCK_WFC_PULSE is FALSE or not set at all, the waveform character set for clock signals is “01”. For a positive pulse, “1” indicates the clock signal is ON for the cycle and “0” is OFF for the cycle.

```
Timing STUCK_timing {
    WaveformTable tset_tp_shift_capture {
        Period '32ns' ;
        Waveforms {
            PI_grp_1 { 01 { '0ns' D; '10ns' D/U; '22ns' D; }}// positive pulse
            PI_grp_2 { 01 { '0ns' U; '10ns' D/U; '22ns' U; }}// negative pulse
        }
    }
}
```

When STIL_CLOCK_WFC_PULSE is TRUE, the waveform character set for clock signals is “0P” or “N1”. The waveform character set for a positive pulse is “0P”. The “P” indicates the clock signal is ON and “0” is OFF for the cycle.

The waveform character set for a negative pulse is “N1”. The “N” indicates the clock signal is ON and “1” is OFF for the cycle.

```
Timing STUCK_timing {
    WaveformTable tset_tp_shift_capture {
        Period '32ns' ;
        Waveforms {
            PI_grp_1 { 0P { '0ns' D; '10ns' D/U; '22ns' D; }}// positive pulse
            PI_grp_2 { N1 { '0ns' U; '10ns' D/U; '22ns' U; }}// negative pulse
        }
    }
}
```

STIL_DUAL_MODE

Enables dual mode support for IJTAG patterns that are in the STIL format.

Usage

```
STIL_DUAL_MODE {1 | 0};
```

Turns on (1) dual mode support for IJTAG patterns that are in the STIL format.

You use this parameter to ensure the IJTAG STIL patterns support dual-mode, where two vectors can be executed by one ATE cycle. To support dual mode, the number of vectors before the loop, inside the loop, between loops, and after the loop must be a multiple of two.

To support this requirement, the tool may partially or fully unroll loops and add padding to the end of the test. Added padded vectors have all outputs masked to X and all clocks turned off to ensure that they do not affect the timing or functionality of the test.

To set to a multiple of 4, see the [STIL_QUAD_MODE](#) parameter keyword.

STIL_FULL_CHAIN

Causes the tool to shorten the list of scan cells by the number of pre shifts and post shifts.

Usage

```
STIL_FULL_CHAIN {1 | 0};
```

Causes the tool to shorten the list of scan cells by the number of pre shifts and post shifts. By default (1), all cells in the scan chain are listed in the STIL file regardless the number of pre shifts and post shifts.

STIL_IDDQ_UPPERCASE

If this is set to 1 or true, IDDQ test points in the STIL file will use the term IDDQTestPoint, if 0 or false, which is the default, the STIL file will use IddqTestPoint.

Usage

```
STIL_IDDQ_UPPERCASE {1 | 0};
```

Some STIL parsers will only accept one or the other.

STIL_MIN_QUOTE

Issuing a 1 with this keyword is for STIL2005 and CTL outputs, and causes the tool to write the STIL file using minimum quoting of signal names that use reserved characters.

Usage

```
STIL_MIN_QUOTE {1 | 0};
```

Issuing a 1 with this keyword is for STIL2005 and CTL outputs, and causes the tool to write the STIL file using minimum quoting of signal names that use reserved characters. Further, the existing STIL1999 output can be changed to use the same minimum quoting rules. The default is 0 for the STIL1999 output.

STIL_NESTED_MACRO

Setting this keyword to 1 when saving STRUCTURAL_STIL, STIL2005, or CTL patterns causes sub procedures to be interpreted as Macros. As Macros, they are nested inside the calling Macros.

Usage

```
STIL_NESTED_MACRO {1 | 0};
```

Setting this keyword to 1 when saving STRUCTURAL_STIL, STIL2005, or CTL patterns causes sub procedures to be interpreted as Macros. As Macros, they are nested inside the calling Macros. The tool uses loop statements, if necessary, to repeat the Macro. This keyword is set to 0 by default.

STIL_NO_SCANSTRUCTURE

Setting this keyword to 1 removes the entire ScanStructures block from the STIL output.

Usage

```
STIL_NO_SCANSTRUCTURE {1 | 0};
```

Setting this keyword to 1 removes the entire ScanStructures block from the STIL output. For design flows where the ScanStructures block is not required, removing the block significantly reduces the size of the STIL file. The ScanStructures block is included by default (0).

STIL_NO_SCANX

If set to 1, this keyword replaces all X scan load values in the STIL pattern output with 0 scan load values. The default is 0.

Usage

```
STIL_NO_SCANX {1 | 0};
```

If set to 1, this keyword replaces all X scan load values in the STIL pattern output with 0 scan load values. The default is 0.

STIL_NOMEASURE_CLOCK

Issuing a 1 with this keyword drops the measure timing from the timing statement for bidirectional clocks and also verifies that this pin is never measured.

Usage

```
STIL_NOMEASURE_CLOCK {1 | 0};
```

Issuing a 1 with this keyword drops the measure timing from the timing statement for bidirectional clocks and also verifies that this pin is never measured. If the pin is measured within the patterns, the output generates an error and returns to the command prompt. To deactivate, issue a 0 (the default) with this keyword.

Examples follow:

```
Parameter file : default
IOclk { LHX { '0ns' X; '300ns' H/L/X; '400ns' X; }
          01 { '0ns' D; '200ns' U/D; '300ns' D } }

Parameter file : STIL_NOMEASURE_CLOCK 1;
IOclk { 01 { '0ns' D; '200ns' U/D; '300ns' D } }

Parameter file : STIL_TRIM_PULSE 1;
                  STIL_NOMEASURE_CLOCK 1;
IOclk { 01 { '200ns' U/D; '300ns' D } }
```

STIL_PAT_ANN

Specifies the annotation string that the tool outputs to the STIL pattern file just prior to each scan pattern.

Usage

```
STIL_PAT_ANN string %special_keyword string2;
```

Specifies the annotation string that the tool outputs to the STIL pattern file just prior to each scan pattern.

```
annotation "string %keywords string"
```

The following example shows lines in a parameter file and the resultant text generated in the output pattern file.

Parameter file entry:

```
STIL_PAT_ANN  "Pattern Number:%pat_num  
(%pat_num_plus1), Cycle Number:%cycle_num"
```

Resultant pattern file statement:

```
Ann { * "Pattern Number:0 (1), Cycle Number:0" * }
```

STIL_PAT_CMT

Turns off (0) the pattern comment that precedes each ATPG pattern. The default is 1.

Usage

```
STIL_PAT_CMT {1 | 0};
```

Turns off (0) the pattern comment that precedes each ATPG pattern. The default is 1.

STIL_PAT_LAB

Turns off (0) the pattern label that precedes each ATPG pattern.

Usage

```
STIL_PAT_LAB {1 | 0};
```

Turns off (0) the pattern label that precedes each ATPG pattern. The default is 1.

STIL_QUAD_MODE

Enables quad mode support for IJTAG patterns that are in the STIL format.

Usage

```
STIL_QUAD_MODE { 1 | 0};
```

Turns on (1) quad mode support for IJAG patterns that are in the STIL format.

STIL_QUOTE_ALL

You use this parameter to ensure the IJTAG STIL patterns support quad-mode, where four vectors can be executed by one ATE cycle. To support quad mode, the number of vectors before the loop, inside the loop, between loops, and after the loop must be a multiple of four.

To support this requirement, the tool may partially or fully unroll loops and add padding to the end of the test. Padded vectors have all output masked to X and all clocks turned off to ensure that they do not affect the timing or functionality of the test.

To set to a multiple of 2, see the [STIL_DUAL_MODE](#) parameter keyword.

STIL_QUOTE_ALL

Causes all user identifiers to be enclosed in double quotes in the STIL output file.

Usage

```
STIL_QUOTE_ALL {1 | 0};
```

Causes all user identifiers to be enclosed in double quotes in the STIL output file. By default (0), user identifiers are not quoted.

If the STIL_QUOTE_ALL and STIL_MIN_QUOTE keywords are both active (1), the tool ignores the STIL_MIN_QUOTE keyword.

STIL_SCAN_ANN1

Specifies the string the tool outputs to the STIL pattern just prior to the first scan pattern.

Usage

```
STIL_SCAN_ANN1 string %special_keyword string2;
```

Specifies the string the tool outputs to the STIL pattern just prior to the first scan pattern. There is only one STIL_SCAN_ANN1 statement written for each pattern file generated.

```
annotation "string %keywords string"
```

The following example shows lines in a parameter file and the resultant text generated in the output pattern file.

Parameter file entry:

```
STIL_SCAN_ANN1 "Scan Chain:%chain, length:%length,  
SI:%scan_in, SO:%scan_out"
```

Resultant pattern file statement:

```
Ann {*  
"Scan Chain:chain1, length:2, SI:scan_in1, SO:Q" *}
```

STIL_STRUCTURAL

Causes the STIL file to be written using a more structural form.

Usage

```
STIL_STRUCTURAL {1 | 0};
```

Causes the STIL file to be written using a more structural form. This keyword set to 1 results in a STIL output form that uses some of the basic hierarchical approaches of CTL output, but not any of the IEEE 1450.6 CTL syntax extensions. As with CTL output, the structural STIL output creates STIL Macro definitions for all used procedures, and a STIL Procedure definition for the test_setup procedure, if present. The start of each pattern still consists of an annotation statement and a pattern label. Each pattern consists of the calls to each specific Macro, passing all needed data. Unlike the CTL output, a new “pattern type” macro will not be created for each pattern, and the pattern data will not be placed in a separate file and included with the “Include” statement.

To produce a flat or non-hierarchical set of vector data, set this keyword to 0 (default).

The following is an example of the structural STIL output:

```
STIL 1.0 ;

Header { ... }

// Parameter File Keyword Settings
// STIL_STRUCTURAL true ;

Signals {
    "IN"[3..0] In; "CLK" In; "SDI" In; "SE" In;
    "OUT"[3..0] Out; "SDO" Out;
}

SignalGroups {

    }
}
```

STIL_TI_TITLE

Turns on a TI-specific title block in the STIL Header block.

Usage

```
STIL_TI_TITLE {1 | 0};
```

Turns on a TI-specific title block in the STIL Header block. This title block contains all of the specific statements from the TITDL output file, and you can use the TITDL-specific keywords to change the fields in the title block. The default is to turn off the title block.

The TITDL-specific keywords include: TITDL_LIBRARY, TITDL_CUSTOMER, TITDL_PARTNUM, TITDL_SETNAME, TITDL_SETTYPE, TITDL_CHAIN_SETTYPE, and TITDL_REVISION.

STIL_TRIM_PULSE

Causes the input timing to drop the leading 0ns force to the off state of the clock.

Usage

```
STIL_TRIM_PULSE {1 | 0};
```

Causes the input timing to drop the leading 0ns force to the off state of the clock (keyword set to 1). Removing the initial force to the off state of a clock may not be appropriate for all testers and translation processes, and you need to understand all downstream processes that use the resultant files. To deactivate, set this keyword to 0 (default).

Examples follow:

```
Parameter file : default
IOclk { LHX { '0ns' X; '300ns' H/L/X; '400ns' X; }
          01 { '0ns' D; '200ns' U/D; '300ns' D } }

Parameter file : STIL_TRIM_PULSE 1;
IOclk { LHX { '0ns' X; '300ns' H/L/X; '400ns' X; }
          01 { '200ns' U/D; '300ns' D } }

Parameter file : STIL_TRIM_PULSE 1;
                  STIL_NOMEASURE_CLOCK 1;
IOclk { 01 { '200ns' U/D; '300ns' D } }
```

STIL_VECTOR_ANN

Specifies the vector types to be added to the output pattern file.

Usage

```
STIL_VECTOR_ANN string %special_keyword string2;
```

Specifies the vector types to be added to the output pattern file.

```
annotation "string %keywords string"
```

Note

 You must not use the “%” symbol as the leading character to any string fragment in conjunction with the %special_keyword.

The STIL_SCAN_ANN1, STIL_PAT_ANN, and STIL_VECTOR_ANN parameter file keywords use a (%special_keyword) that is translated at the specific time and place the annotation statement is written. [Table A-3](#) lists the available special keywords. [Table A-4](#) lists the pattern types. [Table A-5](#) lists the vector types.

Table A-3. STIL Special Keywords

Keyword	Description
%chain	The chain name of the current chain.
%cycle_num	The current ATPG cycle number.
%length	The length of the current chain.
%pat_num	The current ATPG pattern number.
%pat_num_plus1	The current ATPG pattern number plus 1.
%pattern_type	The pattern type, for outputting annotations in the pattern file. It causes one of the pattern types in Table A-4 to be written into the pattern file.
%scan_in	The name of the Primary Input pin for the current chain.
%scan_out	The name of the Primary Output pin for the current chain.
%vector_type	This keyword causes one of the vector types in Table A-5 to be written into the pattern file.

Table A-4. STIL Pattern Types

basic	macrotest	ram_passthru
clock_po	multi_load	ram_sequential
clock_sequential		

Table A-5. STIL Vector Types

CLOCK_PROCEDURE	PRIMARY_CLOCKPO	SHADOW_CONTROL
CLOCK_PROCEDURE_RESTORE	PRIMARY_CLOCKPO_IDDQ	SHADOW_OBSERVE
CORE_ACCESS	PRIMARY_IDDQ	SHIFT

Table A-5. STIL Vector Types (cont.)

CORE_INST_ISOLATE	PRIMARY_MEASURE	SINGLE_SHIFT
CORE_INST_TEST	PRIMARY_MEASURE_IDDQ	SKEW_LOAD
LOAD_UNLOAD	SCAN_IN	SEQ_TRANSPARENT
MASTER_OBSERVE	SCAN_IO	TEST_SETUP
PRIMARY	SCAN_OUT	

STIL_VERG_ESC

Setting this keyword to 1 changes all vectored signal names to scalars.

Usage

```
STIL_VERG_ESC {1 | 0};
```

Setting this keyword to 1 changes all vectored signal names to scalars. For example, the pin name “bus”[0] would change to “bus[0]”.

STIL_WRAP_ANNOTATION

Breaks multi-line annotations into multiple annotation statements.

Usage

```
STIL_WRAP_ANNOTATION {1 | 0};
```

When this keyword is set to 1 or true in the parameter file, then any multi-line annotations are broken into multiple annotation statements, such as:

```
Ann /* this is a long */  
Ann /* multi-line annotation */
```

If not present in the parameter file, the default for this keyword is 0 or off.

TITDL_CHAIN_SETTYPE

Specifies the string used to set the chain type.

Usage

```
TITDL_CHAIN_SETTYPE string;
```

Specifies the string used to set the chain type. If specified, the string is used in the output of Chain_Test-only patterns. If not specified, the default string is “SCANCHK”. To add this to the specific title block, use the STIL_TI_TITLE keyword.

TITDL_CUSTOMER

Specifies the string the tool uses in the CUSTOMER statement in the header of the TITDL output file.

Usage

```
TITDL_CUSTOMER string;
```

Specifies the string the tool uses in the

```
CUSTOMER=string
```

statement in the header of the TITDL output file. If not specified, the default is TEXAS INSTRUMENTS. To add this to the specific title block, use the STIL_TI_TITLE keyword.

TITDL_GROUP_TIMING

Setting this keyword to 1 in conjunction with the “[write_patterns -Titdl](#)” command groups like timing information into a single statement.

Usage

```
TITDL_GROUP_TIMING {1 | 0};
```

Setting this keyword to 1 in conjunction with the “[write_patterns -Titdl](#)” command groups like timing information into a single statement. The default is off.

TITDL_KEEP_SCANOUT

Setting this keyword to 1 causes all SCANOUT statements to be issued, even if all of the scanout values for a specific pattern/chain are X.

Usage

```
TITDL_KEEP_SCANOUT {1 | 0};
```

Setting this keyword to 1 causes all SCANOUT statements to be issued, even if all of the scanout values for a specific pattern/chain are X. The default is 0, which causes the tool to not keep scanout statements whose scanout values are all X when writing TITDL format vectors.

TITDL_LIBRARY

Specifies the string that the tool uses in the LIBRARY_TYPE statement in the header of the TITDL output file.

Usage

```
TITDL_LIBRARY string;
```

Specifies the string that the tool uses in the

```
LIBRARY_TYPE=string
```

statement in the header of the TITDL output file. If not specified, the default is GS20. To add this to the specific title block, use the STIL_TI_TITLE keyword.

TITDL_PARTNUM

Specifies the string the tool uses in the TI_PART_NUMBER statement in the header of the TITDL output file.

Usage

```
TITDL_PARTNUM string;
```

Specifies the string the tool uses in the

```
TI_PART_NUMBER=string
```

statement in the header of the TITDL output file. If not specified, the default is F999999. To add this to the specific title block, see the parameter file keyword STIL_TI_TITLE.

TITDL_PSEUDO_PREFIX

Specifies the string that is prepended to the name of the clock pin to create the name of the pseudo clock pin.

Usage

```
TITDL_PSEUDO_PREFIX string;
```

Specifies the string that is prepended to the name of the clock pin to create the name of the pseudo clock pin. If not specified, the default is “pseudo_”.

For example, this keyword changes the default pseudo prefix:

```
TITDL_PSEUDO_PREFIX ps_ ;
```

And this is the result of what the MUX_PIN statement would look like in the TITDL output. The clock pin is called “clock”, and the added pseudo clock pin is called “ps_clock” because of the use of the above parameter file keyword.

```
...
CONNECT P,
VAR =(in1, in2, clock, ps_clock, out1, out2),
DEFPIN=(IN 4, OUT 2);
PERIOD = 100 NS;
CLOCK VAR=(clock),
HOLD0 = 20 NS, HOLD1 = 10 NS, PATTERN = 010;
CLOCK VAR = (ps_clock),
HOLD0 = 60 NS, HOLD1 = 10 NS, PATTERN = 010;
MUX_PIN clock, VAR=(clock, ps_clock);
DELAY VAR = (in1),
OFFSET = 0 NS;
...
```

TITDL_REVISION

Specifies the string that the tool uses in the REVISION statement in the header of the TITDL output file. I

Usage

```
TITDL_REVISION string;
```

Specifies the string that the tool uses in the

```
REVISION=string
```

statement in the header of the TITDL output file. If not specified, the default is 1.00. To add this to the specific title block, use the STIL_TI_TITLE keyword.

TITDL_SET_DESCRIPTION

Adds a user-specified string for use as the PATTERN_SET_DESCRIPTION.

Usage

```
TITDL_SET_DESCRIPTION string;
```

When set to a string, this is used in both TITDL files and in STIL files that also use [STIL_TI_TITLE](#) to add the PATTERN_SET_DESCRIPTION statement where the string is used as the description.

TITDL_SETNAME

Specifies the string that the tool uses in the PATTERN_SET_NAME statement in the header of the TITDL output file.

Usage

```
TITDL_SETNAME string;
```

Specifies the string that the tool uses in the

```
PATTERN_SET_NAME=string
```

statement in the header of the TITDL output file. The string can be a maximum of twenty characters. If not specified, the default is the filename with no extension. To add this to the specific title block, use the [STIL_TI_TITLE](#) keyword.

TITDL_SETTYPE

Specifies the string that the tool uses in the PATTERN_SET_TYPE statement in the header of the TITDL output file.

Usage

```
TITDL_SETTYPE string;
```

Specifies the string that the tool uses in the

```
PATTERN_SET_TYPE=string
```

statement in the header of the TITDL output file. If not specified, the default is SCAN. To add this to the specific title block, use the [STIL_TI_TITLE](#) keyword.

WGL_ADD_LASTX

Specifies for the tool to add an additional vector to the end of the pattern set (when set to 1).

Usage

```
WGL_ADD_LASTX {1 | 0};
```

Specifies for the tool to add an additional vector to the end of the pattern set (when set to 1). This vector is a non-scan vector with all clocks turned off, all output pins set to “X” (not measuring), and all input pins set to the same value of the previous non-scan vector. To deactivate, set this keyword to 0 (the default).

WGL_ALT_BIDI

Changes the syntax of how bidirectional signals are represented in the vector pin list, and the actual states in the vector.

Usage

```
WGL_ALT_BIDI {1 | 0};
```

Changes the syntax of how bidirectional signals are represented in the vector pin list, and the actual states in the vector. The default representation (keyword set to 0) specifies the bidirectional signal name, a colon, then an I or O, for the direction of that pin. There must be two entries for the bidirectional pin, one specifying the input side and one specifying the output side. The vector lists a separate state for each.

Setting this keyword to 1 changes the representation so that the pin list lists only one entry for the bidirectional pin with no direction, but with two states. Every state in the actual vector is currently separated by spaces. With the addition of this WGL_ALT_BIDI 1 setting, the states for the bidirectional pin will be listed side-by-side with no space separation. The input state will be listed first.

WGL_ALT_BIDI set to 0 (default) — The format of the vector order pin list and vector is as follows:

```
pattern test("A","B","C","BiDi1:I","E","F","G","BiDi1:O")
{Pattern 0 Cycle 0 Loop 0}
vector(+,TP1):=[1 0 1 - 0 1 0 1];
```

WGL_ALT_BIDI set to 1 — The vector order pinlist and vector are changed to the following:

```
pattern test("A","B","C","BiDi1","E","F","G")
{Pattern 0 Cycle 0 Loop 0}
vector(+,TP1):=[1 0 1 -1 0 1 0];
```

WGL_ALT_VECT_ANN

Specifies alternate annotation statements for beginnings of patterns and vector boundaries when this keyword is set to 1.

Usage

```
WGL_ALT_VECT_ANN {1 | 0};
```

Specifies alternate annotation statements for beginnings of patterns and vector boundaries when this keyword is set to 1. These alternate annotations can help the WGL file be processed by other third party tools. The default is 0.

Note

 Using this keyword can produce a WGL file that you cannot read back into the Tessent tools.

WGL_EDGE_STROBE

Specifies whether to include an X state after an edge strobe.

Usage

```
WGL_EDGE_STROBE {1 | 0};
```

The default value of this keyword is 0. This keyword is in effect only when the strobe_window is set to 0 using the “set strobe_window time” statement in the procedure file.

The WGL output specifies edge strobes by using the edge qualifier on the strobe times specified in timeplate definitions. Additionally, an output value showing the X state appears after the strobe time.

If the strobe_window is set to 0, setting this keyword to 1 eliminates from the WGL output this additional output value showing the X state after the strobe time.

The following is an example of an edge strobe statement without and with using WGL_EDGE_STROBE.

WGL_EDGE_STROBE set to 0 (default):

```
"outpin":=output [0ns:X, 300ns:Q'edge, 350ns:X] ;
```

WGL_EDGE_STROBE set to 1

```
"outpin":=output [0ns:X, 300ns:Q'edge] ;
```

WGL_FULL_CHAIN

When set to 1, this keyword alters the scandell and scanchain blocks of the WGL to reflect all cells in the chain, regardless of the number of pre- or post-shifts (number of apply shifts).

Usage

```
WGL_FULL_CHAIN {1 | 0} ;
```

When set to 1, this keyword alters the scandell and scanchain blocks of the WGL to reflect all cells in the chain, regardless of the number of pre- or post-shifts (number of apply shifts). The group statements only reflect what is loaded minus the post shift. The scanstate and group have to match. To deactivate, and for backwards compatibility, issue a 0 (false).

Examples follow.

Original WGL File (WGL_FULL_CHAIN 0)

```
...
scandell
  { Group: grp1 }
  { Chain: REG1 }
  "u22"; "u23"; "u10"; "u11"; "u12";
  groupgrp1REG1 ["u22", "u23", "u10", "u11", "u12"];
end
scanchain
  { Group: grp1 }
  REG1_chain[ "sdi", "u12", "u11", !, "u10", "u23", "u22", "sdo" ];
end
...
scanstate
  OREG1_sts000000_000002 := groupgrp1REG1 (XXXXXX);
  IREG1_sts000000_000002 := groupgrp1REG1 (11010);
...
end
...
```

WGL_FULL_CHAIN 1

```
...
    scancell
        { Group: grp1 }
        { Chain: REG1 }
        "u22"; "u23"; "u10"; "u11"; "u12"; "u13";
        groupgrp1REG1 ["u22", "u23", "u10", "u11", "u12"];
    end
    scanchain
        { Group: grp1 }
        REG1_chain[ "sdi", "u13", "u12", "u11", !, "u10", "u23", "u22",
"sdo"] ;
    end
...
    scanstate
        OREG1_sts000000_000002 := groupgrp1REG1 (XXXXX);
        IREG1_sts000000_000002 := groupgrp1REG1 (11010);
...
end
...
```

WGL_FULL_SCANGROUP

Creates the Scan sections with the full chain (when set to 1).

Usage

```
WGL_FULL_SCANGROUP {1 | 0};
```

Creates the Scan sections with the full chain (when set to 1). This keyword alters the scanchain, scancell, and scanstate blocks in WGL to reflect all cells in the chain, regardless of the number of pre- or post-shifts. Setting the keyword to 0, deactivates this feature.

The following is an example of WGL code when WGL_FULL_SCANGROUP and WGL_FULL_CHAIN are both set to 1:

```
...
    scancell
        { Group: grp1 }
        { Chain: REG1 }
        "u22"; "u23"; "u10"; "u11"; "u12"; "u13";
        groupgrp1REG1 ["u22", "u23", "u10", "u11", "u12", "u13"];
    end
    scanchain
        { Group: grp1 }
        REG1_chain[ "sdi", "u13", "u12", "u11", !, "u10", "u23", "u22",
                    "sdo"];
    end
...
    scanstate
        OREG1_sts000000_000002 := groupgrp1REG1 (XXXXXX);
        IREG1_sts000000_000002 := groupgrp1REG1 (X10100);
...
end
...
```

WGL_GROUP_PIN

Specifies for the WGL output to create signal groups _PI_, _PO_, and _BIDI_ (if there are bidi's) when set to 1.

Usage

```
WGL_GROUP_PIN {1 | 0};
```

Specifies for the WGL output to create signal groups _PI_, _PO_, and _BIDI_ (if there are bidi's) when set to 1. The WGL code then uses these groups in the pattern statement and in actual patterns for grouping states. To deactivate, set this keyword to 0.

WGL_INV_SC

Removes inversion data from scan chain definitions and specifies scan data as it would appear to be shifted in, instead of parallel deposited.

Usage

```
WGL_INV_SC {1 | 0};
```

Removes inversion data from scan chain definitions and specifies scan data as it would appear to be shifted in, instead of parallel deposited. According to the WGL data model, a WGL file

that uses this option no longer correctly matches the design netlist. However, some third-party tools work faster with the inversion data removed. When set to 0 (default), this keyword leaves the inversion data intact.

WGL_NO_SCANX

Replaces all X scan load values in the WGL pattern output with 0 scan load values.

Usage

```
WGL_NO_SCANX {1 | 0};
```

Replaces all X scan load values in the WGL pattern output with 0 scan load values. When set to 0 (default), this keyword deactivates this feature.

WGL_NOMEASURE_CLOCK

Drops the measure timing from the timing statement for bidirectional clocks and also verifies that this pin is never measured.

Usage

```
WGL_NOMEASURE_CLOCK {1 | 0};
```

Drops the measure timing from the timing statement for bidirectional clocks and also verifies that this pin is never measured. If the pin is measured within the patterns, the output generates an error and returns to the command prompt. Setting this keyword to 0 (default), deactivates this feature.

Note that this keyword can cause some WGL readers to have problems reading the file. The tool issues a warning if the keyword is specified in the parameter file and if there is at least one signal using the altered syntax.

Examples follow:

```
Parameter file : default
IOclk := input [ 0ns:D, 200ns:S, 300ns:D ];
IOclk := output [ 0ns:X, 300ns:Q, 400ns:X ];

Parameter file : WGL_NOMEASURE_CLOCK 1;
IOclk := input [ 0ns:D, 200ns:S, 300ns:D ];

Parameter file : WGL_TRIM_PULSE 1;
                  WGL_NOMEASURE_CLOCK 1;
IOclk := input [ 200ns:S, 300ns:D ];
```

WGL_ONE_ILLINOIS

Causes the WGL output to have only one scan state defined per pattern for multiple scan chains that share a single scan input pin.

Usage

```
WGL_ONE_ILLINOIS {1 | 0};
```

Causes the WGL output to have only one scan state defined per pattern for multiple scan chains that share a single scan input pin. In other words, this keyword forces the tool to produce a single scan state for chains that share a common scan input pin (set to 1).

The default behavior when this keyword is set to 0 is to have scan states defined for each scan chain, whether or not they share scan input pins. The default for scan states when multiple scan chains share a common scan input is to list the scan states for each cell in each chain, the same as if the chains did not share a scan input.

WGL_PATTERN_NAME

Changes the default name of the WGL pattern block from “Chain_scan_test” to the value of the string.

Usage

```
WGL_PATTERN_NAME string;
```

Changes the default name of the WGL pattern block from “Chain_scan_test” to the value of the string.

WGL_TRIM_LEADING_P

Removes the leading 0ns:P timing event when a channel uses timing variables .

Usage

```
WGL_TRIM_LEADING_P {1 | 0};
```

Removes the leading 0ns:P timing event when a channel uses timing variables (keyword set to 1). For example, the default behavior produces a timeplate channel that looks like this:

```
"pi_sel_smcard" := input[0ns:P, fd_force:S];
```

When WGL_TRIM_LEADING_P is set to 1 in the parameter file, the timeplate channel looks like this:

```
"pi_sel_smcard" := input [fd_force:S];
```

WGL_TRIM_PULSE

Causes the input timing to drop the leading 0 ns force to the off state of the clock.

Usage

```
WGL_TRIM_PULSE {1 | 0};
```

Causes the input timing to drop the leading 0 ns force to the off state of the clock (keyword set to 1). Removing the initial force to the off state of a clock may not be appropriate for all testers and translation processes, and you need to understand all downstream processes that use the resultant files. Setting this keyword to 0 deactivates this feature.

Note that this keyword generates illegal syntax in the WGL file, which may cause some WGL readers to have problems reading the file. The tool issues a warning message if the keyword is specified in the parameter file and if there is at least one signal using the altered syntax.

Examples follow.

Parameter file : default

```
IOclk := input [ 0ns:D, 200ns:S, 300ns:D ];  
IOclk := output [ 0ns:X, 300ns:Q, 400ns:X ];
```

Parameter file : WGL_TRIM_PULSE 1;

```
IOclk := input [ 200ns:S, 300ns:D ];  
IOclk := output [ 0ns:X, 300ns:Q, 400ns:X ];
```

Parameter file : WGL_TRIM_PULSE 1;
 WGL_NOMEASURE_CLOCK 1;

```
IOclk := input [ 200ns:S, 300ns:D ];
```

WGL_VECTOR_ANN

Adds an annotation statement to be generated in the pattern file to denote the vector type.

Usage

```
WGL_VECTOR_ANN {1 | 0};
```

Adds an annotation statement to be generated in the pattern file to denote the vector type. Setting this keyword to 0 deactivates this feature.

WGL_VERG_ESC

Specifies for buses to be expanded in the declaration sections of the WGL output.

Usage

```
WGL_VERG_ESC {1 | 0};
```

Specifies for buses to be expanded in the declaration sections of the WGL output. Setting this keyword to 0 deactivates this feature.

WGL_VTRAN_PADSC

Pads all scan data to be same length.

Usage

```
WGL_VTRAN_PADSC {1 | 0};
```

Pads all scan data to be same length (keyword set to 1). Padding all scan data to be the same length violates the WGL syntax according to the TDS WGL documentation. However, some third-party tools work better with the scan data padded. Setting this keyword to 0 deactivates this feature.

WGL_WRAP_ANNOTATION

Breaks multi-line annotations into multiple annotation statements.

Usage

```
WGL_WRAP_ANNOTATION {1 | 0};
```

When this keyword is set to 1 or true in the parameter file, then any multi-line annotations are broken into multiple annotation statements, such as:

```
Ann /* this is a long */  
Ann /* multi-line annotation */
```

WGL_WRAP_ANNOTATION

If not present in the parameter file, the default for this keyword is 0 or off.

By default, the tool automatically inserts newlines into annotations when a single line of the annotation exceeds 512 characters, regardless of the setting of WGL_WRAP_ANNOTATION.

Appendix B

HDL Limitations in the Tessent Shell Flow

This appendix describes the HDL limitations which affect functionality in the Tessent Shell Flow. The two tables below summarize the limitations. Full explanations of those limitations along with examples are given in the sections which follow.

The limitations can be categorized by the effect they have on the flow—see the “Effect on Flow” column in [Table B-1](#) on page 4007 and [Table B-2](#) on page 4010.

- **Impacts Compilation and/or Elaboration** — An error will typically be issued by the `read_verilog`, the `read_vhdl`, or the `set_current_design` command.
- **Impacts Design Analysis** — When a limitation in this category is encountered, an error will typically be issued when the tool is tracing through the elaborated circuit. Such errors will typically occur during rules checking and/or in `TS_Bscan` during pad extraction. In most cases tracing in `TS_Ijtag` is not affected. Exceptions are noted in [Table B-1](#) on page 4007 and [Table B-2](#) on page 4010.
- **Impacts Design editing and/or Introspection** — An error will typically be issued when the tool is modifying the design to insert new design components or during execution of an introspection command. Such errors will typically occur in `TS_DesignEditor` or in `TS_Bscan` or `TS_Membist` during design editing.
- **Impacts Design Verification** — An error will typically be issued during test bench generation.
- **Impacts Hierarchical Insertion** — Limitations in this category affect the ability to make needed modifications to designs with child blocks or cores, each with their own workspace. An error will typically be issued when the tool flow performs design rule checking on the interface between child and parent. Such errors will typically occur during design rule checking in the early stages of the flow. Some limitations will result in errors in the child flow and others in the parent flow.

Note

 Language constructs which are not in the RTL-synthesizeable subset are ignored. DC Shell requires that such constructs be surrounded by pragmas; otherwise, an error is generated. If tool edits create a need to update such a construct, for example a Verilog hierarchical name, then a manual edit by the user is required.

HDL Limitations in the Tesson Shell Flow for Verilog and SystemVerilog

The following HDL limitations apply to Verilog and SystemVerilog.

The following table lists and categorizes these limitations.

Table B-1. Verilog and SystemVerilog Limitations

Limitation	Effect on Flow	Workaround and Link to Description
SystemVerilog Interfaces		
Multi-dimensional instantiation of SV interfaces is not supported.	Affects tracing and design editing.	Use a single dimension. See “ Multi-dimensional Instantiation of SystemVerilog Interfaces ” on page 4013
SV interfaces cannot be edited.	Affects design editing.	Replace the interface with the equivalent expanded logic. See “ SystemVerilog Interfaces Cannot Be Edited ” on page 4013.
Outside connections on ports declared using an SV interface type cannot be intercepted.	Affects design editing.	Replace interface usage with equivalent expanded logic. See “ Outside Connections on Interface Type Ports Cannot be Intercepted ” on page 4013.
Insertion of an instance of a module containing a port whose type is an SV interface is not supported.	Affects design editing.	Replace interface usage with equivalent expanded logic. See “ Insertion of an Instance of a Module With a SystemVerilog Interface Port Type ” on page 4014.
A port declared in the root module of a child block or core cannot be declared using an SV generic interface type.	Affects design elaboration, hierarchical insertion, and test bench generation.	Use a known interface type. See “ SystemVerilog Generic Interface Port Declarations in the Root Module of a Child Block ” on page 4014.

Table B-1. Verilog and SystemVerilog Limitations (cont.)

Limitation	Effect on Flow	Workaround and Link to Description
Multiple instantiations of an SV interface cannot be passed as arguments in a single task or function invocation.	Affects RTL quick synthesis needed for checking design rules and ICL extraction.	Uniquify the interface instantiations. See “ System Verilog Interfaces in Task or Function Invocation ” on page 4015.
Nested Modules		
Nested modules are not supported in code which needs to be edited or introspected.	Affects design introspection and editing.	Change the RTL. See “ Nested Modules ” on page 4015.
SystemVerilog Enumerations		
Logic containing SV enum methods such as next, prev, first, and last cannot be traced.	Affects tracing.	Specify the enumerated list values explicitly. See “ SystemVerilog Enum Methods ” on page 4017.
Ports declared using an SV enum type declared in the port declaration itself cannot be intercepted on the inside of the module.	Affects design editing.	Replace the enum type with an integer. See “ SystemVerilog Enum Type in Port Declarations ” on page 4017.
Complex Port Types		
Ports/nets declared using a complex type cannot be addressed in TCL editing and introspection commands.	Affects design introspection and editing.	Replace the complex type usage with equivalent expanded logic. See “ Access to Ports and Nets of Complex Types ” on page 4018.
Unpacked dimensions and other complex types cannot be used in the definitions of root module ports which drive or receive data from inserted DFT logic.	Affects test bench generation.	Use scalars and simple vectors. See “ Unpacked Dimensions and Other Complex Types in Port Declarations of the Root Module of a Design ” on page 4019.
When boundary scan needs to be inserted into a design, top-level port declarations at the chip level are limited to scalars and simple vectors.	Affects tracing and design editing.	Replace the complex type usage with equivalent expanded logic. See “ Complex Types in Top-Level Ports at the Chip Level ” on page 4019.
Functions, Tasks, and Procedural Statements		

Table B-1. Verilog and SystemVerilog Limitations (cont.)

Limitation	Effect on Flow	Workaround and Link to Description
Tracing through logic containing non-constant function calls, task invocations, and/or procedural statements is not supported.	Affects tracing.	Change the RTL. See “ Functions, Tasks, and Procedural Statements for Verilog and SystemVerilog ” on page 4020.
SystemVerilog Extern Modules		
Extern modules in SV are ignored.	Affects design editing.	Change the RTL. See “ SystemVerilog Extern Modules ” on page 4020.
Unrolled Generate Loops		
Design modifications which require unrolling of generate loops may have undesired side effects.	Affects design editing.	See “ Unrolling of Generate Loops Side Effects ” on page 4021.
Insertion of custom logic which connects to a port or net inside an unrolled generate loop when the insertion of the custom logic and the unrolling are done in different insertion phases (unrolling phase first).	Affects design editing.	See “ Insertion of Custom Logic Which Connects to a Port or Net in an Unrolled Generate Loop ” on page 4024.
Parameterized Designs		
For a parameter declared in the root module of a child block or core which is used in logic that will be edited during insertion, such a parameter cannot be overridden in the instantiation of the child block.	Affects hierarchical insertion.	Use a fixed value in place of the parameter or set the default to the same value as the override. See “ Parameter Overrides in the Instantiation of the Root Module of a Child Block ” on page 4025.
Defparams whose paths are not relative to the current scope are not supported.	Affects design compilation / elaboration.	Move the defparam so that the specified path is relative to the current scope or use the parameter override construct. See “ Support for the Defparam Construct ” on page 4025.
Implicit Port Syntax		

Table B-1. Verilog and SystemVerilog Limitations (cont.)

Limitation	Effect on Flow	Workaround and Link to Description
Implicit port syntax (i.e., <code>.*</code>) cannot be used in the instantiation of a child block or core.	Affects hierarchical insertion.	Use expanded syntax. See “ SystemVerilog Implicit Port Syntax in the Instantiation of the Root Module of a Child Block ” on page 4026.
SystemVerilog 2009		
Certain limitations exist for a small subset of constructs specific to SystemVerilog 2009.	Affects design editing.	Avoid the unsupported constructs if they need to be updated to reflect edits during DFT insertion. See “ SystemVerilog 2009 ” on page 4027.

HDL Limitations in the Tessent Shell Flow for VHDL

The following HDL limitations apply to VHDL.

The following table lists and categorizes these limitations.

Table B-2. VHDL Limitations

Limitation	Effect on Flow	Workaround and Link to Description
New Module Insertion		
Insertion of an instance of a VHDL entity containing a port declared using an unconstrained array type is not supported.	Affects design editing.	Always use constrained array types for ports which are arrays in VHDL entities to be inserted into the design. See “ Insertion of VHDL Entities with Unconstrained Ports ” on page 4028.
Insertion of an instance of a VHDL entity containing uninitialized generics is not supported.	Affects design editing.	Always initialize any generics in VHDL entities to be inserted into the design. See “ Insertion of VHDL Entities with Uninitialized Generics ” on page 4028.
Complex Port Types		

Table B-2. VHDL Limitations (cont.)

Limitation	Effect on Flow	Workaround and Link to Description
Ports/nets declared using a complex type cannot be addressed in TCL editing and introspection commands.	Affects design introspection and editing.	Replace the complex type usage with equivalent expanded logic. See “ Access to Ports and Nets of Complex Types ” on page 4029.
The array of array and record constructs cannot be used in the definitions of root module ports which drive or receive data from inserted DFT logic.	Affects test bench generation.	Use simple vectors. See “ Array of Array and Record Types in Port Declarations in the Root Module of a Design ” on page 4029.
When boundary scan needs to be inserted into a design, top-level port declarations at the chip level are limited to scalars and simple vectors.	Affects tracing and design editing.	Replace the complex type usage with equivalent expanded logic. See “ Complex Types in Top-Level Ports at the Chip Level ” on page 4029.
A port declared in the root module of a child block or core cannot be declared using an unconstrained array type.	Affects design elaboration, hierarchical insertion and test bench generation.	Use a constrained array type. See “ Ports with Unconstrained Array Types in the Root Design Entity of a Child Block ” on page 4030.
Procedures, Functions, and Process Statements		
Tracing through logic containing procedure calls, non-constant function calls, and/or process statements is not supported.	Affects tracing.	See “ Procedures, Functions, and Process Statements for VHDL ” on page 4030.
Configurations		
Format preservation is not done when editing VHDL configurations. Such edits are typically needed when uniquifying an entity/architecture pair which appears in a configuration.	Affects design editing.	Avoid the use of pragmas in configurations as they will not be preserved when the configuration needs to be edited. See “ Configurations for VHDL ” on page 4030.
When there are multiple configurations for the same entity, only the elaborated / active one can be edited. The inactive configurations may need manual updates to avoid parsing errors later in the flow.	Affects design editing.	Manually update inactive configurations when needed. See “ Configurations for VHDL ” on page 4030.

Table B-2. VHDL Limitations (cont.)

Limitation	Effect on Flow	Workaround and Link to Description
VHDL 2008		
VHDL 2008 is not fully supported.	Affects design compilation / elaboration and design editing.	Avoid the unsupported VHDL 2008 constructs. See “ VHDL 2008 ” on page 4030.
Parameterized Designs		
For a generic declared in the root module of a child block or core which is used in logic that will be edited during insertion, such a generic cannot be overridden in the instantiation of the child block.	Affects hierarchical insertion.	Use a fixed value in place of the generic or set the default to the same value as the override. See “ Generic Overrides in the Instantiation of the Root Design Entity of a Child Block ” on page 4032.

SystemVerilog Interfaces

Note the following when using SystemVerilog Interfaces.

Multi-dimensional Instantiation of SystemVerilog Interfaces.....	4013
SystemVerilog Interfaces Cannot Be Edited.....	4013
Outside Connections on Interface Type Ports Cannot be Intercepted.....	4013
Insertion of an Instance of a Module With a SystemVerilog Interface Port Type	4014
SystemVerilog Generic Interface Port Declarations in the Root Module of a Child Block 4014	
System Verilog Interfaces in Task or Function Invocation	4015

Multi-dimensional Instantiation of SystemVerilog Interfaces

Tesson tools do not support multi-dimensional instantiations of a SystemVerilog interface. Connections in module port lists which utilize such interface instantiations cannot be traced or modified.

The following example illustrates a multi-dimensional instantiation of a SystemVerilog interface:

```
interface intfA;  
...  
endinterface  
  
module top ( input in1, output o1 );  
...  
intfA my_intf_array [3:0][4:0](); // interface instantiation  
...  
endmodule
```

SystemVerilog Interfaces Cannot Be Edited

Tesson tools cannot modify the definition of a SystemVerilog interface.

Outside Connections on Interface Type Ports Cannot be Intercepted

Tesson tools cannot intercept outside connections on ports which are declared using a SystemVerilog interface type.

This limitation will affect boundary scan insertion for cases in which pad cell keyports are declared using a SystemVerilog interface type. It will also affect the insertion of custom logic.

The following example illustrates the use of a SystemVerilog interface type in the declaration of a module port:

```
interface intfA;  
...  
endinterface  
  
module joe ( intfA p1 );  
...  
endmodule
```

An outside connection on *p1* cannot be intercepted.

Insertion of an Instance of a Module With a SystemVerilog Interface Port Type

Tessent tools cannot insert an instance of a module which has a port declared with a SystemVerilog interface type.

SystemVerilog Generic Interface Port Declarations in the Root Module of a Child Block

In a bottom-up flow SystemVerilog generic interface port declarations cannot be used in the root module of a child block or core.

The following example illustrates a generic interface port:

```
module mem1 (interface pins, input clk);  
...  
endmodule
```

System Verilog Interfaces in Task or Function Invocation

Multiple arguments which are defined as instantiations of the same SV interface type cannot be passed in a single task or function invocation. For example:

```
interface my_intf #( parameter SZ1 = 1 );
    wire w1[SZ1-1: 0];
    wire w2[SZ1-1: 0];

    // some logic around w1,w2 etc...
endinterface

my_intf #(10) intf_obj_1;
my_intf #(20) intf_obj_2;

...
// Single function,task call using objects of same interface
    my_func (intf_obj_1, intf_obj_2, <other_arguments>);
...
...
```

The work around is to uniquify the instantiations of the interface as follows:

```
interface my_intf #( parameter SZ1 = 1 );
    wire w1[SZ1-1: 0];
    wire w2[SZ1-1: 0];

    // some logic around w1,w2 etc...
endinterface

interface my_intf_1 #( parameter SZ1 = 1 );
    wire w1[SZ1-1: 0];
    wire w2[SZ1-1: 0];

    // some logic around w1,w2 etc...
endinterface

my_intf #(10) intf_obj_1;
my_intf_1 #(20) intf_obj_2;

...
// Single function,task call using objects of different interfaces
    my_func (intf_obj_1, intf_obj_2, <other_arguments>);
...
...
```

Nested Modules

Nested modules are not supported in SystemVerilog code which needs to be edited or introspected.

An example of a nested module is as follows:

```
module my_core (input wire clk);
    submod i1 (...);
    module submod (...);
    ...
endmodule
endmodule
```

SystemVerilog Enumerations

Note the following when using SystemVerilog enumerations.

SystemVerilog Enum Methods 4017

SystemVerilog Enum Type in Port Declarations 4017

SystemVerilog Enum Methods

Tesson tools cannot trace a signal through logic written using SystemVerilog enum methods such as next, prev, first, and last.

In the following example the return values of the first and last methods are used as alternatives in a case generate statement:

```
module joe ( input in1, output out1 );
  typedef enum {S[2]} states_t;
  parameter states_t p1 = S1;
  case(p1)
    p1.first : begin
      assign out1 = p1.first;
    end
    p1.last : begin
      assign out1 = p1.last;
    end
  endcase
endmodule
```

The signal *out1* cannot be traced through the above case generate statement.

SystemVerilog Enum Type in Port Declarations

Tesson tools cannot intercept ports which are declared using a SystemVerilog enum type. This limitation may affect the insertion of custom logic.

The following example illustrates a port declaration with an enum type:

```
module top( input enum {stop, go} in1, input clk, output out1 );
  reg r1;
  always_ff @(posedge clk)
    if( in1 == stop )
      r1 <= 1;
    else
      r1 <= 0;
  assign out1 = r1;
endmodule // top
```

The port *in1* cannot be intercepted, that is, the internal net *in1* cannot be disconnected from the port *in1* and connected to a new driver.

Complex Port Types for Verilog and SystemVerilog

Note the following when using complex port types.

Access to Ports and Nets of Complex Types	4018
Unpacked Dimensions and Other Complex Types in Port Declarations of the Root Module of a Design.....	4019
Complex Types in Top-Level Ports at the Chip Level	4019

Access to Ports and Nets of Complex Types

Ports and nets of the following types cannot be introspected and cannot appear in editing commands:

- User-defined types
- Structs (packed and unpacked)
- Unions
- Packed arrays of more than one dimension
- Unpacked arrays of one or more dimensions

The above limitation puts constraints on the types of connections which can be made with custom logic.

The following example illustrates a user-defined type:

```
module top();
    typedef logic [7:0] my_vec_type;
    my_vec_type w1, w2; // variables declared to be of type my_vec_type
endmodule // top
```

The following example illustrates a structure:

```
module top();
    struct {
        logic a;
        logic b;
    } my_struct;
    assign my_struct.a = 1'b0;
endmodule // top
```

Unpacked Dimensions and Other Complex Types in Port Declarations of the Root Module of a Design

Unpacked dimensions and other complex types (see previous section for a list) cannot be used in the definitions of root module ports (including those in child blocks or cores and the chip-level design) which drive or receive data from inserted DFT logic.

An example of an unpacked dimension is the following:

```
input cb_flow_type [18:0];
```

Unpacked dimensions always appear to the right of the port identifier.

Complex Types in Top-Level Ports at the Chip Level

The insertion of boundary scan by Tesson tools imposes certain restrictions on top-level port declarations. In Verilog and SystemVerilog designs top-level port declarations at the chip level are limited to one packed dimension and zero unpacked dimensions, that is scalars and simple vectors.

The following example illustrates a module port declaration with two packed dimensions (which is not allowed):

```
module top( input [1:0] [7:0] in1, output out1 );
endmodule
```

The following example illustrates a module port declaration with one packed dimension and one unpacked dimension (which is not allowed):

```
module top( input [1:0] in1 [7:0], output out1 );
endmodule
```

Packed dimensions are those which appear to the left of the port identifier; unpacked dimensions appear to the right of the port identifier.

Functions, Tasks, and Procedural Statements for Verilog and SystemVerilog

Tessent tools cannot trace a signal through logic written using a non-constant function call, a task invocation or a procedural statement.

SystemVerilog Extern Modules [4020](#)

SystemVerilog Extern Modules

Tessent tools cannot modify the ports lists of any extern module declarations in SystemVerilog designs.

The following example illustrates an extern module declaration:

```
// Prototype of car
extern module car ( input wire in1, output wire out1 );

// Definition of car: the .* syntax tells the compiler to get
// the port list from the prototype
module car (*.*);
endmodule
```

Unrolled Generate Loops for Verilog and SystemVerilog

Note the following when using generate loops.

Unrolling of Generate Loops Side Effects	4021
Insertion of Custom Logic Which Connects to a Port or Net in an Unrolled Generate Loop	4024

Unrolling of Generate Loops Side Effects

Tesson tools need to unroll generate loops for certain types of editing.

This type of transformation in Verilog design files can have undesired side effects. Unrolled generate loops in Verilog design files are, by default, written out as a series of if generate blocks. There is one if generate block for each value of the genvar index in the original generate loop. Text inside the loop such as compiler directives, inactive generate regions, and comments is not preserved. An option is available to preserve such text. In that case the unrolled loops are written out as a series of loop generate blocks of size one. There is one loop generate block for each value of the genvar index in the original generate loop. This is in contrast to how unrolled generate loops in edited SystemVerilog design files are written out: if generate blocks are always used to perform the unrolling and text for compiler directives, inactive generate regions, and comments is preserved. The reason for the different handling is due to lack of support in simple Verilog for localparam declarations inside if generate blocks - those are allowed in SystemVerilog. The localparam construct is needed for format preservation (see below). When the unrolling is done using if generate blocks, hierarchical paths (for example, paths in SDC constraints) which reference objects inside generate loops in Verilog design files will still work in most tools. When the unrolling is done using loop generate blocks of size 1, those hierarchical paths will be invalid without manual intervention. Timing scripts generated by Tesson TimingGen tool will account for the use of loop generate blocks of size one; however, user-generated timing scripts will not be updated and may be invalid after unrolling.

As mentioned above, you have control over the unrolling strategy which is used. The unrolling strategy is set via the `-preserve_paths_for_unrolled_v2001_loops` option in the `set_insertion_options` command. If the value is set to OFF, user-generated timing scripts may be affected.

The example below shows how unrolling is performed in Verilog 2001 design files for both values of the -preserve_paths_for_unrolled_v2001_loops option in the set_insertion_options command:

```
wire [1:0] in1, in2;
generate
genvar i;
for( i = 0; i < 2; i++ )
begin : joe
`ifdef TECHNOLOGY_32NM
    DUT i0 ( .A(in1[i]), .B(in2[i]), ... );
`else
    DUT1 i0 ( .A(in1[i]), .B(in2[i]), ... );
`endif
end for
end generate
```

Here is what is written after unrolling when the -preserve_paths_for_unrolled_v2001_loops option in the set_insertion_options command is set to OFF:

```
wire [1:0] in1, in2;
genvar i;
for( i = 0; i <= 0 ; i++ ) begin : \joe[0]
`ifdef TECHNOLOGY_32NM
    DUT i0 ( .A(in1[i]), .b(in2[i]), ... );
`else
    DUT1 i0 ( .A(in1[i]), .b(in2[i]), ... );
`endif
end for
for( i = 1; i <= 1; i++ ) begin : \joe[1]
`ifdef TECHNOLOGY_32NM
    DUT i0 ( .A(in1[i]), .b(in2[i]), ... );
`else
    DUT1 i0 ( .A(in1[i]), .b(in2[i]), ... );
`endif
end for
```

Generate loops of size 1 are used to perform the unrolling. The compiler directives and the inactive region are preserved. Instance *i0* inside block *\joe[0]* must be referenced (for example in SDC constraints) using the following hierarchical path:

```
\joe[0] [0]/i0
```

Here is what is written after unrolling when the -preserve_paths_for_unrolled_v2001_loops option in the set_insertion_options command is set to ON (assuming that the ` ifdef region is inactive):

```
wire [1:0] in1, in2;
if(1) begin : \joe[0]
    DUT1 i0 ( .A(in1[0]), .b(in2[0]), ... );
end
if(1) begin : \joe[1]
    DUT1 i0 ( .A(in1[1]), .b(in2[1]), ... );
end
```

If generate blocks are used to perform the unrolling. The compiler directives and the inactive region are removed. Instance *i0* inside block *\joe[0]* can be referenced (for example, in SDC constraints) using either of the following hierarchical paths:

```
\joe[0] /io
joe[0]/io
```

If we treat the same example as a SystemVerilog design file, then here is what is written after unrolling, regardless of the setting of the *-preserve_paths_for_unrolled_v2001_loops* option in the *set_insertion_options* command:

```
wire [1:0] in1, in2;
if(1) begin : \joe[0]
localparam i = 0;
`ifdef TECHNOLOGY_32NM
    DUT i0 ( .A(in1[i]), .b(in2[i]), ... );
`else
    DUT1 i0 ( .A(in1[i]), .b(in2[i]), ... );
`endif
end
if(1) begin : \joe[1]
localparam i = 1;
`ifdef TECHNOLOGY_32NM
    DUT i0 ( .A(in1[i]), .b(in2[i]), ... );
`else
    DUT1 i0 ( .A(in1[i]), .b(in2[i]), ... );
`endif
end
```

If generate blocks are used to perform the unrolling. Since localparam declarations are allowed inside if generate blocks in SystemVerilog, the inactive region can be preserved. Without the localparam, the reference to the variable “i” would generate an error.

In summary the pros and cons of setting the *-preserve_paths_for_unrolled_v2001_loops* to ‘off’ (SDC paths are not preserved; however, text format, comments, and compiler directives are preserved) are as follows:

- **Pros** — Compiler directives, inactive regions, and comments are preserved inside unrolled generate loops in Verilog design files.
- **Cons** — User generated timing scripts which reference objects inside unrolled loops may not work. Manual intervention may be required to fix hierarchical paths in such scripts.

Insertion of Custom Logic Which Connects to a Port or Net in an Unrolled Generate Loop

If custom logic is used to make connections to a net or port inside an unrolled generate loop, the escaped names used for the unrolled loop labels in the edited design file must be used in the custom logic.

For example, if the following path is used before the design is first edited:

A/B [0] /P1

then after loop unrolling, the required syntax is as follows:

A/\B [0] /P1

Note the “\” character and the space character after the “]” character.

Parameterized Designs for Verilog and SystemVerilog

Note the following when using parameterized designs.

Parameter Overrides in the Instantiation of the Root Module of a Child Block.....	4025
Support for the Defparam Construct.....	4025

Parameter Overrides in the Instantiation of the Root Module of a Child Block

In a bottom-up flow parameter overrides cannot be used in the instantiation of the root module of a child block or core when the parameters being overridden are used in logic that will be edited during insertion. For example, such a parameter could not be used as the loop count of a generate loop in which memories are instantiated.

Support for the Defparam Construct

Support for the defparam construct is limited to those for which the specified path is relative to the current scope.

For example:

```
module joe( input jPort );
    bar b1();
    bar b2();
    defparam b1.f1.p = 6;
    ...
endmodule

module bar( input bPort );
    foo f1();
    foo f2();
    ...
endmodule

module foo( input fPort );
    parameter p = 3;
    ...
endmodule
```

Implicit Port Syntax

Note the following when using implicit port syntax.

SystemVerilog Implicit Port Syntax in the Instantiation of the Root Module of a Child Block 4026

SystemVerilog Implicit Port Syntax in the Instantiation of the Root Module of a Child Block

In a bottom-up flow SystemVerilog implicit port syntax (i.e., `.*`) cannot be used in the instantiation of the root module of a child block or core.

The following example illustrates the use of implicit port syntax:

```
module top( input in1, output out1 );
...
joe i1( .* );
endmodule

module joe( input in1, output out1 );
...
endmodule
```

SystemVerilog 2009

Tesson Shell supports reading and writing of all of the SV2009 constructs. However, a few constructs cannot be modified in Tesson Shell. Those are as follows:

- Hierarchical references starting from parent hierarchy
- Coverage constructs
 - covergroup/endgroup
- Class constructs
- Program block constructs
 - program/endprogram
- Assertion constructs
 - assert
 - assert property
 - property/endproperty
 - clocking/endclocking
 - sequence/endsequence
- Checker constructs
 - checker/endchecker
- Bind constructs

For example, if a net is renamed in a [move_connections](#) command and it appears in any of those constructs, that update will not be reflected in the construct when the file containing the construct is written out.

New Module Insertion in VHDL

Note the following when inserting VHDL entities.

Insertion of VHDL Entities with Unconstrained Ports [4028](#)

Insertion of VHDL Entities with Uninitialized Generics [4028](#)

Insertion of VHDL Entities with Unconstrained Ports

Insertion of VHDL entities containing ports defined using unconstrained array types is not supported.

See the section entitled “[Ports with Unconstrained Array Types in the Root Design Entity of a Child Block](#)” on page 4030 for an example of an unconstrained array type.

Insertion of VHDL Entities with Uninitialized Generics

Insertion of VHDL entities containing uninitialized generics is not supported. The following is an example:

```
entity Joe is
    generic ( N : INTEGER );
    port( in1 : in std_logic );
end entity;
```

Complex Port Types for VHDL

Note the following when using complex port types.

- Access to Ports and Nets of Complex Types 4029
Array of Array and Record Types in Port Declarations in the Root Module of a Design
4029
Complex Types in Top-Level Ports at the Chip Level 4029
Ports with Unconstrained Array Types in the Root Design Entity of a Child Block .. 4030

Access to Ports and Nets of Complex Types

Net and port objects declared using an array of array or a record type cannot be introspected and cannot appear in editing commands.

The above limitation puts constraints on the types of connections which can be made with custom logic.

Array of Array and Record Types in Port Declarations in the Root Module of a Design

Array of array and record types cannot be used in the definitions of root module ports (including those in child blocks or cores and the chip-level design) which drive or receive data from inserted DFT logic.

The following example illustrates the use of an array of array in the declaration of a port:

```
package pck is
    type myArray is array( 1 downto 0 ) of bit_vector( 0 to 0 );
end;

entity john is
    port( in1 : in myArray; out1 : out bit );
end john;
```

Complex Types in Top-Level Ports at the Chip Level

The insertion of boundary scan by Tesson tools imposes certain restrictions on top-level port declarations. In VHDL designs top-level port declarations at the chip level must be scalars or simple vectors.

Ports with Unconstrained Array Types in the Root Design Entity of a Child Block

Ports declared in the root module of a child block or core cannot be declared using an unconstrained array type. The following is an example of an unconstrained array type:

```
type JOE is array (INTEGER range <>) of std_logic;
```

Procedures, Functions, and Process Statements for VHDL

Tessent tools cannot trace a signal through logic written using a non-constant function call, a procedure invocation or a process statement.

Configurations for VHDL

MemoryBIST and boundary scan insertion are not fully supported in configured designs.

Format is not preserved when configurations need to be edited. Therefore, pragmas and other comments will not be preserved in edited design files which contain configurations.

In addition when there are multiple configurations for the same entity, only the elaborated / active one can be edited. The inactive configurations may need manual updates to avoid parsing errors later in the flow. For example, if a component referenced in a configuration is unqualified, then any inactive configuration(s) for the same entity may need manual updates.

VHDL 2008

Tessent Shell supports the following VHDL 2008 constructs:

- New VHDL 2008 generate block syntax
- Unconstrained element support in arrays and records
- Logical reduction operator
- Expressions which appear directly in a port map (e.g., a boolean or logical expression whose evaluated result is connected to the named port)
- Reading of output ports
- Simplified sensitivity lists
- C-style block comments
- Operations involving both an array and a scalar (e.g., “A_bus and A_sel”; A_sel is 1 bit and it applies to all bits of A_bus)

- Extensions to bit string literals
- Slices in array aggregates

VHDL 2008 constructs which are not in the above list are currently not supported.

Parameterized Designs for VHDL

Note the following when using parameterized designs.

Generic Overrides in the Instantiation of the Root Design Entity of a Child Block . . . 4032

Generic Overrides in the Instantiation of the Root Design Entity of a Child Block

In a bottom-up flow generic overrides cannot be used in the instantiation of the root design entity of a child block or core if those generics are used in logic that will be edited during insertion. Furthermore default values must be specified for such generics.

The following example illustrates a VHDL entity with two generics - one with a default value and one without:

```
entity joe is
    generic (g1:integer; g2:integer :=0);
    ...
end;
```

The generic *g1* is defined without a default value. The generic *g2* is defined with a default value of 0. The above entity cannot be used as the root of a child block if the generic *g1* is used in logic that will be edited during insertion. If *g1* had been specified with a default value, then entity *joe* could be used as the root of a child block only if it is instantiated in the parent block without overrides for the generics.

Appendix C

Getting Help

There are several ways to get help when setting up and using Tesson software tools. Depending on your need, help is available from documentation, online command help, and Mentor Graphics Support.

The Tesson Documentation System	4033
Mentor Support Services.....	4034

The Tesson Documentation System

At the center of the documentation system is the InfoHub that supports both PDF and HTML content. From the InfoHub, you can access all locally installed product documentation, system administration documentation, videos, and tutorials. For users who want to use PDF, you have a PDF bookcase file that provides access to all the installed PDF files.

For information on defining default HTML browsers, setting up browser options, and setting the default PDF viewer, refer to the “[Documentation Options](#)” in the *Mentor Documentation System* manual.

You can access the documentation in the following ways:

- **Shell Command** — On Linux platforms, enter **mgcdocs** at the shell prompt or invoke a Tesson tool with the -manual invocation switch.
- **File System** — Access the Tesson InfoHub or PDF bookcase directly from your file system, without invoking a Tesson tool. For example:

HTML:

```
firefox $MGC_DFT/docs/infohubs/index.html
```

PDF

```
acroread $MGC_DFT/docs/pdfdocs/_bk_tesson.pdf
```

- **Application Online Help** — You can get contextual online help within most Tesson tools by using the “help -manual” tool command. For example:

> help dofile -manual

This command opens the appropriate reference manual at the “dofile” command description.

Mentor Support Services

Mentor provides a range of industry-leading support services that keep design teams productive and up-to-date with Mentor products.

A Mentor support contract includes the following:

- **Software Updates** — Get the latest releases and product enhancements to keep your environment current.
- **Mentor Graphics Support Center** — Access our online knowledge base, personalized to your Mentor products.
- **Support Forums** — Learn, share, and connect with other Mentor users.
- **Technical Support** — Collaborate with Mentor support engineers to solve complex design challenges.
- **Regular Communications** — Receive the latest knowledge base articles and announcements for your Mentor products.
- **Mentor Ideas** — Share ideas and vote for your favorites to shape future products.

More information is available here:

<https://support.mentor.com>

If your site is under a current support contract, but you do not have a Support Center login, register today:

<https://support.mentor.com/register>

Third-Party Information

For information about third-party software included with this release of Tesson products, refer to the [*Third-Party Software for Tesson Products*](#).

End-User License Agreement

The latest version of the End-User License Agreement is available on-line at:
www.mentor.com/eula

IMPORTANT INFORMATION

USE OF ALL SOFTWARE IS SUBJECT TO LICENSE RESTRICTIONS. CAREFULLY READ THIS LICENSE AGREEMENT BEFORE USING THE PRODUCTS. USE OF SOFTWARE INDICATES CUSTOMER'S COMPLETE AND UNCONDITIONAL ACCEPTANCE OF THE TERMS AND CONDITIONS SET FORTH IN THIS AGREEMENT. ANY ADDITIONAL OR DIFFERENT PURCHASE ORDER TERMS AND CONDITIONS SHALL NOT APPLY.

END-USER LICENSE AGREEMENT ("Agreement")

This is a legal agreement concerning the use of Software (as defined in Section 2) and hardware (collectively "Products") between the company acquiring the Products ("Customer"), and the Mentor Graphics entity that issued the corresponding quotation or, if no quotation was issued, the applicable local Mentor Graphics entity ("Mentor Graphics"). Except for license agreements related to the subject matter of this license agreement which are physically signed by Customer and an authorized representative of Mentor Graphics, this Agreement and the applicable quotation contain the parties' entire understanding relating to the subject matter and supersede all prior or contemporaneous agreements. If Customer does not agree to these terms and conditions, promptly return or, in the case of Software received electronically, certify destruction of Software and all accompanying items within five days after receipt of Software and receive a full refund of any license fee paid.

1. ORDERS, FEES AND PAYMENT.

- 1.1. To the extent Customer (or if agreed by Mentor Graphics, Customer's appointed third party buying agent) places and Mentor Graphics accepts purchase orders pursuant to this Agreement (each an "Order"), each Order will constitute a contract between Customer and Mentor Graphics, which shall be governed solely and exclusively by the terms and conditions of this Agreement, any applicable addenda and the applicable quotation, whether or not those documents are referenced on the Order. Any additional or conflicting terms and conditions appearing on an Order or presented in any electronic portal or automated order management system, whether or not required to be electronically accepted, will not be effective unless agreed in writing and physically signed by an authorized representative of Customer and Mentor Graphics.
- 1.2. Amounts invoiced will be paid, in the currency specified on the applicable invoice, within 30 days from the date of such invoice. Any past due invoices will be subject to the imposition of interest charges in the amount of one and one-half percent per month or the applicable legal rate currently in effect, whichever is lower. Prices do not include freight, insurance, customs duties, taxes or other similar charges, which Mentor Graphics will state separately in the applicable invoice. Unless timely provided with a valid certificate of exemption or other evidence that items are not taxable, Mentor Graphics will invoice Customer for all applicable taxes including, but not limited to, VAT, GST, sales tax, consumption tax and service tax. Customer will make all payments free and clear of, and without reduction for, any withholding or other taxes; any such taxes imposed on payments by Customer hereunder will be Customer's sole responsibility. If Customer appoints a third party to place purchase orders and/or make payments on Customer's behalf, Customer shall be liable for payment under Orders placed by such third party in the event of default.
- 1.3. All Products are delivered FCA factory (Incoterms 2010), freight prepaid and invoiced to Customer, except Software delivered electronically, which shall be deemed delivered when made available to Customer for download. Mentor Graphics retains a security interest in all Products delivered under this Agreement, to secure payment of the purchase price of such Products, and Customer agrees to sign any documents that Mentor Graphics determines to be necessary or convenient for use in filing or perfecting such security interest. Mentor Graphics' delivery of Software by electronic means is subject to Customer's provision of both a primary and an alternate e-mail address.

2. **GRANT OF LICENSE.** The software installed, downloaded, or otherwise acquired by Customer under this Agreement, including any updates, modifications, revisions, copies, documentation, setup files and design data ("Software") are copyrighted, trade secret and confidential information of Mentor Graphics or its licensors, who maintain exclusive title to all Software and retain all rights not expressly granted by this Agreement. Except for Software that is embeddable ("Embedded Software"), which is licensed pursuant to separate embedded software terms or an embedded software supplement, Mentor Graphics grants to Customer, subject to payment of applicable license fees, a nontransferable, nonexclusive license to use Software solely: (a) in machine-readable, object-code form (except as provided in Subsection 4.2); (b) for Customer's internal business purposes; (c) for the term of the license; and (d) on the computer hardware and at the site authorized by Mentor Graphics. A site is restricted to a one-half mile (800 meter) radius. Customer may have Software temporarily used by an employee for telecommuting purposes from locations other than a Customer office, such as the employee's residence, an airport or hotel, provided that such employee's primary place of employment is the site where the Software is authorized for use. Mentor Graphics' standard policies and programs, which vary depending on Software, license fees paid or services purchased, apply to the following: (a) relocation of Software; (b) use of Software, which may be limited, for example, to execution of a single session by a single user on the authorized hardware or for a restricted period of time (such limitations may be technically implemented through the use of authorization codes or similar devices); and (c) support services provided, including eligibility to receive telephone support, updates, modifications, and revisions. For the avoidance of doubt, if Customer provides any feedback or requests any change or enhancement to Products, whether in the course of receiving support or consulting services, evaluating Products, performing beta testing or otherwise, any inventions, product improvements, modifications or developments made by Mentor Graphics (at Mentor Graphics' sole discretion) will be the exclusive property of Mentor Graphics.

3. BETA CODE.

- 3.1. Portions or all of certain Software may contain code for experimental testing and evaluation (which may be either alpha or beta, collectively “Beta Code”), which may not be used without Mentor Graphics’ explicit authorization. Upon Mentor Graphics’ authorization, Mentor Graphics grants to Customer a temporary, nontransferable, nonexclusive license for experimental use to test and evaluate the Beta Code without charge for a limited period of time specified by Mentor Graphics. Mentor Graphics may choose, at its sole discretion, not to release Beta Code commercially in any form.
- 3.2. If Mentor Graphics authorizes Customer to use the Beta Code, Customer agrees to evaluate and test the Beta Code under normal conditions as directed by Mentor Graphics. Customer will contact Mentor Graphics periodically during Customer’s use of the Beta Code to discuss any malfunctions or suggested improvements. Upon completion of Customer’s evaluation and testing, Customer will send to Mentor Graphics a written evaluation of the Beta Code, including its strengths, weaknesses and recommended improvements.
- 3.3. Customer agrees to maintain Beta Code in confidence and shall restrict access to the Beta Code, including the methods and concepts utilized therein, solely to those employees and Customer location(s) authorized by Mentor Graphics to perform beta testing. Customer agrees that any written evaluations and all inventions, product improvements, modifications or developments that Mentor Graphics conceived or made during or subsequent to this Agreement, including those based partly or wholly on Customer’s feedback, will be the exclusive property of Mentor Graphics. Mentor Graphics will have exclusive rights, title and interest in all such property. The provisions of this Subsection 3.3 shall survive termination of this Agreement.

4. RESTRICTIONS ON USE.

- 4.1. Customer may copy Software only as reasonably necessary to support the authorized use. Each copy must include all notices and legends embedded in Software and affixed to its medium and container as received from Mentor Graphics. All copies shall remain the property of Mentor Graphics or its licensors. Except for Embedded Software that has been embedded in executable code form in Customer’s product(s), Customer shall maintain a record of the number and primary location of all copies of Software, including copies merged with other software, and shall make those records available to Mentor Graphics upon request. Customer shall not make Products available in any form to any person other than Customer’s employees and on-site contractors, excluding Mentor Graphics competitors, whose job performance requires access and who are under obligations of confidentiality. Customer shall take appropriate action to protect the confidentiality of Products and ensure that any person permitted access does not disclose or use Products except as permitted by this Agreement. Customer shall give Mentor Graphics written notice of any unauthorized disclosure or use of the Products as soon as Customer becomes aware of such unauthorized disclosure or use. Customer acknowledges that Software provided hereunder may contain source code which is proprietary and its confidentiality is of the highest importance and value to Mentor Graphics. Customer acknowledges that Mentor Graphics may be seriously harmed if such source code is disclosed in violation of this Agreement. Except as otherwise permitted for purposes of interoperability as specified by applicable and mandatory local law, Customer shall not reverse-assemble, disassemble, reverse-compile, or reverse-engineer any Product, or in any way derive any source code from Software that is not provided to Customer in source code form. Log files, data files, rule files and script files generated by or for the Software (collectively “Files”), including without limitation files containing Standard Verification Rule Format (“SVRF”) and Tcl Verification Format (“TVF”) which are Mentor Graphics’ trade secret and proprietary syntaxes for expressing process rules, constitute or include confidential information of Mentor Graphics. Customer may share Files with third parties, excluding Mentor Graphics competitors, provided that the confidentiality of such Files is protected by written agreement at least as well as Customer protects other information of a similar nature or importance, but in any case with at least reasonable care. Customer may use Files containing SVRF or TVF only with Mentor Graphics products. Under no circumstances shall Customer use Products or Files or allow their use for the purpose of developing, enhancing or marketing any product that is in any way competitive with Products, or disclose to any third party the results of, or information pertaining to, any benchmark.
- 4.2. If any Software or portions thereof are provided in source code form, Customer will use the source code only to correct software errors and enhance or modify the Software for the authorized use, or as permitted for Embedded Software under separate embedded software terms or an embedded software supplement. Customer shall not disclose or permit disclosure of source code, in whole or in part, including any of its methods or concepts, to anyone except Customer’s employees or on-site contractors, excluding Mentor Graphics competitors, with a need to know. Customer shall not copy or compile source code in any manner except to support this authorized use.
- 4.3. Customer agrees that it will not subject any Product to any open source software (“OSS”) license that conflicts with this Agreement or that does not otherwise apply to such Product.
- 4.4. Customer may not assign this Agreement or the rights and duties under it, or relocate, sublicense, or otherwise transfer the Products, whether by operation of law or otherwise (“Attempted Transfer”), without Mentor Graphics’ prior written consent and payment of Mentor Graphics’ then-current applicable relocation and/or transfer fees. Any Attempted Transfer without Mentor Graphics’ prior written consent shall be a material breach of this Agreement and may, at Mentor Graphics’ option, result in the immediate termination of the Agreement and/or the licenses granted under this Agreement. The terms of this Agreement, including without limitation the licensing and assignment provisions, shall be binding upon Customer’s permitted successors in interest and assigns.
- 4.5. The provisions of this Section 4 shall survive the termination of this Agreement.

5. **SUPPORT SERVICES.** To the extent Customer purchases support services, Mentor Graphics will provide Customer with updates and technical support for the Products, at the Customer site(s) for which support is purchased, in accordance with Mentor Graphics’ then current End-User Support Terms located at <http://supportnet.mentor.com/supportterms>.
6. **OPEN SOURCE SOFTWARE.** Products may contain OSS or code distributed under a proprietary third party license agreement, to which additional rights or obligations (“Third Party Terms”) may apply. Please see the applicable Product documentation (including license files, header files, read-me files or source code) for details. In the event of conflict between the terms of this Agreement

(including any addenda) and the Third Party Terms, the Third Party Terms will control solely with respect to the OSS or third party code. The provisions of this Section 6 shall survive the termination of this Agreement.

7. LIMITED WARRANTY.

- 7.1. Mentor Graphics warrants that during the warranty period its standard, generally supported Products, when properly installed, will substantially conform to the functional specifications set forth in the applicable user manual. Mentor Graphics does not warrant that Products will meet Customer's requirements or that operation of Products will be uninterrupted or error free. The warranty period is 90 days starting on the 15th day after delivery or upon installation, whichever first occurs. Customer must notify Mentor Graphics in writing of any nonconformity within the warranty period. For the avoidance of doubt, this warranty applies only to the initial shipment of Software under an Order and does not renew or reset, for example, with the delivery of (a) Software updates or (b) authorization codes or alternate Software under a transaction involving Software re-mix. This warranty shall not be valid if Products have been subject to misuse, unauthorized modification, improper installation or Customer is not in compliance with this Agreement. MENTOR GRAPHICS' ENTIRE LIABILITY AND CUSTOMER'S EXCLUSIVE REMEDY SHALL BE, AT MENTOR GRAPHICS' OPTION, EITHER (A) REFUND OF THE PRICE PAID UPON RETURN OF THE PRODUCTS TO MENTOR GRAPHICS OR (B) MODIFICATION OR REPLACEMENT OF THE PRODUCTS THAT DO NOT MEET THIS LIMITED WARRANTY. MENTOR GRAPHICS MAKES NO WARRANTIES WITH RESPECT TO: (A) SERVICES; (B) PRODUCTS PROVIDED AT NO CHARGE; OR (C) BETA CODE; ALL OF WHICH ARE PROVIDED "AS IS."
 - 7.2. THE WARRANTIES SET FORTH IN THIS SECTION 7 ARE EXCLUSIVE. NEITHER MENTOR GRAPHICS NOR ITS LICENSORS MAKE ANY OTHER WARRANTIES EXPRESS, IMPLIED OR STATUTORY, WITH RESPECT TO PRODUCTS PROVIDED UNDER THIS AGREEMENT. MENTOR GRAPHICS AND ITS LICENSORS SPECIFICALLY DISCLAIM ALL IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NON-INFRINGEMENT OF INTELLECTUAL PROPERTY.
8. **LIMITATION OF LIABILITY.** TO THE EXTENT PERMITTED UNDER APPLICABLE LAW, IN NO EVENT SHALL MENTOR GRAPHICS OR ITS LICENSORS BE LIABLE FOR INDIRECT, SPECIAL, INCIDENTAL, OR CONSEQUENTIAL DAMAGES (INCLUDING LOST PROFITS OR SAVINGS) WHETHER BASED ON CONTRACT, TORT OR ANY OTHER LEGAL THEORY, EVEN IF MENTOR GRAPHICS OR ITS LICENSORS HAVE BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. IN NO EVENT SHALL MENTOR GRAPHICS' OR ITS LICENSORS' LIABILITY UNDER THIS AGREEMENT EXCEED THE AMOUNT RECEIVED FROM CUSTOMER FOR THE HARDWARE, SOFTWARE LICENSE OR SERVICE GIVING RISE TO THE CLAIM. IN THE CASE WHERE NO AMOUNT WAS PAID, MENTOR GRAPHICS AND ITS LICENSORS SHALL HAVE NO LIABILITY FOR ANY DAMAGES WHATSOEVER. THE PROVISIONS OF THIS SECTION 8 SHALL SURVIVE THE TERMINATION OF THIS AGREEMENT.

9. THIRD PARTY CLAIMS.

- 9.1. Customer acknowledges that Mentor Graphics has no control over the testing of Customer's products, or the specific applications and use of Products. Mentor Graphics and its licensors shall not be liable for any claim or demand made against Customer by any third party, except to the extent such claim is covered under Section 10.
- 9.2. In the event that a third party makes a claim against Mentor Graphics arising out of the use of Customer's products, Mentor Graphics will give Customer prompt notice of such claim. At Customer's option and expense, Customer may take sole control of the defense and any settlement of such claim. Customer WILL reimburse and hold harmless Mentor Graphics for any LIABILITY, damages, settlement amounts, costs and expenses, including reasonable attorney's fees, incurred by or awarded against Mentor Graphics or its licensors in connection with such claims.
- 9.3. The provisions of this Section 9 shall survive any expiration or termination of this Agreement.

10. INFRINGEMENT.

- 10.1. Mentor Graphics will defend or settle, at its option and expense, any action brought against Customer in the United States, Canada, Japan, or member state of the European Union which alleges that any standard, generally supported Product acquired by Customer hereunder infringes a patent or copyright or misappropriates a trade secret in such jurisdiction. Mentor Graphics will pay costs and damages finally awarded against Customer that are attributable to such action. Customer understands and agrees that as conditions to Mentor Graphics' obligations under this section Customer must: (a) notify Mentor Graphics promptly in writing of the action; (b) provide Mentor Graphics all reasonable information and assistance to settle or defend the action; and (c) grant Mentor Graphics sole authority and control of the defense or settlement of the action.
- 10.2. If a claim is made under Subsection 10.1 Mentor Graphics may, at its option and expense: (a) replace or modify the Product so that it becomes noninfringing; (b) procure for Customer the right to continue using the Product; or (c) require the return of the Product and refund to Customer any purchase price or license fee paid, less a reasonable allowance for use.
- 10.3. Mentor Graphics has no liability to Customer if the action is based upon: (a) the combination of Software or hardware with any product not furnished by Mentor Graphics; (b) the modification of the Product other than by Mentor Graphics; (c) the use of other than a current unaltered release of Software; (d) the use of the Product as part of an infringing process; (e) a product that Customer makes, uses, or sells; (f) any Beta Code or Product provided at no charge; (g) any software provided by Mentor Graphics' licensors who do not provide such indemnification to Mentor Graphics' customers; (h) OSS, except to the extent that the infringement is directly caused by Mentor Graphics' modifications to such OSS; or (i) infringement by Customer that is deemed willful. In the case of (i), Customer shall reimburse Mentor Graphics for its reasonable attorney fees and other costs related to the action.
- 10.4. THIS SECTION 10 IS SUBJECT TO SECTION 8 ABOVE AND STATES THE ENTIRE LIABILITY OF MENTOR GRAPHICS AND ITS LICENSORS, AND CUSTOMER'S SOLE AND EXCLUSIVE REMEDY, FOR DEFENSE,

SETTLEMENT AND DAMAGES, WITH RESPECT TO ANY ALLEGED PATENT OR COPYRIGHT INFRINGEMENT OR TRADE SECRET MISAPPROPRIATION BY ANY PRODUCT PROVIDED UNDER THIS AGREEMENT.

11. TERMINATION AND EFFECT OF TERMINATION.

- 11.1. If a Software license was provided for limited term use, such license will automatically terminate at the end of the authorized term. Mentor Graphics may terminate this Agreement and/or any license granted under this Agreement immediately upon written notice if Customer: (a) exceeds the scope of the license or otherwise fails to comply with the licensing or confidentiality provisions of this Agreement, or (b) becomes insolvent, files a bankruptcy petition, institutes proceedings for liquidation or winding up or enters into an agreement to assign its assets for the benefit of creditors. For any other material breach of any provision of this Agreement, Mentor Graphics may terminate this Agreement and/or any license granted under this Agreement upon 30 days written notice if Customer fails to cure the breach within the 30 day notice period. Termination of this Agreement or any license granted hereunder will not affect Customer's obligation to pay for Products shipped or licenses granted prior to the termination, which amounts shall be payable immediately upon the date of termination.
- 11.2. Upon termination of this Agreement, the rights and obligations of the parties shall cease except as expressly set forth in this Agreement. Upon termination of this Agreement and/or any license granted under this Agreement, Customer shall ensure that all use of the affected Products ceases, and shall return hardware and either return to Mentor Graphics or destroy Software in Customer's possession, including all copies and documentation, and certify in writing to Mentor Graphics within ten business days of the termination date that Customer no longer possesses any of the affected Products or copies of Software in any form.
12. **EXPORT.** The Products provided hereunder are subject to regulation by local laws and European Union ("E.U.") and United States ("U.S.") government agencies, which prohibit export, re-export or diversion of certain products, information about the products, and direct or indirect products thereof, to certain countries and certain persons. Customer agrees that it will not export or re-export Products in any manner without first obtaining all necessary approval from appropriate local, E.U. and U.S. government agencies. If Customer wishes to disclose any information to Mentor Graphics that is subject to any E.U., U.S. or other applicable export restrictions, including without limitation the U.S. International Traffic in Arms Regulations (ITAR) or special controls under the Export Administration Regulations (EAR), Customer will notify Mentor Graphics personnel, in advance of each instance of disclosure, that such information is subject to such export restrictions.
13. **U.S. GOVERNMENT LICENSE RIGHTS.** Software was developed entirely at private expense. The parties agree that all Software is commercial computer software within the meaning of the applicable acquisition regulations. Accordingly, pursuant to U.S. FAR 48 CFR 12.212 and DFAR 48 CFR 227.7202, use, duplication and disclosure of the Software by or for the U.S. government or a U.S. government subcontractor is subject solely to the terms and conditions set forth in this Agreement, which shall supersede any conflicting terms or conditions in any government order document, except for provisions which are contrary to applicable mandatory federal laws.
14. **THIRD PARTY BENEFICIARY.** Mentor Graphics Corporation, Mentor Graphics (Ireland) Limited, Microsoft Corporation and other licensors may be third party beneficiaries of this Agreement with the right to enforce the obligations set forth herein.
15. **REVIEW OF LICENSE USAGE.** Customer will monitor the access to and use of Software. With prior written notice and during Customer's normal business hours, Mentor Graphics may engage an internationally recognized accounting firm to review Customer's software monitoring system and records deemed relevant by the internationally recognized accounting firm to confirm Customer's compliance with the terms of this Agreement or U.S. or other local export laws. Such review may include FlexNet (or successor product) report log files that Customer shall capture and provide at Mentor Graphics' request. Customer shall make records available in electronic format and shall fully cooperate with data gathering to support the license review. Mentor Graphics shall bear the expense of any such review unless a material non-compliance is revealed. Mentor Graphics shall treat as confidential information all information gained as a result of any request or review and shall only use or disclose such information as required by law or to enforce its rights under this Agreement. The provisions of this Section 15 shall survive the termination of this Agreement.
16. **CONTROLLING LAW, JURISDICTION AND DISPUTE RESOLUTION.** The owners of certain Mentor Graphics intellectual property licensed under this Agreement are located in Ireland and the U.S. To promote consistency around the world, disputes shall be resolved as follows: excluding conflict of laws rules, this Agreement shall be governed by and construed under the laws of the State of Oregon, U.S., if Customer is located in North or South America, and the laws of Ireland if Customer is located outside of North or South America or Japan, and the laws of Japan if Customer is located in Japan. All disputes arising out of or in relation to this Agreement shall be submitted to the exclusive jurisdiction of the courts of Portland, Oregon when the laws of Oregon apply, or Dublin, Ireland when the laws of Ireland apply, or the Tokyo District Court when the laws of Japan apply. Notwithstanding the foregoing, all disputes in Asia (excluding Japan) arising out of or in relation to this Agreement shall be resolved by arbitration in Singapore before a single arbitrator to be appointed by the chairman of the Singapore International Arbitration Centre ("SIAC") to be conducted in the English language, in accordance with the Arbitration Rules of the SIAC in effect at the time of the dispute, which rules are deemed to be incorporated by reference in this section. Nothing in this section shall restrict Mentor Graphics' right to bring an action (including for example a motion for injunctive relief) against Customer in the jurisdiction where Customer's place of business is located. The United Nations Convention on Contracts for the International Sale of Goods does not apply to this Agreement.
17. **SEVERABILITY.** If any provision of this Agreement is held by a court of competent jurisdiction to be void, invalid, unenforceable or illegal, such provision shall be severed from this Agreement and the remaining provisions will remain in full force and effect.
18. **MISCELLANEOUS.** This Agreement contains the parties' entire understanding relating to its subject matter and supersedes all prior or contemporaneous agreements. Any translation of this Agreement is provided to comply with local legal requirements only. In the event of a dispute between the English and any non-English versions, the English version of this Agreement shall govern to the extent not prohibited by local law in the applicable jurisdiction. This Agreement may only be modified in writing, signed by an authorized representative of each party. Waiver of terms or excuse of breach must be in writing and shall not constitute subsequent consent, waiver or excuse.
